Furthermore, given the concurrence of the Nevada Department of Wildlife and FWS in each exception, this approach is consistent with conservation objectives. The Nevada ARMPA does not use a disturbance density cap, required in the three other Great Basin Region ARMPAs, in light of the disturbance management protocol for BLM-administered lands in Nevada.

In coordination with the FWS, the Nevada ARMPA also allows for an exception to the geothermal NSO, which is an energy development priority for the State and is projected to create very limited disturbance in predictable areas over the life of the plan. For those reasons, this exception is consistent with overall conservation objectives.

Utah

The Utah ARMPA incorporates a number of key strategies for GRSG conservation developed by the State of Utah (*Conservation Plan for Greater Sage-Grouse in Utah*; Utah Greater Sage-Grouse Working Group 2013) and the State of Wyoming (Executive Orders 2011-5, 2013-3, and 2015-4), which establish conservation measures for protecting GRSG and also focus conservation and restoration within key areas deemed most valuable to GRSG. The Utah ARMPA also integrates the State's strategic focus on increasing areas available to GRSG through vegetation treatments and reducing threats from wildfire. The ARMPA provides additional flexibility for development in GHMAs because 96 percent of the breeding GRSG in Utah are within PHMAs. Here, conservation measures are applied in a more targeted manner at the project-implementation stage through the use of lek buffers and RDFs, as well as requiring that compensatory mitigation achieve a net conservation benefit outcome. As such, the Utah ARMPA designates GHMAs as open to wind energy and high voltage transmission ROW development (consistent with the net conservation gain mitigation framework for the ARMPA). The Utah ARMPA also designates GHMAs open to oil and gas development with standard constraints.

Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses this threat.

Oregon

The Oregon ARMPA incorporates key elements of the *Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat* (Hagen 2011). This establishes unique conservation measures for protecting GRSG and also focuses restoration within key areas most valuable to GRSG. The BLM plan adopts the unique disturbance cap approach developed with the State of Oregon in which disturbance is capped at 1 percent per decade, in addition to the 3 percent cap in BSUs and project analysis areas.

The BLM Oregon plans provide additional flexibility for wind development in PHMAs in Harney, Lake, and Malheur Counties by allocating them as avoidance areas (rather than exclusion areas) within PHMAs that are outside of the SFAs. In these counties, priority would be placed on locating commercial-scale wind and solar energy development in nonhabitat areas (i.e., outside of PHMAs and GHMAs) before approving development in PHMAs. The BLM provided this flexibility after recognizing the following:

- The extent of high and medium potential wind areas in PHMAs in these counties
- The fact that wind energy is excluded in SFAs in these counties

- After coordinating with the FWS, determining that the more rigorous disturbance cap of 1 percent per decade and adaptive management triggers adopted by the Oregon plan would compensate for the likely limited wind development in these areas

Due to these factors, the BLM finds these limited areas of flexibility for wind development are consistent with overall conservation objectives of the plan. In addition, the Oregon ARMPA identifies strategic areas where habitat enhancement and restoration are encouraged, as well as other strategic areas to address the impacts associated with climate change.

For additional information on the unique aspects of each plan, refer to Table 1-6 of the attached Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah ARMPAs. The tables provide a crosswalk as to how the ARMPAs address specific threats to GRSG identified in the COT Report through these State-specific management prescriptions.

1.8 DECISION RATIONALE

The ARMPAs provide a comprehensive, coordinated, and effective conservation strategy for addressing the threats identified by the FWS such that the need for additional protections under the ESA may be avoided. The ARMPAs contain objectives to conserve GRSG and their habitat on BLM-administered lands across the remaining range of the species. This is consistent with measures identified or recommended in the NTT Report, the COT Report, recent USGS studies, and other relevant research and analysis.

The BLM- and Forest Service-proposed ARMPAs are an essential component to conserve the GRSG and its habitat. This is in combination with the GRSG conservation actions taken by the individual States in the remaining range of the species and initiatives to address the threat of rangeland fire to curb the spread of nonnative invasive grasses and to promote conservation measures to benefit GRSG on private lands. Combined, all of the ARMPAs associated with the BLM's National GRSG Conservation Strategy would affect approximately 66 million acres of the remaining habitat for the species.

The BLM GRSG Conservation Strategy is built on the following key concepts:

- **Landscape-level—**The planning effort encompasses the remaining habitat of the GRSG on BLM-administered lands, covering 10 western states in the Great Basin and Rocky Mountain regions. As such, the strategy provides a coherent framework across the BLM ARMPAs to implement landscape-level conservation for GRSG, while allowing for flexibility essential to effectively address threats to the GRSG in the context of the agency's multiple-use and sustained yield mandates under FLPMA. The conservation measures included as part of this landscape-level conservation effort address identified threats to the species, recognizing local ecological conditions and incorporating existing conservation efforts where they are consistent with the overall objective of conserving GRSG across its remaining range.
- **Best available science—**The ARMPAs are grounded in the best available science, drawn from published literature and input from recognized experts, State agencies, the USGS, the FWS, and other sources. The COT Report provided a blueprint for GRSG conservation by identifying specific threats to each remaining GRSG population and recommending measures to address each category of threat. The NTT Report provided additional guidance for addressing the most significant threats to the GRSG.

The concepts set forth in a number of reports prepared by the USGS regarding specific threats to GRSG, habitat connectivity, and related issues are reflected in the land allocation and resource management decisions. In addition, a series of reports on how to better reduce the threats of rangeland fire and invasive species were prepared in collaboration with the WAFWA. That and a report to the Secretary of the Interior entitled *An Integrated Rangeland Fire Strategy: Final Report to the Secretary of the Interior* informed the GRSG conservation (US Department of the Interior 2015).

- **Targeted, multi-tiered approach—**The ARMPAs were designed to incorporate a layered management approach to target habitat protection and restoration to the most important habitat management areas as determined by State and Federal GRSG experts. These were largely consistent with the PACs identified in the COT Report, where land allocations and management direction avoid and minimize additional surface disturbance. These areas are designated as PHMAs, within which the ARMPAs provide an added level of protection to eliminate most surface disturbance. They accomplish this by delineating SFAs, derived from areas identified by the FWS as strongholds essential for the species' survival. GHMAs recognize the potential value of habitat areas outside of PACs, as recommended by the COT Report, where surface disturbance is minimized, while providing greater flexibility for other land resource uses.
- **Coordinated—**The ARMPAs were developed through a joint planning process between the BLM and the Forest Service (as a cooperating agency). As a result, Federally administered lands essential to the conservation of the GRSG are managed in a coordinated manner. The FWS provided guidance and input throughout the process to aid land managers in understanding the threats to the GRSG and its habitat. The USGS and NRCS also provided key technical and scientific support.
- **Collaborative—**The ARMPAs reflected extensive input from the relevant States, collaborators, and stakeholders and the public from the outset. The ARMPAs were developed with the benefit of input from the individual States and cooperators who signed formal agreements with the BLM to provide input into the planning process. The Western Governors Association Sage Grouse Task Force was particularly useful in facilitating this kind of collaborative input. The ARMPAs incorporate State and local conservation measures where they are consistent with the overall objective of implementing land use plan conservation measures for the GRSG consistent with the multiple-use and sustained yield mission of the BLM.

The conservation measures in the ARMPAs reflect over a decade of research, analysis, and recommendations for GRSG conservation, including those produced by the WAFWA, the NTT, and the COT. Each of these entities produced a strategy or report that was developed through the collaboration of State and Federal biologists and scientists with extensive experience and expertise in GRSG management and research.

The COT Report, which identified threats to GRSG habitat and the most important habitat to protect provided an important framework for developing the conservation strategy embodied in the sub-regional ARMPAs. The COT, consisting of State and Federal scientists, wildlife biologists, resource managers, and policy advisors, was tasked by the FWS Director "with development of range-wide conservation objectives for the sage-grouse to define the degree to which threats need to be reduced or ameliorated to conserve sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future" (FWS 2013).

In addition, the FIAT Report and the USGS compilation and summary of published scientific studies that evaluate the influence of human activities and infrastructure on GRSG populations (*Conservation Buffer Distance Estimates for Greater Sage-Grouse—A Review* [Manier et al. 2014], and the *Integrated Rangeland Fire Strategy: Final Report to the Secretary of the Interior* [US Department of the Interior 2015]) provided important guidance in developing critical aspects of the ARMPAs and the overall GRSG landscape-level conservation strategy. Beyond these range-wide reports, each of the sub-regional plans used local science, where available, to tailor plan elements to reflect local ecological conditions, threats, and GRSG management experience where consistent with the overall GRSG conservation objectives.

The BLM ARMPAs are the product of extensive coordination, including the active engagement of the FWS in helping to inform land allocation and related management decisions by the land management agencies to ensure they limit or eliminate new surface disturbance as well as improve habitat condition in the most important habitat areas. The ARMPAs also benefit from strong collaboration with the States and reflect the unique landscapes, habitats, approaches, and priorities in each. While the effort to incorporate State-developed conservation measures in each of the sub-regional plans has added complexity in developing the overall conservation strategy, the body of local knowledge and expertise regarding conservation measures for the GRSG is extensive and, ultimately, strengthened the plans. Incorporating these measures in the plans is also likely to increase the commitment of all partners to the task of implementing the plans on completion.

In his transmittal letter accompanying the final COT Report, the FWS Director reaffirmed his charge. "I asked the team to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. … Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels" (FWS 2013).

The ARMPAs are designed to directly address the specific threats to the species identified by the FWS in its 2010 listing determination as more fully explained in the COT Report and the NTT Report. As previously noted, the COT Report stated "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation." Specifically, the COT Report preparers recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal." They further recommended an "avoidance first strategy" and stressed that "threats in PACs must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy" (FWS 2013).

In order to address the identified threats and meet the recommendations of the COT Report, the plans are based first on the identification of important habitat areas for GRSG in which the plans protect remaining habitat and target habitat restoration and improvement actions. Specifically, the plans identify PHMAs that align closely with PACs identified in the COT Report (except for PACs in Nevada and Utah, as specified on page 13 of the COT Report). Within PHMAs, the plans identify SFAs based on the FWS analysis of strongholds for the species based on population density, habitat integrity, and resilience to climate change among other factors. The SFAs serve as a landscape-level anchor for the conservation strategy and are closed or excluded from discretionary surface disturbances. SFAs are also used to prioritize fire protection, habitat restoration, and other habitat management actions (e.g., prioritizing reductions in WHB populations to achieve AML). This approach will allow the BLM to target limited resources to those areas identified by the FWS and reinforced by recent USGS analysis. These resources are those most important to long-term sagebrush ecosystem health and species persistence.

PHMAs and GHMAs boundaries are based on PPH and PGH (except in Utah, where PPH was derived from occupied habitat). Consistent with the BLM's IM 2012-044, PPH and PGH are based on data and maps developed through a collaboration between the BLM and the respective State wildlife agency. PPH and PGH (PHMAs and GHMAs in the Final EISs and now the ARMPAs) were developed using the best available data. Criteria for delineating PPH included breeding bird density (Doherty et al. 2010), GRSG proportionality, lek density, and key seasonal habitats, such as known winter concentration areas. PGH (now GHMAs) are areas of occupied seasonal, connectivity, or year-round habitat outside of PPH.

As discussed in **Section 1.6**, allocations and management actions are targeted to habitat management areas to limit or eliminate surface disturbance. All forms of new development in PHMAs—from energy, to transmission lines, to recreation facilities and grazing structures—are excluded, avoided, or allowed only if the resultant effect is neutral or beneficial to the GRSG. The ARMPAs will also prioritize future oil and gas leasing and development outside of identified GRSG habitat management areas (i.e., SFAs, PHMAs, and GHMAs) to reduce the potential for future conflict with GRSG.

The ARMPAs include additional measures to limit surface disturbance in PHMAs by establishing lek buffers and disturbance limits or caps and density restrictions (except in Nevada) of on average 1 energy facility per 640 acres. These requirements reflect recommendations in the NTT Report and are consistent with certain State strategies that were already in place before the initiation of the BLM's National GRSG Conservation Strategy. As described in **Section 1.6.1**, the BLM determined the appropriate lek buffers to analyze based on the USGS report *Conservation Buffer Distance Estimates for GRSG—A Review* (Manier et al. 2014) based on best available science.

The plans also include actions meant to improve habitat condition to the most important areas for conservation through additional, targeted efforts to protect and restore habitat first in SFAs, then in PHMAs, and finally in areas designated as GHMAs.

Mitigation for activities adversely impacting GRSG or GRSG habitat in PHMAs or GHMAs will be designed to a net conservation gain standard consistent with the recommendation included in the September 2014 FWS document, *Greater Sage-Grouse Range-Wide Mitigation Framework Version 1.0* (FWS 2014b). According to the authors, the Framework was prepared

> "to communicate some of the factors the Service is likely to consider in evaluating the efficacy of mitigation practices and programs in reducing threats to GRSG. The recommendations provided here are consistent with the information and conservation objectives provided in the 2013 Conservation Objectives Team (COT) Report for sage-grouse" (FWS 2014b).

Grazing, which is the most widespread use of the sagebrush ecosystem, will continue in a manner consistent with the objective of conserving the GRSG. Land health standards will incorporate GRSG habitat objectives and vegetative management objectives consistent with the ecological potential of the landscape as recommended by the COT Report to " . . . conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for GRSG (e.g. shrub cover, nesting cover)" (FWS 2013).

The ARMPAs also address the adverse impacts of free-roaming WHBs on GRSG habitat by prioritizing gathers and removing WHBs to achieve AMLs in SFAs, PHMAs, and GHMAs (in that order). The BLM has been working with the National Academy of Sciences to conduct new research of methods to reduce WHB reproduction rates. Through a combination of targeted gathers and the development of an effective agent for controlling future free-roaming WHB reproductive rates, over time, this threat to GRSG may be effectively managed.

Since the interaction of fire and invasive species represents the primary threat to GRSG survival in the Great Basin region, the ARMPAs provide specific guidance for improving efforts to reduce the risk of GRSG habitat loss to wildfire, including fire prevention and the restoration of habitats impacted by fire. The Department of the Interior took a series of actions over 2014 and 2015 to develop a more complete and comprehensive strategy for dealing with this threat. This led to Secretarial Order 3336 and the subsequent report, *An Integrated Rangeland Fire Management Strategy: Final Report to the Secretary of the Interior* (US Department of the Interior 2015).

In accordance with Secretarial Order 3336 and subsequent rangeland fire management strategy, substantial changes in policy and management direction have been made and will continue to be made to enhance BLM's ability to manage the threat of rangeland fire. These will affect all aspects of the rangeland fire management program; they will range from better coordination between resource managers and fire management officers to the identification and prioritization of prevention, suppression, and restoration in SFAs, PHMAs, and GHMAs; to the commitment of additional equipment and crews for rangeland firefighting; to additional funding and policy direction to improve post-fire restoration; to the completion of an initiative to collect, store, and better utilize native seed and sagebrush in post-fire restoration of sagebrush steppe ecosystems. This and the initiative to fight the spread of nonnative invasive species that contribute to higher rangeland fire risk (e.g., cheatgrass) discussed below have fundamentally changed how rangeland fire is managed to benefit sagebrush ecosystems and GRSG habitat.

The COT Report and other more recent research and analysis amplify concern for the contribution of cheatgrass and other invasive annual species to the loss of GRSG habitat associated with increased fire frequency and intensity. Work initiated by the WAFWA and based on recent research by Chambers et al. (2014) led to the development of the FIAT and a subsequent assessment that identified areas of resistance and resilience to fire in SFAs, PHMAs, and GHMAs. Through use of the FIAT Assessment Tool, land managers can more efficiently allocate and use fire resources at initial attack, to stop fire early and prevent catastrophic habitat loss, and to target restoration at those areas important to the species where success is more likely. The BLM is also committed to accelerating the registration and use of chemical and biological agents to stem the spread of cheatgrass and other invasive annual species.

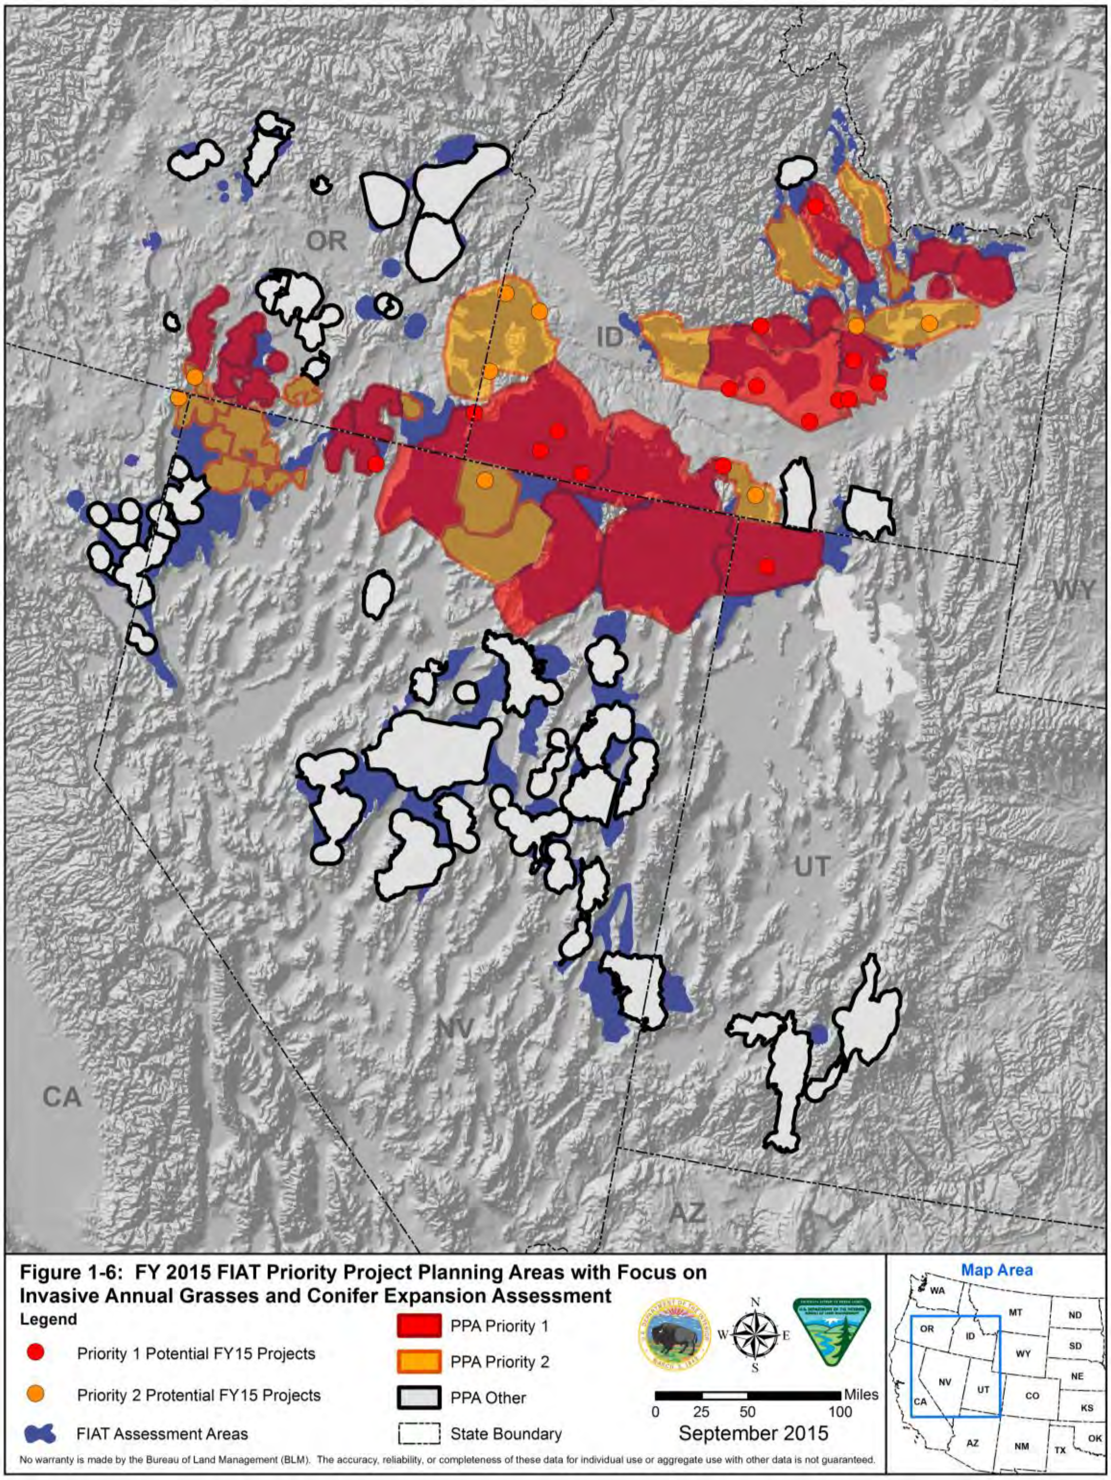
Even prior to completion of the FIAT assessment, the BLM shifted funding for fuels management to protect landscapes of importance to the GRSG. Under the FY 2014 Omnibus Appropriation, the BLM prioritized the funding of treatments and activities within each State that benefit GRSG (see this ROD'

Figure 1-6, FY 2015 FIAT Priority Project Planning Areas with Focus on Invasive Annual Grasses and Conifer Expansion Assessments).

To further supplement these efforts, among other things, the Department of the Interior has recently committed $7.5 million to projects in GRSG habitat to create more resilient landscapes, and the BLM has allocated $12 million to increase firefighting resources aimed at stopping fires while they are small in the Great Basin. In addition, the Department of the Interior has approved policy changes to increase the commitment, flexibility, and time frame for using ES&BAR funding. By adopting a risk-based approach using a rolling average of the acres lost to fire during the previous five fire seasons, ES&BAR funding will be allocated to the BLM to permit an increased focus on the restoration of priority sagebrush-steppe habitats impacted by fire.

In addition, the Sage Grouse Initiative launched by the NRCS in 2010 also contributes to the effort to protect and restore important GRSG habitat. In collaboration with the States and private landowners on private lands and with the BLM and the Forest Service on Federally administered public lands, the NRCS has worked to reduce the encroachment of pinyon-juniper trees and to restore rangeland habitat on private and BLM-administered lands.

Figure 1-6
FY 2015 FIAT Priority Project Planning Areas with Focus on Invasive Annual Grasses and Conifer Expansion Assessments



> Consistent with recommendations contained in the 2006 WAFWA Greater Sage-Grouse Range-wide Conservation Strategy (Stiver et al. 2006), the BLM and Forest Service conservation strategy relies heavily on monitoring and evaluation to assess the success and effectiveness of implementing the management decisions in the ARMPAs. Monitoring plans will be developed in coordination with relevant State and Federal agencies and will incorporate evaluation of GRSG population trends by the States and changes in habitat condition by the Federal land management agencies. The WAFWA report states, "Monitoring provides the 'currency' necessary to evaluate management decisions and to assess progress or problems. Adequate monitoring should be considered an integral and inseparable component of all management actions, and therefore, not optional. Lack of proper monitoring will undoubtedly hinder this large-scale conservation effort" (Stiver et al. 2006).

In addition, the ARMPAs incorporate an adaptive management framework that provides an early warning system of soft triggers to alert resource managers to the need to evaluate the effectiveness of their management strategies should changes occur in population levels or habitat conditions. If the project-level management responses to soft triggers do not adequately address the causes for population or habitat declines and if hard triggers are reached, the ARMPAs identify measures that will be put in place, including plan-level responses, in an effort to reverse the declines.

In summary, the ARMPAs emphasize an "avoidance first" strategy, consistent with the recommendations in the COT Report, by limiting new disturbance and maintaining current intact GRSG habitat. This avoidance first strategy is done by identifying important GRSG habitat areas, then applying allocations that exclude or avoid surface-disturbing activities, appropriately managing grazing, and aggressively suppressing fire that could degrade or fragment remaining GRSG habitat. The plans also include decisions to restore degraded habitat, which, although more difficult and requiring a longer time frame, is important to the long-term conservation of GRSG.

Restoration decisions include specific habitat objectives and making it a priority to treat GRSG habitat for invasive species, particularly cheatgrass, and encroaching pinyon and juniper. These decisions are reinforced by Secretarial Order 3336 and the *Integrated Rangeland Fire Management Strategy* (US Department of the Interior 2015) as well as the NRCS's Sage Grouse Initiative investments in private landowners' conservation efforts. This strategy reflects a high level of commitment by Federal partners to conserve GRSG and its habitat. The actions on Federal lands, which constitute nearly two-thirds of the most important lands for GRSG conservation, will anchor and complement the significant actions being taken by State and local governments and private landowners to conserve the species and its habitat.

The landscape-level strategy consisting of new conservation actions that will go into effect through the BLM ARMPAs, as well as actions being implemented currently to conserve the species, reflect a significant change in management direction and philosophy for the BLM since 2010 and a long-term commitment to assure the conservation of the species by protec[illegible] restoring, and enhancing GRSG habitat consistent with the objectives set in the 2006 WAFWA conservation strategy and embraced by both the NTT and the COT.

This change represents a new model for the BLM in managing the sagebrush landscape. It amplifies the need for collaboration among Federal, State, tribal, and private partners to conserve the GRSG, which is consistent with direction articulated in the NTT Report, as follows:

> "Land uses, habitat treatments, and anthropogenic disturbances will need to be managed below thresholds necessary to conserve not only local sage-grouse populations, but sagebrush communities and landscapes as well. Management priorities will need to be shifted and balanced to maximize benefits to GRSG habitats and populations in priority habitats. Adequacy of management adjustments will be measured by science-based effectiveness monitoring of the biological response of sagebrush landscapes and populations. Ultimately, success will be measured by the maintenance and enhancement of sage-grouse populations well into the future" (NTT 2011, p. 6-7).

The benefits of conserving the sagebrush ecosystem and GRSG habitats resulting from the BLM ARMPs and ARMPAs provide an essential foundation for conserving the GRSG. This, in conjunction with the amended Forest Service Land and Resource Management Plans (LRMPs), affects nearly two-thirds of GRSG habitat across the remaining range of the species. In conjunction with similar conservation efforts by other Federal and State agencies, private landowners, and local partners, the BLM National GRSG Conservation Strategy constitutes a historic conservation effort; it will benefit more than 350 species and the sagebrush ecosystem on which they depend. It is through these landscape-level, science-based, collaborations to conserve the imperiled sagebrush ecosystem that conservation of the GRSG and other sagebrush obligate species can best be achieved and the listing of the GRSG under the ESA may be avoided.

1.9 IMPLEMENTATION

Future decisions made in conformance with the ARMPAs serve to continuously and actively implement its provisions. Management decisions can be characterized as *immediate* or *one-time future* decisions.

Immediate Decisions—These decisions are the land use planning decisions that go into effect when the ROD is signed. These include goals, objectives, allowable uses, and management direction, such as the allocation of lands as open or closed for salable mineral sales, lands open with stipulations for oil and gas leasing, and OHV area designations. These decisions require no additional analysis and guide future land management actions and subsequent site-specific implementation decisions in the Planning Area. Proposals for future actions, such as oil and gas leasing, land adjustments, and other allocation-based actions, will be reviewed against these RMP decisions to determine if the proposal is in conformance with the plan.

One-Time Future Decisions—These are the types of decisions that are not implemented until additional decision-making and site-specific analysis is completed. Examples are implementation of the recommendations to withdraw lands from locatable mineral entry or development of travel management plans. Future one-time decisions require additional analysis and decision-making and are prioritized as part of the BLM budget process. Priorities for implementing one-time RMP decisions will be based on the following criteria:

- Relative importance of the action to the efficacy of the GRSG conservation strategy
- National BLM management direction regarding plan implementation
- Available resources

General Implementation Schedule of One-Time Decisions—Future Decisions discussed in the attached ARMPAs will be implemented over a period of years, depending on budget and staff availability. After issuing the ROD, the BLM will prepare implementation plans that establish tentative time frames for completing one-time decisions identified in these ARMPAs. These actions require additional site-specific decision-making and analysis.

This schedule will assist BLM managers and staff in preparing budget requests and in scheduling work. However, the proposed schedule must be considered tentative and will be affected by future funding, changing program priorities, nondiscretionary workloads, and cooperation by partners and external publics. Yearly review of the plan will provide consistent tracking of accomplishments and will provide information that can be used to develop annual budget requests to continue implementation.

1.9.1 Additional Implementation Guidance and Considerations

Instructional Memoranda—Additional instruction and management direction will be necessary to implement certain land allocation decisions and management direction included in the ARMPAs. For example, additional guidance will be provided to clarify how the BLM will implement the objective of prioritizing future oil and gas leasing and development outside of GRSG habitat. IMs and related guidance will be completed by The BLM Washington Office. The BLM will complete IMs for the following management direction with the intent of completing these IMs within 90 days of the RODs: oil and gas leasing and development prioritization and livestock grazing. Other IMs, including monitoring and mitigation, will be developed as necessary. Issuance of this national guidance will supersede any related national and field level guidance currently in effect. Additional national, state, and field level guidance will be developed as necessary to implement the decisions in the plans.

Map Adjustments and GRSG Seasonal Habitats—PHMAs were designed to include breeding bird density, GRSG proportionality, density of leks, and key seasonal habitats, such as known winter concentration areas. GHMAs were designed to include the areas of occupied seasonal, connectivity, or year-round habitat outside of PHMAs. As additional important habitats are identified (e.g., winter habitat and key connectivity areas), the BLM will map and incorporate these habitats for GRSG, consistent with best available science, through subsequent plan maintenance, revision, or amendment, as appropriate. Priority should be given to ensuring that wintering habitat is identified and captured in all changes in habitat maps subsequent to this decision. In the interim, the BLM will use the existing maps for all decisions.

Continued Commitment to Research and Use of Best Available Science—Through implementation of this strategy, new management issues and questions are likely to arise that may warrant additional guidance or study by technical experts, scientists, and researchers. The BLM is committed to continue working with individuals and institutions with expertise in relevant fields in order to ensure that land and resource management affecting conservation of the GRSG and the sagebrush ecosystem continues to be guided by sound peer-reviewed research and the best available science.

Training—Given the nature and complexity of the management direction in these ARMPAs, the BLM, in collaboration with the Forest Service and the FWS, will develop and implement a schedule of training for key functions, actions, and decisions associated with these plans. In this manner, the BLM will seek to better inform its personnel, partners, cooperators, and stakeholders of the changes in management that will result from this new management model.

CHAPTER 2
DECISION

2.1 SUMMARY OF THE APPROVED MANAGEMENT DECISIONS

The decision is hereby made to approve the Great Basin Region GRSG ARMPAs for the Great Basin Region GRSG Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah (attachments 1 through 4). This ROD serves as the final decision establishing the land use plan amendment decisions outlined in the ARMPAs and is effective on the date it is signed.

The decisions included in this ROD and attached ARMPAs amend the land use plans described in Sections 1.1 of attachments 1 through 4.

The land use decisions conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Land use plan decisions are expressed as goals and objectives (desired outcomes) and allocations, allowable uses, and management decisions anticipated to achieve desired outcomes. Although decisions identified in the ARMPAs are final and effective when this ROD is signed, implementing on-the-ground activities requires additional steps before any of them can begin. The BLM will conduct NEPA analyses, as necessary, for such implementation decisions.

2.2 WHAT THE ROD AND ARMPAS PROVIDE

The ARMPAs include GRSG and GRSG habitat land use plan-level management decisions in the form of the following:

- Goals
- Objectives (desired future conditions)
- Land use allocations and allowable uses
- Management actions

Goals are the broad statements of desired outcomes and are usually not quantifiable.

Objectives are specific desired conditions, usually quantifiable and measurable, and may have time frames for achievement.

Land use allocations specify locations in the Planning Area that are available or unavailable for certain uses and are also used to prioritize conservation and restoration management actions. Examples are decisions on the following:

- What lands are available for livestock grazing, mineral material use, oil and gas leasing, and locatable mineral development
- What lands may be available for disposal via exchange or sale
- What lands are open, closed, or limited to motorized travel

Note that all acreages presented in the approved plans are estimations, even when they are presented to the nearest acre.

Management decisions and actions are those provisions that help in meeting the established goals and objectives. They are the measures that will be applied to guide day-to-day activities on public lands, including but not limited to, stipulations, guidelines, best management practices, and RDFs.

The ARMPAs' management decisions were crafted to incorporate conservation measures into RMPs to conserve, enhance, and restore GRSG habitat by reducing, eliminating, or minimizing identified threats to GRSG and their habitats (see **Section 1.3**).

The EISs conducted for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Amendments sufficiently disclose and analyze all environmental issues associated with mineral leasing on Forest Service-administered lands. The issues would be relevant should the Forest Service consent to a lease or require consultation before it issues a lease. This would comply with applicable mineral leasing and NEPA regulations and would be subject to further site-specific environmental analysis where applicable.

2.3 WHAT THE ROD AND ARMPAS DO NOT PROVIDE

The attached ARMPAs do not contain decisions for public lands outside of GRSG habitat management areas, except for land use plan-level travel management decisions in the Idaho and Southwestern Montana ARMPA.

The ARMPAs do not violate valid existing rights nor contain decisions for the mineral estates that are not administered by the BLM. ARMPA decisions for surface estate only apply to BLM-administered lands. In addition, many decisions are not appropriate at this level of planning and are not included in the ROD. Examples of these types of decisions are the following:

- *Statutory requirements*—The decision will not change the BLM's responsibility to comply with applicable laws, rules, and regulations.
- *National policy*—The decision will not change the BLM's obligation to conform to current or future national policy.
- *Funding levels and budget allocations*—These are determined annually at the national level and are beyond the control of the State District or Field Offices.

Implementation decisions (or activity-level decisions) are management actions tied to a specific location. They generally constitute the BLM's final approval allowing on-the-ground actions to proceed and require appropriate site-specific planning and NEPA analysis. Such decisions may be incorporated into implementation plans (activity or project plans) or may be stand-alone decisions. These ARMPAs do not contain implementation decisions. Future activity-level plans will address the implementation of the ARMPAs. Implementation decisions and management actions that require additional site-specific project planning, as funding becomes available, will require further environmental analysis.

2.4 MODIFICATIONS AND CLARIFICATIONS

The ARMPAs in the Great Basin Region include minor modifications and clarifications to the Proposed RMPAs. These minor modifications and clarifications were made as a result of internal reviews, response to protests, and recommendations provided to the BLM during the Governors' consistency reviews. These modifications and clarifications are hereby adopted by this ROD.

The following modifications and clarifications were made to all of the ARMPAs in the Great Basin Region:

- *ARMPA Formatting*—The plans were reformatted between the Proposed RMPA and ARMPA planning stages for consistency across the Great Basin Region. The order of management actions and the prefixes for the goals, objectives, and management actions were changed in the ARMPAs to provide consistency among the amendments and revisions for GRSG goals and objectives.
- *Forest Service References (applicable only to the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah ARMPAs)*—All references to National Forest System lands in both text and on maps have been removed from the ARMPAs. The Forest Service has completed two separate RODs and land and resource management plan amendments under its planning authorities.
- *Fire*—Management actions and decisions were modified to stress that protecting human life is the single overriding priority for fire and fuels management activities.
- *Livestock Grazing*—The statement, "This does not apply to or impact grazing preference transfers, which are addressed in 43 CFR 4110.2-3," was added to the management action and decision. It reads, "At the time a permittee or lessee voluntarily relinquishes a permit or lease, the BLM will consider whether the public lands where that permitted use was authorized should remain available for livestock grazing or be used for other resource management objectives, such as reserve common allotments or fire breaks."
- *Glossary*—Numerous glossary definitions were deleted because they were not used or referenced in the ARMPAs. If not already contained in the Proposed RMPAs' glossaries, the following terms and definitions were added to the glossary for clarification:
    - **Grazing Relinquishment.** The voluntary and permanent surrender by an existing permittee or lessee, (with concurrence of any base property lienholders), of their priority (preference) to use a livestock forage allocation on public land as well as their permission to use this forage. Relinquishments do not require the consent or approval of the BLM. The BLM's receipt of a relinquishment is not a decision to close areas to livestock grazing.

  - **Transfer of Grazing Preference.** The BLM's approval of an application to transfer grazing preference from one party to another or from one base property to another or both. Grazing preference means a superior or priority position against others for the purposes of receiving a grazing permit or lease. This priority is attached to base property owned or controlled by the permittee or lessee.
  - **Valid Existing Right.** Documented legal rights or interests in the land that allow a person or entity to use said land for a specific purpose and that are still in effect. Such rights include, but are not limited to, fee title ownership, mineral rights, ROWs, easements, permits, and licenses. Such rights may have been reserved, acquired, leased, granted, permitted, or otherwise authorized over time.
  - **Mining Claim.** A parcel of land that a miner takes and holds for mining purposes, having acquired the right of possession by complying with the 1872 Mining Law and local laws and rules. A mining claim may contain as many adjoining locations as the locator may make or buy. There are four categories of mining claims: lode, placer, mill site, and tunnel site.
  - **Energy or Mining Facility.** Human-constructed assets designed and created to serve a particular function and to afford a particular convenience or service that is affixed to a specific locations, such as oil and gas well pads and associated infrastructure.

- *GRSG Habitat Mapping*—Information was added to the ARMPAs to specify that when new information becomes available about GRSG habitat, including seasonal habitats, in coordination with the State wildlife agency and FWS, and based on best available scientific information, the BLM may revise the GRSG habitat management area maps and associated management decisions through plan maintenance or plan amendment or revision, as appropriate.
- *Adaptive Management*—The GRSG Adaptive Management Strategy was revised to include a commitment that the hard and soft trigger data will be evaluated as soon as it becomes available after the ROD is signed and then will be analyzed, at a minimum, annually thereafter.
- *Vegetation*—The desired condition for maintaining a minimum of 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover in SFAs and PHMAs was modified to read as follows: "In all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain all lands ecologically capable of producing sagebrush (but no less than 70 percent) with a minimum of 15 percent sagebrush canopy cover, consistent with specific ecological site conditions. The attributes necessary to sustain these habitats are described in Interpreting Indicators of Rangeland Health" (BLM Tech Ref 1734-6; Pellant 2005).
- *GRSG Habitat Objectives*—For clarification purposes, within each of the ARMPA GRSG habitat objectives tables, native bunchgrass was provided as an example of a perennial grass cover and residual grass was added to the perennial grass cover and height objective.
- *Sagebrush Focal Areas*—Examples of the types of vegetation and conservation actions that will be prioritized within SFAs were provided for clarity in the management action and

decision. These examples were land health assessments and WHB management and habitat restoration actions.

- *Required Design Features*—One of the criteria for demonstrating that a variation to an RDF is warranted was modified to include the following statement: "An alternative RDF, a state-implemented conservation measure, or plan-level protection is determined to provide equal or better protection for GRSG or its habitat."
- *Lands and Realty*—The following management actions and decisions and objectives were clarified:
  - Effects of infrastructure projects, including siting, will be minimized using the best available science, updated as monitoring information on current infrastructure projects becomes available.
  - Within existing designated utility corridors, the 3 percent disturbance cap may be exceeded at the project-scale if the site-specific NEPA analysis indicates that a net conservation gain to the species would be achieved. This exception is limited to projects that fulfill the use for which the corridors were designated (e.g., transmission lines and pipelines) and the designated width of a corridor would not be exceeded as a result of any project collocation.
- *Land Tenure*—Management action associated with land disposals was clarified to include land exchanges as a means of disposal.
- *WAFWA GRSG Conservation Team*—Additional clarification was added to ARMPAs related to the WAFWA GRSG Conservation Teams that were identified in the Proposed RMPAs: "WAFWA management zones will be used to facilitate cross-state issues, such as regional mitigation and adaptive management monitoring and response, through WAFWA GRSG Conservation Teams. These teams will convene and respond to issues at the appropriate scale and will use existing coordination and management structures to the extent possible."
- *Cheatgrass*—The following management action was included consistent with the purpose and need and objectives of the ARMPAs: "Treat areas that contain cheatgrass and other invasive or noxious species to minimize competition and favor establishment of desired species."
- *Valid Existing Rights*—The following management action was added to the ARMPAs: "Consider the likelihood of developing not-yet-constructed surface-disturbing activities, as defined in Table 2 of the Monitoring Framework, under valid existing rights before authorizing new projects in PHMAs."

Additional modifications and clarifications specific to each sub-region ARMPA are summarized below.

2.4.1 Idaho and Southwestern Montana

General Changes

- All exception language that was in the Final EIS in various places was grouped into a stipulation appendix and added to the ARMPA as Appendix G Stipulations.
- Appendix G, Anthropogenic Disturbance and Adaptive Management from the Proposed RMPA, which is now Appendix E in the ARMPA, was modified to delete the reference to

Tables 2 to 7. These tables were deleted from the Final EIS Appendix G before it was made available to the public for protest, but the reference was not deleted in the appendix text. This discrepancy was identified during protest resolution and the Governor's consistency review. These values will be calculated after the ROD is signed (see Adaptive Management below).

- Many editorial changes, including deleting repeated numbers and correcting spelling errors, were made when finalizing the ARMPA.
- On August 7, 2015, President Obama signed into law the Sawtooth National Recreation Area and Jerry Peak Wilderness Act (House Resolution 1138). In accordance with the Wilderness Act (16 USC, Section 1131 et seq.), certain Federal lands in the Challis National Forest and Challis District of the BLM in Idaho, comprising approximately 116,898 acres, were designated as Wilderness, as a component of the National Wilderness Preservation System, known as the Jim McClure-Jerry Peak Wilderness.

  This bill also released the Jerry Peak West, Corral-Horse Basin, and Boulder Creek Wilderness Study Areas, and they are no longer subject to Section 603(c) of the FLPMA.

  Finally the Sawtooth National Recreation Area and Jerry Peak Wilderness Act also directed the BLM to convey certain public lands to Blaine and Custer Counties and the Cities of Challis, Clayton, and Stanley. These conveyances include approximately 53 acres of PHMAs, 10 acres of IHMAs, and 828 acres of GHMAs that are reflected in the ARMPA as being administered by the BLM. Once conveyed, the BLM will adjust the maps and acres as they appear in the ARMPA through plan maintenance to depict that these lands are not subject to the BLM management decisions outlined in the Idaho and Southwestern Montana GRSG ARMPA.

Special Status Species

- The Seasonal Timing Restrictions from Appendix C of the Final EIS were deleted to reduce redundancy because these restrictions were already in the RDFs appendix.

Livestock Grazing

- Livestock Grazing RM 16 and RM 18, which are now MD LG 15 and MD LG 17 in the ARMPA, had the following sentence added as an accepted recommendation made during the Governor's consistency review to clarify management and conservation action prioritization in SFAs: "Management and conservation action prioritization will occur at the Conservation Area (California) scale and be based on GRSG population and habitat trends: Focusing management and conservation actions first in SFAs followed by areas of PHMAs outside SFAs."

Lands and Realty

- Lands and Realty LR-14 from the Proposed RMPA, which is now MD LR 13 in the ARMPA, was modified to remove the statement that lands in PHMAs, IHMAs, and GHMAs would be available for disposal only through exchange. This was removed because it was not consistent with BLM policy, and the net conservation gain clause in MD LR-13 would ensure that disposals through any method would be beneficial to GRSG.

2.4.2 Nevada and Northeastern California

General Changes

- Editorial changes, such as changing should to shall and would to will, to reflect the final decision language.
- Re-categorizing some of the management decisions into other common resource programs. For example, all of the fire and fuels management decisions are numbered under FIRE and are not split into different subcategory names.
- Re-lettering the critical appendices and deleting those that are no longer applicable to the ARMPA.

Special Status Species

- Added clarity to MD SSS 2A 3 by describing the energy and mining facilities where this decision would be applicable; taken directly from the Disturbance Appendix E.
- Added clarity to MD SSS 3A by including references to valid existing rights and applicable law for the requirement of a net conservation gain.
- Specified in MD SSS 8 that this activity would be coordinated with the Nevada Department of Wildlife or California Department Fish and Wildlife and that breeding activity surveys would be done for actions involving mineral activities and ROWs.
- Deleted Action PR 4 from the Proposed RMPA because the BLM does not manage landfills and transfer stations.
- Under the Brood-Rearing/Summer category, clarified that the objective of the 7-inch-deep, rooted perennial bunchgrass in upland habitats was only for a 522-foot (200 meter) area around riparian areas and meadows. The additional reference was added for Casazza et al. 2011.
- Footnote #7 was deleted. The original footnote stated that the "specific height requirements needed to meet the objective will be set at the time of habitat assessment framework assessments." This is incorrect because the height requirements will need to be set well in advance of the habitat assessment framework assessments.
- A new footnote was added as footnote #1: "Any one single habitat indicator does not define whether the habitat objective is or is not met. Instead, the preponderance of evidence from all indicators within that seasonal habitat period must be considered when assessing sage-grouse habitat objectives." This addition was for the purpose of clarification.

Adaptive Management

- Clarified under MD SSS 21 that the BLM will coordinate with the Nevada Department of Wildlife and that the decision was specific to mineral activities and ROW actions.

Fire and Fuels Management

- Deleted "Field Offices" and "Districts" from MD FIRE 3, as there will be a multilayered approach to coordination, including BLM State Offices.

- In Objective FIRE 3, added "in SFAs first" to provide more emphasis to the SFAs over the rest of the PHMAs for this action.
- Modified MD FIRE 26 to delete "Districts," as there will be a multilayered approach to identifying treatment needs for wildfire and invasive species management across the State.
- Added "FWS" as a coordination entity to MD FIRE 31, when ensuring that proposed sagebrush treatments are coordinated with the BLM and State fish and wildlife agencies.

Livestock Grazing

- Management Decision LG 1 was modified for clarity and to include the fact that the BLM would conduct appropriate consultation, cooperation, and coordination.
- Management Decision LG 5 was modified to add supplementary management actions and clarifies that the potential modifications include "but are not limited to" to actions on the list.
- Management Decision LG 5 was modified to make it clear that the management strategies listed are not limited to just those listed under LG 5 by adding "but are not limited to." This was added to clarify a misunderstanding in a protest letter.
- Management Decision LG 7 was clarified to state that "AUMs cannot be applied to another pasture that is already being used by livestock or is being purposefully rested."
- Management Decision LG 15 was modified to state that removing or modifying water developments must be done "In accordance with state water law and…"

Mineral Resources

- Management Decision MR 18 was modified to provide the Barrick Enabling Agreement (March 2015) as an example of appropriate mitigation that can be considered in the future, and the last sentence was removed because it only repeated BLM regulations and is unnecessary.

Lands and Realty

- In order to resolve a protest, MD LR 3 was modified to state that corridors will be 3,500 feet wide "or a different width is specified for congressional designated corridors." This is in response to the Lincoln County Conservation Recreation Development Act (2204), which included congressionally designated corridors that were not included in the plan amendment or the corridor map. The corridor map (Figure 2-10) was also modified to reflect the corridors tied to this act.
- Action LR-LUA 21 from the Proposed Plan was deleted because the Federal Highway Administration and the Nevada Department of Transportation already have valid existing rights associated with their easements and ROWs, and this planning effort would not change the terms and conditions of their existing easements or ROWs. Making this a management action is repetitive and unnecessary.

Travel and Transportation

- Due to confusion that was outlined in protest letters and in the Governor's consistency review, MD TTM 2 was clarified to say that limiting off-highway travel to existing routes in

PHMAs and GHMAs would be "subject to valid existing rights, such as for a mine under a plan of operations."

- Additional language was added to MD TTM 3 to make it clear that the bulleted "guidelines will be considered when undertaking future implementation-level travel planning." This was in response to protest misunderstandings. In addition, bullet three was amended by deleting "developed in this plan amendment," as the criteria is not developed through the plan amendment.

Mitigation

- In order to provide consistency across the Great Basin Regional Planning Area, the two mitigation management decisions were removed from the Adaptive Management, Monitoring, and Mitigation section of Chapter 2 in the Proposed RMPA (these are now separate appendices) and inserted as management decisions independently under the Mitigation section.

2.4.3 Oregon

Lands and Realty

- A typographical error in the socioeconomic analysis of the Proposed RMPA was identified during the protest period. Correction to this error in Section 4.20.3, page 4-345, is as follows: Paragraph beginning "Restrictions to ROW development under Alternatives B, C, D, E, F, and the Proposed Plan…" is replaced with the following:

  "Proposed management under Alternatives B, C, D, E, F, and the Proposed Plan could require investors to consider alternative power line ROW alignments or designs that could increase the costs of constructing new infrastructure. A 2012 WECC study, for example, provides information on transmission line construction costs per mile, which range from $927,000 to $2,967,000 depending on voltage and whether lines are single or double circuit lines. The same study provides cost multipliers for difficult terrains, reaching up to 2.25 in the case of forested lands (WECC 2012). Utilities and other infrastructure investors typically pass these costs on to consumers. Where the rate base is smaller, such as in rural areas, per-customer rate impacts associated with constructing a 10-mile, 230kV transmission line, for example, would be greater compared to the economic impacts on rate payers served by a larger metropolitan utility proposing the same line. Under Alternatives B, C, D, E, and the Proposed Plan, rate payers serviced by local utility providers with small rate bases would be impacted more by costs associated with added route lengths or infrastructure design requirements compared with rate payers serviced by larger, multi-State providers. Where technically and financially feasible, Alternatives B, D, and the Proposed Plan identify burial of power lines as a design option to mitigate impacts on GRSG. New construction costs of underground transmission lines can be between 4 and 14 times higher compared to new overhead construction (PSC 2011), depending on terrain. In rural areas, burial of new distribution lines would be more than double the cost of new overhead construction. Burying existing distribution lines would likely cost between $400,000 and $500,000 per mile in rural areas (EIA 2012). Under all alternatives, where burying new lines would be technically unfeasible or result in costs that could not be absorbed by the rate payers, infrastructure investors would explore other route or design options that avoid impacts to GRSG habitat."

Renewable Energy

- Managed Decision RE-2 was modified to include the statement, "In Harney, Lake, and Malheur Counties, priority would be placed on locating commercial scale wind and solar energy development in non-habitat areas first (i.e., outside of PHMAs and GHMAs) before approving development in PHMAs."

Special Status Species (Greater Sage-Grouse)

- Objective SSS 6 was modified to clarify that the BLM will coordinate with the State of Oregon regarding proposed management changes, the implementation of conservation measures, mitigation, and site-specific monitoring related to adaptive management and human disturbances. This modification was recommended during the Governor's consistency review.

Leasable Mineral Resources

- Based on internal review, MLS 7 from the Proposed RMPA, which is now MD MR 7 in the ARMPA, was modified to include all fluid mineral lease development, including geothermal permits to drill.

2.4.4 Utah

General Changes

- Throughout the Proposed RMPA, the words "would," "could," "should," and "may" were generally removed or revised to reflect the *active* management direction of an ARMPA rather than *potential* management presented when the Proposed RMPA was one of many alternatives that the agency could select.
- Language was added to Objective SSS-3 (Objective GRSG-3 in the Proposed RMPA), MA-SSS-4 (MA-GRSG-4 in the Proposed RMP Amendment), MA-SSS-6 (MA-GRSG-6 in the Proposed RMPA), Objective VEG-1, MA-VEG-1, MA-FIRE-3 and MA-FIRE-4 to clarify that landscapes that include populations of both GRSG and Utah prairie dog, a Federally listed species, be managed for the benefit of both species. This addition is included to ensure that this objective is included in all applicable objectives and management actions, not just the five actions in the Proposed RMPA where this concept and language was already present.
- Throughout the Proposed RMPA there were a number of references to coordinating with the State of Utah, Division of Wildlife Resources, or State biologists. These were all revised to note that such coordination would be with "the appropriate State of Utah agency." This clarification was made at the request of the Governor during his consistency review.
- The Proposed RMPA introduced the term biologically significant unit (BSU) for adaptive management and the disturbance cap to provide a consistent approach for managing and monitoring across the GRSG range. In the Utah Sub-Region, the boundaries of the BSUs follow the population area boundaries within PHMAs. As part of resolving protests, the ARMPA was revised to note that BSUs are PHMAs within population areas. Whenever the

term BSU was used, it was replaced with the more descriptive text, with a parenthetical reference to BSUs for the purposes of coordinating across State lines.

Special Status Species (formerly Greater Sage-Grouse)

- Objective GRSG-1 from the Proposed RMPA, which is now Objective SSS-1 in the ARMPA, was changed to remove reference to WAFWA MZs when addressing designation of PHMAs. This change was made during the Governor's consistency review to more closely reflect the management in the State of Utah's Conservation Plan for GRSG in Utah (2013).
- MA-GRSG-1 from the Proposed RMPA, which is now MA-SSS-1 in the ARMPA was revised to include the following text: "The BLM will apply these goals, objectives, and management actions where the agency has discretion to implement them; the actions do not apply in areas where the BLM does not administer the surface or mineral estate." This is consistent with the planning criteria contained in the sixth bullet on page 1-20 of the Final EIS. This language was added based on an accepted recommendation made by the Governor during the Governor's consistency review.
- The language of MA-GRSG-1 from the Proposed RMPA, which is now MA-SSS-1 in the ARMPA, regarding nonhabitat areas within PHMAs and GHMAs was revised to clarify the intent of the action. This revision was made as a result of internal reviews to ensure the text more accurately reflected the intent behind the management action.
- The introductory language of MA-GRSG-3 from the Proposed RMPA, which is now MA-SSS-3 in the ARMPA, was revised to clarify the intent of the action. This revision was made as a result of internal reviews to ensure the text accurately reflects the intent behind the management action and to focus on land uses that have been identified as threats to GRSG.
- The language of MA-GRSG-3e from the Proposed RMPA, which is now MA-SSS-3e in the ARMPA, was revised to clarify the intent of the noise restrictions. This revision was made as a result of internal reviews to ensure the text accurately reflects the intent behind the management action to focus on land uses that have been identified as threats to GRSG. Further, language was added to identify when "ambient" noise levels would be assessed to avoid managing for continual incremental increases in noise levels.
- The language of MA-GRSG-6 from the Proposed RMPA, which is now MA-SSS-6 in the ARMPA, was revised to clarify the intent of GRSG management outside PHMAs/GHMAs. This revision was made as a result of internal reviews to ensure the text accurately reflects the intent behind the management action. The purpose of this action is to provide direction for managing areas outside PHMAs and GHMAs that have been treated to improve GRSG habitat. The change was necessary to avoid the implication of changing allocations or altering PHMA and GHMA boundaries outside a planning process, while minimizing conflicting land uses in areas where an investment in increasing GRSG habitat have been made.

Livestock Grazing

- The language of MA-GRA-6 from the Proposed RMPA, which is now MA-LG-6 in the ARMPA, was revised. The concepts and intent did not change, but the text was revised to align with similar concepts and intent in the livestock grazing sections in GRSG amendments throughout the Great Basin.

2.5 PROTEST RESOLUTION

The BLM's planning regulations at 43 CFR 1610.5-2 allow any person who participated in the planning process and has an interest that may be adversely affected by the BLM's planning decisions to protest proposed planning decisions within 30 days of when the notice of availability of the Proposed RMP/Final EIS was published in the *Federal Register* (May 29, 2015).

The BLM Director concluded that the BLM had followed all applicable laws, regulations, and policies and had considered all relevant resource information and public input in developing the Proposed RMPAs/Final EISs. Each protesting party has been notified in writing of the Director's findings and the disposition of their protests. The Director resolved the protests without making significant changes to the Proposed RMPAs/Final EISs, though minor clarifications were made and are summarized in **Section 2.4**. The Director's decisions on the protests are summarized in each of the Proposed RMPAs/Final EISs Director's Protest Resolution Reports, which are available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Below are descriptions of the protest resolution process for each of the four Great Basin Region Proposed RMPAs/Final EISs.

2.5.1 Idaho and Southwestern Montana

For the Idaho and Southwestern Montana GRSG Proposed RMPA/Final EIS, the BLM Director received 20 timely protest submissions. All of the protesting parties had standing; however, one submission was dismissed as it did not contain any valid protest points, pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report are as follows:

- Compliance with FLPMA
- Compliance with NEPA
- Compliance with ESA
- Density and disturbance
- Adaptive management
- GRSG habitat objectives
- Livestock grazing
- Mitigation
- Compliance with the Administrative Procedure Act
- Compliance with the Energy Policy Act of 2005
- Areas of critical environmental concern
- Fire and fuels management
- Fluid minerals
- Solid minerals
- Special status species
- Lands and realty

- Travel and transportation management

2.5.2 Nevada and Northeastern California

For the Nevada and Northeastern California GRSG Proposed RMPA/Final EIS, the BLM Director received 40 timely protest submissions. All of the protesting parties had standing; however, two submissions were dismissed as they did not contain any valid protest points, pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report are as follows:

- Compliance with FLPMA
- Compliance with NEPA
- Compliance with ESA
- Density and disturbance
- Adaptive management
- GRSG habitat objectives
- Livestock grazing
- Mitigation
- Compliance with the Administrative Procedure Act
- Compliance with the Energy Policy Act of 2005
- Air quality
- Climate change
- Noise
- Areas of critical environmental concern
- Solid minerals
- Special status species
- Lands with wilderness characteristics
- Lands and realty
- Tribal issues
- WHBs
- Travel and transportation management

2.5.3 Oregon

For the Oregon GRSG Proposed RMPA/Final EIS, the BLM Director received 30 timely protest submissions. All of the protesting parties had standing; however, three submissions were dismissed as they did not contain any valid protest points, pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report are as follows:

- Compliance with FLPMA

- Compliance with NEPA
- Compliance with ESA
- Density and disturbance
- Monitoring
- Areas of critical environmental concern
- Fire and fuels management
- Solid minerals
- Special status species
- Travel and transportation management

2.5.4 Utah

For the Utah GRSG Proposed RMPA/Final EIS, the BLM Director received 43 timely protest submissions. All of the protesting parties had standing; however, three submissions were dismissed as they did not contain any valid protest points, pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report are as follows:

- Compliance with FLPMA
- Compliance with NEPA
- Compliance with ESA
- Density and disturbance
- Adaptive management
- Land use allocations
- GRSG habitat objectives
- Livestock grazing
- Mitigation
- Compliance with the Administrative Procedure Act
- Compliance with the Energy Policy Act of 2005
- Air quality
- Climate change
- Noise
- Areas of critical environmental concern
- Fire and fuels management
- Fluid minerals
- Solid minerals
- Special status species

- Lands and realty
- Travel and transportation management
- Reasonable foreseeable development scenarios

2.6 GOVERNOR'S CONSISTENCY REVIEW

The BLM's planning regulations require that RMPs be "consistent with officially approved or adopted resource-related plans, and the policies and procedures contained therein, of other Federal agencies, state and local governments, and Indian tribes, so long as the guidance and resource management plans also are consistent with the purposes, policies, and programs of Federal laws and regulations applicable to public lands" (43 CFR 1610.3-2[a]).

The general requirement in FLPMA planning regulations is to coordinate the land use planning process with plans of other agencies, States, and local governments to the extent consistent with law (see FLPMA Section 202[c][9] and CFR 1610.3-1[a]) and the respective duties to be consistent with both officially approved or adopted plans (to the extent those plans are consistent with Federal law or to the maximum extent practical; see CFR 1610.3-2[a][b]). In accordance with FLPMA, the BLM was aware of and gave consideration to State, local, and tribal land use plans and provided meaningful public involvement throughout the development of the Proposed RMPAs/Final EISs.

The BLM is aware that there are specific State laws and local plans relevant to aspects of public land management that are discrete from, and independent of, Federal law; however, the BLM is bound by Federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that the BLM's land use plans be consistent with officially approved State and local plans only if those plans are consistent with the purposes, policies, and programs of Federal laws and regulations applicable to public lands.

Where officially approved State and local plans or policies and programs conflict with the purposes, policies, and programs of Federal laws and regulations applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially approved State and local policies and programs (as opposed to plans), this consistency provision applies only to the maximum extent practical. While county and Federal planning processes, under FLPMA, are required to be as integrated and consistent as practical, the Federal agency planning process is not bound by or subject to State or county plans, planning processes, policies, or planning stipulations.

The 60-day Governor's consistency review period ended on July 29, 2015. In the Great Basin Region, the Governors of Idaho, Nevada, Oregon, and Utah submitted letters to their respective BLM State Directors, asserting inconsistencies between the BLM's Proposed RMPAs and their State's or local governments' resource-related plans, policies, and procedures, as well as other concerns that they had with the proposed planning documents.

On August 6, 2015, the BLM State Directors notified the Governors as to whether their recommendations were accepted or rejected. These Governors were then provided with 30 days to appeal the BLM State Director's decisions to the BLM Director. On September 8, 2015, the BLM Director received appeals from the Governors of Idaho and Nevada; on September 11, 2015, the BLM Director received an appeal from the Governor of Utah. The BLM Director reviewed these appeals and rejected the recommendations of the Governors of Idaho, Nevada, and Utah by letters dated

September 16, 2015, before this ROD was issued. The BLM Director's response to these appeals will also be published in the *Federal Register* after this ROD is issued.

In some instances, modifications to the ARMPAs were addressed based on recommendations submitted to the BLM by the applicable Governors. These modifications were made and are summarized in **Section 2.4**.

3. ALTERNATIVES

DO NOT DELETE THIS PAGE from the MS Word file, as this is what marks Heading 1 for the table of contents. (Do delete this page later from the Adobe Acrobat [pdf] file.)

CHAPTER 3
ALTERNATIVES

3.1 ALTERNATIVES CONSIDERED

Each of the Great Basin sub-regional planning efforts analyzed in detail a set of alternatives in the draft and final sub-regional EISs. The alternatives were developed to provide direction for resource programs. Their intent was to meet purpose and need of this planning to identify and incorporate appropriate management direction in land use plans to conserve, enhance, and restore GRSG habitat. This would be accomplished by reducing, eliminating, or minimizing threats to GRSG habitat. All management considered under any of the alternatives complied with Federal laws, rules, regulations, and policies.

Each alternative emphasized an altered combination of resource uses, allocations, and restoration measures to address issues and resolve conflicts among uses so that GRSG goals and objectives were met in varying degrees across the alternatives. The action alternatives offered a range of possible management approaches for responding to planning issues and concerns identified through public scoping and to maintain or increase GRSG abundance and distribution in the Planning Area. While the land use plan goal was the same across alternatives for each sub-region, each alternative contained a discrete set of objectives and management actions, constituting a separate RMP amendment. The goal was met to varying degrees, with the potential for different long-range outcomes and conditions.

The relative emphasis given to particular resources and resource uses differed as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs. When resources or resource uses are mandated by law, there are typically few or no distinctions between alternatives.

3.1.1 Alternative A—No Action Alternative

Alternative A meets the CEQ requirement that a no action alternative be considered. This alternative continues current management direction derived from the existing field and district office RMPs, as amended. Goals and objectives for resources and resource uses are based on the most recent RMP decisions, along with associated amendments and other management decision documents. Laws, regulations, and BLM policies that supersede RMP decisions would apply.

Goals and objectives for BLM-administered lands and mineral estate would not change. Appropriate and allowable uses and restrictions pertaining to such activities as mineral leasing and development, recreation, utility corridor construction, and livestock grazing would also remain the same. The BLM would not modify existing or establish additional criteria for identifying site-specific use levels.

This alternative was not selected as the ARMPAs because it did not meet the purpose and need of this plan amendment. Moreover, it did not include necessary changes to the existing decisions based on the FWS 2010 listing decision, which identified the inadequacy of regulatory mechanisms as a significant threat to GRSG and its habitat. This alternative also did not incorporate the best available science pertaining to GRSG or its habitat.

3.1.2 Alternative B—National Technical Team Report Alternative

Alternative B was based on the conservation measures contained within the NTT Report. The GRSG NTT, comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed *A Report on National Greater Sage-grouse Conservation Measures* in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable GRSG populations and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse MZs. The NTT Report preparers proposed conservation measures based on habitat requirements and other life history aspects of GRSG. Also they described the scientific basis for the conservation measures proposed within each program area. The NTT Report also provided a discussion of and emphasized the importance of standardizing monitoring across the WAFWA Sage-Grouse MZs.

The BLM's Washington Office IM 2012-044 directed the sub-regional planning to analyze the conservation measures developed by the NTT, as appropriate, through the land use planning process and NEPA.

Alternative B would exclude ROW development in PHMAs and would avoid development in GHMAs; it would close PHMAs to fluid mineral leasing, mineral material sales, and nonenergy leasable minerals; and it would recommend withdrawal from locatable mineral entry in all PHMAs. These management actions would reduce surface disturbance in PHMAs and would minimize disturbance in GHMAs, thereby maintaining GRSG habitat.

Management actions for wildfire would focus on suppression in PHMAs and GHMAs, while limiting certain types of fuels treatments. Vegetation management would emphasize sagebrush restoration. Collectively, vegetation and wildfire management would conserve GRSG habitat. Grazing would continue with similar impacts under Alternative B as under Alternative A. The best management practices proposed in the NTT Report would be included as RDFs as part of Alternative B and are listed in Appendix C, Required Design Features (RDFs), of each of the attached ARMPAs.

Alternative B was not selected in its entirety as the ARMPAs because most of the conservation measures in the NTT Report, as appropriate and applicable, were applied primarily to PHMAs, and few conservation measures in the report were provided for in GHMAs. As a result, Alternative B did not provide adequate conservation in GHMAs.

3.1.3 Alternative C—Citizen Groups' Recommended Alternative One

Alternative C was based on an alternative recommended by citizen groups. This alternative emphasizes improving and protecting GRSG habitat and was applied to all occupied GRSG habitat (PHMAs and GHMAs). Alternative C limited commodity development in areas of occupied GRSG habitat and closed or excluded large portions of the Planning Area to many land uses. This included all PHMAs and GHMAs as being closed to livestock grazing, recommended for withdrawal from locatable mineral entry, closed to fluid mineral leasing, closed to salable mineral and nonenergy leasable mineral development, and exclusion areas for ROWs. The Utah Draft RMPA/EIS combined this alternative with Alternative F (discussed below) and included two sub-alternatives under Alternative C for a reduction in livestock grazing and WHB management.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMAs and GHMAs to such an extent that it did not adequately accommodate local needs, customs, and culture. Also, it included proposed actions that are not necessary for GRSG conservation. For example, this alternative closed all allotments to livestock grazing, which, based on best available science, is not required to conserve GRSG and its habitats. Alternative C was also not selected in its entirety because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.4 Alternative D—Draft RMP Amendments' Preferred Alternative

Alternative D, which was identified as the preferred alternative in the Draft EISs, balanced opportunities to use and develop the Planning Area as well as conserving, maintaining, and enhancing GRSG and their habitat. Protective measures were applied to GRSG habitat, while allowing for human disturbances, with stringent mitigation measures. This alternative represents the mix and variety of management actions based on the BLM's analysis and judgment, which best resolve the resource issues and management concerns, while meeting laws, regulations, and policies pertaining to BLM management. As a result of public scoping comments, internal review, and cooperating agency coordination on the Draft RMPAs/EISs, this alternative was modified to become the Proposed RMPAs and was analyzed in the Final EISs. The preferred alternatives, with slight variations, became the proposed plans in the Final EISs.

In PHMAs under Alternative D, disturbance in GRSG habitat would be limited by excluding wind and solar energy development (except for certain counties in Southeastern Oregon, where avoidance is applied), avoiding most ROW development (subject to certain conditions), applying NSO stipulations to fluid mineral development, and closing PHMAs to nonenergy leasable mineral development and mineral material sales. These management actions would protect GRSG habitat, while allowing other activities, subject to conditions. In GHMAs under Alternative D, allocations are less stringent but still aim to protect GRSG habitat (for example, applying moderate constraints and stipulations to fluid minerals in GHMAs).

Under Alternative D, the BLM management would support sagebrush/perennial grass ecosystem restoration, would increase fire suppression in PHMAs and GHMAs, and would manage livestock grazing to maintain or enhance sagebrush and perennial grass ecosystems.

3.1.5 Alternative E: State/Governor's Alternative

Alternative E is the alternative based on information provided by the State or Governor's offices for inclusion and analysis in the EISs. In many instances, the BLM had to adjust what was provided by the

States and Governors to fit such requirements as BLM language and decision-making constructs. This alternative incorporates guidance from specific State conservation strategies, if developed, or recommendations from the State for managing Federal lands. It emphasizes managing GRSG seasonal habitats and maintaining habitat connectivity to support population objectives. Alternative E was identified as a co-Preferred Alternative in the Idaho and Southwestern Montana Draft EIS. California did not provide the BLM with a State GRSG conservation plan and, under this alternative, reverted back to Alternative A, the No Action alternative.

For Nevada, Alternative E would apply an "avoid, minimize, and mitigate" strategy to reduce direct and indirect impacts on GRSG from surface-disturbing activities on BLM-administered lands. The effects on GRSG habitat from certain resource programs, such as grazing, lands and realty, wildfire management, and minerals, would not be directly addressed. This is because the State's plan does not contain land use plan-level allocation decisions, such as ROW exclusion and avoidance areas; it relies largely on the avoid, minimize, and mitigate strategy at the project level.

The FWS March 2010 "warranted, but precluded" ESA listing decision identified the inadequacy of regulatory mechanisms as a significant threat to GRSG. RMP conservation measures were identified as the BLM's principal regulatory mechanism. The BLM believes Alternative E did not incorporate adequate regulatory mechanisms into the existing plan to meet its purpose and need to conserve, enhance, and protect GRSG and its habitat; therefore, the BLM did not select Alternative E as the ARMPA.

For Oregon, Alternative E contains GRSG conservation guidelines from *Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat*. This document describes the Oregon Department of Fish and Wildlife's proposed management of GRSG on Federal lands. It also provides guidance for public land management agencies and land managers for GRSG conservation. GRSG conservation guidelines in the State plan are designed to maintain (at a minimum) or enhance the quality (the optimum) of current habitats. The guidelines would also assist resource managers in achieving the population and habitat objectives of the State plan.

For Idaho, Alternative E incorporates proposed GRSG protection measures recommended by the State of Idaho. Management in Montana would remain unchanged from the current RMPs (Alternative A). Alternative E addresses the following primary threats: fire, invasive weeds, and infrastructure development. It also includes guidance for several secondary GRSG threats, such as recreation, improper livestock grazing, and West Nile virus, for BLM and Forest Service programs that affect GRSG or its habitat.

For Utah, Alternative E1 is based on the State of Utah's *Conservation Plan for Greater Sage-Grouse in Utah* (Utah Greater Sage-Grouse Working Group 2013) and would apply to all BLM-administered lands in Utah. In Alternative E1 conservation measures would be applied to 11 State-identified areas, called Sage-Grouse Management Areas. Emphasis would be placed on expanding GRSG habitat by aggressively treating areas where there are encroaching conifers or invasive species. Alternative E1 includes a general limit on new permanent disturbance of 5 percent of habitat on State or Federally managed lands within any particular GRSG management area; occupied habitat outside of these areas would not receive new management protection and would continue to be managed according to the GRSG actions in existing RMPs and conservation measures associated with existing activity-level plans.

This alternative was not selected in its entirety as the ARMPAs because some components of the State's plans were not consistent with the purposes, policies, and programs of Federal laws and regulations applicable to public lands. However, many goals, objectives, and management actions in the alternative were carried forward.

3.1.6 Alternative F—Citizen Groups' Recommended Alternative Two

Alternative F is also based on a citizen group recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and defines different restrictions for PHMAs and GHMAs. Alternative F would limit commodity development in areas of occupied GRSG habitat and would close or designate portions of the Planning Area to some land uses. This alternative does not apply to the Utah sub-regional planning effort, as it was combined with Alternative C. Under Alternative F, wildfire suppression would be prioritized in PHMAs. Concurrent vegetation management would emphasize sagebrush restoration and enhancement. Alternative F would reduce livestock and WHB management use by 25 percent within PHMAs and GHMAs. While the Utah Draft EIS did not include an Alternative F, it did create two sub-alternatives under Alternative C for livestock grazing and WHBs to consider and analyze a similar reduction.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMAs and GHMAs to such an extent that it did not give adequate accommodation to local needs, customs, and culture.

3.1.7 Proposed Plan Amendment

As a result of public comments, best science, cooperating agency coordination, and internal review of the Draft RMPAs/EISs, the BLM developed the Proposed Plan Amendments/Final EISs for managing BLM-administered lands. In these documents, the BLM focused on addressing public comments, while continuing to meet its legal and regulatory mandates.

The Proposed Plan Amendments/Final EISs are a variation of the preferred alternatives (Alternative D) and are within the range of alternatives analyzed in the Draft EISs. The Proposed Plan Amendments, with slight variations (as outlined in **Section 2.4** of this ROD), became ARMPAs. The BLM adopted the Proposed Plan Amendments as the ARMPAs because they also balance resource protections with resource uses to protect resources, while achieving sustainable resource development.

3.1.8 Environmentally Preferable Alternative

CEQ regulations require that a ROD state which alternatives were considered to be "environmentally preferable" (40 CFR 1505.2[b]). Question 6A of CEQ's *40 Most-Asked Questions* regarding CEQ's NEPA regulations (46 FR 18026) defines that term to ordinarily mean the alternative that best protects, preserves, and enhances historic, cultural, and natural resources.

Under that definition, Alternative C, as presented in each of the sub-regional Proposed RMP Amendments/Final EISs, is the most environmentally preferable. However, NEPA expresses a continuing policy of the Federal government to "use all practicable means and measures…to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans" (Section 101 of NEPA). FLPMA requires the BLM to manage the public lands for multiple-use and sustained yield (see FLPMA Section 302.) Section 102(12) of FLPMA declares a policy of the United States that "the public lands be managed in a manner which recognizes the Nation's need for domestic sources of minerals, food, timber, and fiber from the public lands including implementation of the Mining and Minerals Policy Act of 1970 (84 Stat. 1876, 30 USC, Section 21a) as it pertains to the public lands." For these reasons, Alternative B was not selected as the sub-regional ARMPAs.

3.2 ALTERNATIVES CONSIDERED BUT NOT ANALYZED IN DETAIL

The alternatives listed below by sub-region were considered but were not carried forward for detailed analysis because of one or more of the following reasons:

- They would not meet the requirements of FLPMA or other existing laws and regulations
- They did not meet the purpose and need
- The alternative was already captured within the range of alternative analyzed in the EIS
- They were already part of an existing plan, policy, or administrative function
- They did not fall within the limits of the planning criteria

For additional rationale as to why each of the alternatives listed below by sub-region were not carried forward for detailed analysis, refer to Section 2.11 of each of the sub-regional Proposed Amendments/Final EISs.

Idaho and Southwestern Montana

- FWS-Listing Alternative
- Elimination of Recreational Hunting Alternative
- Predation Alternative
- Close All or Portions of PHMAs or GHMAs to OHV Use Alternative
- Consideration of Coal Mining Alternative

Nevada and Northeastern California

- Close All or Portions of PHMAs or GHMAs to OHV Use Alternative
- Elko County Sage-Grouse Plan Alternative
- Increase Grazing Alternative

Oregon

- FWS-Listing Alternative
- Elimination of Livestock Grazing from all BLM Lands Alternative
- Increase Livestock Grazing Alternative
- Close All or Portions of PHMAs or GHMAs to OHV Use Alternative

Utah

- FWS-Listing Alternative

- Increase Livestock Grazing Alternative
- Make GRSG Habitat Available for Oil Shale and Tar Sands Alternative
- Citizen Proposed Alternatives (in their entirety)
- Adoption of the State of Utah's Sage-Grouse Management Areas as PHMAs for All Alternatives
- Use of Other Habitat Maps Alternatives
- County Sage-Grouse Management Plans Alternative
- COT Report Alternative
- BLM Policies and Regulations Alternative

4. PUBLIC INVOLVEMENT, CONSULTATION, AND COORDINATION

DO NOT DELETE THIS PAGE from the MS Word file, as this is what marks Heading 1 for the table of contents. (Do delete this page later from the Adobe Acrobat [pdf] file.)

THROW THIS PAGE AWAY & DELETE FROM PDF

CHAPTER 4
PUBLIC INVOLVEMENT, CONSULTATION, AND COORDINATION

BLM land use planning is conducted in accordance with NEPA requirements, CEQ regulations, and US Department of the Interior policies and procedures for implementing NEPA, as well as specific BLM planning and NEPA policies. NEPA and associated laws, regulations, and policies require the BLM to seek public involvement early in and throughout the planning process, to develop a range of reasonable alternatives to proposed actions, and to prepare environmental documents that disclose the potential impacts of proposed management.

Public involvement and agency consultation and coordination have been at the heart of the planning process leading to these Great Basin Region ARMPAs. These efforts were achieved through *Federal Register* notices, formal and informal public meetings, individual contacts, media releases, planning bulletins, and a series of GRSG planning-related websites.

This section documents the outreach efforts that have occurred to date. For more plan-specific information related to the public involvement, consultation, and coordination processes that the BLM conducted, please refer to Chapter 3 of the attached ARMPAs.

4.1 PUBLIC INVOLVEMENT

The scoping period for the National GRSG Planning Strategy, including the four sub-regional Planning Areas in the Great Basin Region, began with the publication of the Notice of Intent in the *Federal Register* on December 9, 2011, and ended on March 23, 2012. Beginning in December and ending in February of 2012, the BLM hosted a series of public open house scoping meetings across Northeastern California, Idaho, Southwestern Montana, Nevada, Oregon and Utah. A final National GRSG Planning Strategy Scoping Report was released in May 2012 (BLM and Forest Service 2012).

Notices of Availability for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Draft RMPAs/EISs were published in the *Federal Register* on November 1, 2013. The Oregon Draft RMPA/EIS was released to the public on November 26, 2013.

For the Great Basin Region GRSG Draft RMPAs/EISs, Idaho and Southwestern Montana conducted seven public meetings, Nevada and Northeastern California conducted seven public meetings, Oregon conducted seven public meetings, and Utah conducted eight public meetings between November 2013 and January 2014.

Comments on the Draft RMPAs/EISs received from the public and internal BLM review were considered and incorporated, as appropriate, into the proposed plan amendments. The Great Basin Region received approximately 4,990 substantive comments, contained in 74,240 submissions during the four Draft RMPAs/EISs' comment periods. Comments on the Draft RMPAs/EISs received from the public and internal BLM review were carefully considered and incorporated as appropriate into the proposed plan amendments. Public comments resulted in the addition of clarifying text but did not significantly change the Proposed RMPAs.

Notices of Availability for all of the Great Basin Region GRSG Proposed RMPAs/Final EISs for the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah Sub-regions were released on May 29, 2015. The release of the Notices of Availability initiated a 30-day public protest period and a 60-day Governor's consistency review. Refer to **Sections 2.5** and **2.6** for a full description of the protest period and Governor's consistency review outcomes.

4.2 COOPERATING AGENCIES

A cooperating agency is any Federal, State, or local government agency or Native American tribe that enters into a formal agreement with the lead Federal agency to help develop an environmental analysis. Cooperating agencies and tribes "work with the BLM, sharing knowledge and resources, to achieve desired outcomes for public lands and communities within statutory and regulatory frameworks" (BLM 2005). The benefits of enhanced collaboration among agencies in preparing NEPA analyses are as follows:

- Disclosing relevant information early in the analytical process
- Applying available technical expertise and staff support
- Avoiding duplication with other Federal, State, tribal, and local procedures
- Establishing a mechanism for addressing intergovernmental issues

The BLM entered into a formal MOU for the National GRSG Planning Strategy with the FWS and the Forest Service. In addition, the Great Basin sub-regions also invited local, State, other Federal, and tribal representatives to participate as cooperating agencies for these RMPAs/EISs. In total, there were 13 MOUs signed with Federal agencies, 10 signed with State agencies, 55 signed with counties, and 5 signed with tribal entities. The MOUs outline the interests, expertise, and jurisdictional responsibilities of both the BLM and its cooperating agency partners and also outline their respective roles and responsibilities in the planning and NEPA processes. (Additional information can be found in Chapter 6 of each of the Proposed Amendments/Final EISs.) These cooperating agencies divided by sub-region are provided below.

Great Basin Region-Wide

US Fish and Wildlife Service
US Forest Service

Idaho and Southwestern Montana

Beaverhead County Commissioners
Bingham County Commissioners
Blaine County Commissioners
Cassia County Commissioners
Clark County Commissioners
Craters of the Moon National Monument
Custer County Commissioners
Fremont County Commissioners
Idaho Association of Counties
Idaho Department of Fish and Game
Idaho Governor's Office of Species Conservation
Idaho National Guard
Jefferson County Commissioners
Lemhi County Commissioners
Madison County Commissioners
Montana Fish, Wildlife and Parks
Natural Resources Conservation Service
Owyhee County Commissioners
Power County Commissioners
Twin Falls County Commissioners
US Department of Defense
US Department of Energy (INL)

Nevada and Northeastern California

Churchill County
Elko County
Eureka County
Humboldt County
Lander County
Lassen County
Lincoln County
Mineral County
Modoc County
Natural Resources Conservation Service
Nevada Department of Transportation
Nevada Department of Wildlife
Nevada Department of Conservation and Natural Resources
Nye County
Pershing County
Pyramid Lake Paiute Tribe
Storey County
Summit Lake Paiute Tribe
Susanville Indian Rancheria
US Department of Defense
US Federal Highway Planning Administration

Washoe County
Washoe Tribe
White Pine County

Oregon

Crook County
Deschutes County
Harney County
Harney Soil and Water Conservation District
Lake County
Malheur County
Natural Resources Conservation Service
Oregon Department of Fish and Wildlife
Oregon State University
US Federal Energy Regulatory Commission

Utah

Beaver County
Box Elder County
Carbon County
Confederated Tribes of the Goshute Indian Reservation
Duchesne County
Emery County
Garfield County
Grand County
Iron County
Kane County
Lincoln County (Wyoming)
Millard County
Rich County
Sanpete County
Sevier County
State of Utah (PLPCO)
State of Wyoming
Sweetwater County (Wyoming)
Sweetwater County Conservation District (Wyoming)
Tooele County
Uinta County (Wyoming)
Uintah County (Utah)
Utah County
US Department of Defense
Wayne County
Natural Resources Conservation Service

4.3 FWS SECTION 7 CONSULTATION

Under Section 7 of the ESA, Federal agencies must consult with the FWS when any action the agency carries out, funds, or authorizes *may affect* a listed endangered or threatened species or its designated critical habitat. The four Great Basin sub-regional Final EISs defined potential impacts on threatened and endangered species as a result of management actions proposed in the alternatives analyzed in the Final EISs. (The FWS is a cooperating agency in this planning process.) FWS staff participated in interdisciplinary team meetings and have been provided with drafts of alternative decisions and analyses for discussion and input.

The BLM formally initiated Section 7 consultation with a letter to the FWS, before the release of the Draft RMPAs/EISs, and requested concurrence on which species would require consideration during consultation. Over the ensuing months, regular meetings were held to identify the species that would be analyzed in the biological assessment, to address which actions could affect those species, and to determine whether the implementation of the Proposed Plan amendments "may affect" the species for which this consultation occurred.

Before the release of the Proposed Amendments/Final EISs, the BLM formally submitted the biological assessments to the FWS for review on whether the plans would affect a Federally listed, proposed, or candidate species. The FWS evaluated the biological assessments and concurred with either a "no affect" or "may effect, but will not adversely affect" determination via memorandum for Oregon, Nevada and Northeastern California, and Idaho and Southwestern Montana; these memoranda are appendices to each of the ARMPAs. For Utah, formal consultation was required with the FWS due to a "likely to adversely affect" determination associated with the Utah prairie dog, a threatened species under the ESA. The biological opinion from the FWS is attached to the Utah ARMPA (Appendix J).

4.4 NATIVE AMERICAN AND STATE HISTORIC PRESERVATION OFFICE CONSULTATION

In recognition of the government-to-government relationship between individual tribes and the Federal government, the BLM initiated Native American consultation in preparation of the four Great Basin sub-regional RMPAs/EISs. The BLM coordinated with Native American tribes throughout the planning process. In December 2011, the BLM sent letters to 65 tribal governments. The letters provided initial notification of the RMPAs/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation related to the planning process. Tribes have been participating in the RMPAs/EISs processes through numerous meetings and through personal BLM contacts, and in some cases, as cooperating agencies.

As part of the NEPA scoping and consultation process, the BLM notified the Idaho, Montana, Nevada, California, and Oregon State Historic Preservation Officers (SHPOs) of the opportunities to comment on the planning and NEPA documents prepared for these efforts, as they relate to historic properties in the Planning Areas and the land use plan decisions included in the ARMPAs. The BLM sought information about historic properties in consideration of land use planning decisions in accordance with the National Programmatic Agreement between the BLM, Advisory Council on Historic Preservation, National Conference of SHPOs, and the Idaho, Montana, and Oregon State Protocol Agreement between the BLM and these SHPOs. If the BLM received comments and information from SHPOs and tribes, then it considered and incorporated that information into the Proposed RMPAs/Final EISs and the ARMPAs.

The BLM has met its obligations under Section 106 of the National Historic Preservation Act, 54 USC, Section 306108, as outlined in the National Programmatic Agreement and the State protocols. The BLM will satisfy the requirements of Section 106 of the National Historic Preservation Act for future implementation-level decisions, such as project proposals, including adequate consultation with SHPOs, Tribal Historic Preservation Officers, Native American tribes, and other interested parties. This is consistent with the alternative procedures set forth in the National Programmatic Agreement and relevant State protocols or where applicable to the Section 106 regulations.

For the Utah ARMPA, the BLM completed consultation with the Utah SHPO, in accordance with the 36 CFR 800. In July 2015, the BLM submitted a formal letter, concluding that the land use plan amendments would not adversely affect cultural properties and seeking input and concurrence on those findings. The BLM received a concurrence letter from the Utah SHPO on July 30, 2015. It will satisfy the requirements of Section 106 of the National Historic Preservation Act for future implementation-level decisions, such as project proposals, including adequate consultation with SHPOs, Tribal Historic Preservation Officers, Native American tribes, and other interested parties. This is consistent with the alternative procedures set forth in the National Programmatic Agreement and relevant State protocols and programmatic agreements or where applicable the Section 106 regulations.

CHAPTER 6
APPROVAL

Land Use Plan Decisions

It is the decision of the Bureau of Land Management to approve the Great Basin Region Resource Management Plan Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana Sub-regions, as described in this Record of Decision. The Proposed Plan Amendments and related Final Environmental Impact Statements were published on May 29, 2015, in the *Federal Register* (80 FR 30711). I have resolved all protests and, in accordance with BLM regulations 43 CFR 1610.5-2, my decision on the protests is the final decision of the Department of the Interior. The approval is effective on the date this Record of Decision is signed.

Approved by:

Neil Kornze
Director
Bureau of Land Management

Date

Approval

I hereby approve the land use plan decisions. My approval of the land use plan decisions constitutes the final decision of the Department of the Interior and, in accordance with regulations at 43 CFR 1610.5-2(b) and 43 CFR 4.410(a)(3), it is not subject to appeal under Department regulations at 43 CFR, Part 4. Any challenge to these land use plan decisions must be brought in Federal district court.

Dear Reader Letter (1 page, signed by the Secretary or Assistant Secretary)

Executive Summary (1 page)

Table of Contents

1. INTRODUCTION

1.1 National Greater Sage-Grouse Planning Strategy

In March 2010, the US Fish and Wildlife Service (USFWS) published a 12-Month Finding for Petitions to List the Greater Sage-Grouse (Centrocercus urophasianus) as Threatened or Endangered (75 Federal Register 13910, March 23, 2010). In that finding, the USFWS concluded that GRSG was "warranted, but precluded" for listing as a threatened or endangered species. A "warranted, but precluded" determination is one of three results that may occur after a petition is filed by the public to list a species under the Endangered Species Act (ESA). This finding indicates that immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, a species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

The USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 Federal Register 13910, March 23, 2010). The USFWS identified the principal regulatory mechanisms for the BLM as conservation measures in resource management plans.

In December 2011, the BLM initiated its National Greater Sage-Grouse Planning Strategy and prepared 15 environmental impact statements (EISs), with associated plan amendments and revisions. These documents provided a set of management alternatives focused on specific conservation measures across the range of the GRSG. The 15 approved land use plans and amendments address threats to GRSG identified by state fish and wildlife agencies, the BLM National Technical Team, and the USFWS in the context of its listing decision and the Conservation Objectives Team (COT) report. The COT report was prepared by wildlife biologists from state and federal agencies and provides a blueprint for the EISs. ~~Where consistent with conservation objectives, the GRSG resource management plan amendments adopt unique state and stakeholder developed approaches and priorities.~~ Additional science-based reviews by the US Geological Survey and related scientific literature provided further guidance on specific issues that arose in developing amendments. In addition, regular meetings with the Western Governors Association Sage-Grouse Task Force provided additional opportunities for coordination with member states. Many states have developed conservation strategies or approaches for Greater Sage-Grouse management. Where such State strategies or approaches were completed, the BLM and USFS made every effort to incorporate them or develop complementary strategies and approaches, consistent with achieving long-term conservation of Greater Sage Grouse and taking a landscape approach to conservation. While most major decisions across the plans are the same, as a result of incorporating state-specific approaches at the subregional planning level, there are some differences in the approaches taken in each plan. Each of the subregional plans, and the plans cumulatively, achieve the overarching goal of protection of Greater Sage-Grouse and its habitat. The different state-specific approaches taken in each plan are further described in section xxx.

Comment [KK1]: Probably a little more detail on COT & how it was used to formulate the approved plan??

[Per Sarah Greenberger's recommendation, we need to discuss further the desire to incorporate state developed approaches and priorities balanced with the need for an effective conservation strategy

(reference to the Salazar invitation). We also need to capture some of the major differences between the plans and why those differences exist.]

1.2 Great Basin Region Planning Area

The Great Basin Region is composed of WAFWA Management Zones III (Southern Great Basin), IV (Snake River Plain), and V (Northern Great Basin). The USFWS has identified a number of threats in this region, including wildfire, loss of native habitat to invasive species, and habitat fragmentation. Great Basin regions are further divided into sub-regions; this National Environmental Policy Act (NEPA) analysis is being conducted on the sub-region level. These sub-regions are generally based on the identified threats to the GRSG and the WAFWA Management Zones.

[Insert discussion of the Great Basin Region Planning Area and threats present and widespread in the region. Work with NOC to produce map of the Great Basin Region, depicting sub-regional boundaries. (1 page)]

1.3 Great Basin Region Greater Sage-Grouse Conservation Summary

[Focus the discussion on the 5 factor analysis made in the USFWS listing determination and how the plans cumulatively address the factors presented in the 2010 listing decision. This is how section IV of the Landscape Report was formulated. (1-2 page)]

Comment [KK2]: This could probably be a shortened version of the summary that Jim is developing for the landscape report. Is this the place to provide rationale for the differences between the plans & why they collectively meet the conservation need?

2. DECISION

2.1 Summary of the Approved Management Decisions

[This is the primary decision - to approve the attached ARMPA. (1 paragraph)]

2.2 What the Record of Decision and Approved Resource Management Plan Amendments Provide

[Briefly discuss the types of decisions that are presented in the approved RMPAs, such as the goals, objectives, and management actions to conserve GRSG habitat. (1 paragraph)]

Comment [KK3]: Do we need to explain the differences in plans here? Also provide rationale for the plan we chose?

2.3 What the Record of Decision and Approved Resource Management Plan Amendments Do Not Provide

[Briefly discuss the types of decisions that are not presented in the approved RMPAs (no decisions outside of BLM's jurisdiction for example) and that the plans do not include implementation or site specific decisions. (1-2 paragraphs)]

Comment [KK4]: This is a bit of a challenge in my mind, because certainly how we are going to prioritize work on grazing allotments is not a RMP decision (I would argue its not even an implementation decision – its actually an administrative action that does not require NEPA).

2.5 Modifications and Clarifications

2.5.1 Modifications and Clarifications

[Briefly discuss the minor changes that were made from the release of the PRMPs to now (preparation of the ARMPAs and Greater Sage-Grouse Habitat RMP decisions from the revisions) to clarify the decisions, to better reflect existing policies, and to correct errors brought to our attention. (1 page)]

2.5.2 Protest Resolution

[Overview of the parties that protested on the PRMPAs/FEISs, what their issues were, and how BLM responded to them (were granted and/or dismissed). (1 page)]

2.5.3 Governors Consistency Review

[Brief overview of the GCR process, if/how the BLM modified the ARMPAs based on the Governor's recommendations or a description as to why the BLM dismissed the Governor's recommendations (1 page)].

3. ALTERNATIVES CONSIDERED

3.1 No Action Alternative

[A paragraph that describes the current management alternative (1 paragraph).]

3.2 Environmentally Preferred Alternatives Considered in all Sub-Regions

[Include a paragraph describing the NTT and citizen based alternatives that were considered across all four sub-regions, and provide rationale as to why they were not selected as the ARMPA. (2 paragraphs)]

Comment [KK5]: All of them? Are they all environmentally preferred?

3.3 Alternatives Considered and Specific to Individual Separate Sub-regions

[This section would include four sub-sections for each plan and will include separate paragraphs (extracted from the executive summaries from the FEISs) for each of the unique alternatives considered for each sub-region). (1 page)]

Comment [KK6]: If we keep this high-level, we should only need subsections for the "extra" alternatives I would think – it seems like the set of alternatives in all plans were pretty standardized.

4. MANAGEMENT CONSIDERATIONS

[Identify and discuss all such factors including any essential considerations of national policy which were balanced by the DOI in making its decision to approve the ARMPAs and state how those considerations entered into its decision. (1/2 page)]

Comment [KK7]: I'm not sure I understand what goes here, can we get an example?

5. MITIGATION MEASURES

All practical means to avoid or minimize environmental harm are encompassed in the attached Approved Resource Management Plan Amendments and associated appendices. Mitigation measures, including the application of required design features have been identified.

[Summarize the additional mitigation framework commitments being made as part of this planning effort. (1 paragraph)]

6. PLAN MONITORING

[Summarize the monitoring strategy, emphasizing the process for effectiveness and implementation monitoring. (1-2 paragraphs)]

7. CONSULTATION AND COORDINATION

[Initiate section with the national level cooperators (Forest Service and FWS) and then include subsections for each of the 4 ARMPAs to talk about cooperating agencies, Section 7 consultation, and tribal consultation. (1-2 pages)]

Comment [KK8]: Does this really need to be this long, can't we talk in generalities & reference the ARMP or PRMP/FEIS for more details?

8. APPROVAL

Bureau of Land Management Director Recommendation

I recommend adoption of the National Greater Sage-grouse Conservation Strategy – Great Basin Region Approved Resource Management Plan (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub-regions, as described in this Record of Decision. The final EISs have considered all valid issues raised during scoping and address all relevant comments raised on review of the draft RMPs and amendments, and their associated EISs. All planning protests filed with the Director under administrative review procedures in 43 CFR 1610.5-2 have been resolved. No inconsistencies were identified after review by the Governors of Nevada, California, Oregon, Utah, Idaho, and Montana as provided by 43 CFR 1610.3.2. The Approved Resource Management Plans and Amendments represent the agencies' appropriate conservation measures to conserve, enhance and/or restore Greater Sage-Grouse ~~habitat~~ by reducing, eliminating, or minimizing threats to Greater Sage-Grouse habitat.

Neil Kornze, BLM Director | Date

Department of Interior Approval

I concur with the decisions in the National Greater Sage-grouse Conservation Strategy – Great Basin Region Approved Resource Management (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub regions, as described in this Record of Decision.

Sally Jewell, Secretary of Interior | Date

In Reply, Refer to:
(WO210)(1610)

Dear Reader:

Enclosed are the Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah,). The ROD approves the four Great Basin Region ARMPAs, which are part of fifteen other sub-regional RMP Amendments and RMP revisions associated with the National Greater Sage-Grouse Planning Strategy that was initiated on December 11, 2011.

The Bureau of Land Management (BLM) ARMPAs provide a range wide, comprehensive, science-based, collaborative strategy for addressing previously identified threats to the Greater Sage-Grouse (GRSG). This strategy, while designed to address issues leading to the 2010 “warranted but precluded” decision by the U.S. Fish and Wildlife Service (FWS), was guided by over a decade of research, analysis and recommendations for GRSG conservation produced by the Conservation Objectives Team (COT), Western Association of Fish and Wildlife Agencies (WAFWA), the BLM National Technical Team and (NTT). Each of these reports was developed by a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research. Science-based decision-making and collaboration with the FWS, the U.S. Forest Service, and state and local partners were fundamental during the development of the land use plan decisions within these ARMPAs to address the identified threats to GRSG.

It is important to note that this ROD and these ARMPAs are specific only to BLM administered lands. Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft EISs and Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

The Federal Land Policy Management Act (FLPMA) requires the development and maintenance, and, as appropriate, the revision of land use plans for public lands. The National Environmental Policy Act (NEPA) requires Federal agencies to prepare an Environmental Impact Statement (EIS) for major Federal actions that could significantly affect the environment. In fulfillment of these requirements, the Draft RMP Amendments/Draft EISs incorporating analysis and input provided by the public; local, State, and

other Federal agencies and organizations; Native American tribes; Cooperating Agencies, and BLM personnel were published in the fall of 2013. The 90-day public comment periods ensued, with more than 4,990 substantive comments from 1,348 letters that were submitted. These comments were reviewed, summarized and considered in preparing the Proposed RMP Amendments/Final EISs.

The Proposed RMP Amendments/Final EISs were made available on May 29, 2015, for a 30-day protest period. X protest letters were received, of which X were valid protests in need of resolution. Protest issues are addressed and resolved in the Protest Summary Report, available on line at: http://www.blm.gov/nv/st/en/fo/wfo/blm_information/rmp.html.

After much consideration, the BLM now approves the Proposed RMP Amendments as the land use planning documents that will guide Greater Sage-Grouse habitat management in the Great Basin Region for the life of the plan amendment.

Copies of the ROD and ARMPAs can be obtained from the BLM's National Greater Sage-Grouse webpage at: http://www.blm.gov/wo/st/en/prog/more/sagegrouse.html.

The BLM extends special appreciation to the extensive public involvement and the involvement of groups, organizations, Cooperating Agencies; local, State, and other Federal agencies; and Native American tribal representatives who contributed to the completion of these ARMPAs. This participation informed and improved the planning process and the planning documents. Your continued involvement is encouraged as the ARMPAs are implemented and monitored for the conservation of Greater Sage-Grouse and their habitat.

Sincerely,
X

Enclosure:
1. Record of Decision and Approved Resource Management Plan Amendments

Summary

This~~e~~ Record of Decision (ROD) is the culmination of an unprecedented effort in public land management to meet the multiple-use and sustained-yield management objectives for public lands administered by the Bureau of Land Management (BLM) in accordance with the Federal Land Policy and Management Act of 1976 (FLPMA). ~~directs the United States (US) Department of the Interior (DOI), Bureau of Land Management (BLM) to develop and periodically revise or amend its resource management plans (RMPs), which guide management of BLM-administered lands.~~

In response to a 2010 determination by the U.S. Fish and Wildlife Service (FWS) that the greater sage-grouse listing under the Endangered Species Act (ESA) is "warranted but precluded" by other priorities, the BLM, in coordination with the U.S. Department of Agriculture Forest Service (Forest Service) has developed a targeted, multi-tiered, landscape-level management approach, based on the best available science, that offers the highest level of protection for GRSG in the most important habitat areas to address the specific threats identified in the 2010 U.S. Fish and Wildlife "warranted but precluded" decision and Conservation Objectives Team (COT) report.

This~~e~~ Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs)~~ROD and ARMPAs~~ for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon; and Utah ~~provides a layered management approach that offers the highest level of protection for Greater Sage-Grouse in the most valuable habitat to address the specific threats identified in the 2010 U.S. Fish and Wildlife "warranted but precluded" decision and Conservation Objectives Team report.~~ includes ~~L~~land use allocations in the ARMPAs that would limit or eliminate new surface disturbance in Priority Habitat Management Areas (PHMA), while minimizing disturbance in General Habitat Management Areas (GHMA). In addition to establishing protective land use allocations, the ARMPAs would implement a suite of management ~~tools~~ actions, such as the establishment of disturbance limits, GRSG habitat objectives, ~~and monitoring~~, mitigation requirements~~approaches~~, monitoring protocols, and adaptive

Comment [JRL1]: The are not tools, but management actions to be implemented by the plans. DDCT is a tool, but establishing disturbance limits is a management action management triggers and responses, as well as~~nd~~ other conservation ~~protective~~ measures throughout the range. ~~These overlapping and reinforcing~~ The cumulative effect of these conservation measures would work in concert to protect, improve, and restore GRSG habitat ~~condition~~ across the remaining range of the species in the Great Basin and provide ~~consistency in~~ greater certainty that~~how the~~ BLM land and resource management ~~manages~~ activities in GRSG habitat in the Great Basin Region can lead to conservation of the GRSG and other sage steppe associated species in the region.

In conjunction with the management actions for GRSG included in the ROD and ARMPAs and ARMPRs for the Rocky Mountain GRSG subregion, this ROD and ARMPAs for the Great Basin subregion provides management direction to protect and restore habitat essential to the conservation of the GRSG across its remaining range. This conservation strategy, developed in collaboration with the 11 states in which the ARMPAs and ARMPRs apply, in addition to other state and federal actions underway and in development, represents an unprecedented, collaborative effort among federal land management agencies and the states to manage an entire ecosystem and associated flora and fauna, in order to "conserve the sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future". [Dan Ashe. Transmittal letter to COT report. 2014]

Comment [JRL2]: This is the suite of actions facilitated by the plans

Comment [JRL3]: Certainty is better than "consistency" as that has become a "trigger" for negative response

Comment [JRL4]: Tie to ultimate goal and to benefit to other species and the ecosystem overall.

1. INTRODUCTION

1.1 Threats to Greater Sage-Grouse

Currently, Greater sage-grouse occupy an~~d~~ area that has been estimated to be a reduction of 44% from the historically occupied range. In addition, populations in most or the range have been demonstrated to have declined from 1965- 2003, the period where data was collected most intensively.

The decline of the greater sage-grouse (GRSG) and its sagebrush steppe habitat has been the focus of fish and wildlife agency and conservationists' concerns for decades. In 1954 the Western Association of Fish and Wildlife Agencies (WAFWA) formed a technical committee to monitor the distribution and abundance of sage-grouse. WAFWA formalized a program of interstate coordination and cooperation in 1995 to address the issues of sage-grouse population losses and degradation of sagebrush ecosystems in order to: *1) Maintain the present distribution of sage grouse and 2) Maintain the present abundance of sage-grouse.* In 1999 WAFWA amended the objectives to: *1) Maintain and increase where possible the present distribution of sage grouse and 2) Maintain and increase where possible the present abundance of sage grouse.* The Bureau of Land Management, USFWS, and U.S. Forest Service formally joined with WAFWA in range-wide conservation efforts in 2000.

Between May 1999 and December 2003, eight petitions were filed with the U.S. Fish and Wildlife Service (USFWS) to have sage-grouse protected under provisions of the Endangered Species Act (ESA). In 2001 the USFWS determined that greater sage-grouse in the Columbia Basin of Washington state warranted protection under provisions of the ESA. On January 12, 2005, the FWS issued a decision that listing the GRSG for protection under the ESA was not warranted. However, in response to July 14, 2006 Western Watersheds Project filing alleging that the FWS 2005 finding was incorrect and arbitrary, the U.S. District Court of Idaho ruled that the 2005 finding was "arbitrary and capricious" and remanded it to the FWS for further consideration. Ultimately, as a result, in 2010 the FWS issued a finding that listing of the Greater sage-grouse was "warranted but precluded". Subsequent to that finding, and in accordance with a settlement agreement [details?] the FWS committed to make a final determination regarding the need to list the GRSG by September 30, 2015. Two factors led to the FWS decision to list the species as "warranted but precluded": threats to habitat and the inadequacy of existing regulatory mechanisms.

Primary threats affecting GRSG habitat on Forest Service and BLM-administered lands include infrastructure (power lines, communication towers, fences, roads, and railroads), and energy development (traditional oil and gas, mining, renewable energy, transmission corridors) within WAFWA GRSG Management Zone I, II and VII; and Fire, Invasive Weeds, and Pinyon-Juniper Encroachment within WAFWA GRSG Management Zone III, IV, V and VI. Improper grazing (livestock and wild horse) and climate change may be a threat across all management zones, and all threats exist to some degree across the range of the species. *Differences in ecological conditions within each MZ affect the susceptibility of these areas to the various threats facing* *sagebrush ecosystems and its potential for restoration. (FWS FRN 2010).* (See reference to WAFWA Management Zones (MZ) below.)

Additional information regarding potential threats to the GRSG is contained in the BLM National Technical Team (NTT) report and the Conservation Objectives Team (COT) reports. A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG – as articulated in the COT report – is summarized in Table X [Include from Final Landscape report.]

In addition, the Service found that existing local, state and federal regulatory mechanisms were not sufficient to address threats to the habitat. For the BLM and the Forest Service, which manage more than 50 of the remaining habitat rangewide, regulatory mechanisms are the agencies' Resource Management Plans and Land Resource Management Plans, respectively.

The Federal Land Policy and Management Act of 1976 (FLPMA) is the primary Federal law governing most land uses on BLM-administered lands, and directs development and implementation of Resource Management Plans (RMPs) [1] which direct management at a local level. As a designated sensitive species under BLM Manual 6840, GRSG conservation must be addressed in the development and implementation of RMPs on BLM lands. RMPs are the basis for all actions and authorizations involving BLM administered lands and resources. They authorize and establish allowable resource uses, resource condition goals and objectives to be attained, program constraints, general management practices needed to attain the goals and objectives, general implementation sequences, intervals and standards for monitoring and evaluating RMPs to determine effectiveness, and the need for amendment or revision (43 CFR 1601.0-5(k)).

Management of activities on National Forest System lands are guided principally by the National Forest Management Act (NFMA) (16 U.S.C. 1600-1614, August 17, 1974, as amended 1976, 1978, 1980, 1981, 1983, 1985, 1988, and 1990). NFMA specifies that the Forest Service must have a Land and Resource Management Plan (LRMP)[1] (16 U.S.C. 1604) to guide and set standards for all natural resource management activities on each National Forest or National Grassland. All of the LRMPs that currently guide the management of GRSG habitats on Forest Service lands were developed using the 1982 implementing regulations for land and resource management planning (1982 Rule, 36 CFR 219).

This Record of Decision (ROD) approves the Bureau of Land Management's (BLM) attached ARMPAs for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM administered lands. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other

---

[1] Throughout this report, BLM Resource Management Plans (RMPs) and Forest Service Land and Resource Management Plans (LRMPs) will simply be referred to as Land Use Plans or LUPs.

applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft EISs and Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and associated Land and Resource Management Plans under their planning authorities.

1.2~~1~~ National Greater Sage-Grouse Planning Strategy

The BLM and the Forest Service collectively manage the majority of the GRSG habitat (i.e., the range of GRSG not including the Columbia Basin or Bi-State Distinct Population Segments) addressed in this planning effort. Efforts to conserve the habitat of this species did not begin with the 2011 BLM/ Forest Service Planning Strategy, but rather, have been ongoing for many years.

The Western Association of Fish and Wildlife Agencies (WAFWA) 2004 *Range-wide Conservation Assessment for Greater Sage-Grouse and Sagebrush Habitats* was the first range-wide assessment of GRSG using the vast amount of population data collected over the previous 60 years, habitat information spanning the previous 100 years, and literature dating back 200 years. The goal of the assessment, contributed to by the BLM and the Forest Service, was to present an unbiased and scientific documentation of dominant issues and their effects on GRSG populations and sagebrush habitats. http://sagemap.wr.usgs.gov/docs/Greater_Sage-grouse_Conservation_Assessment_060404.pdf

In November 2004, the BLM released its *National Sage-Grouse Habitat Conservation Strategy*, which encouraged GRSG habitat conservation through consultation, cooperation, and communication with WAFWA, the U.S. Fish and Wildlife Service (FWS), the Forest Service, the U.S. Geological Survey (USGS), State wildlife agencies, local GRSG working groups, and various other public and private partners.

In 2006, WAFWA completed a *Greater Sage-Grouse Comprehensive Conservation Strategy*, with the assistance of the BLM, the Forest Service, and other contributors. The overall goal of the Strategy was to maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain those populations. The Strategy outlined the critical need to develop the associations among local, state, provincial, tribal, and federal agencies, non-governmental organizations, and individual citizens to design and implement cooperative actions to support robust populations of GRSG and the landscapes and habitats upon which they depend. The catalyst for this effort was widespread concern for declining populations and reduced distribution of GRSG. The WAFWA Sage-Grouse Management Zones were delineated in this Strategy. http://www.wafwa.org/documents/pdf/GreaterSage-grouseConservationStrategy2006.pdf

In 2008, the BLM created two national teams to investigate possible BLM management options for GRSG conservation as well as summarizing BLM's ongoing conservation efforts. A product of this effort was one of the first range-wide priority habitat maps for GRSG that were referred to as "key habitat". At the time, the primary purpose for the key habitat map was to inform and help prioritize fire suppression efforts in GRSG habitat on BLM lands. An additional outcome of this team was the signing of a Memorandum of Understanding by the WAFWA; the BLM, FWS, USGS in the Department of the Interior; and the US Department of Agriculture Forest Service and NRCS, to provide for cooperation among the participating state and federal land managers and wildlife management and science agencies in the conservation and management of GRSG sagebrush habitats and other sagebrush-dependent wildlife throughout the Western United States and Canada. http://www.blm.gov/style/medialib/blm/wo/Planning_and_Renewable_Resources/fish__wildlife_and/fwp.Par.95958.File.dat/SagegrouseMOU.pdf

In 2010, BLM commissioned an effort to map breeding densities of GRSG across the West. A conference was convened with the state wildlife agencies to get approval and to coordinate the lek survey data needed for this effort. This modelling project, through an agreement with the FWS, mapped known active leks across the West. This model served as a standard starting point for all states to identify priority habitat.
http://www.blm.gov/wo/st/en/prog/more/fish__wildlife_and/sage-grouse-conservation/bird_density.print.html

In March 2010, the US Fish and Wildlife Service (USFWS) published their 12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered (75 Federal Register 13910, March 23, 2010). In that finding, the USFWS concluded that GRSG was "warranted, but precluded" for listing as a threatened or endangered species. A warranted, but precluded determination is one of three results that may occur after a petition is filed by the public to list a species under the Endangered Species Act (ESA). This finding indicates that immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, the~~a~~ species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

The USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 Federal Register 13910, March 23, 2010). The USFWS identified the principal regulatory mechanisms for the BLM and Forest Service as conservation measures in land use plans.

~~Consistent with the National GRSG Planning Strategy, the BLM as the lead agency, together with the U.S. Forest Service as a cooperating agency, prepared 15 environmental impact statements (EISs), with associated plan amendments and revisions. These documents provide a set of management alternatives focused on specific conservation measures across the range of the GRSG (see **Figure X**, National Greater Sage-Grouse Planning Strategy Boundaries) to address the threats identified in the 2010 USFWS "warranted but precluded" decision. .~~

~~*[Insert Figure X here.]*~~

~~Science-based decision-making and collaboration with state and local partners were fundamental to the National GRSG Planning Strategy. The 17 ARMPAs and ARMPs address threats to GRSG identified by state fish and wildlife agencies, the BLM National Technical Team (NTT), and the USFWS in the context of its listing decision and the Conservation Objectives Team (COT) report.~~

Formatted: Normal

Comment [JRL7]: If we reference a specific "Strategy", we need to explain its genesis. Should we use lower case instead or provide additional history. Former would be simpler.

Comment [JRL8]: 17?

Formatted: Font: (Default) +Body (Calibri), Highlight

Comment [JRL9]: The COT had not been published prior to completion of the draft EISs.

The GRSG National Technical Team (NTT), comprised of BLM, ~~Forest Service,~~ FWS, USGS, NRCS, and State specialists, completed A Report on National Greater Sage-Grouse Conservation Measures in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized importance on standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

Beginning in XXXX [date(s)] and consistent with the National GRSG Planning Strategy, the BLM as the lead agency, together with the U.S. Forest Service as a cooperating agency, developed 15 environmental impact statements (EISs), with associated plan amendments and revisions. The draft EISs displayed a set of management alternatives focused on specific conservation measures (see **Figure X**, National Greater Sage-Grouse Planning Strategy Boundaries) to address the threats identified in the 2010 USFWS "warranted but precluded" decision as well as GRSG management recommendations included in the BLM National Technical Team (NTT) report.

In 2012, FWS convened the~~a~~ Conservation Objectives Team (COT) of state and federal representatives to produce a peer-reviewed report ~~recommendation regarding~~ which identified the principal threats to GRSG survival -- based upon the FWS 2010 listing decision -- and the degree to which these threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. ~~The final, peer-reviewed COT Report provided a brief overview of the threats to the greater sage-grouse's survival based upon the FWS 2010 listing decision and an assessment of the extent to which these threats affected remaining GRSG populations.~~ (See Figure A and Table A.) The COT report also identified Priority Areas for Conservation (PACs) and emphasized that "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". http://www.fws.gov/greatersagegrouse/documents/COT-Report-with-Dear-Interested-Reader-Letter.pdf

Additional science-based reviews by the US Geological Survey and related scientific literature provided further guidance on specific issues that arose in developing the ARMPAs.

The BLM also adopted unique state and stakeholder developed approaches and priorities within the ARMPAs. In 2011, then Secretary of the Interior Ken Salazar sent letters to each of the sage-grouse state governors asking for a report and recommendations on how to best move forward with a multi-state conservation sage-grouse plan. Most states across the range provided recommendations for the management of the BLM lands in their state to conserve sage grouse. In all cases, this input was incorporated into ~~state conservation plans that were part of~~ the range of alternatives analyzed in the Final EISs. Components of these state recommendations~~conservation plans~~ were used to develop the ARMPAs.

In addition, the Western Governors Association Sage Grouse Task Force was established in 2011 to identify and ~~implement~~ recommend ~~high priority~~ state and federal conservation actions ~~and integrate ongoing actions~~ necessary to preclude the need for the GRSG to be listed under the ESA. This group, which includes designees from the 11 western states where GRSG is found as well as representatives from USFWS, BLM, Natural Resources Conservation Service, US Forest Service, US Geological Survey, and the Department of the Interior, played an integral role throughout this land use planning process.

Comment [JRL10]: Forest Service was not a part of the NTT.

Comment [JRL11]: SUGGEST INCLUSION OF FIGURE ILLUSTRATING WAFWA ZONES.

Comment [JRL12]: CAPs or lower case?

Comment [JRL15]: Is this correct? Haven't seen this letter.

Comment [JRL16]: Confusing to refer to state recommendations for managing BLM land in a state as "state plans". Suggest this alternative. Most readers would think of state plans as state plans to manage lands within their jurisdiction.

Comment [JRL17]: SGTF did not implement

1.3~~2~~ Address~~Ameliorat~~ing Threats to the Greater Sage-Grouse ~~through the National Greater Sage-Grouse Planning Strategy~~

~~*[Need to verify with Jim and Karen what elements from the Landscape Report they would like to see here. Right now, we only included content from Section VII (Summary) of the Landscape Report, but we can change this if needed. We can even include some of the pie charts and figures from the LR if necessary.]*~~

The 2006 WAFWA *Greater Sage Grouse Comprehensive Conservation Strategy* stated goal for management of the GRSG was to "maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain these populations".[2] The NTT report also endorsed this goal "as a guiding philosophy against which management actions and policies of BLM should be weighed"[3] And, in establishing the COT, with the backing of the SGTF, FWS Director Dan Ashe affirmed the commitment to the goal for GRSG conservation originally articulated in the 2006 WAFWA report -- reversing negative population trends and achieving a neutral or positive population trend -- and emphasized the following,

Formatted: Font: 11 pt

> "The Service interprets this recommendation to mean that actions and measures should be put in place now that will eventually arrest what has been a continuing declining trend. Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels."

The four Great Basin ARMPAs addressed by this ROD and the 13 ARMPAs/ARMPs in the Rocky Mountain Region subregion are the result ~~product~~ of the National GRSG Planning Strategy~~, the four Great Basin ARMPAs~~ and ~~13 ARMPAs/ARMPs in the Rocky Mountain Region,~~ were developed to remove or reduce identified threats to the species and are an essential component of the effort to conserve GRSG and obviate a listing of the species under ESA. Across ten western States, the Great Basin and Rocky Mountain sub-regional ARMPs/ARMPAs contain updated land use plan direction on nearly 60 percent of the remaining habitat for the species. These ARMPAs/ARMPs are the product of extensive coordination between the BLM and the Forest Service and~~, including t~~ the active engagement of the USFWS in helping to inform land allocation and related management decisions by the BLM and Forest Service. The plans~~y~~ also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, and circumstances in each.

~~This section highlights the m~~Major components of the ~~that are presented in the~~ attached ARMPAs ~~that~~ developed ~~were constructed~~ to address the specific threats to the viability of the GRSG, as identified in the USFWS 2010 listing decision and COT Report (many of which were also identified by the BLM's NTT Report) are summarized below.

~~*Land Allocations*~~

---

[2] WAFWA 2006 Strategy. The 2006 objectives built on an initial framework and commitment made by the WAFWA directors, the BLM and the FWS in 2000 with the signing of an interagency sagebrush/sage-grouse conservation MOU.

[3] Sage-grouse National Technical Team. "A Report on National Greater Sage-Grouse Conservation Measures". December 21, 2011.

The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT stated, "[m]aintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". To achieve this, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT emphasized ~~recommended~~ an "avoidance first strategy" and stressed that threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

Formatted: Font: 11 pt

To adequately address the reasons for the 2010 "warranted" determination by the FWS – and specific threats summarized in the COT report -- it was clear to BLM and Forest Service land and resource managers that additional regulatory measures on federal public lands would be necessary to deal with present or threatened destruction, modification, or curtailment of habitat or range. These measures would need to be incorporated into land use plans that guide management actions on lands within the remaining range of the GRSG administered by the agencies to conserve GRSG such that listing under the ESA was no longer necessary.

In December 2011, the BLM and the Forest Service published a Notice of Intent to prepare Environmental Impact Statements and Supplemental Environmental Impact Statements to incorporate GRSG Conservation Measures into Land Use Plans and Land and Resource Management Plans across the range of the species. A total of 15 subregional LUPs would amend or revise 78 BLM RMPs and 20 Forest LRMPs across the range of the species.

The federal public land conservation strategy reflects several key concepts:

- **Landscape-level**: The planning effort focuses on the remaining habitat of the GRSG on BLM and Forest Service lands, covering 10 western states in the Great Basin and Rocky Mountain regions.
- **Best Available Science** – The proposed LUPs are grounded in the best available science, drawn from published literature and input from recognized experts, state agencies, the US Geological Survey, the FWS and other sources. The COT report provided a "blueprint" for GRSG conservation by identifying specific threats to each remaining GRSG population and recommending measures to address each category of threat and the NTT report, prepared by the BLM, provided options for dealing with the most significant threats to the GRSG. A series of reports on how to improve efforts to reduce the threats of rangeland fire and invasive species prepared in collaboration with the Western Association of Fish and Wildlife Agencies also provided crucial guidance in formulating the conservation strategy.
- **Targeted, Multi-Tiered Approach** – The proposed LUPs were designed to incorporate a layered management approach to avoid or minimize additional surface disturbance in the most valuable habitat, known as Priority Habitat Management Areas (PHMA), which are largely consistent with PACs identified in the COT Report. Within PHMA, the proposed LUPs provide an added level of protection to limit or eliminate new surface disturbance through the delineation of Sagebrush Focal Areas (SFA), derived from areas identified by the FWS as "strongholds" essential for the species' survival. In General Habitat Management Areas (GHMA), the proposed LUPs seek to minimize disturbance while providing greater flexibility for land use activities.

- **Coordinated**: The BLM and Forest Service proposed LUPs were developed through a joint planning process led by the BLM with the Forest Service as partners. The USFWS provided guidance and input throughout the process to aid land managers in understanding the threats and the certainty and effectiveness of proposed land management actions in addressing those threats. The USGS and NRCS also provided key technical and scientific support.
- **Collaborative**: The proposed LUPs reflected the input of states and local stakeholders from the outset and were developed with the benefit of input from the individual states and cooperators who signed formal agreements with the BLM to provide input into the planning process. The Sage Grouse Task Force (SGTF) was particularly useful in facilitating this kind of collaborative input. The proposed LUPs reflect state and stakeholder developed approaches and economic priorities where consistent with conservation objectives.

Conservation Measures for Habitat Protection, Restoration, and Improvement

Land Allocations

Formatted: Font: Italic

In order to protect the most important GRSG habitat areas, the conservation strategy began with mapping areas of important habitat across the remaining range of the GRSG and within each state. In collaboration with state fish and wildlife agencies, the BLM and Forest Service identified areas as preliminary priority habitat (PPH) and preliminary general habitat (PGH). Maps were revised and refined as further mapping was conducted and state fish and wildlife agencies – often in collaboration with GRSG experts and researchers – provided more detailed analysis of habitat characteristics and populations. The proposed LUPs reflect this input. Priority Habitat Management Areas (PHMAs) largely coincide with identified Priority Areas for Conservation (PACs) in the COT Report. Final general habitat areas are identified as General Habitat Management Areas (GHMAs). Some states developed additional habitat categories which can be found in specific state plans.

The proposed LUPs also identify Sagebrush Focal Areas (SFAs) on a portion of the landscape. SFAs are a subset of PHMAs. SFAs correspond to the areas identified by the FWS as GRSG "strongholds" as detailed in an October 27, 2014 memo from FWS Director Ashe to BLM Director Kornze and Forest Service Chief Tidwell in response to a request to "identify a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection"[4] (http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf)

The SFAs reflect a subset of these strongholds, since the FWS map included areas that are not administered by the BLM or Forest Service or were outside the planning area. The FWS memo advised that "[s]trong, durable, and meaningful protection of federally administered lands in these areas will provide additional certainty and help obtain confidence for long term sage grouse

---

[4] Memorandum from Dan Ashe to Director, BLM and Chief, USFS, "Greater Sage Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important Landscapes. October 27, 2014.

persistence." The BLM and Forest Service proposed LUPs mapped approximately 66 million acres of PHMA and GHMA. Of this, approximately 35 million acres are identified as PHMA and 31 million acres are GHMA. SFAs consist of 11 million acres of BLM and Forest Service-administered lands in PHMAs. (See Figure B.)

This tiered habitat framework provides for a nested or layered conservation design with the greatest protections and limited new surface disturbance in SFAs, a high degree of certainty that the integrity of PHMAs can be maintained through land allocations to avoid or minimize additional surface disturbance, and protection of remaining habitats in GHMAs, with more flexibility for land use activities that would be designed to minimize impacts on existing GRSG leks. In all GRSG habitat areas, anthropogenic surface disturbing activities would be mitigated and, fire-impacted landscapes would be actively restored and protected with a priority on SFAs, then PHMAs, and GHMAs.

To avoid or minimize further surface disturbance in PHMAs the proposed LUPs either exclude or avoid major new surface disturbing activities. In SFAs, in addition to PHMA decisions, proposed LUPs also apply a no surface occupancy stipulation with no exceptions for oil and gas leasing and recommend these areas for withdrawal from future locatable mineral entry. To further protect and enhance habitat in SFAs and PHMAs, the BLM and Forest Service will prioritize rangeland fire management (either through appropriate pre-suppression activities, suppression or post-fire restoration), gathers of wild horses and burros, and review of grazing permits for compliance with land health standards, vegetative objectives and permit terms and conditions that incorporate GRSG habitat management objectives in these areas.

The combination of habitat classifications and land allocation decisions proposed for inclusion in the proposed LUPs will provide the greatest protection for those areas identified as SFAs and meet the stated objective for these areas "where it is most important that the BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species"[5] and target habitat protection and restoration activities to those areas of highest importance. The proposed LUPs also largely avoid or exclude major development in PHMAs, in areas without an implemented all lands regulatory approach,[6] through avoidance for transmission, and exclusion for other major surface disturbing activities (e.g., solar and wind energy development).

In response, the four Great Basin ARMPAs provide land use allocations and management guidance for PHMAs to avoid new disturbance and minimize any disturbance associated with projects that might be developed in PHMA in the future. Allocations to avoid and minimize additional disturbance in PHMA included the application of a no surface occupancy (NSO) stipulation associated with any future leasing and development of oil, gas, and geothermal reserves in PHMAs. With the exception of a few areas in Utah and in eastern Nevada, there is low potential for fluid minerals in the Great Basin Region. To benefit GRSG conservation efforts and to assist developers in reducing the time and cost

[5] USFWS memorandum. Greater Sage Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important Landscapes. October 27, 2014.

[6] An all lands regulatory approach refers to a management strategy in which certain activities likely to affect the conservation of GRSG, including activities on state and private lands, are regulated, such as through the Wyoming Greater Sage Grouse Conservation Plan, Greater Sage Grouse Core Area Protection Executive Order.

associated with oil and gas leasing development, the BLM will prioritize new leasing in areas outside of PHMAs and GHMAs.

Similarly, mineral development, with the exception of locatable minerals governed under the 1872 Mining Act, is closed in PHMAs for non-energy leasable minerals and saleable minerals. An exception is granted for free use permits and the expansion of existing active pits for mineral material sales and expansion of existing non-energy leasable development. There is no potential for coal development in the Great Basin outside of Utah. In Utah, at the time of a new coal lease or lease modification, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods recognizing that PHMAs are “essential habitat” for purposes of suitability determinations.

In all PHMA in the Great Basin Region, new rights of way and development for transmission lines, pipelines, and related infrastructure will be avoided through restrictions on land use authorizations. Exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs, unless the development results in a net conservation gain to the GRSG or its habitat.

Comment [JRL18]: I don’t recall this exception.

Renewable energy development (solar and wind) is excluded in PHMAs in the four Great Basin ARMPAs, with the exception of three counties in southeastern Oregon where an avoidance allocation is applied.

In general, all forms of new development would be excluded, avoided, or developed only if the resultant effect is a net conservation gain to the GRSG or its habitat. This is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0*, published by the FWS in September 2014, which states that mitigation “be strategically designed to result in net overall positive outcomes for sage-grouse.” In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation gain for the GRSG.

Formatted: No Spacing, Space After: 0 pt, Add space between paragraphs of the same style

~~In response, the four Great Basin ARMPAs provide land use allocations and management guidance for PHMAs to avoid new disturbance and minimize any disturbance associated with projects that might be developed in PHMA in the future. Allocations to avoid and minimize additional disturbance in PHMA included the application of a no surface occupancy (NSO) stipulation associated with any future leasing and development of oil, gas, and geothermal reserves in PHMAs. With the exception of a few areas in Utah and in eastern Nevada, there is low potential for fluid minerals in the Great Basin Region. To benefit GRSG conservation efforts and to assist developers in reducing the time and cost associated with oil and gas leasing development, the BLM will encourage new leasing in areas outside of PHMAs, and GHMAs.~~

~~Similarly, mineral development, with the exception of locatable minerals governed under the 1872 Mining Act, is closed in PHMAs for non-energy leasable minerals and saleable minerals. An exception is granted for free use permits and the expansion of existing active pits for mineral material sales and expansion of existing non-energy leasable development. There is no potential for coal development in the Great Basin outside of Utah. In Utah, at the time of a new coal lease or lease modification, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods recognizing that PHMAs are “essential habitat” for purposes of suitability determinations.~~

~~In all PHMA in the Great Basin Region, new rights of way and development for transmission lines, pipelines, and related infrastructure will be avoided through restrictions on land use authorizations.~~

~~Exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs, unless necessary for health and safety purposes.~~

Comment [JRL19]: I don't recall this exception.

~~Renewable energy development (solar and wind) is excluded in PHMAs in the four Great Basin ARMPAs, with the exception of a few counties in southeastern Oregon where an avoidance allocation is applied.~~

~~In general, all forms of new development would be excluded, avoided, or developed only if the resultant effect is a net conservation benefit to the GRSG or its habitat. In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation benefit for the GRSG.~~

While ~~the majority of compelling~~ restrictions on future development in PHMA are intended to avoid oir minimize additional surface disturbance, ~~are placed in PHMA,~~ restrictions on development in GHMA are less stringent and can accommodate a limited amount of disturbance. Disturbance associated with oil and gas development, for example, is subject to a controlled surface use and timing limitation stipulation rather than an NSO stipulation. However, any disturbance is subject to mitigation and should seek to first avoid and then minimize any impacts to GRSG or its habitat, while offsetting unavoidable impacts to a standard that produces a net conservation gain for the species. As noted in the COT report, " … Conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur. …If development or vegetation manipulation activities outside of PACs are proposed, the project proponent should work with federal , state or local agencies and interested stakeholders to ensure consistency with sage-grouse habitat needs."

In addition, the ARMPAs direct the BLM to prioritize oil and gas leasing and development outside of identified SFAs, PHMAs, and GHMAs in order to encourage new development in areas that would not conflict with GRSG and thus maximize the potential to limit disturbance to remaining GRSG habitat.

Formatted: Normal, Space After: 6 pt, Don't add space between paragraphs of the same style

~~An added element of habitat protection was provided for GRSG strongholds in the ARMPAs by identifying Sagebrush Focal Areas (SFAs), a subset of PHMAs. SFAs correspond to the areas identified by the FWS as GRSG "strongholds" as detailed in an October 27, 2014 memo from FWS Director Ashe to BLM Director Kornze and Forest Service Chief Tidwell in response to a request to "identify a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection"(http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf). Beyond that in PHMA, management decisions to be applied to SFAs include NSO stipulation with no exceptions for oil, gas, and geothermal development; recommendation that these areas be withdrawn by the Secretary from mineral entry under the 1872 Mining Act, and prioritizing grazing permit renewal, wildhorse and burro management, and vegetation management. While the SFAs have minimal land surface disturbance and, based on existing, available data, limited mineral potential, valid existing rights – as in all habitat – will be recognized and be able to proceed in accordance with their legal rights.~~

~~*Management Direction, Prioritization, and Mitigation*~~

In addition to land allocations to protect SFAs, PHMAs, and GHMAs, the ARMPAs guide other uses of these landscapes to meet COT objectives consistent with existing, authorized uses of GRSG habitats and the sagebrush landscape.

Grazing is the most widespread use of the sagebrush steppe ecosystem in the Great Basin states. The COT Report recommendation for grazing states, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage-grouse (e.g. shrub cover, nesting cover)." To ensure that grazing continues in a manner consistent with the objective of conserving the GRSG and its habitat, the four Great Basin ARMPAs require the incorporation of GRSG seasonal habitat objectives into grazing permits, consistent with the ecological site potential of the local areas. [Incorporate additional measures for veg objectives]

To address the localized threat due to negative influences of grazing by free-roaming equids (wild horses and burros (WHB)), the BLM will complete rangeland health assessments for HMAs containing GRSG habitat using an interdisciplinary team of specialists (e.g. range, wildlife, and riparian). The BLM will prioritize gathers and population growth suppression techniques in HMAs in GRSG habitat, unless removals are necessary in other areas to address higher priority environmental issues, including herd health impacts – placing emphasis on addressing conflicts with WHBs in SFAs, PHMAs, and GHMAs. In SFAs and PHMA, the BLM will assess and adjust AMLs through the NEPA process within HMAs when WHBs are identified as a significant causal factor in not meeting land health standards, even if current AML is not being exceeded. The BLM will develop or amend herd management area plans to incorporate GRSG habitat objectives and management considerations for all HMAs within GRSG habitat, with emphasis placed on SFAs and PHMAs.

Formatted: Font: 11 pt

The BLM will focus on maintaining HMAs in GRSG habitat within established AML ranges to achieve and maintain GRSG habitat objectives and consider removals or exclusion of WHB during or immediately following emergency situations (such as fire, floods, and drought) to facilitate meeting GRSG habitat objectives where HMAs overlap with GRSG habitat. When conducting NEPA analysis for WHB management activities, water developments, or other rangeland improvements for WHB, the BLM will address the direct and indirect effects to GRSG populations and habitat. The BLM will coordinate with professionals from other federal and state agencies, researchers at universities, and others to utilize and evaluate new management tools (e.g., population growth suppression, inventory techniques, and telemetry) for implementing the WHB program.

~~The Great Basin ARMPAs place a priority on completing land heath assessments in SFAs, then PHMAs and GHMAs. The assessments will evaluate if grazing standards and guidelines are met, ensure that GRSG seasonal habitat objectives are also being met or are making progress towards being met, and ensure that the GRSG seasonal habitat objectives are incorporated into grazing permits.~~

~~Direction in the ARAMPs also incorporates GRSG seasonal habitat objectives into establishment of allowable management levels (AMLs). Prioritization of horse gathers and removal to reach AMLs in SFAs, PHMAs, and GHMAs (in that order) will be conducted.~~

Through required design features, buffers, and other management actions, proposed LUPs allow range developments which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. The NV/CA and OR proposed LUP removes livestock ponds built in perennial channels that are negatively impacting riparian habitats and do not permit new ones to be built in these areas subject to valid existing rights.

Formatted: Font: 11 pt

Management actions and required design features will ensure that the impact of fences on GRSG is minimized. Methods to be applied include marking fences in high-risk areas for collision and locating fences to limit or eliminate the impact on GRSG.

~~Fire represents the greatest threat to sage-grouse habitat in the Great Basin Region. Recognizing the nature and extent of this threat, the ARMPAs provide specific guidance for improving efforts to reduce the risk of GRSG habitat loss to wildfire. The four ARMPAs include specific guidance for fire prevention and the restoration of lands impacted by fire. The Great Basin ARMPAs also provide for a more aggressive, targeted effort to prevent and suppress fires that could impact thousands of acres of sage-grouse habitat, as well as restore areas with high potential to survive the impacts of climate change and subsequent rangeland fires.~~

To ameliorate the threat from recreational activities, new facilities or expansion of existing facilities (e.g., roads, trails, campgrounds) will not be authorized on BLM-administered and National Forest System land unless the development results in a net conservation gain to GRSG its habitat. During renewal, amendment, or reauthorization, terms and conditions in existing permits and operating plans will be modified to protect and/or restore GRSG habitat.

In PHMA and GHMA (except only in PHMA in Northwest Colorado), travel would be limited to vehicle routes. Initially, vehicles would be limited to existing routes until implementation travel management planning could be completed to designate routes; on Forest Service lands travel is limited to the Forest Service travel management system. Travel management plans, including route inventories, NEPA analysis, and route designation will be completed in a subsequent public planning process.

To ameliorate the threat from new land authorizations for infrastructure, the proposed LUPs provide that major pipeline and transmission line development will be avoided in all GRSG habitats through restrictions on land use authorizations(except in GHMA in Wyoming, Utah and Idaho). Exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated.

GHMA in Wyoming, Utah and Idaho would be available to rights-of-way for infrastructure due to the extent and quality of the habitat as well as the percentage of GRSG contained in PHMA in those states. An additional consideration in Wyoming is the extent of the protections for GRSG on private and state land. These factors gave BLM confidence, after input from FWS, that conservation objectives can be met with this additional flexibility provided in GHMA.

Formatted: Normal, Space After: 6 pt, Don't add space between paragraphs of the same style

Formatted: Font: (Default) +Body (Calibri), Bold

Although future high voltage transmission lines will be avoided in PHMA, the planning, siting, and environmental review of three priority lines has been underway for a number of years. These lines are critical to expanding access to renewable sources of energy and to improving the reliability of the Western grid. For these reasons, planning for these lines will proceed and potential impacts to GRSG will be fully mitigated through the mitigation identified in the site-specific NEPA for those projects.

To ameliorate the threat from fire, the proposed LUPs seek to fight the spread of cheatgrass and other invasive species, position wildland fire management resources for more effective rangeland fire response, and accelerate the restoration of fire-impacted landscapes to native grasses and sagebrush. Prescribed fire will not be used unless necessary to facilitate site preparation for restoration of GRSG habitat. If prescribed fire is used to facilitate site preparation for restoration the associated NEPA analysis must identify how the project would move towards GRSG desired conditions, why alternative techniques were not selected, and how potential threats to GRSG habitat would be minimized.

Through both the proposed LUPs and the final report to the Secretary on an Integrated Rangeland Fire Management Strategy[7](see section VI for more information), changes in land management practices and fire management policies and practices to prevention, suppression, and restoration landscapes impacted by fire have been adopted. Section VI further details the activities and actions that the BLM and the Forest Service will conduct to ameliorate the threat to GRSG and its habitat from rangeland fire. The BLM/Forest Service are involved in several west-wide efforts with other Federal, state, and private partners to address the threat of rangeland fire.

In addition, Secretarial Order 3336 on Rangeland Fire made clear that "**protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, priority GRSG habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department".** (emphasis added) The strategy places a Departmental priority on activities to prevent, suppress, and restore fire-impacted landscapes in areas identified by the Fire and Invasives Assessment Tool (FIAT) in priority habitat, using recent information derived from a report prepared by WAFWA to assist in addressing the threat of rangeland fire. The FIAT process, applying recent science, identified highly resistant and resilient landscapes to target fire management activities to these most important lands. In addition, through the issuance of a Leaders' Intent letter, signed by the Secretaries of Agriculture and the Interior, rangeland fire was identified as an "additional priority" for the firefighting community in making strategic decisions with regard to the allocation of resources for firefighting in 2015. Additional resources have been allocated and will be targeted to fuel treatments (including invasive species control), suppression (through the prepositioning of fire-fighting resources and the training of additional Rural Fire Protection Associations, local volunteer firefighters, and veteran fire fighters), and habitat restoration in these areas. Firefighting assets (aircraft, firefighters and related equipment) will be located near areas of high priority for rangeland fire.

Formatted: Normal, Right: 0", Space After: 6 pt, Don't add space between paragraphs of the same style, Line spacing: single

A related concern is conservation strategies to limit the spread of cheatgrass in the Great Basin, which negatively affects the establishment of native grasses and sage-steppe vegetation and increases the risk of rangeland fire. To respond, all proposed Great Basin subregion ARMPAs include the following vegetation objective: *In all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain a minimum of 70% of lands capable of producing sagebrush with at least 10 to 30% sagebrush canopy cover. The attributes necessary to sustain these habitats are described in Interpreting Indicators of Rangeland Health (BLM Tech Ref 1734-6).*[8]

Formatted: Tab stops: Not at 0" + 2.25" + 2.69"

Through guidance in the proposed ARMPAs supplemented by the Integrated Rangeland Fire Management Strategy, a commitment has been made to address the invasion and expansion of cheatgrass, medusa head, and other invasive grasses through expanded efforts to treat impacted acres and to accelerate and expand efforts to restore lands impacted by fire with native grasses and sagebrush seedlings. Efforts are underway to increase the acreages to be treated with chemical and biological agents to kill and stem the spread of invasive species and to accelerate the registration of other biologicals useful in addressing the threat of cheatgrass invasion.

[7] *An Integrated Rangeland Fire Management Strategy: Final Report to the Secretary*. Department of the Interior. May 1, 2015.

~~Lek protection~~

In addition to land allocations and management actions included in the Great Basin ARMPAs to conserve the GRSG, additional measures were included to ensure that disturbance to leks could be reduced or minimized through the application of disturbance caps and required minimum buffers.

Reducing Habitat Disturbance

Disturbance Caps

Formatted: Font: Not Bold, Italic

In addition to the management actions and allocations discussed in detail in the sections above, the proposed ARMPAs also limit the amount of anthropogenic disturbances in PHMAs through the use of disturbance caps. If the 3% or 5% (depending on state) anthropogenic disturbance is exceeded on lands (regardless of land ownership) within PHMA in any given Biologically Significant Unit (BSU), no further discrete anthropogenic disturbances (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.) will be permitted by the BLM and Forest Service within PHMAs in that Biologically Significant Unit. In Wyoming, a different process, which does not include an analysis at the Biologically Significant Unit, is used as described below. If the disturbance cap is exceeded on all lands (regardless of land ownership) within a proposed project analysis area in a PHMA, then no further anthropogenic disturbance will be permitted by the BLM and the Forest Service until disturbance in the proposed project analysis area has been reduced to be under the cap (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.). Most proposed plans will implement a 3% disturbance cap, with a few modifications. Oregon does not allow more than 1% new anthropogenic disturbance per decade, not to exceed 3% disturbance at any time. In Nevada, exceeding a 3% disturbance cap can occur at the BSU and/or the project level as long as the outcome results in a net conservation benefit and is approved by a cadre of high-level federal and state managers. Wyoming proposed plans are consistent with the State of Wyoming's Core Area Strategy, which limits all disturbances, including wildfire and vegetation treatments, within a project area (referred to as the Density and Disturbance Calculation Tool (DDCT) analysis area) to 5% within PHMAs.

The DDCT is a spatially based tool used in Wyoming that calculates both the average density of disruptive activities and total surface disturbance within the area affected by the project, or DDCT assessment area. The DDCT assessment area is created based on buffers around proposed projects (first buffer) in protected GRSG core areas, and subsequent buffers around any occupied, core area leks within the first buffer. A four mile buffer is used to identify 75% of the GRSG use around a lek. All activities will be evaluated within the context of maximum allowable disturbance (disturbance percentages, location and number of disturbances) of suitable GRSG habitat within the DDCT assessment area. In Montana, if the BLM determines that the State of Montana has adopted a GRSG Habitat Conservation Program that contains comparable components to those found in the State of Wyoming's Core Area Strategy including an all lands approach for calculating anthropogenic disturbances, a clear methodology for measuring the density of operations, and a fully operational density and disturbance calculation tool (such as the DDCT), the 3% disturbance cap would be converted to a 5% cap for all sources of habitat alteration, including wildfire and vegetation treatments, within a project analysis area.

Limiting Density of Disturbance

Formatted: Font: Not Bold, Italic

The proposed plans have also incorporated a cap on the density of energy and mining facilities to encourage consolidation of structures and to reduce habitat fragmentation. The cap is set at an average of one facility per 640 acres in PHMA in a project authorization area, consistent with guidance contained in the NTT report. If the disturbance density in the PHMA in a proposed project area is on average less than 1 facility per 640 acres, the analysis will proceed through the NEPA process incorporating mitigation measures into an alternative. If the disturbance density is greater than an average of 1 facility per 640 acres, the proposed project will either be deferred until the density of energy and mining facilities is less than the cap or co-located into an existing disturbed area (subject to applicable laws and regulations, such as the 1872 Mining Law, valid existing rights, etc.). The one facility per 640 density decision does not apply to Nevada. In Wyoming, the proposed LUPs are consistent with the State of Wyoming's Core Area Strategy, which limits oil and gas development density to an average of one pad per 640 acres and uses the Density and Disturbance Calculation Tool described above.

Buffering Development Impacts

Formatted: Font: Italic

With the exception of proposed LUPs in Wyoming, where the state plan is considered adequate to conserve GRSG, all proposed plans will evaluate impacts to leks from actions requiring NEPA analysis. In addition to any other relevant information determined to be appropriate (e.g. State wildlife agency plans), the BLM will assess and address impacts from the following activities using the lek buffer-distances as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). The Forest Service has incorporated the buffers as guidelines in the plan amendments. The BLM and Forest Service will apply the lek buffer-distances specified as the lower end of the interpreted range in the report unless justifiable departures are determined to be appropriate (see below, and as subject to applicable laws and regulations, such as the Mining Law of 1872, as Amended, valid existing rights, etc.). The lower end of the interpreted range of the lek buffer-distances is as follows:

- Linear features (roads) within 3.1 miles of leks
- Infrastructure related to energy development within 3.1 miles of leks.
- Tall structures (e.g., communication or transmission towers, transmission lines) within 2 miles of leks.
- Low structures (e.g., fences, rangeland structures) within1.2 miles of leks.
- Surface disturbance (continuing human activities that alter or remove the natural vegetation) within 3.1 miles of leks.
- Noise and related disruptive activities including those that do not result in habitat loss (e.g., motorized recreational events) at least 0.25 miles from leks.

Justifiable departures to decrease or increase from these distances, based on local data, best available science, landscape features, and other existing protections (e.g., land use allocations, state regulations) may be appropriate for determining activity impacts. The USGS report recognized "that because of variation in populations, habitats, development patterns, social context, and other factors, for a particular disturbance type, there is no single distance that is an appropriate buffer for all populations and habitats across the sage-grouse range". The USGS report also states that "various protection measures have been developed and implemented… [which have] the ability (alone or in concert with others) to protect important habitats, sustain populations, and support multiple-use demands for public lands". All variations in lek buffer-distances will require appropriate analysis and disclosure as part of activity authorization. In determining lek locations, the BLM will use the most recent active or occupied lek data available from the state wildlife agency.

For BLM and Forest Service actions in PHMAs (not including Wyoming), the BLM will apply the lek buffer-distances identified above as required conservation measures and the Forest Service as guidelines to fully address the impacts to leks as identified in the NEPA analysis. Impacts should be avoided by locating the action outside of the applicable lek buffer-distance(s) identified above. If the action cannot be located outside of the buffer-distance, the BLM and Forest Service may approve actions in PHMAs that are within the applicable lek buffer-distance identified above only if:

- The BLM, and the Forest Service, with input from the state fish and wildlife agency, determines, based on best available science, landscape features, and other existing protections, that a buffer distance other than the distance identified above offers the same or greater level of protection to GRSG and its habitat, including conservation of seasonal habitat outside of the analyzed buffer area.

For BLM and Forest Service actions in GHMAs (not including Wyoming), the BLM and Forest Service will apply the lek buffer-distances identified above as required conservation measures to fully address the impacts to leks as identified in the NEPA analysis.

- Impacts should first be avoided by locating the action outside of the applicable lek buffer-distance(s) identified above.
- The BLM and Forest Service may approve actions in GHMAs within the applicable lek buffer distance only if:
    - Based on best available science, landscape features, and other existing protections, (e.g., land use allocations, state regulations), the BLM or Forest Service (as appropriate) determine that a lek buffer distance other than the applicable distance identified above offers the same or a greater level of protection to GRSG and its habitat, including conservation of seasonal habitat outside of the analyzed buffer area; or
    - The BLM or Forest Service (as appropriate) determine that impacts to GRSG and its habitat are minimized such that the project will cause minor or no new disturbance (ex. co-location with existing authorizations); and
    - Any residual impacts within the lek buffer-distances are addressed through compensatory mitigation measures sufficient to ensure a net conservation gain.

The State of Wyoming's Core Area Strategy was developed by buffering leks by 5.3 miles and is designed to protect birds and habitat within core areas using a suite of tools and mechanisms that work in concert to conserve GRSG by reducing habitat loss and fragmentation through lek buffers, disturbance limits, excluded activities, and a sophisticated mapping utility to monitor the amount and density of disturbance. The combined effect of these overlapping and reinforcing mechanisms gives FWS confidence that the lek-buffer distances in the Core Area Strategy will be protective of breeding GRSG.

Mitigation Requirements

During the implementation of the proposed LUPs, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in GRSG habitat loss and degradation, the BLM and the Forest Service will require and ensure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation; Wyoming will apply a net conservation gain standard to actions in PHMA only. This will be achieved by avoiding, minimizing, and compensating for unavoidable impacts by applying beneficial conservation actions to offset remaining impacts associated with the action. This standard is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0* published by the FWS in September, 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse"[9]**.** Mitigation will follow the regulations from the White House Council on Environmental Quality (CEQ) (40 CFR 1508.20; e.g. avoid, minimize, and compensate) and be implemented on BLM-managed lands in a manner consistent with Departmental guidance for landscape mitigation pursuant to Secretarial Order 3330[10]. If impacts from BLM and Forest Service management actions and authorized third party actions result in habitat loss and degradation that remain after applying avoidance and minimization measures (i.e. residual impacts), then compensatory mitigation projects will be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation.

The BLM and Forest Service, via a WAFWA Management Zone GRSG Conservation Team will develop a WAFWA Management Zone Regional Mitigation Strategy that will inform the NEPA decision making process including the application of the mitigation hierarchy for BLM and Forest Service actions and third party authorizations that result in habitat loss and degradation. A robust and transparent Regional Mitigation Strategy will contribute to GRSG habitat conservation by reducing, eliminating, or minimizing threats and compensating for residual impacts to GRSG and its habitat. Within 90 days of the issuance of the Record of Decisions, the BLM will establish a WAFWA Management Zone GRSG Conservation Team to help guide the conservation of GRSG. This team will include membership from the respective states, Forest Service, USFWS, NRCS, and other local governments. The zonal mitigation strategy will be developed within one year of the issuance of the Record of Decisions.

Formatted: Font: (Default) Times New Roman, Italic

Required Design Features

Formatted: Font: Not Bold, Italic

Required Design Features (RDFs) are required for certain activities in all GRSG habitat, including PHMA, GHMA, IHMA in Idaho and OHMA in Nevada (see Appendix B for RDFs for all proposed LUPs except Wyoming where the RDFs apply to PHMA only and BMPs apply to GHMA). RDFs establish the minimum specifications for certain activities to help mitigate adverse impacts. However, the applicability and overall effectiveness of each RDF cannot be fully assessed until the project level when the project location and design are known. Because of site-specific circumstances, some RDFs may not apply to some projects (e.g., a resource is not

---

[9] USFWS. Greater Sage Grouse Range-Wide Mitigation Framework: Version 1.0. September 3, 2014.
[10] Secretarial Order 3330. Improving Mitigation Policies and Practices of the Department of the Interior. October 2013.

present on a given site) and/or may require slight variations (e.g., a larger or smaller protective area). All variations in RDFs would require that at least one of the following be demonstrated in the NEPA analysis associated with the project/activity:

- A specific RDF is documented to not be applicable to the site-specific conditions of the project/activity (e.g. due to site limitations or engineering considerations). Economic considerations, such as increased costs, do not necessarily require that an RDF be varied or rendered inapplicable;
- An alternative RDF is determined to provide equal or better protection for GRSG or its habitat;
- A specific RDF will provide no additional protection to GRSG or its habitat.

Formatted: Font: Italic

Habitat Restoration Measures

Formatted: Adjust space between Latin and Asian text, Adjust space between Asian text and numbers

The BLM *Greater Sage Grouse Invasive Annual Grasses & Conifer Expansion Assessment* (FIAT 2014) modeled conifer expansion for PACs to provide an initial stratification to determine where conifer removal would benefit important sagebrush habitats. This information is being used to identify and design projects to change vegetation composition and/or structure to modify potential fire behavior for the purpose of improving fire suppression effectiveness and limiting fire spread and intensity due to invasive grasses and conifer encroachment. Consistent with this assessment, the BLM ARMPAs include management actions to remove invading conifers and other undesirable species, and prioritize vegetation treatments closest to occupied GRSG habitats and near occupied leks.

In addition, since 2010, through NRCS' Sage Grouse Initiative (SGI), over 400,000 acres of private lands have been treated for removal of pinyon-juniper targeted in PACs and BLM has additionally treated over 400,000 acres of public lands. The SGI is a successful partnership with federal and state agencies, ranchers, and private landowners has been a model of cooperation and collaboration consistent with the recommendations of the authors of the 2006 WAFWA report as well as those of the COT and NTT. Additional details on the SGI and actions taken by BLM and Forest Service are included in Section VI. See also *www.**sagegrouseinitiative**.com* for additional information on SGI).

Formatted: Font: Italic

Post-Fire Habitat Restoration

Native seed stocks have been expanded to increase their availability to aid in the restoration of native vegetation in burned sagebrush areas.[11] In collaboration with the USDA and western governors, a new seed strategy has been developed to increase the capacity to collect, store, and allocate native seed for to improve habitat restoration in priority habitat areas. Finally, the Wildland Fire Departmental Manual will be revised to incorporate direction to identify rangeland fire as a critical priority in the Department and to ensure that resource allocations reflect this priority. For example, in the Manual, Emergency Stabilization (ES) and Burned Area Rehabilitation (BAR) funds for restoration of lands damaged by fire will be made available for 2 years and 5 years respectively (currently limited to 1 and 3 years respectively) to aid in ensuring effective restoration of burned areas.

---

[11] Also addresses specific concerns raised in the NTT report. p 27

~~Disturbance caps of 3% in PHMA were established in accordance with recommendations contained in the NTT and COT reports. Disturbance will be calculated based on established Biologically Significant Units developed by interagency teams for each of the four sub-regional planning efforts in the Great Basin, as well as at the proposed project scale analysis area, and will include proximity to leks in the calculation.~~

~~The ARMPAs provide direction to apply and analyze lek buffer-distances in PHMA and GHMA as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). The BLM will apply the lek buffer-distances specified as the lower end of the interpreted range in the report unless justifiable departures are determined to be appropriate~~

~~Consistent with recommendations contained in the 2006 WAFWA *Greater Sage-Grouse Range-wide Conservation Strategy*, the BLM conservation strategy places heavy reliance on monitoring and evaluation to assess the success of management decisions incorporated in ARMPAs, ultimately, in the effectiveness of implementing these plans. Monitoring plans will be interagency in nature and incorporate evaluation of greater sage-grouse population trends by the states and changes in habitat condition by the Federal land management agencies.~~

~~In addition, the conservation strategy incorporates an adaptive management framework that provides an "early warning system" of "soft triggers" to alert resource managers to the need to evaluate the effectiveness of their management strategies should declines in population levels or habitat conditions occur. If management responses to soft triggers do not adequately address the causes for population or habitat declines and "hard triggers" are reached, more significant changes in management actions and land allocations will immediately be implemented to conserve the species.~~

Response to Climate Change

With regard to the threat of climate change, the proposed ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the Integrated Rangeland Fire Management Strategy will further this effort. The Fire and Invasives Assessment Team (FIAT) assessments that supported the development of the Rangeland Fire Management Strategy [previously referenced?] are specifically designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). Additionally, by limiting or eliminating anthropogenic surface disturbance, especially in the contiguous SFAs, and restoring habitat through mitigation efforts, connectivity and availability of sagebrush habitat are expected to increase thus contributing to increased climate resilience.

Other Management Actions to Enhance GSRG Conservation Success

Commitment to Monitoring

Monitoring tied to proposed LUP decisions has two parts: (1) implementation monitoring (i.e., are decisions being implemented in a timely manner, are actions taken consistent with the plan decisions), and (2) effectiveness monitoring (i.e., are the decisions and implementation actions

Formatted: No Spacing, None, Space Before: 0 pt, After: 0 pt, Add space between paragraphs of the same style, Don't keep with next, Don't keep lines together

Formatted: Font: (Default) Times New Roman, 11 pt, Not Bold, Font color: Auto achieving the desired conservation goals). Through effectiveness monitoring, BLM can answer questions about how decisions and actions impact GRSG habitat. Understanding the effectiveness and validating results of LUPs and management decisions is an important part of measuring performance under the Government Performance Results Act. For example, riparian condition is a primary measure for LUP effectiveness (see WO IM 2010-101). Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, size of patches, etc.). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by state wildlife agencies and other partners, will allow linking real or potential habitat changes (from both natural events and management actions) to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to ameliorate negative effects with appropriate conservation actions.

The BLM Assessment, Inventory, and Monitoring (AIM) Strategy (Toevs et al. 2011 and IB2012-080) describes a vision for integrated, cross-program assessment, inventory, and monitoring of resources at multiple scales of management. Following the AIM Strategy, the BLM is modernizing its resource monitoring approach to more efficiently and effectively meet local, regional, and national resource information needs. The AIM Strategy provides a process for the BLM to collect quantitative information on the condition, trend, amount, location, and spatial pattern of natural resources on the public lands. Each AIM-Monitoring survey, at any scale of inquiry (from the plot level to west-wide deployments), uses a set of core indicators, standardized field methods, remote sensing, and a statistically-valid study design to provide nationally-consistent and scientifically-defensible information to determine conditions (e.g., rangeland health) and trends on public lands.

The National-scale deployment of AIM, known as the Landscape Monitoring Framework (LMF), commenced in 2011 in coordination with NRCS, with the collection of 1,000 plots of field-collected monitoring data across the Western U.S. LMF aims to provide non-biased estimates of vegetation and soil condition and trend using a statistically balanced sample design across BLM lands. A group of GRSG habitat and sagebrush plant community subject matter experts from BLM, USFWS, WAFWA, NRCS, ARS, state wildlife agencies, and academia identified those vegetation indicators collected at LMF sampling points that inform GRSG habitat needs. The common indicators that were identified include: species composition, foliar cover, height of the tallest sagebrush and herbaceous plant, inter-canopy gap, percent of invasive species, sagebrush shape, and bare ground. To increase the precision of estimates of sagebrush conditions within the range of GRSG, additional plot locations in occupied GRSG habitat (Sage-grouse Intensification) were added in 2013. The common indicators are also collected on sampling locations in the NRCS Rangeland Monitoring Survey. The GRSG baseline data will be collected over a five year period and an annual report will be prepared describing the status of the indicators. Beginning in year six, the annual status report will be accompanied with a trend report which will be available on an annual basis thereafter contingent upon continuation of the current monitoring budget. This information, in combination with mapping information, mid-scale habitat suitability indicator measures, and sagebrush availability information will be used to assess the effectiveness of the planning strategy.

The BLM has made significant commitments in the ARMPAs to monitoring actions to conserve GRSG habitats at multiple scales. The results from the monitoring will inform the agencies of the effectiveness of efforts to reduce disturbance and restore seasonal habitats in priority areas, and of the status of the triggers set in the proposed LUPs for adaptive management. The BLM and the Forest Service will report annually on the results of the monitoring efforts.

Adaptive Management

Each proposed LUP includes an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are not specific to any particular project, but identify habitat and population thresholds. Triggers are based on the two key metrics that are being monitored - habitat loss and/or population declines.

Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the proposed LUPs, the BLM and Forest Service response is to apply more conservative or restrictive conservation measures to mitigate for the specific causal factor in the decline of populations and/or habitats, with consideration of local knowledge and conditions. In each proposed LUP, a soft trigger begins a dialogue between the state, FWS, and the BLM or Forest Service to see if the causal factor can be determined and what implementation-level activities can be used to reverse any trend. These adjustments will be made to preclude tripping a "hard" trigger (which signals more severe habitat loss or population declines). Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the BLM and Forest Service proposed LUPs. In the event that new scientific information becomes available demonstrating that the hard trigger would be insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM and Forest Service proposed LUPs, the BLM and/or Forest Service will immediately assess what further actions may be needed to protect GRSG and its habitat and ensure that conservation options are not foreclosed. This could include a formal directive such as an IM or a plan amendment, which, to the extent that it is supported scientifically, may be drawn from the range of alternatives analyzed in the development of the proposed LUPs.

1.4~~3~~ Great Basin Region Planning Area

One of two regions that make up the National Greater Sage-Grouse Planning Strategy, the Great Basin Region is composed of four sub-regions, which include the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah sub-regions (see **Figure X** – Great Basin Region Greater Sage-Grouse Sub-regions). Four separate National Environmental Policy Act (NEPA) analyses were conducted separately for each sub-region. These sub-regional boundaries were generally developed based on the identified threats to the GRSG and the Western Association of Fish and Wildlife Agencies (WAFWA) Management Zones. Seven WAFWA Management Zones across the west were delineated in the *WAWFA 2006 Greater Sage-Grouse Comprehensive Strategy*. These large polygons were based on similar sage-grouse populations and sub-populations identified within seven floristic provinces.

The Great Basin Region consists of WAFWA Management Zones III (Southern Great Basin), IV (Snake River Plain), and V (Northern Great Basin). The USFWS has identified a number of threats in this region, focusing on the present and widespread threats of wildfire, loss of native habitat to invasive species, and habitat fragmentation. Other threats, many of which are more localized by nature, include anthropogenic disturbances associated with energy development, mining, infrastructure, recreation, urbanization, sagebrush elimination, as well as disturbance associated with free-roaming equids and livestock grazing.

The Great Basin Region planning area boundaries included all lands regardless of jurisdiction (see **Figure X** - Great Basin Region Planning Area - Greater Sage-Grouse Habitat Management Areas). **Table X** outlines the amount of surface acres that are administered by specific Federal agencies, states, local governments, and lands that are privately owned in the four sub regions that make up the Great Basin. The planning area includes other BLM-administered lands that are not allocated as habitat management areas for GRSG. The ARMPAs do not establish any additional management for these lands; these lands will continue to be managed according to the existing land use plan for the areas.

The decision area for the Great Basin Region ARMPAs is BLM-administered lands in GRSG habitat management areas (see **Figure X** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas), including surface and split-estate lands with BLM subsurface mineral rights. Any decisions in the Great Basin Region ARMPAs apply only to BLM-administered lands, including split-estate lands within GRSG habitat management areas (the decision area). These decisions are limited to providing land use planning direction specific to conserving GRSG and its habitat.

GRSG habitat management areas on BLM-administered lands in the decision area consists of lands allocated as Priority Habitat Management Areas (PHMA), General Habitat Management Areas (GHMA), Other Habitat Management Areas (OHMA, applicable only to the Nevada and Northeastern California), and Important Habitat Management Areas (IHMA, applicable only to Idaho). **Table X** identifies surface acres of PHMA, GHMA, OHMA, and IHMA in the decision area for the Great Basin Region.

PHMA, GHMA, OHMA, and IHMA are defined as follows:

- **PHMA**— BLM-administered lands identified as having the highest value to maintaining sustainable GRSG populations. The boundaries and management strategies for PHMA are derived from and generally follow the Preliminary Priority Habitat boundaries identified in the Draft LUPA/EIS. Areas of PHMA largely coincide with areas identified as Priority Areas for Conservation in the COT report.
- **GHMA**— BLM-administered lands where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMA are derived from and generally follow the Preliminary General Habitat boundaries identified in the Draft LUPA/EIS.
- **OHMA** —BLM-administered lands identified as unmapped habitat in the Draft LUPA/EIS that are within the planning area and contain seasonal or connectivity habitat areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse Habitat in Nevada and Northeastern California; Coates et al. 2014,) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.
- **IHMA** —BLM-administered lands that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. There are no IHMAs designated within southwestern Montana. The IHMA boundaries and management strategies are derived from and generally follow the Preliminary Medial Management Area (PMMA) and Important Habitat Zone (IHZ) boundaries identified in Alternatives D and E, respectively, of the Draft LUPA/EIS, but may be modified based on the objectives of each alternative. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the Proposed Plan.

The Great Basin Region ARMPAs also identify specific Sagebrush Focal Areas (SFAs), which are allocations that are a subset of PHMA (see **Figure X** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas). The SFAs were derived from GRSG stronghold areas described in a USFWS memorandum to the BLM titled Greater Sage-Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important Landscapes (USFWS 2014). The memorandum and associated maps provided by the USFWS identify areas that represent recognized strongholds for GRSG that have been noted and referenced as having the highest densities of GRSG and other criteria important for the persistence of the species.

Table X
Land Management in the Great Basin Planning Area

Surface Land Management	NV/NE CA	ID/SW MT	Utah	Oregon	Great Basin Total
BLM	45,359,000	12,449,000	20,387,200	12,615,900	**90,811,100**
Forest Service	9,719,900	13,252,400	7,396,300	6,454,800	**36,823,400**
Private	11,857,800	13,637,700	10,818,200	10,907,900	**47,221,600**
Bureau of Indian Affairs (tribal)	922,000	343,600	1,140,000	191,900	**2,975,500**
USFWS	805,900	121,900	121,900	482,500	**1,491,700**
Other	326,100	414,400	30,400	100,700	**871,600**
State	195,600	2,646,100	5,137,200	723,100	**8,702,000**
National Park Service	160,100	511,700	1,365,600	0	**2,037,400**
Other federal	3,200	562,200	0	61,300	**626,700**
Bureau of Reclamation	431,200	116,300	800	52,700	**601,000**
Local government	17,800	0	0	900	**18,700**
Department of Defense	402,000	127,400	1,812,300	64,500	**2,406,200**
Total acres	**70,200,600**	**44,142,200**	**48,209,900**	**31,656,300**	**194,208,300**

2. DECISION

2.1 Summary of the Approved Management Decisions

The decision is hereby made to approve the Great Basin Region Greater Sage-Grouse ARMPAs for the Great Basin Region Greater Sage-Grouse Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah (attachments A, B, C, and D). This ROD serves as the final decision establishing the land use plan amendment decisions outlined in the ARMPAs and is effective on the date it is signed. No further administrative remedies are available for these land use plan decisions.

The decisions included in this ROD and attached ARMPAs amend the land use plans described in Sections 1.1 of attachments A, B, C, and D. This ROD and ARMPAs become effective on the date this ROD is signed. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

The land use decisions provide conservation measures to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Land use plan decisions are expressed as goals, objectives (desired outcomes), allowable uses, and management decisions anticipated to achieve desired outcomes. Although decisions identified in the ARMPAs are final and effective upon signing of this ROD, they generally require additional implementation decision steps before on-the-ground activities can begin. Subsequent NEPA analysis will be conducted, as necessary, for such implementation decisions.

2.2 What the Record of Decision and Approved Resource Management Plan Amendments Provide

The ARMPAs include GRSG and GRSG habitat land use plan level management decisions in the form of:

- Goals
- Objectives (Desired Future Conditions)
- Land Use Allocations
- Management Actions

Goals are the broad statements of desired outcomes, and are usually not quantifiable.

Objectives are specific desired conditions, usually quantifiable and measurable, and may have timeframes for achievement.

Land use allocations specify locations within the planning area that are available or not for certain uses. These include decisions such as what lands are available for livestock grazing, mineral material use, oil and gas leasing, and locatable mineral development, what lands may be available for disposal via exchange and/ or sale, and what lands are open, closed, or limited to motorized travel (please note that all acreages presented in the Approved Plan are estimations even when presented to the nearest acre).

Management actions include those provisions that help in meeting the established goals and objectives and include measures that will be applied to guide day-to-day activities on public lands, including but not limited to stipulations, guidelines, best management practices (BMPs), and required design features.

The ARMPAs' management decisions were crafted to alleviate identified threats to Greater Sage-grouse and their habitats (see **Section 1.X**).

2.3 What the Record of Decision and Approved Resource Management Plan Amendments Do Not Provide

The attached ARMPAs do not contain decisions for public lands outside of GRSG habitat management areas, except for travel management decisions in the Idaho and Southwestern Montana ARMPA.

The ARMPAs do not affect valid existing rights.

The ARMPAs do not contain decisions for the mineral estates of lands located in the planning area for lands under the jurisdiction of other Federal agencies such as the Forest Service, or for private or State-owned lands and minerals that are not administered by the BLM. ARMPA decisions for surface estate only apply to BLM managed lands. In addition, many decisions are not appropriate at this level of planning and are not included in the ROD. Examples of these types of decisions include:

- *Statutory requirements.* The decision will not change the BLM's responsibility to comply with applicable laws, rules, and regulations.
- *National policy.* The decision will not change BLM's obligation to conform to current or future National policy.
- *Funding levels and budget allocations.* These are determined annually at the National level and are beyond the control of the State/District of Field offices.

Implementation decisions (or activity-level decisions) are management actions tied to a specific location. Implementation decisions generally constitute the BLM's final approval allowing on-the-ground actions to proceed and require appropriate site-specific planning and NEPA analysis. Such decisions may be incorporated into implementation plans (activity or project plans) or may exist as stand-alone decisions. These ARMPAs do not contain implementation decisions. Future activity-level plans will address the implementation of the ARMPAs. Implementation decisions and management actions that require additional site-specific project planning, as funding becomes available, will require further environmental analysis.

2.4 Modifications and Clarifications

During preparation of the ARMPAs for all four sub-regions, minor changes were made to the Proposed RMP Amendments to correct errors and to clarify decisions. Clarifications and corrections made since the Proposed RMP Amendments were published on May 29, 2015 and are hereby adopted by this ROD.

2.4.1 Modifications and Clarifications by Sub-region

Modifications and clarifications are summarized below for each of the sub-regional ARMPAs.

<u>Idaho and Southwestern Montana</u>

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Nevada and Northeastern California

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Oregon

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Utah

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

2.4.2 Protest Resolution

BLM's planning regulations at 43 CFR 1610.5-2 allow any person who participated in the planning process and has an interest that may be adversely affected by BLM's planning decisions to protest proposed planning decisions within 30 days from the date the Notice of Availability of the Proposed RMPA/Final EIS was published in the Federal Register (May 29, 2015). Below are descriptions of the protest resolution process for each of the four sub-regional PRMPAs/FEISs.

These decisions are final for the Department of the Interior. With the exception of the granted protest issues, the Director concluded that the BLM followed the applicable laws, regulations, and policies and considered all relevant resource information and public input in developing the Proposed Land Use Plan Amendments/Final EISs. Each protesting party will be notified in writing of the Director's findings and the disposition of their protests. The BLM Director resolved the protests without making significant changes to the Proposed Land Use Plan Amendments/Final EISs, though minor clarifications were made and are summarized in Section 2.5.1.

Idaho and Southwestern Montana

For the Idaho and Southwestern Montana GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Idaho and Southwestern Montana GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Nevada and Northeastern California

For the Nevada and Northeaster California GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Nevada and Northeastern California Sub-Regional GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Oregon

For the Oregon GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Oregon GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Utah

For the Utah GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Utah GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

2.4.3 Governors Consistency Review

The BLM's planning regulations require that RMPs be "consistent with officially approved or adopted resource-related plans, and the policies and procedures contained therein, of other federal agencies, state and local governments, and Indian tribes, so long as the guidance and RMPs also are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands" (43 CFR 1610.3-2(a)). The general requirement in FLPMA/planning regulations is to coordinate the land use planning process with plans of other agencies, states, and local governments to the extent consistent with law (see FLPMA s. 202(c)(9) and 1610.3-1(a)); and the respective duties to be consistent with both officially approved or adopted plans (to the extent those plans are consistent with federal law, or to maximum extent practical) (see 1610.3-2(a)(b)). In accordance with FLPMA, the BLM was aware of and gave consideration to state, local, and tribal land use plans and provided meaningful public involvement of the Proposed RMP Amendments/Final EISs.

The BLM is aware that there are specific state laws and local plans relevant to aspects of public land management that are discrete from, and independent of, federal law. However, the BLM is bound by federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that BLM's land use plans be consistent with officially-approved state and local plans only if those plans are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands. Where officially-approved state and local plans or policies and programs conflict with the purposes, policies, and programs of federal law applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially-approved state and local policies and programs (as opposed to plans), this consistency provision only applies to the maximum extent practical. While county and federal planning processes, under FLPMA, are required to be as integrated and consistent as practical, the federal agency planning process is not bound by or subject to state or county plans, planning processes, policies, or planning stipulations.

In some instances, modifications to the Proposed RMP Amendments were addressed based on recommendations submitted to the BLM by the applicable states. These modifications to the ARMPAs are summarized below by sub-region and are now part of the attached ARMPAs.

Idaho and Southwestern Montana

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Nevada and Northeastern California

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Oregon

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Utah

Will need to populate the "X" areas towards the end of the GCR process (end of July).

3. ALTERNATIVES

3.1 Alternatives Considered

Each of the Great Basin sub-regional planning efforts analyzed in detail a unique set of alternatives in the draft and final sub-regional EISs. The alternatives were developed to provide direction for resource programs influencing land management for the protection and enhancement of Greater Sage-grouse and its habitat. All management under any of the alternatives complied with federal laws, rules, regulations, and policies.

Each alternative emphasized an altered combination of resource uses, allocations, and restoration measures to address issues and resolve conflicts among uses so that GRSG goals and objectives were met in varying degrees across the alternatives. The alternatives differed in how fast the goals would be met, the degree to which they would be met, the emphasis placed on certain programs and activities, and whether active or passive management would occur.

The action alternatives offered a range of possible management approaches for responding to planning issues and concerns identified through public scoping, and to maintain or increase GRSG abundance and distribution in the planning area. While the land use plan goal was the same across alternatives for each sub-region, each alternative contained a discrete set of objectives and management actions constituting a separate RMP amendment. The goal was met in varying degrees, with the potential for different long-range outcomes and conditions.

The relative emphasis given to particular resources and resource uses differed as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs. When resources or resource uses are mandated by law or are not tied to planning issues, there are typically few or no distinctions between alternatives.

3.1.1 Alternative A – No Action Alternative

Alternative A meets the CEQ requirement that a No Action Alternative be considered. This alternative continues current management direction and prevailing conditions derived from the existing field/district office RMPs, as amended. Goals and objectives for resources and resource uses are based on the most recent RMP decisions, along with associated amendments, activity-and implementation-level plans, and other management decision documents. Laws, regulations, and BLM policies that supersede RMP decisions would apply. Many of the underlying RMPs/MFPs are outdated and

Goals and objectives for BLM-administered lands and mineral estate would not change. Appropriate and allowable uses and restrictions pertaining to activities such as mineral leasing and development, recreation, construction of utility corridors, and livestock grazing would also remain the same. The BLM would not modify existing or establish additional criteria to guide the identification of site-specific use levels for implementation activities.

This alternative was not selected as the ARMPAs because it did not meet the purpose and need of this plan amendment. This alternative did not include changes that are needed to be made to the existing decisions based on the USFWS 2010 listing petition decision that identified inadequacy of regulatory mechanisms as a significant threat to GRSG and its habitat. This alternative did not incorporate the best available science pertaining to GRSG or its habitat.

3.1.2 Alternative B: National Technical Team Report Alternative

Alternative B was based on the conservation measures contained within the National Technical Team (NTT) Report. The GRSG National Technical Team (NTT), comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed *A Report on National Greater Sage-Grouse Conservation Measures* in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized importance on standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. The Report can be accessed at: http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

The BLM's Washington Office Instructional Memorandum (IM) Number 2012-044 directed the sub-regional planning efforts to analyze the conservation measures developed by the NTT, as appropriate, through the land use planning process and NEPA.

Alternative B would exclude ROW development in PHMA and avoid development in GHMA, would close PHMA to fluid mineral leasing, mineral material sales, and nonenergy leasable minerals, and would recommend withdrawal from locatable mineral entry in all PHMA. These management actions would reduce surface disturbance in PHMA and would minimize disturbance in GHMA, thereby maintaining GRSG habitat. Management actions for wildfire would focuse on suppression in PHMA and GHMA, while limiting certain types of fuels treatments. Vegetation management would emphasize sagebrush restoration. Collectively, vegetation and wildfire management would conserve GRSG habitat. Grazing would continue with similar impacts under Alternative B as under Alternative A. The best management practices (BMPs) proposed in the NTT report would be included as required design features as part of Alternative B and are listed in Appendix X, Required Design Features (RDFs), of this document.

This alternative was not selected in its entirety as the ARMPAs because the majority of the conservation measures in the NTT Report, as appropriate and applicable, were applied primarily to PHMA, and few conservation measures in the Report were provided for in GHMA. As a result, most management actions in GHMA reverted back to the No Action Alternative, which was found to not meet the purpose and need for the Amendments. Alternative B was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.3 Alternative C: Citizen Groups' Recommended Alternative One

Alternative C was based on a citizen groups' recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and was applied to all occupied GRSG habitat (PHMA and GHMA. Alternative C limited commodity development in areas of occupied GRSG habitat, and closed or excluded large portions of the planning area to many land uses. This included all PHMA and GHMA as being closed to livestock grazing, recommended for withdrawal, closed to fluid mineral leasing, closed to salable mineral and non-energy leasable mineral development, and exclusion areas for right-of-ways. The Utah LUPA/Draft EIS combined this alternative with Alternative F (discussed below).

Alternative C is the most restrictive approach to GRSG conservation. It would eliminate all future ROWs, fluid mineral leasing, nonenergy leasable mineral development, and mineral material sales on GRSG habitat. Alternative C would also recommend withdrawal from locatable mineral entry for all GRSG habitat. It would manage all GRSG habitat as PHMA. This alternative would substantially reduce surface disturbance in all GRSG habitat. Under Alternative C, the BLM would take a passive management approach to vegetation management and fuels treatments. Additionally, all GRSG habitat would be unavailable for livestock grazing.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which is not required by best available science from GRSG and its habitats. Alternative C was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.4 Alternative D: Draft RMP Amendments' Preferred Alternative

Alternative D, which were identified as the Preferred Alternative in the Draft EISs, balanced opportunities to use and develop the planning area as well as conserving, maintaining, and enhancing GRSG and their habitat. Protective measures were applied to GRSG habitat, while still allowing for anthropogenic disturbances that require stringent mitigation measures. This alternative represents the mix and variety of management actions based on BLM's analysis and judgment, which best resolve the resource issues and management concerns while accommodating laws, regulations, and policies pertaining to BLM management. As a result of public scoping comments, internal review, and cooperating agency coordination on the Draft RMP Amendments/EISs, this alternative was modified to become the Proposed RMP Amendments and analyzed in the FEISs. The Preferred Alternatives, with slight variations, became the Proposed Plan in the FEISs.

In PHMA under Alternative D, there would be limitation on disturbance in GRSG habitat by excluding wind and solar energy development (except for certain counties in Southeastern Oregon where avoidance is applied), avoiding all other ROW development, applying no surface occupancy stipulations to fluid mineral development, and closing PHMA to nonenergy leasable mineral development and mineral material sales. These management actions would protect GRSG habitat, while allowing other activities, subject to conditions. In GHMA under Alternative D, allocation decisions were not consistent across the Great Basin. For example, in the Nevada and Northeastern California Proposed Amendment, nonenergy leasable mineral development and mineral material sales would be closed in GHMA, while in the Oregon, Utah, and Idaho and Southwestern Montana Proposed Amendments, these allocations in GHMA were open.

Under Alternative D, the BLM management would support sagebrush/perennial grass ecosystem enhancements, would increase fire suppression in PHMA and GHMA, and would manage livestock grazing to maintain or enhance sagebrush and perennial grass ecosystems.

3.1.5 Alternative E: State/Governor's Alternative

Alternative E is the alternative provided by the State or Governor's offices for inclusion and analysis in the EISs. It incorporates guidance from specific State Conservation strategies and emphasizes management of GRSG seasonal habitats and maintaining habitat connectivity to support population objectives. This alternative was identified as a co-Preferred Alternative in the Idaho and Southwestern Montana Draft EIS. California did not provide the BLM with a state GRSG conservation plan and under this alternative, reverted back to Alternative A, the no-action alternative.

For Nevada, Alternative E would apply an avoid, minimize, and mitigate strategy to reduce direct and indirect impacts on GRSG from surface-disturbing activities on BLM-administered lands. Effects on

GRSG habitat from certain resource programs, such as grazing, lands and realty, wildfire management, and minerals, would not be directly addressed because allocation decisions were not part of the state's plan.

For Oregon, Alternative E contains GRSG conservation guidelines from Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat. The state plan describes the Oregon Department of Fish and Wildlife's proposed management of GRSG. It also provides guidance for public land management agencies and land managers for GRSG conservation. GRSG conservation guidelines in the state plan are designed to maintain (at a minimum) or enhance the quality (the optimum) of current habitats. The guidelines would also assist resource managers in achieving the population and habitat objectives of the state plan.

For Idaho, Alternative E incorporates proposed GRSG protection measures recommended by the State of Idaho. Management in Montana would remain unchanged from the current RMPs (Alternative A). Alternative E addresses the following primary threats: fire, invasive weeds, and infrastructure development. It also includes guidance for several secondary GRSG threats such as recreation, improper livestock grazing, and West Nile virus for BLM and Forest Service programs that affect GRSG or its habitat.

For Utah, the planning area includes all occupied GRSG habitat in Utah. Alternative E1 is based on the State of Utah's Conservation Plan for Greater Sage-Grouse in Utah and would apply to all BLM-administered lands in Utah. Alternative E1 was designed to eliminate the threats facing the GRSG while balancing the economic and social needs of the residents of Utah. Conservation measures would be applied to 11 areas that the state identified, called Sage-Grouse Management Areas (SGMAs). Emphasis would be placed on expanding GRSG habitat by aggressively treating areas where there are encroaching conifers or invasive species. Alternative E1 includes a general limit on new permanent disturbance of 5 percent of habitat on state or federally managed lands within any particular SGMAs. Occupied habitat outside of the state-identified SGMAs would not receive new management protection. They would continue to be managed according to the GRSG actions in existing RMPs and conservation measures associated with existing activity-level plans.

This alternative was not selected, in whole, as the ARMPAs because some components of the state's plans were not consistent with the purposes, policies and programs of Federal laws and regulations applicable to public lands. However, many goals, objectives, and management actions in the ARMPA were carried forward.

3.1.6 – Alternative F: Citizen Groups' Recommended Alternative Two

Alternative F is also based on a citizen group recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and defines different restrictions for PHMA and GHMA. Alternative F would limit commodity development in areas of occupied GRSG habitat, and would close or designate portions of the planning area to some land uses. This alternative does not apply to the Utah sub-regional planning effort, as it was combined with Alternative C. Under Alternative F, wildfire suppression would be prioritized in PHMA, while limiting certain types of fuels treatments necessary to protect GRSG habitat. Concurrent vegetation management would emphasize sagebrush restoration and enhancement. Alternative F would reduce livestock and wild horse and burro management utilization by 25 percent within PHMA and GHMA.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which is not required by best available science from GRSG and its habitats. Alternative F was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.7 – Proposed Plan Amendment

As a result of public comments, best science, cooperating agency coordination, and internal review of the Draft RMP Amendments/EISs, the BLM has developed the Proposed Amendments/Final EISs for managing BLM-administered lands. The Proposed Amendments/Final EISs focus on addressing public comments, while continuing to meet the BLM's legal and regulatory mandates. The Proposed Amendments/Final EISs are a variation of the preferred alternatives (Alternative D) and are within the range of alternatives analyzed in the DEISs. The Proposed Plans, with slight variations (as outlined in Section 2.5 of this ROD), became ARMPAs.

3.1.8 Environmentally Preferable Alternative Considered in all Sub-Regions

Council on Environmental Quality (CEQ) regulations require that a ROD state which alternatives were considered to be "environmentally preferable" (40 CFR 1505.2(b)). Question 6A of CEQ's 40 most-asked questions regarding CEQ's NEPA regulations defines that term to ordinarily mean the alternative which best protects, preserves, and enhances historic, cultural, and natural resources.

Under that definition, Alternative C, as presented in each of the sub-regional Proposed RMP Amendments/Final EISs is the most environmentally preferable. However, NEPA expresses a continuing policy of the federal government to "use all practicable means and measures…to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans" (Section 101 of NEPA).

Alternative C is most protective of resources, specifically GRSG habitat in the planning area and thus would be the most "environmentally preferable" as that term is defined in Question 6A of CEQ's 40 asked questions regarding NEPA, but both NEPA and FLPMA recognize resource uses as part of the policy of the United States and under the standard of FLPMA's multiple-use mandate, the Proposed Plan was determined to be the most balanced.

3.2 Alternatives Considered But Not Analyzed in Detail

The alternatives listed below by sub-region were considered but were not carried forward for detailed analysis because of one or more of the following reasons:

- They would not meet the requirements of FLPMA or other existing laws and regulations;
- They did not meet the purpose and need;
- The alternative was already captured within the range of alternative analyzed in the EIS;
- They were already part of an existing plan, policy, or administrative function; or
- They did not fall within the limits of the planning criteria.

For additional rationale as to why each of the alternatives listed below by sub-region were not carried forward for detailed analysis, refer Section 2.11of each of the sub-regional Proposed Amendments/Final EISs.

Idaho and Southwestern Montana

- USFWS-Listing Alternative
- Elimination of Recreational Hunting Alternative
- Predation Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Consideration of Coal Mining Alternative

Nevada and Northeastern California

- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Elko County Sage-Grouse Plan Alternative
- Increase Grazing Alternative

Oregon

- USFWS-Listing Alternative
- Elimination of Livestock Grazing from all BLM Lands Alternative
- Increase Livestock Grazing Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative

Utah

- USFWS-Listing Alternative
- Increase Livestock Grazing Alternative
- Make GRSG Habitat Available for Oil Shale and Tar Sands Alternative
- Citizen Proposed Alternatives (in their entirety)
- Adoption of the State of Utah’s Sage-Grouse Management Areas as PHMA for all Alternatives
- Use of Other Habitat Maps Alternatives
- County Sage-Grouse Management Plans Alternative
- Conservation Objectives Team (COT) Report Alternative
- BLM Policies and Regulations Alternative

4. MANAGEMENT CONSIDERATIONS

The BLM is tasked to provide multiple use management for public lands by the Federal Land Policy and Management Act (FLPMA) and numerous other laws and regulations that govern the management of public lands. Due to the diversity of community needs and stakeholders affected by management of BLM lands, there has been both support and opposition to certain components of the Proposed Plans. BLM's objective in choosing the Proposed Plan Amendments as the ARMPAs was to address diverse needs and concerns in a fair manner and provide a practical and workable framework for management of public lands in Greater Sage-grouse habitat. The BLM is ultimately responsible for preparing these ARMPAs consistent with its legal mandates that reflect collective professional judgment using the best available science. The ARMPAs provide a balance between those reasonable measures necessary to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat to meet the purpose and need of these plan amendments, and the ongoing public need for use of the public lands within the Great Basin Region planning area.

The ARMPAs were selected because they will reduce or eliminate threats to Greater Sage-Grouse at a landscape scale, improve and sustain properly functioning resource conditions, and consider needs and demands for existing or potential resource commodities and values. In the end, Greater Sage-Grouse habitat will be managed by integrating ecological, economic, and social principles in a manner that safeguards the long term sustainability, diversity and productivity of the land.

In 2012, at the FWS convened a Conservation Objectives Team (COT) of state and federal representatives to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The final, peer-reviewed COT Report provided a brief overview of the threats to the greater sage-grouse's survival based upon the FWS 2010 listing decision and an assessment of the extent to which these threats affected remaining GRSG populations. **Table XX** provides a crosswalk between the threats to GRSG and their habitat identified in the COT Report and the key management responses from the ARMPAs that aim to ameliorate these threats.

Table XX
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
All threats	• Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met. • Require and ensure mitigation that provides a net conservation gain to GRSG and its habitat. • Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner. • Apply buffers necessary based on project type and location to address impacts on leks when authorizing actions in GRSG habitat. • Apply Required Design Features (RDFs) when authorizing actions that affect GRSG habitat. • Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.
All development threats, including mining, infrastructure, and energy development.	• PHMA: Implement an anthropogenic disturbance cap of 3% within the Biologically Significant Unit and proposed project analysis areas in PHMA (slight variations to this management component in the State of Nevada only) • PHMA: Apply a disturbance density cap of 1 facility per 640 acres (except in the State of Nevada)

Table XX
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
Energy development—fluid minerals, including geothermal resources	• PHMA: Open to fluid mineral leasing subject to a No Surface Occupancy (NSO) stipulation without waiver or modification, and with limited exceptions. In SFAs, a NSO stipulation would be applied without waiver, modification, or exception. • GHMA: Open to fluid mineral leasing subject to Controlled Surface Use (CSU) and Timing Limitation (TL) lease stipulations (except in the State of Utah where some portions of GHMA are open with standard lease stipulations)
Energy development—wind energy	• PHMA: Exclusion area (not available for wind energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Avoidance area (may be available for wind energy development with special stipulations) (except in the States of Utah and Idaho, where these areas would open to wind energy development)
Energy development—solar energy	• PHMA: Exclusion area (not available for solar energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Exclusion area (not available for solar energy development under any conditions) (except in the States of Oregon and Montana where these areas are avoidance areas for solar energy development and the State of Idaho, where these areas would open to solar energy development)
Infrastructure—major ROWs	• PHMA: Avoidance area (may be available for major ROWs with special stipulations) • GHMA: Avoidance area (may be available for major ROWs with special stipulations) (except in the State of Utah where GHMA is open)
Infrastructure—minor ROWs	• PHMA: Avoidance area (may be available for minor ROWs with special stipulations)
Mining—locatable minerals	• SFA: Recommend withdrawal from the Mining Law of 1872
Mining—nonenergy leasable minerals	• PHMA: Closed area (not available for nonenergy leasable minerals)
Mining—salable minerals	• PHMA: Closed area (not available for salable minerals) with a limited exception (may remain open to free use permits and expansion of existing active pits if criteria are met)
Livestock grazing	• Prioritize the review and processing of grazing permits/leases in SFAs followed by PHMA. • The NEPA analysis for renewals and modifications of grazing permits/leases will include specific management thresholds, based on the

Table XX
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
	GRSG Habitat Objectives Table, Land Health Standards and ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis. • Prioritize field checks in SFAs followed by PHMA to ensure compliance with the terms and conditions of grazing permits.
Free-roaming equid management	• Prioritize gathers in SFAs, followed by other PHMAs. • Manage Herd Management Areas (HMAs) in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives. • Prioritize rangeland health assessment, gathers and population growth suppression techniques, monitoring, and review and adjustment of AMLs and preparation of Herd Management Area Plans in GRSG habitat.
Range management structures	• Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. • Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas subject to valid existing rights.
Recreation	• PHMA: Do not construct new recreation facilities unless required for health and safety purposes. • Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain.
Fire	• Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection. • Prioritize post-fire treatments in SFAs, other PHMAs and GHMAs.
Nonnative, invasive plant species	• Improve GRSG habitat by treating annual grasses. • Treat sites in PHMA and GHMA that contain invasive species infestations through an integrated pest management approach.
Sagebrush removal	• PHMA: Maintain a minimum of 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover. • All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and/or juniper expansion	• Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.
Agricultural conversion and exurban development	• GRSG habitat will be retained in federal management.

5. MITIGATION MEASURES

In all GRSG habitat, in undertaking BLM management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the GRSG including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. Actions which result in habitat loss and degradation include those identified as threats which contribute to GRSG disturbance as identified by the FWS in its 2010 listing decision (75 FR 13910), COT report, and depicted in the ARMPAs' Monitoring Framework (which can be found in Appendix X of each of the attached ARMPAs). Mitigation will follow the regulations from the CEQ (40 CFR, Part 1508.20; e.g. avoid, minimize, and compensate). If impacts from BLM management actions and authorized third-party actions (which are consistent with the goals, objectives, and management actions in the attached ARMPAs) that result in habitat loss and degradation remain after applying avoidance and minimization measures (i.e., residual impacts), then compensatory mitigation projects would be used to provide a net conservation gain to the species. Any compensatory mitigation would be durable, timely, and in addition to what would have resulted without the compensatory mitigation (see the concepts of durability, timeliness, and additionality as described further in the Mitigation Strategy, which can be found in Appendix X of each of the attached ARMPAs).

All practical means to avoid or minimize environmental harm, specifically to Greater Sage-Grouse and its habitat are encompassed in the attached ARMPAs and associated appendices. Mitigation measures, including the application of required design features have been identified.

6. PLAN MONITORING

The BLM's Monitoring framework (Appendix X of each of the attached ARMPAs) describes the process that the BLM will use to monitor implementation and effectiveness of ARMPA decisions. The monitoring framework includes methods, data standards, and intervals of monitoring at broad- and mid-scales; consistent indicators to measure descriptions for each of the scales; analysis and reporting methods; and the incorporation of monitoring results into adaptive management.

The BLM has committed to consistently and systematically monitor the land use plans implementation actions authorized within the designated sage-grouse management areas (e.g., Sagebrush Focal Areas, Priority Habitat Management Areas, General Habitat Management Areas). An annual Implementation Monitoring Report will describe the number and types of authorized actions in each of the sage-grouse management areas and will document whether the authorized actions are in conformance with the applicable land use plan. The reporting structure will be based on the BLM program areas and use the completion date of the decision from the NEPA document in the ePlanning system.

Effectiveness monitoring includes monitoring disturbance in habitats, as well as landscape habitat attributes. To monitor habitats, the BLM will measure and track attributes of GRSG habitat management areas at the broad scale, and attributes of habitat availability, patch size, linkage/connectivity habitat, edge effect, and human disturbances at the mid-scale. Disturbance monitoring will measure and track changes in the amount of sagebrush in the landscape and changes in the human footprint, including changes in density of energy development. The framework also includes: (1) methods for analyzing and reporting for field offices, states, and BLM districts; (2) geospatial and tabular data for disturbance mapping (e.g., geospatial footprint of new permitted disturbances) and management action effectiveness.

The monitoring data will also provide the indicator estimates for adaptive management. The BLM will adjust management decisions through an adaptive management process (consistent with and in accordance with applicable law, as described in each of the specific adaptive management strategies outlined in Appendix X of the attached ARMPAs).

7. PUBLIC INVOLVEMENT, CONSULTATION AND COORDINATION

The BLM land use planning is conducted in accordance with NEPA requirements, CEQ regulations, and US Departments of the Interior and Agriculture policies and procedures implementing NEPA, as well as specific BLM planning and NEPA policies. The NEPA and associated laws, regulations, and policies require the BLM to seek public involvement early in and throughout the planning process to develop a range of reasonable alternatives to proposed actions and to prepare environmental documents that disclose the potential impacts of proposed alternatives.

Public involvement and agency consultation and coordination have been at the heart of the planning process leading to these Great Basin Region ARMPAs. These efforts were achieved through Federal Register notices, public and informal meetings, individual contacts, media releases, planning bulletins, and a series of GRSG planning-related Web sites. This section documents the outreach efforts that have occurred to date.

7.1 Public Involvement

The scoping period for the National GRSG Planning Strategy, including the four sub-regional planning areas in the Great Basin Region, began with the publication of the NOI in the Federal Register on December 9, 2011, and ended on March 23, 2012. Beginning in December and ending in February of 2012, the BLM hosted a series of public open house scoping meetings across Northeastern California, Idaho, Southwestern Montana, Nevada, Oregon and Utah. A final National GRSG Planning Strategy Scoping Report was released in May 2012.

A Notice of Availability (NOA) for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Draft RMP Amendments/EISs were published in the Federal Register on November 1, 2013. The Oregon Draft RMP Amendment/EIS was released to the public on November 26, 2013.

For the Great Basin Region GRSG Proposed RMP Amendments/FEIS, Idaho and Southwestern Montana conducted seven public meetings; Nevada and Northeastern California conducted seven public meetings, Oregon conducted seven public meetings, and Utah conducted eight public meetings between November 2013 and January 2014.

Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were considered and incorporated, as appropriate, into the Proposed Plans. The Great Basin Region received approximately 4,990 substantive comments, contained in 74,240 submissions during the four Draft EISs' comment periods. Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were carefully considered and incorporated as appropriate into the Proposed Plan Amendments. Public comments resulted in the addition of clarifying text, but did not significantly change Proposed RMP Amendments.

A Notice of Availability (NOA) for the Great Basin Region GRSG Proposed RMP Amendments and Final EISs for the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah Sub-Regions were released on May 29, 2015. The release of the EPA's NOA initiated a 30 day public protest period and a 60 day governors' consistency review. Refer to **Section 2.5** for a full description of the protest period and governors' consistency review outcomes.

7.2 Cooperating Agencies

A cooperating agency is any federal, state, or local government agency or Native American tribe that enters into a formal agreement with the lead federal agency to help develop an environmental analysis. Cooperating Agencies and tribes "work with the BLM, sharing knowledge and resources, to achieve desired outcomes for public lands and communities within statutory and regulatory frameworks" (BLM 2005). The benefits of enhanced collaboration among agencies in preparing NEPA analyses are:

- Disclosing relevant information early in the analytical process
- Applying available technical expertise and staff support
- Avoiding duplication with other federal, state, tribal, and local procedures
- Establishing a mechanism for addressing intergovernmental issues

The BLM entered into a formal Memorandum of Understanding (MOU) for the National GRSG Planning Strategy with the USFWS and the U.S. Forest Service. In addition, the Great Basin sub-regions' also invited local, state, other federal, and tribal representatives to participate as Cooperating Agencies for these RMP Amendments/EISs. In total, there were 11 MOUs signed with Federal agencies, 10 MOUs signed with state agencies, 55 MOUs signed with counties, and 5 MOUs signed with tribal entities. The MOUs outline the interests, expertise, and jurisdictional responsibilities of both the BLM and its cooperating agency partners and also outlines their respective roles and responsibilities in the planning and NEPA processes. For a full list of these cooperating agencies divided by sub-region, refer to the Cooperating Agencies List at the beginning of this ROD. Additional information can also be found in Chapter 6 of each of the Proposed Amendments/FEISs.

7.2 FWS Section 7 Consultation

Consultation with FWS is required under Section 7(c) of the ESA before the start of any BLM project that may affect any federally listed or endangered species or its habitat. These planning processes are considered a major project, and the four Great Basin sub-regional Final EISs defined potential impacts on threatened and endangered species as a result of management actions proposed in the alternatives analyzed in the FEISs. The FWS is a cooperating agency in this planning process. FWS staff participated in interdisciplinary team meetings and has been provided drafts of alternative decisions and analyses for discussion and input.

The BLM formally initiated Section 7 consultation with a letter to the USFWS prior to the release of the Draft RMP Amendments/EISs, and requested concurrence on which species would require consideration during consultation. Over the ensuing months, regular meetings were held to identify the species that would be analyzed in the biological assessment, to address which actions could affect those species, and to determine whether the implementation of the Proposed Plan Amendments "may affect" the species for which this consultation occurred.

Prior to the release of the Proposed Amendments/FEISs, the BLM formally submitted the biological assessments to the USFWS for review. The USFWS evaluated the biological assessments and concurred with the "no affect" determination via memorandum for Oregon, Nevada and Northeastern California, and Idaho and Southwestern Montana, which are appendices to each of these ARMPAs. For Utah, formal consultation was required with the FWS due to a "likely to adversely affect" determination associated with the threatened listed Utah Prairie Dog. The biological opinion from the FWS is attached to the Utah ARMPA (Appendix X of Attachment X).

[Verify that the above paragraph is applicable to UT once BLM UT hears back from their local FWS.]

7.3 Native American Consultation

In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation efforts related to preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent letters to 65 tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts.

The Draft RMP Amendments/EISs were provided to the Idaho, Montana, Nevada, California, Oregon, and Utah State Historic Preservation Offices (SHPO) concurrently with its release to the public. The Proposed Plan RMP Amendments/FEISs were also provided to the SHPOs.

[Verify that the above paragraph is applicable to UT.]

8. APPROVAL

Land Use Plan Amendment Decisions

It is the decision of the Bureau of Land Management (BLM) to approve the Great Basin Region Approved Resource Management Plan (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub-regions, as described in this Record of Decision. The Proposed Plan Amendments and related Final Environmental Impact Statements (EIS) were published on May 29, 2015, in the Federal Register (80 FR 30711). I have resolved all protests and, in accordance with BLM regulations 43 CFR 1610.5-2, my decision on the protests is the final decision of the Department of Interior. The approval is effective on the date this Record of Decision is signed.

Approved by:

Neil Kornze Director Bureau of Land Management	Date

Secretarial Approval

I hereby approve the land use plan amendments decisions. My approval of the land use plan decisions constitutes the final decision of the Department of the Interior and, in accordance with regulations at 43 CFR 4.410(a)(3), is not subject to appeal under Department regulations at 43 CFR Part 4. Any challenge to these land use plan decisions must be brought in Federal district court.

Approved by:

Sally Jewell Secretary Department of the Interior	Date

(WO210)(1610)

Dear Reader:

Enclosed are the Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah~~,~~). The ROD approves the four Great Basin Region ARMPAs, which are part of fifteen other sub-regional RMP Amendments and RMP revisions associated with the National Greater Sage-Grouse Planning Strategy that was initiated on December 11, 2011.

Comment [KK1]: 17?

The Bureau of Land Management (BLM) ARMPAs provide a range wide, comprehensive, science-based, collaborative strategy for addressing previously identified threats to the Greater Sage-Grouse (GRSG). This strategy, ~~while~~ designed to address issues leading to the 2010 “warranted but precluded” decision by the U.S. Fish and Wildlife Service (FWS), was guided by over a decade of research, analysis and recommendations for GRSG conservation produced by the Conservation Objectives Team (COT), Western Association of Fish and Wildlife Agencies (WAFWA), and the BLM National Technical Team ~~and~~ (NTT). Each of these reports was developed by a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research. Science-based decision-making and collaboration with the FWS, the U.S. Forest Service, and state and local partners were fundamental during the development of the land use plan decisions within these ARMPAs to address the identified threats to GRSG.

It is important to note that this ROD and these ARMPAs are specific only to BLM~~-~~administered lands. Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft EISs and Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

The Federal Land Policy Management Act (FLPMA) requires the development and maintenance, and, as appropriate, the revision of land use plans for public lands. The National Environmental Policy Act (NEPA) requires Federal agencies to prepare an Environmental Impact Statement (EIS) for major Federal actions that could significantly affect the environment. In fulfillment of these requirements, the Draft RMP Amendments/Draft EISs, incorporating analysis and input provided by the public; local, State, and

other Federal agencies and organizations; Native American tribes; Cooperating Agencies, and BLM personnel were published in the fall of 2013. The 90-day public comment periods ensued, with more than 4,990 substantive comments from 1,348 letters that were submitted. These comments were reviewed, summarized and considered in preparing the Proposed RMP Amendments/Final EISs.

Comment [KK2]: Great basin only?

The Proposed RMP Amendments/Final EISs were made available on May 29, 2015, for a 30-day protest period. X protest letters were received, of which X were valid protests in need of resolution. Protest issues are addressed and resolved in the Protest Summary Report, available on line at: http://www.blm.gov/nv/st/en/fo/wfo/blm_information/rmp.html.

After much consideration, the BLM now approves the ~~Proposed~~ RMP Amendments as the land use planning documents that will guide ~~Greater Sage-Grouse~~GRSG habitat management in the Great Basin Region for the life of the plan amendment.

Copies of the ROD and ARMPAs can be obtained from the BLM's National ~~Greater Sage-Grouse~~GRSG webpage at: http://www.blm.gov/wo/st/en/prog/more/sagegrouse.html.

The BLM extends special appreciation to the extensive public involvement and the involvement of groups, organizations, Cooperating Agencies; local, State, and other Federal agencies; and Native American tribal representatives who contributed to the completion of these ARMPAs. This participation informed and improved the planning process and the planning documents. Your continued involvement is encouraged as the ARMPAs are implemented and monitored for the conservation of ~~Greater Sage-Grouse~~GRSG and their habitat.

Sincerely,
X

Enclosure:
1. Record of Decision and Approved Resource Management Plan Amendments

Summary

This~~e~~ Record of Decision (ROD) is the culmination of an unprecedented effort in public land management to meet the multiple-use and sustained-yield management objectives for public lands administered by the Bureau of Land Management (BLM) in accordance with the Federal Land Policy and Management Act of 1976 (FLPMA). ~~directs the United States (US) Department of the Interior (DOI), Bureau of Land Management (BLM) to develop and periodically revise or amend its resource management plans (RMPs), which guide management of BLM-administered lands.~~

In response to a 2010 determination by the U.S. Fish and Wildlife Service (FWS) that the greater sage-grouse listing under the Endangered Species Act (ESA) is "warranted but precluded" by other priorities, the BLM, in coordination with the U.S. Department of Agriculture Forest Service (Forest Service) has developed a targeted, multi-tiered, landscape-level management approach, based on the best available science, that offers the highest level of protection for Greater Sage-Grouse (GRSG) in the most important habitat areas to address the specific threats identified in the 2010 U.S. Fish and Wildlife "warranted but precluded" decision and Conservation Objectives Team (COT) report.

This~~e~~ Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs)~~ROD and ARMPAs~~ for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon; and Utah ~~provides a layered management approach that offers the highest level of protection for Greater Sage-Grouse in the most valuable habitat to address the specific threats identified in the 2010 U.S. Fish and Wildlife "warranted but precluded" decision and Conservation Objectives Team report.~~ includes ~~L~~land use allocations in the ARMPAs that ~~would~~ limit or eliminate new surface disturbance in Priority Habitat Management Areas (PHMA), while minimizing disturbance in General Habitat Management Areas (GHMA). In addition to establishing protective land use allocations, the ARMPAs ~~would~~ implement a suite of management ~~tools~~ actions, such as the establishment of disturbance limits, GRSG habitat objectives, ~~and monitoring,~~ mitigation requirements~~approaches~~, monitoring protocols, and adaptive

Comment [JRL3]: The are not tools, but management actions to be implemented by the plans. DDCT is a tool, but establishing disturbance limits is a management action management triggers and responses, as well as~~nd~~ other conservation ~~protective~~ measures throughout the range. ~~These overlapping and reinforcing~~ The cumulative effect of these conservation measures ~~would~~ work in concert to protect, improve, and restore GRSG habitat ~~condition~~ across the remaining range of the species in the Great Basin and provide ~~consistency in~~ greater certainty that~~how the~~ BLM land and resource management ~~manages~~ activities in GRSG habitat in the Great Basin Region can lead to conservation of the GRSG and other sagebrush--steppe associated species in the region.

In conjunction with the management actions for GRSG included in the ROD and ARMPAs and ARMPRs for the Rocky Mountain GRSG subregion, -this ROD and ARMPAs for the Great Basin subregion provides management direction to protect and restore habitat essential to the conservation of the GRSG across its remaining range. This conservation strategy, developed in collaboration with the 11 states in which the ARMPAs and ARMPRs apply, in addition to other state and federal actions underway and in development, represents an unprecedented, collaborative effort among federal land management agencies and the states to manage an entire ecosystem and associated flora and fauna, in order to "conserve the sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future". [Dan Ashe. Transmittal letter to COT report. 2014]

Comment [JRL4]: This is the suite of actions facilitated by the plans

Comment [JRL5]: Certainty is better than "consistency" as that has become a "trigger" for negative response

Comment [JRL6]: Tie to ultimate goal and to benefit to other species and the ecosystem overall.

1. INTRODUCTION

This Record of Decision (ROD) approves the Bureau of Land Management's (BLM) attached approved Resource Management Plans (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM-administered lands. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) as amended and other applicable laws. The BLM prepared environmental impact statements (EISs) in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

Comment [KK7]: Either ROD & BLM carry from the dear readers letter or all acronyms need to be redefined here.

Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All four of these Draft EISs and Final EISs and associated Land Use Plans included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

1.1 Great Basin Region Planning Area

One of two regions that make up the National Greater Sage-Grouse Planning Strategy, the Great Basin Region is composed of four sub-regions, the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah sub-regions (see **Figure X** – Great Basin Region Greater Sage-Grouse Sub-regions). Four separate National Environmental Policy Act (NEPA) analyses were conducted, one for each sub-region. These sub-regional boundaries were developed considering the identified threats to the GRSG and the Western Association of Fish and Wildlife Agencies (WAFWA) Management Zones. Seven WAFWA Management Zones across the west were delineated in the *WAWFA 2006 Greater Sage-Grouse Comprehensive Strategy*. These large polygons were based on similar sage-grouse populations and sub-populations identified within seven floristic provinces.

The Great Basin Region consists of WAFWA Management Zones III (Southern Great Basin), IV (Snake River Plain), and V (Northern Great Basin). The USFWS has identified a number of threats in this region, focusing on the present and widespread threats of wildfire, loss of native habitat to invasive species, and habitat fragmentation. Other threats, some of which are more localized by nature, include anthropogenic disturbances associated with energy development, mining, infrastructure, recreation, urbanization, sagebrush elimination, as well as disturbance associated with free-roaming equids and livestock grazing.

Comment [KK8]: changed from many to some because there are a lot of "Y" for some of these items - see threats table

The Great Basin Region planning area boundaries include all lands regardless of jurisdiction (see **Figure X** - Great Basin Region Planning Area - Greater Sage-Grouse Habitat Management Areas). **Table X** outlines the amount of surface acres that are administered by specific Federal agencies, states, local governments, and lands that are privately owned in the four sub regions that make up the Great Basin. The planning area includes other BLM-administered lands that are not allocated as habitat management areas for GRSG. The ARMPAs do not establish any additional management for these lands; these lands will continue to be managed according to the existing land use plan for the areas.

Comment [KK9]: does this statement imply that we cannot make adjustments via maintenance action to the habitat boundaries? - since we very explicitly say that anything that is not inside of a habitat management area is not part of this decision making.

The decision area for the Great Basin Region ARMPAs is BLM-administered lands in GRSG habitat management areas (see **Figure X** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas), including surface and split-estate lands with BLM subsurface mineral rights. Any decisions in the Great Basin Region ARMPAs apply only to BLM-administered lands, including split-estate lands within GRSG habitat management areas (the decision area). These decisions are limited to providing land use planning direction specific to conserving GRSG and its habitat.

1.2~~1~~ THREATS TO GREATER SAGE-GROUSE

Currently, ~~Greater sage-grouse~~GRSG occupy an~~d~~ area that has been estimated to be a reduction of 44% from the historically occupied range. In addition, populations in most or all the range have been demonstrated to have declined from 1965- 2003, the period where data was collected most intensively.

The decline of the ~~greater sage-grouse (~~GRSG~~)~~ and its sagebrush--steppe habitat has been the focus of fish and wildlife agency and conservationists' concerns for decades. In 199~~5~~4 the Western Association of Fish and Wildlife Agencies (WAFWA) formed a technical committee to monitor the distribution and abundance of ~~sage-grouse~~GRSG. WAFWA formalized a program of interstate coordination and cooperation in 1995 to address the issues of ~~sage-grouse~~GRSG population losses and degradation of sagebrush ecosystems in order to: 1) Maintain the present distribution of ~~sage-grouse~~GRSG and 2) Maintain the present abundance of ~~sage-grouse~~GRSG. In 1999 WAFWA amended the objectives to: 1) Maintain and increase where possible the present distribution of ~~sage-grouse~~GRSG and 2) Maintain and increase where possible the present abundance of ~~sage-grouse~~GRSG. The Bureau of Land Management, USFWS, and U.S. Forest Service formally joined with WAFWA in range-wide conservation efforts in 2000.

Between May 1999 and December 2003, eight petitions were filed with the U.S. Fish and Wildlife Service (USFWS) to have sage-grouse protected under provisions of the Endangered Species Act (ESA). In 2001 the USFWS determined that greater sage-grouse in the Columbia Basin of Washington state warranted protection under provisions of the ESA. On January 12, 2005, the FWS issued a decision that listing the GRSG for protection under the ESA was not warranted. However, in response to July 14, 2006 Western Watersheds Project filing alleging that the FWS 2005 finding was incorrect and arbitrary, the U.S. District Court of Idaho ruled that the 2005 finding was "arbitrary and capricious" and remanded it to the FWS for further consideration. Ultimately, as a result, in 2010 the FWS issued a finding that listing of the Greater sage-grouse was "warranted but precluded". Subsequent to that finding, and in accordance with a settlement agreement [details?] the FWS committed to make a final determination regarding the need to list the GRSG by September 30, 2015. Two factors led -to the FWS decision to list the species as "warranted but precluded": threats to habitat and the inadequacy of existing regulatory mechanisms.

Primary threats affecting GRSG habitat on Forest Service and BLM-administered lands include infrastructure (power lines, communication towers, fences, roads, and railroads), and energy development (traditional oil and gas, mining, renewable energy, transmission corridors) within WAFWA GRSG Management Zone I, II and VII; and Fire, Invasive Weeds, and Pinyon-Juniper Encroachment within WAFWA GRSG Management Zone III, IV, V and VI. Improper grazing (livestock and wild horse) and climate change may be a threat across all management zones, and all threats exist to some degree across the range of the species. *Differences in ecological conditions within each MZ affect the susceptibility of these areas to the various threats facing sagebrush ecosystems and its potential for restoration. (FWS FRN 2010).* (See reference to WAFWA Management Zones (MZ) below.)

Additional information regarding potential threats to the GRSG is contained in the BLM National Technical Team (NTT) report and the Conservation Objectives Team (COT) reports. A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG – as articulated in the COT report – is summarized in Table A~~X~~. ~~[Include from Final Landscape report.]~~

In addition, the Service found that existing local, state and federal regulatory mechanisms were not sufficient to address threats to the habitat. For the BLM and the Forest Service, which manage more than 50 percent of the remaining habitat rangewide, regulatory mechanisms are the agencies' Resource Management Plans (RMPs) and Land and Resource Management Plans, respectively.

~~The Federal Land Policy and Management Act of 1976 (FLPMA) is the primary Federal law governing most land uses on BLM-administered lands, and directs development and implementation of Resource Management Plans (RMPs)[1] which direct management at a local level. As a designated sensitive species under BLM Manual 6840, GRSG conservation must be addressed in the development and implementation of RMPs on BLM lands. RMPs are the basis for all actions and authorizations involving BLM administered lands and resources. They authorize and establish allowable resource uses, resource condition goals and objectives to be attained, program constraints, general management practices needed to attain the goals and objectives, general implementation sequences, intervals and standards for monitoring and evaluating RMPs to determine effectiveness, and the need for amendment or revision (43 CFR 1601.0-5(k)).~~

~~Management of activities on National Forest System lands are guided principally by the National Forest Management Act (NFMA) (16 U.S.C. 1600-1614, August 17, 1974, as amended 1976, 1978, 1980, 1981, 1983, 1985, 1988, and 1990). NFMA specifies that the Forest Service must have a Land and Resource Management Plan (LRMP)[1] (16 U.S.C. 1604) to guide and set standards for all natural resource management activities on each National Forest or National Grassland. All of the LRMPs that currently guide the management of GRSG habitats on Forest Service lands were developed using the 1982 implementing regulations for land and resource management planning (1982 Rule, 36 CFR 219).~~

~~[1] Throughout this report, BLM Resource Management Plans (RMPs) and Forest Service Land and Resource Management Plans (LRMPs) will simply be referred to as Land Use Plans or LUPs.~~

Comment [KK11]: THIS MIGHT NOW BE ABOVE

Comment [KK12]: Delete or move to management considerations or the first paragraph of the intro?

As a result, the BLM and Forest Service initiated this planning effort to provide the needed federal regulatory mechanisms and certainty, as well as to address the individual threats listed in Table X. This Record of Decision (ROD) approves the Bureau of Land Management's (BLM) attached ARMPAs for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM administered lands. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft EISs and Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and associated Land and Resource Management Plans (LRMPs) under their planning authorities.

Table A. Threats to GRSG in the Great Basin Region (Utah) as identified by the Conservation Objectives Team (COT; 2013). Threats are characterized as: Y = threat is present and widespread, L = threat present but localized, and U = unknown.

1.32~~1~~ ~~National Greater Sage-Grouse Planning Strategy~~Early GRSG Conservation

Comment [KK13]: This section is all background things that happened before the plans started. It isn't the national GRSG planning strategy

The BLM and the Forest Service collectively manage the majority of the GRSG habitat on Federal lands (i.e., the range of GRSG not including the Columbia Basin or Bi-State Distinct Population Segments) addressed in this planning effort. Efforts to conserve the habitat of this species did not begin with the 2011 BLM/-Forest Service Planning Strategy, but rather, have been ongoing for many years.

The Western Association of Fish and Wildlife Agencies (WAFWA) 2004 *Range-wide Conservation Assessment for Greater Sage-Grouse and Sagebrush Habitats* was the first range-wide assessment of GRSG using the vast amount of population data collected over the previous 60 years, habitat information spanning the previous 100 years, and literature dating back 200 years. The goal of the assessment, contributed to by the BLM and the Forest Service, was to present an unbiased and scientific documentation of dominant issues and their effects on GRSG populations and sagebrush habitats. http://sagemap.wr.usgs.gov/docs/Greater_Sage-grouse_Conservation_Assessment_060404.pdf

In November 2004, the BLM released its *National Sage-Grouse Habitat Conservation Strategy*, which encouraged GRSG habitat conservation through consultation, cooperation, and communication with WAFWA, the U.S. Fish and Wildlife Service (FWS), the Forest Service, the U.S. Geological Survey (USGS), State wildlife agencies, local GRSG working groups, and various other public and private partners.

In 2006, WAFWA completed a *Greater Sage-Grouse Comprehensive Conservation Strategy*, with the assistance of the BLM, the Forest Service, and other contributors. The overall goal of the Strategy was to maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain those populations. The Strategy outlined the critical need to develop the associations among local, state, provincial, tribal, and federal agencies, non-governmental organizations, and individual citizens to design and implement cooperative actions to support robust populations of GRSG and the landscapes and habitats upon which they depend. The catalyst for this effort was widespread concern for declining populations and reduced distribution of GRSG. The WAFWA Sage-Grouse Management Zones were delineated in this Strategy. http://www.wafwa.org/documents/pdf/GreaterSage-grouseConservationStrategy2006.pdf

Comment [JRL14]: Link later if decide to use WAFWA zones to frame strategy

In 2008, the BLM created two national teams to investigate possible BLM management options for GRSG conservation as well as summarizing BLM's ongoing conservation efforts. A product of this effort was one of the first range-wide priority habitat maps for GRSG that were referred to as "key habitat". At the time, the primary purpose for the key habitat map was to inform and help prioritize fire suppression efforts in GRSG habitat on BLM lands. An additional outcome of this team was the signing of a Memorandum of Understanding by the WAFWA; the BLM, FWS, USGS in the Department of the Interior; and the US Department of Agriculture Forest Service and NRCS, to provide for cooperation among the participating state and federal land managers and wildlife management and science agencies in the conservation and management of GRSG sagebrush habitats and other sagebrush-dependent wildlife throughout the Western United States and Canada. http://www.blm.gov/style/medialib/blm/wo/Planning_and_Renewable_Resources/fish__wildlife_and/fwp.Par.95958.File.dat/SagegrouseMOU.pdf

In 2010, BLM commissioned an effort to map breeding densities of GRSG across the West. A conference was convened with the state wildlife agencies to get approval and to coordinate the lek survey data needed for this effort. This modelling project, through an agreement with the FWS, mapped known active

leks across the West. This model served as a standard starting point for all states to identify priority habitat.
http://www.blm.gov/wo/st/en/prog/more/fish__wildlife_and/sage-grouse-conservation/bird_density.print.html

In March 2010, the US Fish and Wildlife Service (USFWS) published their 12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered (75 Federal Register 13910, March 23, 2010). In that finding, the USFWS concluded that GRSG was "warranted, but precluded" for listing as a threatened or endangered species. A warranted, but precluded determination is one of three results that may occur after a petition is filed by the public to list a species under the Endangered Species Act (ESA). This finding indicates that immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, the~~a~~ species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

The USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 Federal Register 13910, March 23, 2010). The USFWS identified the principal regulatory mechanisms for the BLM and Forest Service as conservation measures in land use plans.

~~Consistent with the National GRSG Planning Strategy, the BLM as the lead agency, together with the U.S. Forest Service as a cooperating agency, prepared 15 environmental impact statements (EISs), with associated plan amendments and revisions. These documents provide a set of management alternatives focused on specific conservation measures across the range of the GRSG (see Figure X, National Greater Sage-Grouse Planning Strategy Boundaries) to address the threats identified in the 2010 USFWS "warranted but precluded" decision. .~~

Comment [JRL15]: CAPs or lower case?

1.4 National Greater Sage Grouse Planning Strategy

Based on the identified threats to the GRSG, especially inadequate regulatory mechanisms, and the FWS's timeline for making a listing decision on this species, the BLM recognized the need to incorporate explicit objectives and adequate conservation measures into RMPs by 2015 to conserve GRSG habitat and avoid the need to list the species under the Endangered Species Act. In August, 2011, the BLM chartered a planning strategy to evaluate the adequacy of BLM RMPs and address revisions and amendments throughout the range of the GRSG (with the exception of the bi-state population in California and Nevada, and the Washington state distinct population segment, which were addressed through other planning efforts). This Charter established the teams, team membership, and team operating procedures for the BLM's National GRSG Planning Strategy. The BLM's objective for chartering this planning strategy effort was to develop new or revised regulatory mechanisms through RMPs to conserve and

restore the GRSG and its habitat on BLM-administered lands on a range-wide basis for the long-term (Figure C).
http://www.blm.gov/style/medialib/blm/wo/Communications_Directorate/public_affairs/sage-grouse_planning/documents.Par.2415.File.dat/Final%20Signed%20GSG%20Planning%20Strategy%20Charter.pdf

~~*[Insert Figure X here.]*~~

~~Science-based decision-making and collaboration with state and local partners were fundamental to the National GRSG Planning Strategy. The 17 ARMPAs and ARMPs address threats to GRSG identified by state fish and wildlife agencies, the BLM National Technical Team (NTT), and the USFWS in the context of its listing decision and the Conservation Objectives Team (COT) report.~~

[Insert Figure C~~X~~ here.]

Two national teams, and numerous other studies were used to help inform the planning efforts. The GRSG National Technical Team (NTT), comprised of BLM, ~~Forest Service,~~ FWS, USGS, NRCS, and State specialists, completed A Report on National Greater Sage-Grouse Conservation Measures in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats in the FWS listing action (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized the importance of~~n~~ standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones.
http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

In 2012, FWS convened the~~a~~ Conservation Objectives Team (COT) of state and federal representatives to produce a peer-reviewed report ~~recommendation regarding~~ which identified the principal threats to GRSG survival -- based upon the FWS 2010 listing decision -- and the degree to which these threats need to be reduced or ameliorated to conserve the ~~greater sage-grouse~~GRSG so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. ~~The final, peer-reviewed COT Report provided a brief overview of the threats to the greater sage-grouse's survival based upon the FWS 2010 listing decision and an assessment of the extent to which these threats affected remaining GRSG populations.~~ (See Figure A and Table A.) The COT report also identified Priority Areas for Conservation (PACs) and emphasized that "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation".
http://www.fws.gov/greatersagegrouse/documents/COT-Report-with-Dear-Interested-Reader-Letter.pdf

Additional science-based reviews by the US Geological Survey and related scientific literature provided further guidance on specific issues that arose in developing the ARMPAs.

To adequately address the reasons for the 2010 "warranted" determination by the FWS – and specific threats summarized in the COT report -- it was clear to BLM and Forest Service land

Comment [JRL16]: If we reference a specific "Strategy", we need to explain its genesis. Should we use lower case instead or provide additional history. Former would be simpler.

Comment [JRL17]: 17?

Comment [JRL18]: The COT had not been published prior to completion of the draft EISs.

Comment [JRL19]: Forest Service was not a part of the NTT.

Comment [JRL20]: SUGGEST INCLUSION OF FIGURE ILLUSTRATING WAFWA ZONES.

Comment [JRL21]: Was not a recommendation

Comment [JRL22]: Suggest including table with list of threats from COT report.

and resource managers that additional regulatory measures on federal public lands would be necessary to deal with present or threatened destruction, modification, or curtailment of habitat or range. These measures would need to be incorporated into land use plans that guide management actions on lands within the remaining range of the GRSG administered by the agencies to conserve GRSG such that listing under the ESA was no longer necessary.

In December 2011, the BLM and the Forest Service published a Notice of Intent to prepare Environmental Impact Statements and Supplemental Environmental Impact Statements to incorporate GRSG Conservation Measures into Land Use Plans (LUPs) ~~and Land and Resource Management Plans~~ across the range of the species. A total of 15 subregional LUPs would amend or revise 78 BLM RMPs and 20 Forest LRMPs across the range of the species.

The federal public land conservation strategy reflects several key concepts:

- **Landscape-level**: The planning effort focuses on the remaining habitat of the GRSG on BLM and Forest Service lands, covering 10 western states in the Great Basin and Rocky Mountain regions.
- **Best Available Science** – The proposed LUPs are grounded in the best available science, drawn from published literature and input from recognized experts, state agencies, the US Geological Survey, the FWS and other sources. The COT report provided a "blueprint" for GRSG conservation by identifying specific threats to each remaining GRSG population and recommending measures to address each category of threat and the NTT report, prepared by the BLM, provided options for dealing with the most significant threats to the GRSG. A series of reports on how to improve efforts to reduce the threats of rangeland fire and invasive species prepared in collaboration with the Western Association of Fish and Wildlife Agencies also provided crucial guidance in formulating the conservation strategy.
- **Targeted, Multi-Tiered Approach** – The proposed LUPs were designed to incorporate a layered management approach to avoid or minimize additional surface disturbance in the most valuable habitat, known as Priority Habitat Management Areas (PHMA), which are largely consistent with PACs identified in the COT Report. Within PHMA, the proposed LUPs provide an added level of protection to limit or eliminate new surface disturbance through the delineation of Sagebrush Focal Areas (SFA), derived from areas identified by the FWS as "strongholds" essential for the species' survival. In General Habitat Management Areas (GHMA), the proposed LUPs seek to minimize disturbance while providing greater flexibility for land use activities.
- **Coordinated**: The BLM and Forest Service proposed LUPs were developed through a joint planning process led by the BLM with the Forest Service as partners. The USFWS provided guidance and input throughout the process to aid land managers in understanding the threats and the certainty and effectiveness of proposed land management actions in addressing those threats. The USGS and NRCS also provided key technical and scientific support.
- **Collaborative**: The proposed LUPs reflected the input of states and local stakeholders from the outset and were developed with the benefit of input from the individual states and cooperators who signed formal agreements with the BLM to provide input into the planning process. The Sage Grouse Task Force (SGTF) was particularly useful in facilitating this kind of collaborative input. The proposed LUPs reflect state and

> stakeholder developed approaches and economic priorities where consistent with conservation objectives.

The BLM ~~also~~ adopted unique state and stakeholder developed approaches and priorities within the ARMPAs. In 2011, then Secretary of the Interior Ken Salazar sent letters to each of the sage-grouse state governors asking for a report and recommendations on how to best move forward with a multi-state conservation sage-grouse plan. Most states across the range provided recommendations for the management of the BLM lands in their state to conserve ~~sage-grouse~~GRSG. In all cases, this input was incorporated into ~~state conservation plans that were part of~~ the range of alternatives analyzed in the Final EISs. Components of these state recommendations ~~conservation plans~~ were used to develop the ARMPAs.

Comment [JRL23]: Is this correct? Haven't seen this letter.

Comment [JRL24]: Confusing to refer to state recommendations for managing BLM land in a state as "state plans". Suggest this alternative. Most readers would think of state plans as state plans to manage lands within their jurisdiction.

In addition, the Western Governors Association Sage Grouse Task Force was established in 2011 to identify and ~~implement~~ recommend ~~high priority~~ state and federal conservation actions ~~and integrate ongoing actions~~ necessary to preclude the need for the GRSG to be listed under the ESA. This group, which includes designees from the 11 western states where GRSG is found as well as representatives from USFWS, BLM, Natural Resources Conservation Service, US Forest Service, US Geological Survey, and the Department of the Interior, played an integral role throughout this land use planning process.

Comment [JRL25]: SGTF did not implement

1.53~~2~~ Address~~Ameliorat~~ing Threats to the Greater Sage-Grouse ~~through the National Greater Sage-Grouse Planning Strategy~~

~~*[Need to verify with Jim and Karen what elements from the Landscape Report they would like to see here. Right now, we only included content from Section VII (Summary) of the Landscape Report, but we can change this if needed. We can even include some of the pie charts and figures from the LR if necessary.]*~~

The 2006 WAFWA *Greater Sage Grouse Comprehensive Conservation Strategy* stated goal for management of the GRSG was to "maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain these populations".[2] The NTT report also endorsed this goal "as a guiding philosophy against which management actions and policies of BLM should be weighed"[3] And, in establishing the COT, with the backing of the SGTF, FWS Director Dan Ashe affirmed the commitment to the goal for GRSG conservation originally articulated in the 2006 WAFWA report -- reversing negative population trends and achieving a neutral or positive population trend -- and emphasized the following,

> "The Service interprets this recommendation to mean that actions and measures should be put in place now that will eventually arrest what has been a continuing declining trend. Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels."

---

[2] WAFWA 2006 Strategy. The 2006 objectives built on an initial framework and commitment made by the WAFWA directors, the BLM and the FWS in 2000 with the signing of an interagency sagebrush/sage-grouse conservation MOU.

[3] Sage-grouse National Technical Team. "A Report on National Greater Sage-Grouse Conservation Measures". December 21, 2011.

The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT stated, "[m]aintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". To achieve this, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT emphasized an "avoidance first strategy" and stressed that threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

The four Great Basin ARMPAs addressed by this ROD and the 13 ARMPAs/ARMPs in the Rocky Mountain Region subregion are the result ~~product~~ of the National GRSG Planning Strategy~~, the four Great Basin ARMPAs~~ and ~~13 ARMPAs/ARMPs in the Rocky Mountain Region,~~ were developed to remove or reduce identified threats to the species and are an essential component of the effort to conserve GRSG and ~~obviate~~ avoid a listing of the species under ESA. Across ten western States, the Great Basin and Rocky Mountain sub-regional ARMPs/ARMPAs contain updated land use plan direction on ~~nearly~~ approximately ~~6~~50 percent of the remaining habitat for the species. These ARMPAs/ARMPs are the product of extensive coordination between the BLM and the Forest Service and~~, including t~~ the active engagement of the USFWS in helping to inform land allocation and related management decisions by the BLM and Forest Service. The plans~~y~~ also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, and circumstances in each.

Comment [KK26]: From Stephanie – not sure if this is BLM only or includes FS

~~This section highlights the m~~Major components of -the ~~that are presented in the~~ attached ARMPAs ~~that~~ developed ~~were constructed~~ to address the specific threats to the viability of the GRSG, as identified in the USFWS 2010 listing decision and COT Report (many of which were also identified by the BLM's NTT Report) are listed in Table XX and summarized below. Throughout the ARMPAs, a particular focus is placed on an "avoidance first strategy" as emphasized in the COT report by limiting new disturbance and maintaining current intact GRSG habitat. This avoidance first strategy is accomplished through identification and allocation of important GRSG habitat and excluding or avoiding surface disturbing activities, appropriately managing grazing, and aggressively suppressing fire that could degrade or fragment remaining GRSG habitat. The plans also include decisions to restore degraded habitat, which although more difficult and requiring a longer time frame, is important to the long-term viability of GRSG. Restoration decisions include specific habitat objectives, and a priority on treating GRSG habitat for invasive species, particularly cheatgrass, and encroaching pinyon and juniper. These decisions are reinforced by Secretarial Order 3336 and the *Integrated Rangeland Fire Management Strategy* which provide a framework, specific actions, and Department-wide priority on managing Federal lands, particularly in the Great Basin, to protect and restore sagebrush-steppe habitat.

Table XX
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
All threats	• Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met. • Require and ensure mitigation that provides a net conservation gain to GRSG and its habitat. • Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner. • Apply buffers necessary based on project type and location to address impacts on leks when authorizing actions in GRSG habitat. • Apply Required Design Features (RDFs) when authorizing actions that affect GRSG habitat. • Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.
All development threats, including mining, infrastructure, and energy development.	• PHMA: Implement an anthropogenic disturbance cap of 3% within the Biologically Significant Unit and proposed project analysis areas in PHMA (slight variations to this management component in the State of Nevada only) • PHMA: Apply a disturbance density cap of 1 facility per 640 acres (except in the State of Nevada)
Energy development—fluid minerals, including geothermal resources	• PHMA: Open to fluid mineral leasing subject to a No Surface Occupancy (NSO) stipulation without waiver or modification, and with limited exceptions. In SFAs, a NSO stipulation would be applied without waiver, modification, or exception. • GHMA: Open to fluid mineral leasing subject to Controlled Surface Use (CSU) and Timing Limitation (TL) lease stipulations (except in the State of Utah where some portions of GHMA are open with standard lease stipulations)
Energy development—wind energy	• PHMA: Exclusion area (not available for wind energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Avoidance area (may be available for wind energy development with special stipulations) (except in the States of Utah and Idaho, where these areas would open to wind energy development)
Energy development—solar energy	• PHMA: Exclusion area (not available for solar energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Exclusion area (not available for solar energy development under any conditions) (except in the States of Oregon and Montana where these areas are avoidance areas for solar energy development and the State of Idaho, where these areas would open to solar energy development)

Comment [KK27]: there is a NV exception for geothermal that we need to capture here

Table XX
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
Infrastructure—major ROWs	• PHMA: Avoidance area (may be available for major ROWs with special stipulations) • GHMA: Avoidance area (may be available for major ROWs with special stipulations) (except in the State of Utah where GHMA is open)
Infrastructure—minor ROWs	• PHMA: Avoidance area (may be available for minor ROWs with special stipulations)
Mining—locatable minerals	• SFA: Recommend withdrawal from the Mining Law of 1872
Mining—nonenergy leasable minerals	• PHMA: Closed area (not available for nonenergy leasable minerals)
Mining—salable minerals	• PHMA: Closed area (not available for salable minerals) with a limited exception (may remain open to free use permits and expansion of existing active pits if criteria are met)
Livestock grazing	• Prioritize the review and processing of grazing permits/leases in SFAs followed by PHMA. • The NEPA analysis for renewals and modifications of grazing permits/leases will include specific management thresholds, based on the GRSG Habitat Objectives Table, Land Health Standards and ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis. • Prioritize field checks in SFAs followed by PHMA to ensure compliance with the terms and conditions of grazing permits.
Free-roaming equid management	• Prioritize gathers in SFAs, followed by other PHMAs. • Manage Herd Management Areas (HMAs) in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives. • Prioritize rangeland health assessment, gathers and population growth suppression techniques, monitoring, and review and adjustment of AMLs and preparation of Herd Management Area Plans in GRSG habitat.
Range management structures	• Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. • Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas subject to valid existing rights.
Recreation	• PHMA: Do not construct new recreation facilities unless required for health and safety purposes. • Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain.

Table XX
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
	• PHMA & GHMA: OHV use limited to existing routes (routes to be designated through future travel management planning)
Fire	• Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection. • Prioritize post-fire treatments in SFAs, other PHMAs and GHMAs.
Nonnative, invasive plant species	• Improve GRSG habitat by treating annual grasses. • Treat sites in PHMA and GHMA that contain invasive species infestations through an integrated pest management approach.
Sagebrush removal	• PHMA: Maintain a minimum of 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover. • All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and/or juniper expansion	• Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.
Agricultural conversion and exurban development	• GRSG habitat will be retained in federal management.

~~***Land Allocations***~~

~~The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT stated, "[m]aintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". To achieve this, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT emphasized recommended an "avoidance first strategy" and stressed that threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."~~

~~To adequately address the reasons for the 2010 "warranted" determination by the FWS -- and specific threats summarized in the COT report -- it was clear to BLM and Forest Service land and resource managers that additional regulatory measures on federal public lands would be necessary to deal with present or threatened destruction, modification, or curtailment of habitat or range. These measures would need to be incorporated into land use plans that guide management actions on lands within the remaining range of the GRSG administered by the agencies to conserve GRSG such that listing under the ESA was no longer necessary.~~

~~In December 2011, the BLM and the Forest Service published a Notice of Intent to prepare Environmental Impact Statements and Supplemental Environmental Impact Statements to incorporate GRSG Conservation Measures into Land Use Plans and Land and Resource Management Plans across the range of the species. A total of 15 subregional LUPs would amend or revise 78 BLM RMPs and 20 Forest LRMPs across the range of the species.~~

~~The federal public land conservation strategy reflects several key concepts:~~

~~**Landscape-level**: The planning effort focuses on the remaining habitat of the GRSG on BLM and Forest Service lands, covering 10 western states in the Great Basin and Rocky Mountain regions.~~

Formatted: No bullets or numbering

~~**Best Available Science** – The proposed LUPs are grounded in the best available science, drawn from published literature and input from recognized experts, state agencies, the US Geological Survey, the FWS and other sources. The COT report provided a "blueprint" for GRSG conservation by identifying specific threats to each remaining GRSG population and recommending measures to address each category of threat and the NTT report, prepared by the BLM, provided options for dealing with the most significant threats to the GRSG. A series of reports on how to improve efforts to reduce the threats of rangeland fire and invasive species prepared in collaboration with the Western Association of Fish and Wildlife Agencies also provided crucial guidance in formulating the conservation strategy.~~

~~**Targeted, Multi-Tiered Approach** – The proposed LUPs were designed to incorporate a layered management approach to avoid or minimize additional surface disturbance in the most valuable habitat, known as Priority Habitat Management Areas (PHMA), which are largely consistent with PACs identified in the COT Report. Within PHMA, the proposed LUPs provide an added level of protection to limit or eliminate new surface disturbance through the delineation of Sagebrush Focal Areas (SFA), derived from areas identified by the FWS as "strongholds" essential for the species' survival. In General Habitat Management Areas (GHMA), the proposed LUPs seek to minimize disturbance while providing greater flexibility for land use activities.~~

~~**Coordinated**: The BLM and Forest Service proposed LUPs were developed through a joint planning process led by the BLM with the Forest Service as partners. The USFWS provided guidance and input throughout the process to aid land managers in understanding the threats and the certainty and effectiveness of proposed land management actions in addressing those threats. The USGS and NRCS also provided key technical and scientific support.~~

~~**Collaborative**: The proposed LUPs reflected the input of states and local stakeholders from the outset and were developed with the benefit of input from the individual states and cooperators who signed formal agreements with the BLM to provide input into the planning process. The Sage-Grouse Task Force (SGTF) was particularly useful in facilitating this kind of collaborative input. The proposed LUPs reflect state and stakeholder developed approaches and economic priorities where consistent with conservation objectives.~~

1.5.1 Conservation Measures for Habitat Protection, Restoration, and Improvement

Land Allocations

In order to protect the most important GRSG habitat areas, the conservation strategy began with mapping areas of important habitat across the remaining range of the GRSG and within each state. In collaboration with state fish and wildlife agencies, the BLM and Forest Service identified areas as preliminary priority habitat (PPH) and preliminary general habitat (PGH). Maps were revised and refined as further mapping was conducted and state fish and wildlife agencies – often in collaboration with GRSG experts and researchers – provided more detailed analysis of habitat characteristics and populations. The ~~proposed LUPs~~ ARMPAs reflect this input and have generally aligned these habitats with Habitat Management Areas in the ARMPAs. ~~Priority Habitat Management Areas (PHMAs) largely coincide with identified Priority Areas for Conservation (PACs) in the COT Report. Final general habitat areas are identified as General Habitat Management Areas (GHMAs). Some states developed additional habitat categories which can be found in specific state plans.~~ GRSG habitat management areas on BLM-administered lands in the decision area consists of lands allocated as Priority Habitat Management Areas (PHMA) which largely coincide with Priority Areas for Conservation in the COT report, General Habitat Management Areas (GHMA), Other Habitat Management Areas (OHMA, applicable only to the Nevada and Northeastern California), and Important Habitat Management Areas (IHMA, applicable only to Idaho). **Table X** identifies surface acres of PHMA, GHMA, OHMA, and IHMA in the decision area for the Great Basin Region.

PHMA, GHMA, OHMA, and IHMA are defined as follows:

- **PHMA**— BLM-administered lands identified as having the highest value to maintaining sustainable GRSG populations. The boundaries and management strategies for PHMA are derived from and generally follow the Preliminary Priority Habitat boundaries identified in the Draft LUPA/EIS. Areas of PHMA largely coincide with areas identified as Priority Areas for Conservation in the COT report.
- **GHMA**— BLM-administered lands where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMA are derived from and generally follow the Preliminary General Habitat boundaries identified in the Draft LUPA/EIS.
- **OHMA** —BLM-administered lands identified as unmapped habitat in the Draft LUPA/EIS that are within the planning area and contain seasonal or connectivity habitat areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse

Habitat in Nevada and Northeastern California; Coates et al. 2014.) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.

- **IHMA** —BLM-administered lands that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. There are no IHMAs designated within southwestern Montana. The IHMA boundaries and management strategies are derived from and generally follow the Preliminary Medial Management Area (PMMA) and Important Habitat Zone (IHZ) boundaries identified in Alternatives D and E, respectively, of the Draft LUPA/EIS, but may be modified based on the objectives of each alternative. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the ARMPA.

Table X

Surface Acres of PHMA, GHMA, OHMA, and IHMA in the Decision Area for the Great Basin Region

BLM administered surface acres	PHMA	GHMA	OHMA	IHMA
Idaho and Southwestern MT	4,627,200	2,179,700	0	2,737,600
Utah	2,023,400	502,500	0	0
Oregon	4,547,000	5,660,150	0	0
Nevada and Northeastern CA	9,309,700	5,720,600	5,876,600	0
Total Acres	**20,507,300**	**14,062,950**	**5,876,600**	**2,737,600**

Source: BLM GIS 2015

The ~~proposed LUPs~~ARMPAs also identify Sagebrush Focal Areas (SFAs) on a portion of the landscape. SFAs are a subset of PHMAs~~.~~ (see **Figure X** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas). SFAs correspond to the areas identified by the FWS as GRSG “strongholds” as detailed in an October 27, 2014 memo from FWS Director Ashe to BLM Director Kornze and Forest Service Chief Tidwell in response to a request to “identify a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection”[4] (http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf)

Comment [KK28]: would be helpful to identify the acres of SFA in each state

~~The SFAs reflect a subset of these strongholds, since the FWS map included areas that are not administered by the BLM or Forest Service or were outside the planning area.~~ The FWS memo advised that “[s]trong, durable, and meaningful protection of federally administered lands in these areas will provide additional certainty and help obtain confidence for long term sage grouse persistence.” ~~The BLM and Forest Service proposed LUPs mapped approximately 66 million acres of PHMA and GHMA. Of this, approximately 35 million acres are identified as PHMA and 31 million acres are GHMA. SFAs consist of 11 million acres of BLM and Forest Service-administered lands in PHMAs. (See Figure B.)~~

Comment [KK29]: I don't think we need to say this – the following quote makes clear that these are only meant to apply to federally administered lands

---

[4] Memorandum from Dan Ashe to Director, BLM and Chief, USFS, “Greater Sage Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important Landscapes. October 27, 2014.

This tiered habitat framework provides for a nested or layered conservation design with the greatest protections and limited new surface disturbance in SFAs, a high degree of certainty that the integrity of PHMAs can be maintained through ~~land allocations~~management decisions to avoid or minimize additional surface disturbance, and protection of remaining habitats in GHMAs, with more flexibility for land use activities that would be designed to minimize impacts on existing GRSG leks. In all GRSG habitat areas, anthropogenic surface disturbing activities would be mitigated, and ~~fire-impacted~~degraded landscapes, due to fire or other causes, would be actively restored and protected with a priority on SFAs, then PHMAs, and then GHMAs. The combination of habitat classifications and land allocation decisions in the ARMPAs will provide the greatest protection for those areas identified as SFAs and meet the stated objective for these areas “where it is most important that the BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species.”[5]

Habitat Protection/Surface Disturbance

To avoid or minimize further surface disturbance in PHMAs the ~~proposed LUPs~~ARMPAs either exclude or avoid major new surface disturbing activities. In SFAs, in addition to PHMA decisions described below and shown in Table XX, ~~proposed LUPs~~ARMPAs ~~also~~ apply a no surface occupancy stipulation with no exceptions for oil and gas leasing and recommend these areas for withdrawal from future locatable mineral entry. ~~To further protect and enhance habitat in SFAs and PHMAs, the BLM and Forest Service will prioritize rangeland fire management (either through appropriate pre-suppression activities, suppression or post-fire restoration), gathers of wild horses and burros, and review of grazing permits for compliance with land health standards, vegetative objectives and permit terms and conditions that incorporate GRSG habitat management objectives in these areas.~~

~~The combination of habitat classifications and land allocation decisions proposed for inclusion in the proposed LUPs will provide the greatest protection for those areas identified as SFAs and meet the stated objective for these areas “where it is most important that the BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species”[6] and target habitat protection and restoration activities to those areas of highest importance. The proposed LUPs also largely avoid or exclude major development in PHMAs, in areas without an implemented all lands regulatory approach,[7] through avoidance for transmission, and exclusion for other major surface disturbing activities (e.g., solar and wind energy development).~~

Comment [KK30]: Not applicable to GB

~~In response, the~~The four Great Basin ARMPAs provide land use allocations and management guidance for PHMAs to avoid new disturbance and minimize any disturbance associated with projects that might be developed in PHMA in the future. Allocations to avoid and minimize additional disturbance in PHMA included the application of a no surface occupancy (NSO) stipulation associated with any future leasing and development of oil, gas, and geothermal reserves in PHMAs. With the exception of a few areas in Utah and in eastern Nevada, there is low potential for fluid minerals in the Great Basin Region. ~~To benefit GRSG conservation efforts and to assist developers in reducing the time and cost associated with oil and gas leasing development, the BLM will prioritize new leasing in areas outside of PHMAs and GHMAs.~~

Comment [KK31]: there is a NV exception for geothermal that we need to capture here

---

[5] USFWS memorandum. Greater Sage Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important Landscapes. October 27, 2014.

~~[6] USFWS memorandum. Greater Sage Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important Landscapes. October 27, 2014.~~

~~[7] An all lands regulatory approach refers to a management strategy in which certain activities likely to affect the conservation of GRSG, including activities on state and private lands, are regulated, such as through the Wyoming Greater Sage Grouse Conservation Plan, Greater Sage Grouse Core Area Protection Executive Order.~~

Similarly, mineral development, with the exception of locatable minerals governed under the 1872 Mining Act, is closed in PHMAs for non-energy leasable minerals and saleable minerals. An exception is granted for free use permits and the expansion of existing active pits for mineral material sales and expansion of existing non-energy leasable development. There is no potential for coal development in the Great Basin outside of Utah. In Utah, at the time of a new coal lease or lease modification, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods recognizing that PHMAs are "essential habitat" for purposes of suitability determinations.

In all PHMAs in the Great Basin Region, ~~R~~renewable energy development (solar and wind) is excluded~~ in PHMAs in the four Great Basin ARMPAs~~, with the exception of three counties in southeastern Oregon where an avoidance allocation is applied; and ~~.~~
new rights of way and development for transmission lines, pipelines, and related infrastructure ~~will be~~is avoided through restrictions on land use authorizations. Where the allocation is avoidance, ~~E~~exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs, unless the development results in a net conservation gain to the GRSG or its habitat.

Comment [JRL32]: I don't recall this exception. KK – there is this exception – see Table XX

~~Renewable energy development (solar and wind) is excluded in PHMAs in the four Great Basin ARMPAs, with the exception of three counties in southeastern Oregon where an avoidance allocation is applied.~~

~~In general, all forms of new development would be excluded, avoided, or developed only if the resultant effect is a net conservation gain to the GRSG or its habitat. This is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0*, published by the FWS in September 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse." In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation gain for the GRSG.~~

Comment [KK33]: Since this is PHMA & GHMA, I moved it down

~~In response, the four Great Basin ARMPAs provide land use allocations and management guidance for PHMAs to avoid new disturbance and minimize any disturbance associated with projects that might be developed in PHMA in the future. Allocations to avoid and minimize additional disturbance in PHMA included the application of a no surface occupancy (NSO) stipulation associated with any future leasing and development of oil, gas, and geothermal reserves in PHMAs. With the exception of a few areas in Utah and in eastern Nevada, there is low potential for fluid minerals in the Great Basin Region. To benefit GRSG conservation efforts and to assist developers in reducing the time and cost associated with oil and gas leasing development, the BLM will encourage new leasing in areas outside of PHMAs, and GHMAs.~~

~~Similarly, mineral development, with the exception of locatable minerals governed under the 1872 Mining Act, is closed in PHMAs for non-energy leasable minerals and saleable minerals. An exception is granted for free use permits and the expansion of existing active pits for mineral material sales and expansion of existing non-energy leasable development. There is no potential for coal development in the Great Basin outside of Utah. In Utah, at the time of a new coal lease or lease modification, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods recognizing that PHMAs are "essential habitat" for purposes of suitability determinations.~~

~~In all PHMA in the Great Basin Region, new rights of way and development for transmission lines, pipelines, and related infrastructure will be avoided through restrictions on land use authorizations.~~

~~Exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs, unless necessary for health and safety purposes.~~

Comment [JRL34]: I don't recall this exception. KK – there is this exception – see Table XX

~~Renewable energy development (solar and wind) is excluded in PHMAs in the four Great Basin ARMPAs, with the exception of a few counties in southeastern Oregon where an avoidance allocation is applied.~~

~~In general, all forms of new development would be excluded, avoided, or developed only if the resultant effect is a net conservation benefit to the GRSG or its habitat. In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation benefit for the GRSG.~~
While ~~the majority of compelling~~ restrictions on future development in PHMA are intended to avoid o~~i~~r minimize additional surface disturbance, ~~are placed in PHMA,~~ restrictions on development in GHMA are less stringent and can accommodate a limited amount of disturbance. Disturbance associated with oil and gas development, for example, is subject to a controlled surface use and timing limitation stipulation rather than an NSO stipulation, see Table XX for more details on GHMA management decisions. ~~However, any disturbance is subject to mitigation and should seek to first avoid and then minimize any impacts to GRSG or its habitat, while offsetting unavoidable impacts to a standard that produces a net conservation gain for the species. As noted in the COT report, "… Conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur. …If development or vegetation manipulation- activities outside of PACs are proposed, the project proponent should work with federal , state or local agencies and interested stakeholders to ensure consistency with sage-grouse habitat needs."~~

Comment [KK35]: Replaced with text just below – so mitigation is described once

In addition to areas where uses are excluded or avoided, the ARMPAs direct the BLM to proactively prioritize oil and gas leasing and development outside of identified SFAs, PHMAs, and GHMAs in order to encourage new development in areas that would not conflict with GRSG and thus maximize the potential to limit disturbance to remaining GRSG habitat. ~~To benefit GRSG conservation efforts and to~~This approach will also assist developers in reducing the time and cost associated with oil and gas leasing development by avoiding sensitive areas and decreasing the need for compensatory mitigation~~, the BLM will prioritize new leasing in areas outside of PHMAs and GHMAs.~~

In general, all forms of new development would be excluded, avoided, or developed only if the resultant effect is a net conservation gain to the GRSG or its habitat, assuring that existing habitat would be protected and providing opportunities through compensatory mitigation to restore degraded habitats. This is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0*, published by the FWS in September 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse." In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation gain for the GRSG. With regards to GHMA, a~~A~~s noted in the COT report, "… Conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur. …If development or vegetation manipulation- activities outside of PACs are proposed, the project proponent should work with federal , state or local agencies and interested stakeholders to ensure consistency with sage-grouse habitat needs."

Comment [KK36]: Does this belong here or with other restoration decisions?

~~An added element of habitat protection was provided for GRSG strongholds in the ARMPAs by identifying Sagebrush Focal Areas (SFAs), a subset of PHMAs. SFAs correspond to the areas identified by the FWS as GRSG "strongholds" as detailed in an October 27, 2014 memo from FWS Director Ashe to BLM Director Kornze and Forest Service Chief Tidwell in response to a request to "identify a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection"(http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf). Beyond that in PHMA, management decisions to be applied to SFAs include NSO stipulation with no exceptions for oil, gas, and geothermal development; recommendation that these areas be withdrawn by the Secretary from mineral entry under the 1872 Mining Act, and prioritizing grazing permit renewal, wildhorse and burro management, and vegetation management. While the SFAs have minimal land surface disturbance and, based on existing, available data, limited mineral potential, valid existing rights – as in all habitat – will be recognized and be able to proceed in accordance with their legal rights.~~

~~Management Direction, Prioritization, and Mitigation~~

~~In addition to land allocations to protect SFAs, PHMAs, and GHMAs, the ARMPAs guide other uses of these landscapes to meet COT objectives consistent with existing, authorized uses of GRSG habitats and the sagebrush landscape.~~

In addition to major surface disturbing activities such as energy and infrastructure development, the ARMPAs address other activities, including grazing, wild horse and burro management, and recreation. Grazing is the most widespread use of the sagebrush steppe ecosystem in the Great Basin states. The COT Report recommendation for grazing states, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage-grouse (e.g. shrub cover, nesting cover)." To ensure that grazing continues in a manner consistent with the objective of conserving the GRSG and its habitat, the four Great Basin ARMPAs require the incorporation of GRSG seasonal habitat objectives into grazing permits, consistent with the ecological site potential of the local areas, prioritize the review and monitoring of grazing permits, and take numerous actions to avoid and minimize the impacts of range management structures (see Table XX). ~~[Incorporate additional measures for veg objectives]~~

To address the localized threat due to negative influences of grazing by free-roaming equids (wild horses and burros (WHB)), the BLM will focus on maintaining WHB Herd Management Areas in GRSG habitat within established AML ranges to achieve and maintain GRSG habitat objectives, including completing~~e~~ rangeland health assessments, ~~for HMAs containing GRSG habitat using an interdisciplinary team of specialists (e.g. range, wildlife, and riparian). The BLM will~~ prioritizing~~e~~ gathers and population growth suppression techniques, and developing or amending Herd Management Area plans to incorporate GRSG habitat objectives and management considerations. ~~in HMAs in GRSG habitat, unless removals are necessary in other areas to address higher priority environmental issues, including herd health impacts – placing emphasis on addressing conflicts with WHBs in SFAs, PHMAs, and GHMAs.~~ In SFAs and PHMA, the BLM will assess and adjust AMLs through the NEPA process within HMAs when WHBs are identified as a significant causal factor in not meeting land health standards, even if current AML is not being exceeded. ~~The BLM will develop or amend herd management area plans to incorporate GRSG habitat objectives and management considerations for all HMAs within GRSG habitat, with emphasis placed on SFAs and PHMAs.~~

~~The BLM will focus on maintaining HMAs in GRSG habitat within established AML ranges to achieve and maintain GRSG habitat objectives and consider removals or exclusion of WHB during or immediately following emergency situations (such as fire, floods, and drought) to facilitate meeting~~

~~GRSG habitat objectives where HMAs overlap with GRSG habitat. When conducting NEPA analysis for WHB management activities, water developments, or other rangeland improvements for WHB, the BLM will address the direct and indirect effects to GRSG populations and habitat. The BLM will coordinate with professionals from other federal and state agencies, researchers at universities, and others to utilize and evaluate new management tools (e.g., population growth suppression, inventory techniques, and telemetry) for implementing the WHB program.~~

~~The Great Basin ARMPAs place a priority on completing land heath assessments in SFAs, then PHMAs and GHMAs. The assessments will evaluate if grazing standards and guidelines are met, ensure that GRSG seasonal habitat objectives are also being met or are making progress towards being met, and ensure that the GRSG seasonal habitat objectives are incorporated into grazing permits.~~

~~Direction in the ARAMPs also incorporates GRSG seasonal habitat objectives into establishment of allowable management levels (AMLs). Prioritization of horse gathers and removal to reach AMLs in SFAs, PHMAs, and GHMAs (in that order) will be conducted.~~

~~Through required design features, buffers, and other management actions, proposed LUPs allow range developments which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. The NV/CA and OR proposed LUP removes livestock ponds built in perennial channels that are negatively impacting riparian habitats and do not permit new ones to be built in these areas subject to valid existing rights.~~

~~Management actions and required design features will ensure that the impact of fences on GRSG is minimized. Methods to be applied include marking fences in high-risk areas for collision and locating fences to limit or eliminate the impact on GRSG.~~

~~Fire represents the greatest threat to sage-grouse habitat in the Great Basin Region. Recognizing the nature and extent of this threat, the ARMPAs provide specific guidance for improving efforts to reduce the risk of GRSG habitat loss to wildfire. The four ARMPAs include specific guidance for fire prevention and the restoration of lands impacted by fire. The Great Basin ARMPAs also provide for a more aggressive, targeted effort to prevent and suppress fires that could impact thousands of acres of sage-grouse habitat, as well as restore areas with high potential to survive the impacts of climate change and subsequent rangeland fires.~~

To ameliorate the threat from recreational activities, new facilities or expansion of existing facilities (e.g., roads, trails, campgrounds) will not be authorized in PHMA ~~on BLM-administered and National Forest System land~~ unless the development results in a net conservation gain to GRSG its habitat. ~~During renewal, amendment, or reauthorization, terms and conditions in existing permits and operating plans will be modified to protect and/or restore GRSG habitat.~~

In PHMA and GHMA ~~(except only in PHMA in Northwest Colorado),~~ travel would be limited to vehicle routes. Initially, vehicles would be limited to existing routes until implementation travel management planning could be completed to designate routes~~; on Forest Service lands travel is limited to the Forest Service travel management system~~. Travel management plans, including route inventories, NEPA analysis, and route designation will be completed in a subsequent public planning process.

~~To ameliorate the threat from new land authorizations for infrastructure, the proposed LUPs provide that major pipeline and transmission line development will be avoided in all GRSG habitats through restrictions on land use authorizations(except in GHMA in Wyoming, Utah and Idaho). Exceptions would~~

~~be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated.~~

~~GHMA in Wyoming, Utah and Idaho would be available to rights-of-way for infrastructure due to the extent and quality of the habitat as well as the percentage of GRSG contained in PHMA in those states. An additional consideration in Wyoming is the extent of the protections for GRSG on private and state land. These factors gave BLM confidence, after input from FWS, that conservation objectives can be met with this additional flexibility provided in GHMA.~~

~~Although future high voltage transmission lines will be avoided in PHMA, the planning, siting, and environmental review of three priority lines has been underway for a number of years. These lines are critical to expanding access to renewable sources of energy and to improving the reliability of the Western grid. For these reasons, planning for these lines will proceed and potential impacts to GRSG will be fully mitigated through the mitigation identified in the site-specific NEPA for those projects.~~

Habitat Management, Restoration, and Improvement

In addition to management of resource uses and avoiding surface disturbance, the ARMPAs identify management actions to promote the restoration and improvement of GRSG habitat, particularly addressing the threats of invasive species, pinyon and juniper expansion, and fire, as well as climate change. As with the management of uses, habitat management, restoration, and improvement action is prioritized first in SFAs, followed by PHMA, and then GHMA. The ARMPAs specify seasonal habitat objectives necessary for GRSG, used both to evaluate grazing and wild horse and burro management and for restoration purposes. These objectives include maintaining a minimum of 70% of lands capable of producing sagebrush with 10-30% canopy cover, and addressing species richness and composition, as well as meeting land health standards considering the ecological potential for the site.

The ARMPAs include specific decisions related to treatment and removal of invasive annual grasses, removal of encroaching pinyon juniper, prioritization of fire suppression in SFA, PHMA, and GHMA, and post-fire restoration. The ARMPAs also describe a robust compensatory mitigation program, which will be developed in coordination with the states, to provide for habitat protection and restoration activities that produce a net conservation gain for the GRSG, see Section 5 for more information.

To ameliorate the threat from fire, the ~~proposed LUPs~~ARMPs seek to fight the spread of cheatgrass and other invasive species, position wildland fire management resources for more effective rangeland fire response, and accelerate the restoration of fire-impacted landscapes to native grasses and sagebrush. Prescribed fire will not be used unless necessary to facilitate site preparation for restoration of GRSG habitat. ~~If prescribed fire is used to facilitate site preparation for restoration the associated NEPA analysis must identify how the project would move towards GRSG desired conditions, why alternative techniques were not selected, and how potential threats to GRSG habitat would be minimized.~~ The BLM *Greater Sage Grouse Invasive Annual Grasses & Conifer Expansion Assessment* (FIAT 2014) modeled conifer expansion for PACs to provide an initial stratification to determine where conifer removal would benefit important sagebrush habitats. This information is being used to identify and design projects to change vegetation composition and/or structure to modify potential fire behavior for the purpose of improving fire suppression effectiveness and limiting fire spread and intensity due to invasive grasses and conifer encroachment. Consistent with this assessment, the BLM ARMPAs include management actions to remove invading conifers and other undesirable species, and prioritize vegetation treatments closest to occupied GRSG habitats and near occupied leks. Through guidance in the proposed ARMPAs supplemented by the *Integrated Rangeland Fire Management Strategy*, a commitment has been made to address the invasion and expansion of cheatgrass, medusa head, and other invasive grasses through expanded efforts to treat impacted acres and to accelerate and expand efforts to restore lands impacted by fire with native grasses and sagebrush seedlings. Efforts are underway to increase the acreages to be treated with chemical and biological agents to kill and stem the spread of invasive species and to accelerate the registration of other biologicals useful in addressing the threat of cheatgrass invasion.~~.~~

~~Through both the proposed LUPs and the final report to the Secretary on an Integrated Rangeland Fire Management Strategy[8](see section VI for more information), changes in land management practices and fire management policies and practices to prevention, suppression, and restoration landscapes impacted by fire have been adopted. Section VI further details the activities and actions that the BLM and the Forest Service will conduct to ameliorate the threat to GRSG and its habitat from rangeland fire. The BLM/Forest Service are involved in several west-wide efforts with other Federal, state, and private partners to address the threat of rangeland fire.~~

In addition to and complementing the ARMPAs described in this ROD, ~~,~~Secretarial Order 3336 on Rangeland Fire made clear that "**protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, priority GRSG habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department".** (emphasis added) The strategy places a Departmental priority on activities to prevent, suppress, and restore fire-impacted landscapes in areas identified by the Fire and Invasives Assessment Tool (FIAT) in priority habitat, using recent information derived from a report prepared by WAFWA to assist in addressing the threat of rangeland fire. The FIAT process, applying recent science, identified highly resistant and resilient landscapes to target fire management activities to these most important lands. In addition, through the issuance of a Leaders' Intent letter, signed by the Secretaries of Agriculture and the Interior, rangeland fire was identified as an "additional priority" for the firefighting community in making strategic decisions with regard to the allocation of resources for firefighting in 2015. Additional resources have been allocated and will be targeted to fuel treatments (including invasive species control), suppression (through the prepositioning of fire-fighting resources and the training of additional Rural Fire Protection Associations, local volunteer firefighters, and veteran fire fighters), and habitat restoration in these areas. Firefighting assets (aircraft, firefighters and related equipment) will be located near areas of high priority for rangeland fire.

Comment [KK37]: Should this be included in the ROD or is the previous paragraph sufficient (since it ties more to the AMRMPA instead of just being about the rangeland fire strategy?)

~~Response to Climate Change~~

With regard to the threat of climate change, the proposed ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the *Integrated Rangeland Fire Management Strategy* will further this effort. The Fire and Invasives Assessment Team (FIAT) assessments that inform that ARMPAs and supported the development of the *Integrated Rangeland Fire Management Strategy* ~~[previously referenced?]~~ are specifically designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). Additionally, by limiting or eliminating anthropogenic surface disturbance, especially in the ~~contiguous~~ SFAs, ensuring the integrity of the PHMAs, and restoring habitat through fuels management, post-fire restoration, and mitigation efforts,

---

~~[8] *An Integrated Rangeland Fire Management Strategy: Final Report to the Secretary*. Department of the Interior. May 1, 2015.~~

connectivity and availability of sagebrush habitat are expected to increase thus contributing to increased climate resilience.

~~A related concern is conservation strategies to limit the spread of cheatgrass in the Great Basin, which negatively affects the establishment of native grasses and sage-steppe vegetation and increases the risk of rangeland fire. To respond, all proposed Great Basin subregion ARMPAs include the following vegetation objective: *In all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain a minimum of 70% of lands capable of producing sagebrush with at least 10 to 30% sagebrush canopy cover. The attributes necessary to sustain these habitats are described in Interpreting Indicators of Rangeland Health (BLM Tech Ref 1734-6).*[9]~~

~~Through guidance in the proposed ARMPAs supplemented by the Integrated Rangeland Fire Management Strategy, a commitment has been made to address the invasion and expansion of cheatgrass, medusa head, and other invasive grasses through expanded efforts to treat impacted acres and to accelerate and expand efforts to restore lands impacted by fire with native grasses and sagebrush seedlings. Efforts are underway to increase the acreages to be treated with chemical and biological agents to kill and stem the spread of invasive species and to accelerate the registration of other biologicals useful in addressing the threat of cheatgrass invasion.~~

~~***Lek protection***~~

~~In addition to land allocations and management actions included in the Great Basin ARMPAs to conserve the GRSG, additional measures were included to ensure that disturbance to leks could be reduced or minimized through the application of disturbance caps and required minimum buffers.~~

1.5.2 Other Measures to Reduce~~ing~~ Habitat Disturbance

Comment [KK38]: This might be better above the section that I titled habitat management, restoration, and improvement since it goes back to talking about managing uses and goes better with the section I titled "habitat protection and surface disturbance"

In addition to land allocations and management actions included in the Great Basin ARMPAs to conserve the GRSG, additional measures were included to ensure that disturbance to leks could be reduced or minimized through the application of disturbance caps, density limits, and required minimum buffers.

Disturbance Caps

In addition to the management actions and allocations discussed in detail in the sections above, the ~~proposed~~ ARMPAs ~~also~~ limit the amount of anthropogenic disturbances in PHMAs through the use of disturbance caps. In general, if the 3% ~~or 5% (depending on state)~~ anthropogenic disturbance is exceeded on lands (regardless of land ownership) within PHMA in any given Biologically Significant Unit (BSU), no further discrete anthropogenic disturbances (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.) will be permitted ~~by the BLM and Forest Service~~ within PHMAs in that Biologically Significant Unit. ~~In Wyoming, a different process, which does not include an analysis at the Biologically Significant Unit, is used as described below.~~ If the disturbance cap is exceeded on all lands (regardless of land ownership) within a proposed project analysis area in a PHMA, then no further anthropogenic disturbance will be permitted ~~by the BLM and the Forest Service~~ until disturbance in the proposed project analysis area has been reduced to be under the cap (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.). ~~Most proposed plans will implement a 3% disturbance cap, with a few modifications.~~The ARMPAs have a few modifications to the disturbance cap: Oregon does not allow more than 1% new anthropogenic

---

disturbance per decade, not to exceed 3% disturbance at any time. In Nevada, exceeding a 3% disturbance cap can occur at the BSU and/or the project level as long as the outcome results in a net conservation benefit and is approved by a cadre of high-level federal and state managers. ~~Wyoming proposed plans are consistent with the State of Wyoming's Core Area Strategy, which limits all disturbances, including wildfire and vegetation treatments, within a project area (referred to as the Density and Disturbance Calculation Tool (DDCT) analysis area) to 5% within PHMAs.~~

~~The DDCT is a spatially based tool used in Wyoming that calculates both the average density of disruptive activities and total surface disturbance within the area affected by the project, or DDCT assessment area. The DDCT assessment area is created based on buffers around proposed projects (first buffer) in protected GRSG core areas, and subsequent buffers around any occupied, core area leks within the first buffer. A four mile buffer is used to identify 75% of the GRSG use around a lek. All activities will be evaluated within the context of maximum allowable disturbance (disturbance percentages, location and number of disturbances) of suitable GRSG habitat within the DDCT assessment area. In Montana, if the BLM determines that the State of Montana has adopted a GRSG Habitat Conservation Program that contains comparable components to those found in the State of Wyoming's Core Area Strategy including an all lands approach for calculating anthropogenic disturbances, a clear methodology for measuring the density of operations, and a fully operational density and disturbance calculation tool (such as the DDCT), the 3% disturbance cap would be converted to a 5% cap for all sources of habitat alteration, including wildfire and vegetation treatments, within a project analysis area.~~

Limiting Density of Disturbance

The ~~proposed plans~~ARMPAs ~~have also~~ incorporate~~d~~ a cap on the density of energy and mining facilities to encourage consolidation of structures and to reduce habitat fragmentation. The cap is set at an average of one facility per 640 acres in PHMA in a project authorization area, consistent with guidance contained in the NTT report. If the disturbance density in the PHMA in a proposed project area is on average less than 1 facility per 640 acres, the analysis will proceed through the NEPA process incorporating mitigation measures into an alternative. If the disturbance density is greater than an average of 1 facility per 640 acres, the proposed project will either be deferred until the density of energy and mining facilities is less than the cap or co-located into an existing disturbed area, ~~(~~subject to applicable laws and regulations, such as the 1872 Mining Law, valid existing rights, etc~~.)~~. The one facility per 640 density decision does not apply to Nevada. ~~In Wyoming, the proposed LUPs are consistent with the State of Wyoming's Core Area Strategy, which limits oil and gas development density to an average of one pad per 640 acres and uses the Density and Disturbance Calculation Tool described above.~~

Buffering Development Impacts

~~With the exception of proposed LUPs in Wyoming, where the state plan is considered adequate to conserve GRSG, all proposed plans will~~ The ARMPAs require that ~~evaluate~~ impacts to leks be evaluated for~~from~~ actions requiring NEPA analysis. In addition to any other relevant information determined to be appropriate (e.g. State wildlife agency plans), the BLM will assess and address impacts from ~~the following~~ certain activities using the lek buffer-distances as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). The lek buffer distances required vary by type of disturbance (road, energy development, infrastructure, etc.) and are fully described in Appendix XX of the ARMPAs.~~The Forest Service has incorporated the buffers as guidelines in the plan amendments. The BLM and Forest Service will apply the lek buffer-distances specified as the lower end of the interpreted range in the report unless justifiable departures are~~

Comment [KK39]: is this a common appendix that we can reference?

~~determined to be appropriate (see below, and as subject to applicable laws and regulations, such as the Mining Law of 1872, as Amended, valid existing rights, etc.). The lower end of the interpreted range of the lek buffer distances is as follows:~~
~~Linear features (roads) within 3.1 miles of leks~~
~~Infrastructure related to energy development within 3.1 miles of leks.~~
~~Tall structures (e.g., communication or transmission towers, transmission lines) within 2 miles of leks.~~
~~Low structures (e.g., fences, rangeland structures) within1.2 miles of leks.~~
~~Surface disturbance (continuing human activities that alter or remove the natural vegetation) within 3.1 miles of leks.~~
~~Noise and related disruptive activities including those that do not result in habitat loss (e.g., motorized recreational events) at least 0.25 miles from leks.~~

~~Justifiable departures to decrease or increase from these distances, based on local data, best available science, landscape features, and other existing protections (e.g., land use allocations, state regulations) may be appropriate for determining activity impacts. The USGS report recognized "that because of variation in populations, habitats, development patterns, social context, and other factors, for a particular disturbance type, there is no single distance that is an appropriate buffer for all populations and habitats across the sage-grouse range". The USGS report also states that "various protection measures have been developed and implemented… [which have] the ability (alone or in concert with others) to protect important habitats, sustain populations, and support multiple-use demands for public lands". All variations in lek buffer distances will require appropriate analysis and disclosure as part of activity authorization. In determining lek locations, the BLM will use the most recent active or occupied lek data available from the state wildlife agency.~~

~~For BLM and Forest Service actions in PHMAs (not including Wyoming), the BLM will apply t~~The lek buffer ~~-~~distances ~~identified above~~ will be applied as required conservation measures ~~measures and the Forest Service as guidelines~~ to fully address the impacts to leks as identified in the NEPA analysis. Impacts should be avoided by locating the action outside of the applicable lek buffer-distance(s)~~-~~ as defined in the ARMPAs~~identified above~~. In PHMA, i~~I~~f the action cannot be located outside of the buffer-distance, the BLM ~~and Forest Service~~ may approve actions in PHMAs that are within the applicable lek buffer-distance ~~identified above~~ only if ~~:~~
~~The BLM, and the Forest Service, with input from the state fish and wildlife agency, determines, based on best available science, landscape features, and other existing protections, that a buffer distance other than the distance identified above~~a different buffer distance offers the same or greater level of protection to GRSG and its habitat. ~~, including conservation of seasonal habitat outside of the analyzed buffer area.~~
~~For BLM and Forest Service actions in GHMAs (not including Wyoming), the BLM and Forest Service will apply the lek buffer-distances identified above as required conservation measures to fully address the impacts to leks as identified in the NEPA analysis.~~
~~Impacts should first be avoided by locating the action outside of the applicable lek buffer-distance(s) identified above.~~
~~The BLM and Forest Service may approve actions i~~In GHMAs actions may be approved within the applicable lek buffer distance only if ~~:~~
~~Based on best available science, landscape features, and other existing protections, (e.g., land use allocations, state regulations), the BLM or Forest Service (as appropriate) determine that a lek buffer distance other than the applicable distance identified above~~ a different distance offers the same or a greater level of protection to GRSG and its habitat, including conservation of seasonal habitat outside of the analyzed buffer area; or
~~The BLM or Forest Service (as appropriate) determine that~~ impacts to GRSG and its habitat are minimized such that the project will cause minor or no new disturbance (ex. co-location with existing authorizations) ~~;~~and

~~A~~any residual impacts within the lek buffer-distances are addressed through compensatory mitigation measures sufficient to ensure a net conservation gain.

~~The State of Wyoming's Core Area Strategy was developed by buffering leks by 5.3 miles and is designed to protect birds and habitat within core areas using a suite of tools and mechanisms that work in concert to conserve GRSG by reducing habitat loss and fragmentation through lek buffers, disturbance limits, excluded activities, and a sophisticated mapping utility to monitor the amount and density of disturbance. The combined effect of these overlapping and reinforcing mechanisms gives FWS confidence that the lek-buffer distances in the Core Area Strategy will be protective of breeding GRSG.~~

~~*Mitigation Requirements*~~

~~During the implementation of the proposed LUPs, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in GRSG habitat loss and degradation, the BLM and the Forest Service will require and ensure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation; Wyoming will apply a net conservation gain standard to actions in PHMA only. This will be achieved by avoiding, minimizing, and compensating for unavoidable impacts by applying beneficial conservation actions to offset remaining impacts associated with the action. This standard is consistent with the recommendation included in the~~ ~~*Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0*~~ ~~published by the FWS in September, 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse"[10]. Mitigation will follow the regulations from the White House Council on Environmental Quality (CEQ) (40 CFR 1508.20; e.g. avoid, minimize, and compensate) and be implemented on BLM-managed lands in a manner consistent with Departmental guidance for landscape mitigation pursuant to Secretarial Order 3330[11]. If impacts from BLM and Forest Service management actions and authorized third party actions result in habitat loss and degradation that remain after applying avoidance and minimization measures (i.e. residual impacts), then compensatory mitigation projects will be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation.~~

~~The BLM and Forest Service, via a WAFWA Management Zone GRSG Conservation Team will develop a WAFWA Management Zone Regional Mitigation Strategy that will inform the NEPA decision making process including the application of the mitigation hierarchy for BLM and Forest Service actions and third party authorizations that result in habitat loss and degradation. A robust and transparent Regional Mitigation Strategy will contribute to GRSG habitat conservation by reducing, eliminating, or minimizing threats and compensating for residual impacts to GRSG and its habitat. Within 90 days of the issuance of the Record of Decisions, the BLM will establish a WAFWA Management Zone GRSG Conservation Team to help guide the conservation of GRSG. This team will include membership from the respective states, Forest Service, USFWS, NRCS, and other local governments. The zonal mitigation strategy will be developed within one year of the issuance of the Record of Decisions.~~

Comment [KK40]: Mitigation has it own section (V) and I didn't think it quite fit between buffers & RDFs, so I added a bit of the text here to Section 5 and referenced it from the new section above habitat management, restoration, and improvement

---

~~[10] USFWS. Greater Sage Grouse Range-Wide Mitigation Framework: Version 1.0. September 3, 2014.~~

~~[11] Secretarial Order 3330. Improving Mitigation Policies and Practices of the Department of the Interior. October 2013.~~

Required Design Features

Required Design Features (RDFs) and Best Management Practices (BMPs) are required for certain activities in all GRSG habitat, including PHMA, GHMA, IHMA in Idaho and OHMA in Nevada ~~(see Appendix B for RDFs for all proposed LUPs except Wyoming where the RDFs apply to PHMA only and BMPs apply to GHMA).~~ RDFs establish the minimum specifications for certain activities to help mitigate adverse impacts. However, the applicability and overall effectiveness of each RDF cannot be fully assessed until the project level when the project location and design are known. Because of site-specific circumstances, some RDFs may not apply to some projects (e.g., a resource is not present on a given site) and/or may require slight variations (e.g., a larger or smaller protective area). RDFs and BMPs have been developed for oil and gas development, infrastructure, range developments, and other surface disturbing activities and are fully described in Appendix XX of the ARMPAs.~~All variations in RDFs would require that at least one of the following be demonstrated in the NEPA analysis associated with the project/activity:~~

~~A specific RDF is documented to not be applicable to the site-specific conditions of the project/activity (e.g. due to site limitations or engineering considerations). Economic considerations, such as increased costs, do not necessarily require that an RDF be varied or rendered inapplicable;~~
~~An alternative RDF is determined to provide equal or better protection for GRSG or its habitat;~~
~~A specific RDF will provide no additional protection to GRSG or its habitat.~~

Comment [KK41]: is this a common appendix that we can reference?

~~*Habitat Restoration Measures*~~

Comment [KK42]: Moved up under a new section titled "habitat management, restoration, and improvement)

~~The BLM Greater Sage Grouse Invasive Annual Grasses & Conifer Expansion Assessment (FIAT 2014) modeled conifer expansion for PACs to provide an initial stratification to determine where conifer removal would benefit important sagebrush habitats. This information is being used to identify and design projects to change vegetation composition and/or structure to modify potential fire behavior for the purpose of improving fire suppression effectiveness and limiting fire spread and intensity due to invasive grasses and conifer encroachment. Consistent with this assessment, the BLM ARMPAs include management actions to remove invading conifers and other undesirable species, and prioritize vegetation treatments closest to occupied GRSG habitats and near occupied leks.~~

~~In addition, since 2010, through NRCS' Sage Grouse Initiative (SGI), over 400,000 acres of private lands have been treated for removal of pinyon-juniper targeted in PACs and BLM has additionally treated over 400,000 acres of public lands. The SGI is a successful partnership with federal and state agencies, ranchers, and private landowners has been a model of cooperation and collaboration consistent with the recommendations of the authors of the 2006 WAFWA report as well as those of the COT and NTT. Additional details on the SGI and actions taken by BLM and Forest Service are included in Section VI. See also for additional information on SGI).~~

~~*Post-Fire Habitat Restoration*~~

~~Native seed stocks have been expanded to increase their availability to aid in the restoration of native vegetation in burned sagebrush areas.[12] In collaboration with the USDA and western governors, a new seed strategy has been developed to increase the capacity to collect, store, and allocate native seed for to improve habitat restoration in priority habitat areas. Finally, the~~

~~[12] Also addresses specific concerns raised in the NTT report. p 27~~

~~Wildland Fire Departmental Manual will be revised to incorporate direction to identify rangeland fire as a critical priority in the Department and to ensure that resource allocations reflect this priority. For example, in the Manual, Emergency Stabilization (ES) and Burned Area Rehabilitation (BAR) funds for restoration of lands damaged by fire will be made available for 2 years and 5 years respectively (currently limited to 1 and 3 years respectively) to aid in ensuring effective restoration of burned areas.~~

~~Disturbance caps of 3% in PHMA were established in accordance with recommendations contained in the NTT and COT reports. Disturbance will be calculated based on established Biologically Significant Units developed by interagency teams for each of the four sub-regional planning efforts in the Great Basin, as well as at the proposed project scale analysis area, and will include proximity to leks in the calculation.~~

~~The ARMPAs provide direction to apply and analyze lek buffer-distances in PHMA and GHMA as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). The BLM will apply the lek buffer-distances specified as the lower end of the interpreted range in the report unless justifiable departures are determined to be appropriate~~

~~Consistent with recommendations contained in the 2006 WAFWA *Greater Sage-Grouse Range-wide Conservation Strategy*, the BLM conservation strategy places heavy reliance on monitoring and evaluation to assess the success of management decisions incorporated in ARMPAs, ultimately, in the effectiveness of implementing these plans. Monitoring plans will be interagency in nature and incorporate evaluation of greater sage-grouse population trends by the states and changes in habitat condition by the Federal land management agencies.~~

~~In addition, the conservation strategy incorporates an adaptive management framework that provides an "early warning system" of "soft triggers" to alert resource managers to the need to evaluate the effectiveness of their management strategies should declines in population levels or habitat conditions occur. If management responses to soft triggers do not adequately address the causes for population or habitat declines and "hard triggers" are reached, more significant changes in management actions and land allocations will immediately be implemented to conserve the species.~~

~~*Response to Climate Change*~~

Comment [KK43]: Moved up under a new section titled "habitat management, restoration, and improvement)

~~With regard to the threat of climate change, the proposed ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the Integrated Rangeland Fire Management Strategy will further this effort. The Fire and Invasives Assessment Team (FIAT) assessments that supported the development of the Rangeland Fire Management Strategy [previously referenced?] are specifically designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). Additionally, by limiting or eliminating anthropogenic surface disturbance, especially in the contiguous SFAs, and restoring habitat through mitigation efforts, connectivity and availability of sagebrush habitat are expected to increase thus contributing to increased climate resilience.~~

1.5.3 Other Management Actions to Enhance GSRG Conservation Success

Commitment to Monitoring

Comment [KK44]: There is also monitoring is section 6. However, this clearly needs to be co-located with Adaptive Management, so either Adaptive Management needs to move to section 6 or Monitoring needs to move here. . I think our RODs are supposed to have the monitoring section as standalone, so we need to be sure we understand that.

Monitoring tied to ~~proposed LUP~~the ARMPAs ~~decisions~~ has two parts: (1) implementation monitoring (i.e., are decisions being implemented in a timely manner, are actions taken consistent with the plan decisions), and (2) effectiveness monitoring (i.e., are the decisions and implementation actions achieving the desired conservation goals). Through effectiveness monitoring, BLM can answer questions about how decisions and actions impact GRSG habitat. Understanding the effectiveness and validating results of ~~LUPs~~ARMPAs and management decisions is an important part of measuring performance under the Government Performance Results Act. For example, riparian condition is a primary measure for ~~LUP~~ARMPA effectiveness (see WO IM 2010-101). Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, size of patches, etc.). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by state wildlife agencies and other partners, will allow linking real or potential habitat changes (from both natural events and management actions) to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to ameliorate negative effects with appropriate conservation actions.

The BLM Assessment, Inventory, and Monitoring (AIM) Strategy (Toevs et al. 2011 and IB2012-080) describes a vision for integrated, cross-program assessment, inventory, and monitoring of resources at multiple scales of management. Following the AIM Strategy, the BLM is modernizing its resource monitoring approach to more efficiently and effectively meet local, regional, and national resource information needs. The AIM Strategy provides a process for the BLM to collect quantitative information on the condition, trend, amount, location, and spatial pattern of natural resources on the public lands. Each AIM-Monitoring survey, at any scale of inquiry (from the plot level to west-wide deployments), uses a set of core indicators, standardized field methods, remote sensing, and a statistically-valid study design to provide nationally-consistent and scientifically-defensible information to determine conditions (e.g., rangeland health) and trends on public lands.

The National-scale deployment of AIM, known as the Landscape Monitoring Framework (LMF), commenced in 2011 in coordination with NRCS, with the collection of 1,000 plots of field-collected monitoring data across the Western U.S. LMF aims to provide non-biased estimates of vegetation and soil condition and trend using a statistically balanced sample design across BLM lands. A group of GRSG habitat and sagebrush plant community subject matter experts from BLM, USFWS, WAFWA, NRCS, ARS, state wildlife agencies, and academia identified those vegetation indicators collected at LMF sampling points that inform GRSG habitat needs. The common indicators that were identified include: species composition, foliar cover, height of the tallest sagebrush and herbaceous plant, inter-canopy gap, percent of invasive species, sagebrush shape, and bare ground. To increase the precision of estimates of sagebrush conditions within the range of GRSG, additional plot locations in occupied GRSG habitat (Sage-grouse Intensification) were added in 2013. The common indicators are also collected on sampling locations in the NRCS Rangeland Monitoring Survey. The GRSG baseline data will be collected over a five year period and an annual report will be prepared describing the status of the indicators. Beginning in year six, the annual status report will be accompanied with a trend report which will be available on an annual basis thereafter contingent upon continuation of the current monitoring budget. This information, in combination with mapping information, mid-scale habitat suitability indicator measures, and sagebrush availability information will be used to assess the effectiveness of the planning strategy.

The BLM has made significant commitments in the ARMPAs to monitoring actions to conserve GRSG habitats at multiple scales. The results from the monitoring will inform the agencies of the effectiveness of efforts to reduce disturbance and restore seasonal habitats in priority areas, and of the status of the triggers set in the proposed LUPs for adaptive management. The BLM and the Forest Service will report annually on the results of the monitoring efforts.

Adaptive Management

~~Each~~The ~~proposed LUP~~ARMPAs include~~s~~ an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are not specific to any particular project, but identify habitat and population thresholds. Triggers are based on the two key metrics that are being monitored - habitat loss and/or population declines. Adaptive Management with specific triggers provide additional certainty that the regulatory mechanisms included in the ARMPAs are robust and able to respond to a variety of conditions and circumstances quickly and effectively to conserve GRSG habitat.

Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the proposed LUPs, the BLM and Forest Service response is to apply more conservative or restrictive conservation measures to mitigate for the specific causal factor in the decline of populations and/or habitats, with consideration of local knowledge and conditions. In each proposed LUP, a soft trigger begins a dialogue between the state, FWS, and the BLM or Forest Service to see if the causal factor can be determined and what implementation-level activities can be used to reverse any trend. These adjustments will be made to preclude tripping a “hard” trigger (which signals more severe habitat loss or population declines). Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the BLM and Forest Service proposed LUPs. In the event that new scientific information becomes available demonstrating that the hard trigger would be insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM and Forest Service proposed LUPs, the BLM and/or Forest Service will immediately assess what further actions may be needed to protect GRSG and its habitat and ensure that conservation options are not foreclosed. This could include a formal directive such as an IM or a plan amendment, which, to the extent that it is supported scientifically, may be drawn from the range of alternatives analyzed in the development of the proposed LUPs.

~~1.43 Great Basin Region Planning Area~~

~~One of two regions that make up the National Greater Sage-Grouse Planning Strategy, the Great Basin Region is composed of four sub-regions, which include the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah sub-regions (see **Figure X** – Great Basin Region Greater Sage-Grouse Sub-regions). Four separate National Environmental Policy Act (NEPA) analyses were conducted separately for each sub-region. These sub-regional boundaries were generally developed based on the identified threats to the GRSG and the Western Association of Fish and Wildlife Agencies (WAFWA) Management Zones. Seven WAFWA Management Zones across the west were delineated in the *WAWFA 2006 Greater Sage-Grouse Comprehensive Strategy*. These large polygons were based on similar sage-grouse populations and sub-populations identified within seven floristic provinces.~~

~~The Great Basin Region consists of WAFWA Management Zones III (Southern Great Basin), IV (Snake River Plain), and V (Northern Great Basin). The USFWS has identified a number of threats in this region, focusing on the present and widespread threats of wildfire, loss of native habitat to invasive species, and habitat fragmentation. Other threats, many of which are more localized by nature, include anthropogenic disturbances associated with energy development, mining, infrastructure, recreation, urbanization, sagebrush elimination, as well as disturbance associated with free-roaming equids and livestock grazing.~~

~~The Great Basin Region planning area boundaries included all lands regardless of jurisdiction (see **Figure X** – Great Basin Region Planning Area – Greater Sage-Grouse Habitat Management Areas). **Table X** outlines the amount of surface acres that are administered by specific Federal agencies, states, local governments, and lands that are privately owned in the four sub-regions that make up the Great Basin. The planning area includes other BLM-administered lands that are not allocated as habitat management~~

~~areas for GRSG. The ARMPAs do not establish any additional management for these lands; these lands will continue to be managed according to the existing land use plan for the areas.~~

~~The decision area for the Great Basin Region ARMPAs is BLM-administered lands in GRSG habitat management areas (see **Figure X** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas), including surface and split-estate lands with BLM subsurface mineral rights. Any decisions in the Great Basin Region ARMPAs apply only to BLM-administered lands, including split-estate lands within GRSG habitat management areas (the decision area). These decisions are limited to providing land use planning direction specific to conserving GRSG and its habitat.~~

~~GRSG habitat management areas on BLM-administered lands in the decision area consists of lands allocated as Priority Habitat Management Areas (PHMA), General Habitat Management Areas (GHMA), Other Habitat Management Areas (OHMA, applicable only to the Nevada and Northeastern California), and Important Habitat Management Areas (IHMA, applicable only to Idaho). **Table X** identifies surface acres of PHMA, GHMA, OHMA, and IHMA in the decision area for the Great Basin Region.~~

~~PHMA, GHMA, OHMA, and IHMA are defined as follows:~~

- ~~**PHMA** – BLM-administered lands identified as having the highest value to maintaining sustainable GRSG populations. The boundaries and management strategies for PHMA are derived from and generally follow the Preliminary Priority Habitat boundaries identified in the Draft LUPA/EIS. Areas of PHMA largely coincide with areas identified as Priority Areas for Conservation in the COT report.~~
- ~~**GHMA** – BLM-administered lands where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMA are derived from and generally follow the Preliminary General Habitat boundaries identified in the Draft LUPA/EIS.~~
- ~~**OHMA** – BLM-administered lands identified as unmapped habitat in the Draft LUPA/EIS that are within the planning area and contain seasonal or connectivity habitat areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse Habitat in Nevada and Northeastern California; Coates et al. 2014,) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.~~
- ~~**IHMA** – BLM-administered lands that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. There are no IHMAs designated within southwestern Montana. The IHMA boundaries and management strategies are derived from and generally follow the Preliminary Medial Management Area (PMMA) and Important Habitat Zone (IHZ) boundaries identified in Alternatives D and E, respectively, of the Draft LUPA/EIS, but may be modified based on the objectives of each alternative. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the Proposed Plan.~~

~~The Great Basin Region ARMPAs also identify specific Sagebrush Focal Areas (SFAs), which are allocations that are a subset of PHMA (see **Figure X** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas). The SFAs were derived from GRSG stronghold areas described in a USFWS memorandum to the BLM titled Greater Sage-Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important Landscapes (USFWS 2014). The memorandum and associated maps provided by the USFWS identify areas that represent recognized strongholds for GRSG that have been noted and referenced as having the highest densities of GRSG and other criteria important for the persistence of the species.~~

[Figure X & Figure X will be inserted here once NOC has completed them.]

2. DECISION

2.1 Summary of the Approved Management Decisions

The decision is hereby made to approve the Great Basin Region Greater Sage-Grouse ARMPAs for the Great Basin Region Greater Sage-Grouse Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah (attachments A, B, C, and D). This ROD serves as the final decision establishing the land use plan amendment decisions outlined in the ARMPAs and is effective on the date it is signed. No further administrative remedies are available for these land use plan decisions.

The decisions included in this ROD and attached ARMPAs amend the land use plans described in Sections 1.1 of attachments A, B, C, and D. This ROD and ARMPAs become effective on the date this ROD is signed. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

The land use decisions provide conservation measures to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Land use plan decisions are expressed as goals and~~,~~ objectives (desired outcomes), and allocations, allowable uses, and management decisions anticipated to achieve desired outcomes. Although decisions identified in the ARMPAs are final and effective upon signing of this ROD, they generally require additional implementation decision steps before on-the-ground activities can begin. Subsequent NEPA analysis will be conducted, as necessary, for such implementation decisions.

2.2 What the Record of Decision and Approved Resource Management Plan Amendments Provide

The ARMPAs include GRSG and GRSG habitat land use plan level management decisions in the form of:

- Goals
- Objectives (Desired Future Conditions)
- Land Use Allocations and Allowable Uses
- Management Actions

Goals are the broad statements of desired outcomes, and are usually not quantifiable.

Objectives are specific desired conditions, usually quantifiable and measurable, and may have timeframes for achievement.

Land use allocations specify locations within the planning area that are available or not for certain uses. These include decisions such as what lands are available for livestock grazing, mineral material use, oil and gas leasing, and locatable mineral development, what lands may be available for disposal via exchange and/ or sale, and what lands are open, closed, or limited to motorized travel (please note that all acreages presented in the Approved Plan are estimations even when presented to the nearest acre).

Comment [KK45]: We also use these allocations to prioritize conservation and restoration management actions, not just allowable uses

Management actions include those provisions that help in meeting the established goals and objectives and include measures that will be applied to guide day-to-day activities on public lands, including but not limited to stipulations, guidelines, best management practices (BMPs), and required design features.

Comment [KK46]: Are we really considering BMPs RMP decisions? Does that mean they cannot be changed without a RMP amendment?

The ARMPAs' management decisions were crafted to alleviate identified threats to ~~Greater Sage-grouse~~GRSG and their habitats (see **Section 1.X**).

2.3 What the Record of Decision and Approved Resource Management Plan Amendments Do Not Provide

The attached ARMPAs do not contain decisions for public lands outside of GRSG habitat management areas, except for travel management decisions in the Idaho and Southwestern Montana ARMPA.

The ARMPAs do not affect valid existing rights.

The ARMPAs do not contain decisions for the mineral estates of lands located in the planning area for lands under the jurisdiction of other Federal agencies such as the Forest Service, or for private or State-owned lands and minerals that are not administered by the BLM. ARMPA decisions for surface estate only apply to BLM managed lands. In addition, many decisions are not appropriate at this level of planning and are not included in the ROD. Examples of these types of decisions include:

Comment [KK47]: This is a "what the ROD & ARMPA does provide" not what it doesn't – and it would be helpful to have the same "what the subsurface decisions do apply to" sentence.

- *Statutory requirements.* The decision will not change the BLM's responsibility to comply with applicable laws, rules, and regulations.
- *National policy.* The decision will not change BLM's obligation to conform to current or future National policy.
- *Funding levels and budget allocations.* These are determined annually at the National level and are beyond the control of the State/District of Field offices.

Implementation decisions (or activity-level decisions) are management actions tied to a specific location. Implementation decisions generally constitute the BLM's final approval allowing on-the-ground actions to proceed and require appropriate site-specific planning and NEPA analysis. Such decisions may be incorporated into implementation plans (activity or project plans) or may exist as stand-alone decisions. These ARMPAs do not contain implementation decisions. Future activity-level plans will address the implementation of the ARMPAs. Implementation decisions and management actions that require additional site-specific project planning, as funding becomes available, will require further environmental analysis.

2.4 Modifications and Clarifications

During preparation of the ARMPAs for all four sub-regions, minor changes were made to the Proposed RMP Amendments to correct errors and to clarify decisions. Clarifications and corrections made since the Proposed RMP Amendments were published on May 29, 2015 ~~and~~ are hereby adopted by this ROD.

2.4.1 Modifications and Clarifications by Sub-region

Modifications and clarifications are summarized below for each of the sub-regional ARMPAs.

Idaho and Southwestern Montana

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Nevada and Northeastern California

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Oregon

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Utah

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

2.4.2 Protest Resolution

BLM's planning regulations at 43 CFR 1610.5-2 allow any person who participated in the planning process and has an interest that may be adversely affected by BLM's planning decisions to protest proposed planning decisions within 30 days from the date the Notice of Availability of the Proposed RMPA/Final EIS was published in the Federal Register (May 29, 2015). Below are descriptions of the protest resolution process for each of the four sub-regional PRMPAs/FEISs.

These decisions are final for the Department of the Interior. With the exception of the granted protest issues, the Director concluded that the BLM followed the applicable laws, regulations, and policies and considered all relevant resource information and public input in developing the Proposed Land Use Plan Amendments/Final EISs. Each protesting party will be notified in writing of the Director's findings and the disposition of their protests. The BLM Director resolved the protests without making significant changes to the Proposed Land Use Plan Amendments/Final EISs, though minor clarifications were made and are summarized in Section 2.5.1.

Idaho and Southwestern Montana

For the Idaho and Southwestern Montana GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Idaho and Southwestern Montana GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Nevada and Northeastern California

For the Nevada and Northeaster California GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Nevada and Northeastern California Sub-Regional GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Oregon

For the Oregon GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Oregon GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Utah

For the Utah GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Utah GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

2.4.3 Governors Consistency Review

The BLM's planning regulations require that RMPs be "consistent with officially approved or adopted resource-related plans, and the policies and procedures contained therein, of other federal agencies, state and local governments, and Indian tribes, so long as the guidance and RMPs also are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands" (43 CFR 1610.3-2(a)). The general requirement in FLPMA/planning regulations is to coordinate the land use planning process with plans of other agencies, states, and local governments to the extent consistent with law (see FLPMA s. 202(c)(9) and 1610.3-1(a)); and the respective duties to be consistent with both officially approved or adopted plans (to the extent those plans are consistent with federal law, or to maximum extent practical) (see 1610.3-2(a)(b)). In accordance with FLPMA, the BLM was aware of and gave consideration to state, local, and tribal land use plans and provided meaningful public involvement of the Proposed RMP Amendments/Final EISs.

The BLM is aware that there are specific state laws and local plans relevant to aspects of public land management that are discrete from, and independent of, federal law. However, the BLM is bound by federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that BLM's land use plans be consistent with officially-approved state and local plans only if those plans are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands. Where officially-approved state and local plans or policies and programs conflict with the purposes, policies, and programs of federal law applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially-approved state and local policies and programs (as opposed to plans), this consistency provision only applies to the maximum extent practical. While county and federal planning processes, under FLPMA, are required to be as integrated and consistent as practical, the federal agency planning process is not bound by or subject to state or county plans, planning processes, policies, or planning stipulations.

In some instances, modifications to the Proposed RMP Amendments were addressed based on recommendations submitted to the BLM by the applicable states. These modifications to the ARMPAs are summarized below by sub-region and are now part of the attached ARMPAs.

Idaho and Southwestern Montana

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Nevada and Northeastern California

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Oregon

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Utah

Will need to populate the "X" areas towards the end of the GCR process (end of July).

3. ALTERNATIVES

3.1 Alternatives Considered

Each of the Great Basin sub-regional planning efforts analyzed in detail a ~~unique~~ set of alternatives in the draft and final sub-regional EISs. The alternatives were developed to provide direction for resource programs influencing land management for the protection and enhancement of ~~Greater Sage-grouse~~GRSG and its habitat. All management under any of the alternatives complied with federal laws, rules, regulations, and policies.

Each alternative emphasized an altered combination of resource uses, allocations, and restoration measures to address issues and resolve conflicts among uses so that GRSG goals and objectives were met in varying degrees across the alternatives. The alternatives differed in how fast the goals would be met, the degree to which they would be met, the emphasis placed on certain programs and activities, and whether active or passive management would occur.

Comment [KK48]: Does the analysis actually differentiate between alternatives on how fast & to what degree goals would be met? If not, perhaps we don't want to say this. Also, this sentence & the next paragraph seem to be saying the same thing

The action alternatives offered a range of possible management approaches for responding to planning issues and concerns identified through public scoping, and to maintain or increase GRSG abundance and distribution in the planning area. While the land use plan goal was the same across alternatives for each sub-region, each alternative contained a discrete set of objectives and management actions constituting a separate RMP amendment. The goal was met in varying degrees, with the potential for different long-range outcomes and conditions.

The relative emphasis given to particular resources and resource uses differed as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs.

When resources or resource uses are mandated by law or are not tied to planning issues, there are typically few or no distinctions between alternatives.

Comment [KK49]: These are amendments, so why would we have any decisions not tied to a planning issue – is this more of a revision thing?

3.1.1 Alternative A – No Action Alternative

Alternative A meets the CEQ requirement that a No Action Alternative be considered. This alternative continues current management direction and prevailing conditions derived from the existing field/district office RMPs, as amended. Goals and objectives for resources and resource uses are based on the most recent RMP decisions, along with associated amendments, activity-and implementation-level plans, and other management decision documents. Laws, regulations, and BLM policies that supersede RMP decisions would apply. ~~Many of the underlying RMPs/MFPs are outdated and~~

Comment [KK50]: What does this mean – that the analysis assumed RFD the same as today?

Comment [KK51]: Really – are there implementation level decisions included in no action?

Goals and objectives for BLM-administered lands and mineral estate would not change. Appropriate and allowable uses and restrictions pertaining to activities such as mineral leasing and development, recreation, construction of utility corridors, and livestock grazing would also remain the same. The BLM would not modify existing or establish additional criteria to guide the identification of site-specific use levels for implementation activities.

This alternative was not selected as the ARMPAs because it did not meet the purpose and need of this plan amendment. This alternative did not include changes that are needed to be made to the existing decisions based on the USFWS 2010 listing petition decision that identified inadequacy of regulatory mechanisms as a significant threat to GRSG and its habitat. This alternative did not incorporate the best available science pertaining to GRSG or its habitat.

3.1.2 Alternative B: National Technical Team Report Alternative

Alternative B was based on the conservation measures contained within the National Technical Team (NTT) Report. The GRSG National Technical Team (NTT), comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed *A Report on National Greater Sage-Grouse Conservation Measures* in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized the importance of~~n~~ standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. The Report can be accessed at: http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

The BLM's Washington Office Instructional Memorandum (IM) Number 2012-044 directed the sub-regional planning efforts to analyze the conservation measures developed by the NTT, as appropriate, through the land use planning process and NEPA.

Alternative B would exclude ROW development in PHMA and avoid development in GHMA, would close PHMA to fluid mineral leasing, mineral material sales, and nonenergy leasable minerals, and would recommend withdrawal from locatable mineral entry in all PHMA. These management actions would reduce surface disturbance in PHMA and would minimize disturbance in GHMA, thereby maintaining GRSG habitat. Management actions for wildfire would focus~~e~~ on suppression in PHMA and

GHMA, while limiting certain types of fuels treatments. Vegetation management would emphasize sagebrush restoration. Collectively, vegetation and wildfire management would conserve GRSG habitat. Grazing would continue with similar impacts under Alternative B as under Alternative A. The best management practices (BMPs) proposed in the NTT report would be included as required design features as part of Alternative B and are listed in Appendix X, Required Design Features (RDFs), of this document.

Comment [KK52]: Or of each plan – will this be part of each plan appendix or a standalone appendix that each plan appendix references?

This alternative was not selected in its entirety as the ARMPAs because the majority of the conservation measures in the NTT Report, as appropriate and applicable, were applied primarily to PHMA, and few conservation measures in the Report were provided for in GHMA. As a result, most management actions in GHMA reverted back to the No Action Alternative, which was found to not meet the purpose and need for the Amendments. Alternative B was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

Comment [KK53]: Might need to explain what this means – it is in all the alternatives we don't choose & I don't know what it means

3.1.3 Alternative C: Citizen Groups' Recommended Alternative One

Alternative C was based on a citizen groups' recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and was applied to all occupied GRSG habitat (PHMA and GHMA. Alternative C limited commodity development in areas of occupied GRSG habitat, and closed or excluded large portions of the planning area to many land uses. This included all PHMA and GHMA as being closed to livestock grazing, recommended for withdrawal from locatable mineral entry, closed to fluid mineral leasing, closed to salable mineral and non-energy leasable mineral development, and exclusion areas for right-of-ways. The Utah LUPA/Draft EIS combined this alternative with Alternative F (discussed below).

Comment [KK54]: I added this. Is this right? What was the withdrawal for?

Alternative C is the most restrictive approach to GRSG conservation. It would eliminate all future ROWs, fluid mineral leasing, nonenergy leasable mineral development, and mineral material sales on GRSG habitat. Alternative C would also recommend withdrawal from locatable mineral entry for all GRSG habitat. It would manage all GRSG habitat as PHMA. This alternative would substantially reduce surface disturbance in all GRSG habitat. Under Alternative C, the BLM would take a passive management approach to vegetation management and fuels treatments. Additionally, all GRSG habitat would be unavailable for livestock grazing.

Comment [KK55]: Seems to be a repeat of last 2 sentences in previous paragraph

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which, based on best available science, is not required ~~by best available science from~~to conserve GRSG and its habitats. Alternative C was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.4 Alternative D: Draft RMP Amendments' Preferred Alternative

Alternative D, which was~~ere~~ identified as the Preferred Alternative in the Draft EISs, balanced opportunities to use and develop the planning area as well as conserving, maintaining, and enhancing GRSG and their habitat. Protective measures were applied to GRSG habitat, while still allowing for anthropogenic disturbances ~~that require~~with stringent mitigation measures. This alternative represents the mix and variety of management actions based on BLM's analysis and judgment, which best resolve the resource issues and management concerns while ~~accommodating~~ meeting laws, regulations, and policies pertaining to BLM management. As a result of public scoping comments, internal review, and cooperating agency coordination on the Draft RMP Amendments/EISs, this alternative was modified to become the Proposed RMP Amendments and analyzed in the FEISs. The Preferred Alternatives, with slight variations, became the Proposed Plans in the FEISs.

In PHMA under Alternative D, there would be limitation on disturbance in GRSG habitat by excluding wind and solar energy development (except for certain counties in Southeastern Oregon where avoidance is applied), avoiding all other ROW development, applying no surface occupancy stipulations to fluid mineral development, and closing PHMA to nonenergy leasable mineral development and mineral material sales. These management actions would protect GRSG habitat, while allowing other activities, subject to conditions. In GHMA under Alternative D, allocation decisions were not consistent across the Great Basin. For example, in the Nevada and Northeastern California Proposed Amendment, nonenergy leasable mineral development and mineral material sales would be closed in GHMA, while in the Oregon, Utah, and Idaho and Southwestern Montana Proposed Amendments, these allocations in GHMA were open.

Comment [KK56]: Can we mention those that are consistent? How about, allocations are less stringent, but still aim to protect GRSG habitat, for example through avoidance areas for wind and solar development, but also providing more flexibility from state to state in the Great Basin. Table XX shows a lot of consistency so I don't want this sentence to just hang out there as if we were willy-nilly in our decision making for GHMA.

Under Alternative D, the BLM management would support sagebrush/perennial grass ecosystem ~~enhancements~~restoration, would increase fire suppression in PHMA and GHMA, and would manage livestock grazing to maintain or enhance sagebrush and perennial grass ecosystems.

3.1.5 Alternative E: State/Governor's Alternative

Alternative E is the alternative provided by the State or Governor's offices for inclusion and analysis in the EISs. It incorporates guidance from specific State Conservation strategies, if developed, or recommendations from the state on management of Federal lands and emphasizes management of GRSG seasonal habitats and maintaining habitat connectivity to support population objectives. This alternative was identified as a co-Preferred Alternative in the Idaho and Southwestern Montana Draft EIS. California did not provide the BLM with a state GRSG conservation plan and under this alternative, reverted back to Alternative A, the no-action alternative.

Comment [KK57]: Is this right? – I suggest this because capitalized "State Conservation" implies an actual plan exists, but from the paragraphs below, it seems more like the states made recommendations on how BLM should manage – rather than a statewide, all lands conservation strategy.

For Nevada, Alternative E would apply an avoid, minimize, and mitigate strategy to reduce direct and indirect impacts on GRSG from surface-disturbing activities on BLM-administered lands. Effects on GRSG habitat from certain resource programs, such as grazing, lands and realty, wildfire management, and minerals, would not be directly addressed because allocation decisions were not part of the state's plan.

For Oregon, Alternative E contains GRSG conservation guidelines from Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat. The state plan describes the Oregon Department of Fish and Wildlife's proposed management of GRSG. It also provides guidance for public land management agencies and land managers for GRSG conservation. GRSG conservation guidelines in the state plan are designed to maintain (at a minimum) or enhance the quality (the optimum) of current habitats. The guidelines would also assist resource managers in achieving the population and habitat objectives of the state plan.

Comment [KK58]: Does this plan include private and state lands or just federal lands?

For Idaho, Alternative E incorporates proposed GRSG protection measures recommended by the State of Idaho. Management in Montana would remain unchanged from the current RMPs (Alternative A). Alternative E addresses the following primary threats: fire, invasive weeds, and infrastructure development. It also includes guidance for several secondary GRSG threats such as recreation, improper livestock grazing, and West Nile virus for BLM and Forest Service programs that affect GRSG or its habitat.

For Utah, the planning area includes all occupied GRSG habitat in Utah. Alternative E1 is based on the State of Utah's Conservation Plan for Greater Sage-Grouse in Utah and would apply to all BLM-administered lands in Utah. Alternative E1 was designed to eliminate the threats facing the GRSG while balancing the economic and social needs of the residents of Utah. Conservation measures would be applied to 11 areas that the state identified, called Sage-Grouse Management Areas (SGMAs). Emphasis would be placed on expanding GRSG habitat by aggressively treating areas where there are encroaching conifers or invasive species. Alternative E1 includes a general limit on new permanent disturbance of 5 percent of habitat on state or federally managed lands within any particular SGMAs. Occupied habitat outside of the state-identified SGMAs would not receive new management protection. They would continue to be managed according to the GRSG actions in existing RMPs and conservation measures associated with existing activity-level plans.

This alternative was not selected, in whole, as the ARMPAs because some components of the state's plans were not consistent with the purposes, policies and programs of Federal laws and regulations applicable to public lands. However, many goals, objectives, and management actions in the ARMPA were carried forward.

3.1.6 – Alternative F: Citizen Groups' Recommended Alternative Two

Alternative F is also based on a citizen group recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and defines different restrictions for PHMA and GHMA. Alternative F would limit commodity development in areas of occupied GRSG habitat, and would close or designate portions of the planning area to some land uses. This alternative does not apply to the Utah sub-regional planning effort, as it was combined with Alternative C. Under Alternative F, wildfire suppression would be prioritized in PHMA, while limiting certain types of fuels treatments ~~necessary to protect GRSG habitat~~. Concurrent vegetation management would emphasize sagebrush restoration and enhancement. Alternative F would reduce livestock and wild horse and burro management utilization by 25 percent within PHMA and GHMA.

Comment [KK59]: Opinion?

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which is not required by best available science from GRSG and its habitats. Alternative F was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

Comment [KK60]: According to the paragraph above grazing is not closed, but is reduced by 25% - think we need a different example for this alternative

3.1.7 – Proposed Plan Amendment

As a result of public comments, best science, cooperating agency coordination, and internal review of the Draft RMP Amendments/EISs, the BLM has developed the Proposed Amendments/Final EISs for managing BLM-administered lands. The Proposed Amendments/Final EISs focus on addressing public comments, while continuing to meet the BLM's legal and regulatory mandates. The Proposed Amendments/Final EISs are a variation of the preferred alternatives (Alternative D) and are within the range of alternatives analyzed in the DEISs. The Proposed Plans, with slight variations (as outlined in Section 2.5 of this ROD), became ARMPAs.

3.1.8 Environmentally Preferable Alternative Considered in all Sub-Regions

Council on Environmental Quality (CEQ) regulations require that a ROD state which alternatives were considered to be "environmentally preferable" (40 CFR 1505.2(b)). Question 6A of CEQ's 40 most-asked questions regarding CEQ's NEPA regulations defines that term to ordinarily mean the alternative which best protects, preserves, and enhances historic, cultural, and natural resources.

Under that definition, Alternative C, as presented in each of the sub-regional Proposed RMP Amendments/Final EISs is the most environmentally preferable. However, NEPA expresses a continuing policy of the federal government to "use all practicable means and measures…to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans" (Section 101 of NEPA).

Alternative C is most protective of resources, specifically GRSG habitat in the planning area and thus would be the most "environmentally preferable" as that term is defined in Question 6A of CEQ's 40 asked questions regarding NEPA, but both NEPA and FLPMA recognize resource uses as part of the policy of the United States and under the standard of FLPMA's multiple-use mandate, the Proposed Plan was determined to be the most balanced.

Comment [KK61]: Repeat of first sentence of previous paragraph?

3.2 Alternatives Considered But Not Analyzed in Detail

The alternatives listed below by sub-region were considered but were not carried forward for detailed analysis because of one or more of the following reasons:

- They would not meet the requirements of FLPMA or other existing laws and regulations;
- They did not meet the purpose and need;
- The alternative was already captured within the range of alternative analyzed in the EIS;
- They were already part of an existing plan, policy, or administrative function; or
- They did not fall within the limits of the planning criteria.

For additional rationale as to why each of the alternatives listed below by sub-region were not carried forward for detailed analysis, refer to Section 2.11of each of the sub-regional Proposed Amendments/Final EISs.

Idaho and Southwestern Montana

- USFWS-Listing Alternative
- Elimination of Recreational Hunting Alternative
- Predation Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Consideration of Coal Mining Alternative

Nevada and Northeastern California

- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Elko County Sage-Grouse Plan Alternative
- Increase Grazing Alternative

Oregon

- USFWS-Listing Alternative
- Elimination of Livestock Grazing from all BLM Lands Alternative
- Increase Livestock Grazing Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative

Utah

- USFWS-Listing Alternative
- Increase Livestock Grazing Alternative
- Make GRSG Habitat Available for Oil Shale and Tar Sands Alternative
- Citizen Proposed Alternatives (in their entirety)
- Adoption of the State of Utah's Sage-Grouse Management Areas as PHMA for all Alternatives
- Use of Other Habitat Maps Alternatives
- County Sage-Grouse Management Plans Alternative
- Conservation Objectives Team (COT) Report Alternative
- BLM Policies and Regulations Alternative

4. MANAGEMENT CONSIDERATIONS

The BLM is tasked to provide multiple use management for public lands by the Federal Land Policy and Management Act (FLPMA) and numerous other laws and regulations that govern the management of public lands. Due to the diversity of community needs and stakeholders affected by management of BLM lands, there has been both support and opposition to certain components of the Proposed Plans. BLM's objective in choosing the Proposed Plan Amendments as the ARMPAs was to address diverse needs and concerns in a fair manner and provide a practical and workable framework for management of public lands in ~~Greater Sage-grouse~~GRSG habitat. The BLM is ultimately responsible for preparing these ARMPAs consistent with its legal mandates that reflect collective professional judgment using the best available science. The ARMPAs provide a balance between those reasonable measures necessary to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat to meet the purpose and need of these plan amendments, and the ongoing public need for use of the public lands within the Great Basin Region planning area.

The ARMPAs were selected because they will reduce or eliminate threats to ~~Greater Sage-Grouse~~GRSG at a landscape scale, improve and sustain properly functioning resource conditions, and consider needs and demands for existing or potential resource commodities and values. In the end, ~~Greater Sage-Grouse~~GRSG habitat will be managed by integrating ecological, economic, and social principles in a manner that safeguards the long term sustainability, diversity and productivity of the land.

In 2012, ~~at~~ the FWS convened a Conservation Objectives Team (COT) of state and federal representatives to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The final, peer-reviewed COT Report provided a brief overview of the threats to the greater sage-grouse's survival based upon the FWS 2010 listing decision and an assessment of the extent to which these threats affected remaining GRSG populations. **Table XX** provides a crosswalk between the threats to GRSG and their habitat identified in the COT Report and the key management responses from the ARMPAs that aim to ameliorate these threats.

Comment [KK62]: I moved Table XX up. It might make sense to reference the new Table A (threats) as well as this Table XX here but we probably don't need much text

~~Table XX~~

~~Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats~~

~~Threats to GRSG and its Habitat (from COT Report)~~	~~Key Management Responses of the Great Basin Region GRSG ARMPAs~~
~~All threats~~	- ~~Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met.~~ - ~~Require and ensure mitigation that provides a net conservation gain to GRSG and its habitat.~~ - ~~Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner.~~ - ~~Apply buffers necessary based on project type and location to address impacts on leks when authorizing actions in GRSG habitat.~~ - ~~Apply Required Design Features (RDFs) when authorizing actions that affect GRSG habitat.~~ - ~~Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.~~
~~All development threats, including mining, infrastructure, and energy development.~~	- ~~PHMA: Implement an anthropogenic disturbance cap of 3% within the Biologically Significant Unit and proposed project analysis areas in PHMA (slight variations to this management component in the State of Nevada only)~~ - ~~PHMA: Apply a disturbance density cap of 1 facility per 640 acres (except in the State of Nevada)~~
~~Energy development – fluid minerals, including geothermal resources~~	- ~~PHMA: Open to fluid mineral leasing subject to a No Surface Occupancy (NSO) stipulation without waiver or modification, and with limited exceptions. In SFAs, a NSO stipulation would be applied without waiver, modification, or exception.~~ - ~~GHMA: Open to fluid mineral leasing subject to Controlled Surface Use (CSU) and Timing Limitation (TL) lease stipulations (except in the State of Utah where some portions of GHMA are open with standard lease stipulations)~~
~~Energy development – wind energy~~	- ~~PHMA: Exclusion area (not available for wind energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas)~~ - ~~GHMA: Avoidance area (may be available for wind energy development with special stipulations) (except in the States of Utah and Idaho, where these areas would open to wind energy development)~~
~~Energy development – solar energy~~	- ~~PHMA: Exclusion area (not available for solar energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas)~~ - ~~GHMA: Exclusion area (not available for solar energy development under any conditions) (except in the States of Oregon and Montana where these areas are avoidance areas for solar energy development and the State of Idaho, where these areas would open to solar energy~~

~~Table XX~~

~~Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats~~

~~Threats to GRSG and its Habitat (from COT Report)~~	**~~Key Management Responses of the Great Basin Region GRSG ARMPAs~~**
	~~development)~~
~~Infrastructure – major ROWs~~	• ~~PHMA: Avoidance area (may be available for major ROWs with special stipulations)~~ • ~~GHMA: Avoidance area (may be available for major ROWs with special stipulations) (except in the State of Utah where GHMA is open)~~
~~Infrastructure – minor ROWs~~	• ~~PHMA: Avoidance area (may be available for minor ROWs with special stipulations)~~
~~Mining – locatable minerals~~	• ~~SFA: Recommend withdrawal from the Mining Law of 1872~~
~~Mining – nonenergy leasable minerals~~	• ~~PHMA: Closed area (not available for nonenergy leasable minerals)~~
~~Mining – salable minerals~~	• ~~PHMA: Closed area (not available for salable minerals) with a limited exception (may remain open to free use permits and expansion of existing active pits if criteria are met)~~
~~Livestock grazing~~	• ~~Prioritize the review and processing of grazing permits/leases in SFAs followed by PHMA.~~ • ~~The NEPA analysis for renewals and modifications of grazing permits/leases will include specific management thresholds, based on the GRSG Habitat Objectives Table, Land Health Standards and ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis.~~ • ~~Prioritize field checks in SFAs followed by PHMA to ensure compliance with the terms and conditions of grazing permits.~~
~~Free-roaming equid management~~	• ~~Prioritize gathers in SFAs, followed by other PHMAs.~~ • ~~Manage Herd Management Areas (HMAs) in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives.~~ • ~~Prioritize rangeland health assessment, gathers and population growth suppression techniques, monitoring, and review and adjustment of AMLs and preparation of Herd Management Area Plans in GRSG habitat.~~
~~Range management structures~~	• ~~Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats.~~ • ~~Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas subject to valid existing rights.~~
~~Recreation~~	• ~~PHMA: Do not construct new recreation facilities unless required for health and safety purposes.~~

~~**Table XX**~~

~~**Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats**~~

~~**Threats to GRSG and its Habitat (from COT Report)**~~	~~**Key Management Responses of the Great Basin Region GRSG ARMPAs**~~
	~~• Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain.~~
~~Fire~~	~~• Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection.~~ ~~• Prioritize post-fire treatments in SFAs, other PHMAs and GHMAs.~~
~~Nonnative, invasive plant species~~	~~• Improve GRSG habitat by treating annual grasses.~~ ~~• Treat sites in PHMA and GHMA that contain invasive species infestations through an integrated pest management approach.~~
~~Sagebrush removal~~	~~• PHMA: Maintain a minimum of 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover.~~ ~~• All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.~~
~~Pinyon and/or juniper expansion~~	~~• Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.~~
~~Agricultural conversion and exurban development~~	~~• GRSG habitat will be retained in federal management.~~

5. MITIGATION MEASURES

In all GRSG habitat, in undertaking BLM management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the GRSG including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. Actions which result in habitat loss and degradation include those identified as threats which contribute to GRSG disturbance as identified by the FWS in its 2010 listing decision (75 FR 13910), COT report, and depicted in the ARMPAs' Monitoring Framework (which can be found in Appendix X of each of the attached ARMPAs). Mitigation will follow the regulations from the CEQ (40 CFR, Part 1508.20; e.g. avoid, minimize, and compensate). If impacts from BLM management actions and authorized third-party actions (which are consistent with the goals, objectives, and management actions in the attached ARMPAs) that result in habitat loss and degradation remain after applying avoidance and minimization measures (i.e., residual impacts), then compensatory mitigation projects would be used to provide a net conservation gain to the species. Any compensatory mitigation would be durable, timely, and in addition to what would have resulted without the compensatory mitigation (see the concepts of durability, timeliness, and additionality as described further in the Mitigation Strategy, which can be found in Appendix X of each of the attached ARMPAs).

All practical means to avoid or minimize environmental harm, specifically to ~~Greater Sage-Grouse~~GRSG and its habitat are encompassed in the attached ARMPAs and associated appendices. Mitigation measures, including the application of required design features have been identified.

The ARMPAs also identify the development of regional mitigation strategies, in partnership with the states, to guide and target mitigation to achieve the greatest benefit to GRSG and habitat conservation and restoration. Within 90 days of the issuance of the Record of Decisions, the BLM will establish a WAFWA Management Zone GRSG Conservation Team to develop a WAFWA Management Zone Regional Mitigation Strategy that will inform the NEPA decision making process including the application of the mitigation hierarchy for actions and third party authorizations that result in habitat loss and degradation. A robust and transparent Regional Mitigation Strategy will contribute to GRSG habitat conservation by reducing, eliminating, or minimizing threats and compensating for residual impacts to GRSG and its habitat. The mitigation strategy will be developed within one year of the issuance of the Record of Decisions.

6. PLAN MONITORING

Comment [KK63]: This currently appears twice – see also 1.5.3 where it is paired with adaptive management.

The BLM's Monitoring framework (Appendix X of each of the attached ARMPAs) describes the process that the BLM will use to monitor implementation and effectiveness of ARMPA decisions. The monitoring framework includes methods, data standards, and intervals of monitoring at broad- and mid-scales; consistent indicators to measure descriptions for each of the scales; analysis and reporting methods; and the incorporation of monitoring results into adaptive management.

The BLM has committed to consistently and systematically monitor the land use plans implementation actions authorized within the designated sage-grouse management areas (e.g., Sagebrush Focal Areas, Priority Habitat Management Areas, General Habitat Management Areas). An annual Implementation Monitoring Report will describe the number and types of authorized actions in each of the sage-grouse management areas and will document whether the authorized actions are in conformance with the applicable land use plan. ~~The reporting structure will be based on the BLM program areas and use the completion date of the decision from the NEPA document in the ePlanning system.~~

Effectiveness monitoring includes monitoring disturbance in habitats, as well as landscape habitat attributes. To monitor habitats, the BLM will measure and track attributes of GRSG habitat management areas at the broad scale, and attributes of habitat availability, patch size, linkage/connectivity habitat, edge effect, and human disturbances at the mid-scale. Disturbance monitoring will measure and track changes in the amount of sagebrush in the landscape and changes in the human footprint, including changes in density of energy development. The framework also includes: (1) methods for analyzing and reporting for field offices, states, and BLM districts; (2) geospatial and tabular data for disturbance mapping (e.g., geospatial footprint of new permitted disturbances) and management action effectiveness.

The monitoring data will also provide the indicator estimates for adaptive management. The BLM will adjust management decisions through an adaptive management process (consistent with and in accordance with applicable law, as described in each of the specific adaptive management strategies outlined in Appendix X of the attached ARMPAs).

Comment [KK64]: What is this? Seems kind of wonky, can we say what we mean. Also, we need to talk more about adaptive management & the triggers – see 1.5.3

7. PUBLIC INVOLVEMENT, CONSULTATION AND COORDINATION

The BLM land use planning is conducted in accordance with NEPA requirements, CEQ regulations, and US Department~~s~~ of the Interior ~~and Agriculture~~ policies and procedures implementing NEPA, as well as specific BLM planning and NEPA policies. The NEPA and associated laws, regulations, and policies require the BLM to seek public involvement early in and throughout the planning process, to develop a range of reasonable alternatives to proposed actions, and to prepare environmental documents that disclose the potential impacts of proposed alternatives.

Public involvement and agency consultation and coordination have been at the heart of the planning process leading to these Great Basin Region ARMPAs. These efforts were achieved through Federal Register notices, public formal and informal meetings, individual contacts, media releases, planning bulletins, and a series of GRSG planning-related Web sites. This section documents the outreach efforts that have occurred to date.

7.1 Public Involvement

The scoping period for the National GRSG Planning Strategy, including the four sub-regional planning areas in the Great Basin Region, began with the publication of the NOI in the Federal Register on December 9, 2011, and ended on March 23, 2012. Beginning in December and ending in February of 2012, the BLM hosted a series of public open house scoping meetings across Northeastern California, Idaho, Southwestern Montana, Nevada, Oregon and Utah. A final National GRSG Planning Strategy Scoping Report was released in May 2012.

A Notice of Availability (NOA) for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Draft RMP Amendments/EISs were published in the Federal Register on November 1, 2013. The Oregon Draft RMP Amendment/EIS was released to the public on November 26, 2013.

For the Great Basin Region GRSG Proposed RMP Amendments/FEIS, Idaho and Southwestern Montana conducted seven public meetings~~;~~, Nevada and Northeastern California conducted seven public meetings, Oregon conducted seven public meetings, and Utah conducted eight public meetings between November 2013 and January 2014.

Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were considered and incorporated, as appropriate, into the Proposed Plans. The Great Basin Region received approximately 4,990 substantive comments, contained in 74,240 submissions during the four Draft EISs' comment periods. Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were carefully considered and incorporated as appropriate into the Proposed Plan Amendments. Public comments resulted in the addition of clarifying text, but did not significantly change Proposed RMP Amendments.

A Notice of Availability (NOA) for the Great Basin Region GRSG Proposed RMP Amendments and Final EISs for the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah Sub-Regions were released on May 29, 2015. The release of the EPA's NOA initiated a 30 day public protest period and a 60 day governors' consistency review. Refer to **Section 2.5** for a full description of the protest period and governors' consistency review outcomes.

7.2 Cooperating Agencies

A cooperating agency is any federal, state, or local government agency or Native American tribe that enters into a formal agreement with the lead federal agency to help develop an environmental analysis. Cooperating Agencies and tribes "work with the BLM, sharing knowledge and resources, to achieve desired outcomes for public lands and communities within statutory and regulatory frameworks" (BLM 2005). The benefits of enhanced collaboration among agencies in preparing NEPA analyses are:

- Disclosing relevant information early in the analytical process
- Applying available technical expertise and staff support
- Avoiding duplication with other federal, state, tribal, and local procedures
- Establishing a mechanism for addressing intergovernmental issues

The BLM entered into a formal Memorandum of Understanding (MOU) for the National GRSG Planning Strategy with the USFWS and the U.S. Forest Service. In addition, the Great Basin sub-regions' also invited local, state, other federal, and tribal representatives to participate as Cooperating Agencies for these RMP Amendments/EISs. In total, there were 11 MOUs signed with Federal agencies, 10 MOUs signed with state agencies, 55 MOUs signed with counties, and 5 MOUs signed with tribal entities. The MOUs outline the interests, expertise, and jurisdictional responsibilities of both the BLM and its cooperating agency partners and also outlines their respective roles and responsibilities in the planning and NEPA processes. For a full list of these cooperating agencies divided by sub-region, refer to the Cooperating Agencies List at the beginning of this ROD. Additional information can also be found in Chapter 6 of each of the Proposed Amendments/FEISs.

Comment [KK65]: Just in GB or for the whole planning effort? I counted 13 federal agencies (if every state repeat is a separate MOU)

7.2 FWS Section 7 Consultation

Consultation with FWS is required under Section 7(c) of the ESA before the start of any BLM project that may affect any federally listed or endangered species or its habitat. These planning processes are considered a major project, and the four Great Basin sub-regional Final EISs defined potential impacts on threatened and endangered species as a result of management actions proposed in the alternatives analyzed in the FEISs. The FWS is a cooperating agency in this planning process. FWS staff participated in interdisciplinary team meetings and has been provided drafts of alternative decisions and analyses for discussion and input.

The BLM formally initiated Section 7 consultation with a letter to the USFWS prior to the release of the Draft RMP Amendments/EISs, and requested concurrence on which species would require consideration during consultation. Over the ensuing months, regular meetings were held to identify the species that would be analyzed in the biological assessment, to address which actions could affect those species, and to determine whether the implementation of the Proposed Plan Amendments "may affect" the species for which this consultation occurred.

Prior to the release of the Proposed Amendments/FEISs, the BLM formally submitted the biological assessments to the USFWS for review. The USFWS evaluated the biological assessments and concurred with the "no affect" determination via memorandum for Oregon, Nevada and Northeastern California, and Idaho and Southwestern Montana, which are appendices to each of these ARMPAs. For Utah, formal consultation was required with the FWS due to a "likely to adversely affect" determination associated with the threatened listed Utah Prairie Dog. The biological opinion from the FWS is attached to the Utah ARMPA (Appendix X of Attachment X).

[Verify that the above paragraph is applicable to UT once BLM UT hears back from their local FWS.]

7.3 Native American Consultation

In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation efforts related to preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent letters to 65 tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts.

The Draft RMP Amendments/EISs were provided to the Idaho, Montana, Nevada, California, Oregon, and Utah State Historic Preservation Offices (SHPO) concurrently with its release to the public. The Proposed Plan RMP Amendments/FEISs were also provided to the SHPOs.

[Verify that the above paragraph is applicable to UT.]

8. APPROVAL

Land Use Plan Amendment Decisions

It is the decision of the Bureau of Land Management (BLM) to approve the Great Basin Region Approved Resource Management Plan (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub-regions, as described in this Record of Decision. The Proposed Plan Amendments and related Final Environmental Impact Statements (EIS) were published on May 29, 2015, in the Federal Register (80 FR 30711). I have resolved all protests and, in accordance with BLM regulations 43 CFR 1610.5-2, my decision on the protests is the final decision of the Department of Interior. The approval is effective on the date this Record of Decision is signed.

Approved by:

Neil Kornze Director Bureau of Land Management	Date

Secretarial Approval

I hereby approve the land use plan amendments decisions. My approval of the land use plan decisions constitutes the final decision of the Department of the Interior and, in accordance with regulations at 43 CFR 4.410(a)(3), is not subject to appeal under Department regulations at 43 CFR Part 4. Any challenge to these land use plan decisions must be brought in Federal district court.

Approved by:

Sally Jewell Secretary Department of the Interior	Date

(WO210)(1610)

Dear Reader:

Enclosed are the Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah,). The ROD approves the four Great Basin Region ARMPAs, which are part of fifteen other sub-regional RMP Amendments and RMP revisions associated with the National Greater Sage-Grouse Planning Strategy that was initiated on December 11, 2011.

The Bureau of Land Management (BLM) ARMPAs provide a range wide, comprehensive, science-based, collaborative strategy for addressing previously identified threats to the Greater Sage-Grouse (GRSG). This strategy, ~~while~~ designed to address issues leading to the 2010 “warranted but precluded” decision by the U.S. Fish and Wildlife Service (FWS), was guided by over a decade of research, analysis and recommendations for GRSG conservation produced by the Conservation Objectives Team (COT), Western Association of Fish and Wildlife Agencies (WAFWA), the BLM National Technical Team and (NTT). Each of these reports was developed by a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research. Science-based decision-making and collaboration with the FWS, the U.S. Forest Service, and state and local partners were fundamental during the development of the land use plan decisions within these ARMPAs to address the identified threats to GRSG.

It is important to note that this ROD and these ARMPAs are specific only to BLM-administered lands. Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft EISs and Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

The Federal Land Policy Management Act (FLPMA) requires the development and maintenance, and, as appropriate, the revision of land use plans for public lands. The National Environmental Policy Act (NEPA) requires Federal agencies to prepare an Environmental Impact Statement (EIS) for major Federal actions that could significantly affect the environment. In fulfillment of these requirements, the Draft RMP Amendments/Draft EISs, incorporating analysis and input provided by the public; local, State, and

other Federal agencies and organizations; Native American tribes; Cooperating Agencies, and BLM personnel were published in the fall of 2013. The 90-day public comment periods ensued, with more than 4,990 substantive comments from 1,348 letters that were submitted. These comments were reviewed, summarized and considered in preparing the Proposed RMP Amendments/Final EISs.

Comment [KK1]: Are these numbers for just Great Basin or all 15 (14)?

The Proposed RMP Amendments/Final EISs were made available on May 29, 2015, for a 30-day protest period. X protest letters were received, of which X were valid protests in need of resolution. Protest issues are addressed and resolved in the Protest Summary Report, available on line at: http://www.blm.gov/nv/st/en/fo/wfo/blm_information/rmp.html.

After much consideration, the BLM now approves the ~~Proposed~~ RMP Amendments as the land use planning documents that will guide ~~Greater Sage-Grouse~~GRSG habitat management in the Great Basin Region for the life of the plan amendment.

Copies of the ROD and ARMPAs can be obtained from the BLM's National ~~Greater Sage-Grouse~~GRSG webpage at: http://www.blm.gov/wo/st/en/prog/more/sagegrouse.html.

The BLM extends special appreciation to the extensive public involvement and the involvement of groups, organizations, Cooperating Agencies; local, State, and other Federal agencies; and Native American tribal representatives who contributed to the completion of these ARMPAs. This participation informed and improved the planning process and the planning documents. Your continued involvement is encouraged as the ARMPAs are implemented and monitored for the conservation of ~~Greater Sage-Grouse~~GRSG and their habitat.

Sincerely,
X

Enclosure:
1. Record of Decision and Approved Resource Management Plan Amendments

Summary

The Federal Land Policy and Management Act of 1976 as amended (FLPMA) directs the United States (US) Department of the Interior (DOI), Bureau of Land Management (BLM) to develop and periodically revise or amend its resource management plans (RMPs), which guide management of BLM-administered lands.

Comment [KK2]: Is this necessary?

The ROD and ARMPAs for the Great Basin Region GRSG Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon,~~;~~ and Utah provides a layered management approach that offers the highest level of protection for Greater Sage-Grouse (GRSG) in the most valuable habitat to address the specific threats identified in the 2010 U.S. Fish and Wildlife "warranted but precluded" decision and Conservation Objectives Team report. Land use allocations in the ARMPAs ~~would~~ limit or eliminate new surface disturbance in Priority Habitat Management Areas (PHMA), while minimizing disturbance in General Habitat Management Areas (GHMA). In addition to establishing protective land use allocations, the ARMPAs ~~would~~ implement a suite of management tools, such as disturbance limits, GRSG habitat objectives and monitoring, mitigation approaches, adaptive management triggers and responses, and other protective measures throughout the range. These overlapping and reinforcing conservation measures ~~would~~ work in concert to improve and restore GRSG habitat condition and provide consistency in how the BLM manages activities in GRSG habitat in the Great Basin Region.

1. INTRODUCTION

This Record of Decision (ROD) approves the Bureau of Land Management's (BLM) attached approved Resource Management Plans (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM~~-~~administered lands. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) as amended and other applicable laws. The BLM prepared environmental impact statements (EISs) in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

Comment [KK3]: Either ROD & BLM carry from the dear readers letter or all acronyms need to be redefined here.

Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft EISs and Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

1.1 National Greater Sage-Grouse Planning Strategy

In March 2010, the US Fish and Wildlife Service (USFWS) published their 12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered (75 Federal Register 13910, March 23, 2010). In that finding, the USFWS concluded that GRSG was "warranted, but precluded" for listing as a threatened or endangered species. A warranted, but precluded determination is one of three results that may occur after a petition is filed by the public to list a species under the Endangered Species Act (ESA). This finding indicates that immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, a species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

The USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 Federal Register 13910, March 23, 2010). The USFWS identified the principal regulatory mechanisms for the BLM and Forest Service as conservation measures in land use plans.

Consistent with the National GRSG Planning Strategy, the BLM as the lead agency, together with the U.S. Forest Service as a cooperating agency, prepared 15 environmental impact statements (EISs), with associated plan amendments and revisions. These documents provide a set of management alternatives focused on specific conservation measures across the range of the GRSG (see **Figure X**, National Greater Sage-Grouse Planning Strategy Boundaries) to address the threats identified in the 2010 USFWS "warranted but precluded" decision.~~.~~

Comment [KK4]: Could include table showing threats by population in this section (LR Table A)

[Insert Figure X here.]

Science-based decision-making and collaboration with state and local partners were fundamental to the National GRSG Planning Strategy. The 17 ARMPAs and ARMPs address threats to GRSG identified by state fish and wildlife agencies, the BLM National Technical Team (NTT), and the USFWS in the context of its listing decision and the Conservation Objectives Team (COT) report.

Comment [KK5]: 15?

The GRSG National Technical Team (NTT), comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed A Report on National Greater Sage-Grouse Conservation Measures in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized the importance of~~n~~ standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

Comment [KK6]: Were they on NTT?

In 2012, FWS convened a Conservation Objectives Team (COT) of state and federal representatives to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the ~~greater sage-grouse~~GRSG so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The final, peer-reviewed COT Report provided a brief overview of the threats to the ~~greater sage-grouse's~~GRSG's survival based upon the FWS 2010 listing decision and an assessment of the extent to which these threats affected remaining GRSG populations.
http://www.fws.gov/greatersagegrouse/documents/COT-Report-with-Dear-Interested-Reader-Letter.pdf

Additional science-based reviews by the US Geological Survey and related scientific literature provided further guidance on specific issues that arose in developing the ARMPAs.

The BLM also adopted unique state and stakeholder developed approaches and priorities within the ARMPAs. In 2011, then Secretary of the Interior Ken Salazar sent letters to each of the sage-grouse state governors asking for a report and recommendations on how to best move forward with a multi-state conservation sage-grouse plan. Most states across the range provided state conservation plans that were part of the range of alternatives analyzed in the Final EISs. Components of these state conservation plans were used to develop the ARMPAs.

In addition, the Western Governors Association Sage Grouse Task Force was established in 2011 to identify and implement high priority conservation actions and integrate ongoing actions necessary to preclude the need for the GRSG to be listed under the ESA. This group, which includes designees from the 11 western states where GRSG is found as well as representatives from USFWS, BLM, Natural Resources Conservation Service, US Forest Service, US Geological Survey, and the Department of the Interior, played an integral role throughout this land use planning process.

1.2 Ameliorating Threats to the Greater Sage-Grouse through the National Greater Sage-Grouse Planning Strategy

[Need to verify with Jim and Karen what elements from the Landscape Report they would like to see here. Right now, we only included content from Section VII (Summary) of the Landscape Report, but we can change this if needed. We can even include some of the pie charts and figures from the LR if necessary.]

The product of the National GRSG Planning Strategy, the four Great Basin ARMPAs and 13 ARMPAs/ARMPs in the Rocky Mountain Region, are an essential component of the effort to conserve GRSG and obviate a listing of the species under ESA. Across ten western States, the Great Basin and Rocky Mountain sub-regional ARMPs/ARMPAs contain updated land use plan direction on nearly 60 percent of the remaining habitat for the species. These ARMPAs/ARMPs are the product of extensive coordination, including the active engagement of the USFWS in helping to inform land allocation and related management decisions by the BLM. They also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, and circumstances in each.

Comment [KK7]: The numbers that I received from Stephanie most recently are more like 50%

This section highlights the major components that are presented in the attached ARMPAs that were constructed to address the specific threats to the viability of the GRSG, as identified in the USFWS 2010 listing decision and COT Report (many of which were also identified by the BLM's NTT Report).

Land Allocations

The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT recommended an "avoidance first strategy" and stressed that threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

In response, the four Great Basin ARMPAs provide land use allocations and management guidance for PHMAs to avoid new disturbance and minimize any disturbance associated with projects that might be developed in PHMA in the future. Allocations to avoid and minimize additional disturbance in PHMA included the application of a no surface occupancy (NSO) stipulation associated with any future leasing and development of oil, gas, and geothermal reserves in PHMAs. With the exception of a few areas in Utah and in eastern Nevada, there is low potential for fluid minerals in the Great Basin Region. To benefit GRSG conservation efforts and to assist developers in reducing the time and cost associated with oil and gas leasing development, the BLM will encourage new leasing in areas outside of PHMAs, and GHMAs.

Formatted: Normal, Right: 0.2", Line spacing: Multiple 1.05 li

Similarly, mineral development, with the exception of locatable minerals governed under the 1872 Mining Act, is closed in PHMAs for non-energy leasable minerals and saleable minerals. An exception is granted for free use permits and the expansion of existing active pits for mineral material sales and expansion of existing non-energy leasable development. There is no potential for coal development in the Great Basin outside of Utah. In Utah, at the time of a new coal lease or lease modification, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods recognizing that PHMAs are "essential habitat" for purposes of suitability determinations.

In all PHMA in the Great Basin Region, new rights of way and development for transmission lines, pipelines, and related infrastructure will be avoided through restrictions on land use authorizations. Exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs, unless necessary for health and safety purposes.

Renewable energy development (solar and wind) is excluded in PHMAs in the four Great Basin ARMPAs, with the exception of a few counties in southeastern Oregon where an avoidance allocation is applied.

In general, all forms of new development would be excluded, avoided, or developed only if the resultant effect is a net conservation benefit to the GRSG or its habitat. In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation benefit for the GRSG.
While the majority of compelling restrictions are placed in PHMA, restrictions on development in GHMA are less stringent and can accommodate a limited amount of disturbance. Disturbance associated with oil and gas development, for example, is subject to a controlled surface use and timing limitation stipulation rather than an NSO stipulation. However, any disturbance is subject to mitigation and should seek to first avoid and then minimize any impacts to GRSG or its habitat, while offsetting unavoidable impacts to a standard that produces a net conservation gain for the species.

An added element of habitat protection was provided for GRSG strongholds in the ARMPAs by identifying Sagebrush Focal Areas (SFAs), a subset of PHMAs. SFAs correspond to the areas identified by the FWS as GRSG "strongholds" as detailed in an October 27, 2014 memo from FWS Director Ashe to BLM Director Kornze and Forest Service Chief Tidwell in response to a request to "identify a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection"(http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf). Beyond that in PHMA, management decisions to be applied to SFAs include NSO stipulation with no exceptions for oil, gas, and geothermal development; recommendation that these areas be withdrawn by the Secretary from mineral entry under the 1872 Mining Act, and prioritizing grazing permit renewal, wildhorse and burro management, and vegetation management. While the SFAs have minimal land surface disturbance and, based on existing, available data, limited mineral potential, valid existing rights – as in all habitat – will be recognized and be able to proceed in accordance with their legal rights.

Management Direction, Prioritization, and Mitigation

In addition to land allocations to protect SFAs, PHMAs, and GHMAs, the ARMPAs guide other uses of these landscapes to meet COT objectives consistent with existing, authorized uses of GRSG habitats and the sagebrush landscape.

Grazing is the most widespread use of the sagebrush steppe ecosystem in the Great Basin states. The COT Report recommendation for grazing states, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage-grouse (e.g. shrub cover, nesting cover)." To ensure that grazing continues in a manner consistent with the objective of conserving the GRSG and its habitat, the four Great Basin ARMPAs require the incorporation of GRSG seasonal habitat objectives into grazing permits, consistent with the ecological site potential of the local areas.

The Great Basin ARMPAs place a priority on completing land heath assessments in SFAs, then PHMAs and GHMAs. The assessments will evaluate if grazing standards and guidelines are met, ensure that GRSG seasonal habitat objectives are also being met or are making progress towards being met, and ensure that the GRSG seasonal habitat objectives are incorporated into grazing permits.

Direction in the AR~~A~~MPAs also incorporates GRSG seasonal habitat objectives into establishment of allowable management levels (AMLs). Prioritization of horse gathers and removal to reach AMLs in SFAs, PHMAs, and GHMAs (in that order) will be conducted.

Fire represents the greatest threat to sage-grouse habitat in the Great Basin Region. Recognizing the nature and extent of this threat, the ARMPAs provide specific guidance for improving efforts to reduce the risk of GRSG habitat loss to wildfire. The four ARMPAs include specific guidance for fire prevention and the restoration of lands impacted by fire. The Great Basin ARMPAs also provide for a more aggressive, targeted effort to prevent and suppress fires that could impact thousands of acres of sage-grouse habitat, as well as restore areas with high potential to survive the impacts of climate change and subsequent rangeland fires.

Although future high voltage transmission lines will be avoided in PHMA, the planning, siting, and environmental review of three priority lines has been underway for a number of years. These lines are critical to expanding access to renewable sources of energy and to improving the reliability of the Western grid. For these reasons, planning for these lines will proceed and potential impacts to GRSG will be fully mitigated through the mitigation identified in the site-specific NEPA for those projects.

Lek protection

In addition to land allocations and management actions included in the Great Basin ARMPAs to conserve the GRSG, additional measures were included to ensure that disturbance to leks could be reduced or minimized through the application of disturbance caps and required minimum buffers.

Disturbance caps of 3% in PHMA were established in accordance with recommendations contained in the NTT and COT reports. Disturbance will be calculated based on established Biologically Significant Units developed by interagency teams for each of the four sub-regional planning efforts in the Great Basin, as well as at the proposed project scale analysis area, and will include proximity to leks in the calculation.

The ARMPAs provide direction to apply and analyze lek buffer-distances in PHMA and GHMA as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). The BLM will apply the lek buffer-distances specified as the lower end of the interpreted range in the report unless justifiable departures are determined to be appropriate

Consistent with recommendations contained in the 2006 WAFWA *Greater Sage-Grouse Range-wide Conservation Strategy,* the BLM conservation strategy places heavy reliance on monitoring and evaluation to assess the success of management decisions incorporated in ARMPAs, ultimately, in the effectiveness of implementing these plans. Monitoring plans will be interagency in nature and incorporate evaluation of greater sage-grouse population trends by the states and changes in habitat condition by the Federal land management agencies.

In addition, the conservation strategy incorporates an adaptive management framework that provides an "early warning system" of "soft triggers" to alert resource managers to the need to evaluate the effectiveness of their management strategies should declines in population levels or habitat conditions occur. If management responses to soft triggers do not adequately address the causes for population or habitat declines and "hard triggers" are reached, more significant changes in management actions and land allocations will immediately be implemented to conserve the species.

1.3 Great Basin Region Planning Area

One of two regions that make up the National Greater Sage-Grouse Planning Strategy, the Great Basin Region is composed of four sub-regions, which include the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah sub-regions (see **Figure X** – Great Basin Region Greater Sage-Grouse Sub-regions). Four separate National Environmental Policy Act (NEPA) analyses were conducted, ~~separately~~ one for each sub-region. These sub-regional boundaries were generally developed based on the identified threats to the GRSG and the Western Association of Fish and Wildlife Agencies (WAFWA) Management Zones. Seven WAFWA Management Zones across the west were delineated in the *WAWFA 2006 Greater Sage-Grouse Comprehensive Strategy*. These large polygons were based on similar sage-grouse populations and sub-populations identified within seven floristic provinces.

The Great Basin Region consists of WAFWA Management Zones III (Southern Great Basin), IV (Snake River Plain), and V (Northern Great Basin). The USFWS has identified a number of threats in this region, focusing on the present and widespread threats of wildfire, loss of native habitat to invasive species, and habitat fragmentation. Other threats, many of which are more localized by nature, include anthropogenic disturbances associated with energy development, mining, infrastructure, recreation, urbanization, sagebrush elimination, as well as disturbance associated with free-roaming equids and livestock grazing.

The Great Basin Region planning area boundaries included all lands regardless of jurisdiction (see **Figure X** - Great Basin Region Planning Area - Greater Sage-Grouse Habitat Management Areas). **Table X** outlines the amount of surface acres that are administered by specific Federal agencies, states, local governments, and lands that are privately owned in the four sub regions that make up the Great Basin. The planning area includes other BLM-administered lands that are not allocated as habitat management areas for GRSG. The ARMPAs do not establish any additional management for these lands; these lands will continue to be managed according to the existing land use plan for the areas.

The decision area for the Great Basin Region ARMPAs is BLM-administered lands in GRSG habitat management areas (see **Figure X** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas), including surface and split-estate lands with BLM subsurface mineral rights. Any decisions in the Great Basin Region ARMPAs apply only to BLM-administered lands, including split-estate lands within GRSG habitat management areas (the decision area). These decisions are limited to providing land use planning direction specific to conserving GRSG and its habitat.

GRSG habitat management areas on BLM-administered lands in the decision area consists of lands allocated as Priority Habitat Management Areas (PHMA), General Habitat Management Areas (GHMA), Other Habitat Management Areas (OHMA, applicable only to the Nevada and Northeastern California), and Important Habitat Management Areas (IHMA, applicable only to Idaho). **Table X** identifies surface acres of PHMA, GHMA, OHMA, and IHMA in the decision area for the Great Basin Region.

PHMA, GHMA, OHMA, and IHMA are defined as follows:

- **PHMA**— BLM-administered lands identified as having the highest value to maintaining sustainable GRSG populations. The boundaries and management strategies for PHMA are derived from and generally follow the Preliminary Priority Habitat boundaries identified in the Draft LUPA/EIS. Areas of PHMA largely coincide with areas identified as Priority Areas for Conservation in the COT report.
- **GHMA**— BLM-administered lands where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMA are derived from and generally follow the Preliminary General Habitat boundaries identified in the Draft LUPA/EIS.
- **OHMA** —BLM-administered lands identified as unmapped habitat in the Draft LUPA/EIS that are within the planning area and contain seasonal or connectivity habitat areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse

Habitat in Nevada and Northeastern California; Coates et al. 2014,) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.

- **IHMA** —BLM-administered lands that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. There are no IHMAs designated within southwestern Montana. The IHMA boundaries and management strategies are derived from and generally follow the Preliminary Medial Management Area (PMMA) and Important Habitat Zone (IHZ) boundaries identified in Alternatives D and E, respectively, of the Draft LUPA/EIS, but may be modified based on the objectives of each alternative. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the Proposed Plan.

The Great Basin Region ARMPAs also identify specific Sagebrush Focal Areas (SFAs), which are allocations that are a subset of PHMA (see **Figure X** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas). The SFAs were derived from GRSG stronghold areas described in a USFWS memorandum to the BLM titled Greater Sage-Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important Landscapes (USFWS 2014). The memorandum and associated maps provided by the USFWS identify areas that represent recognized strongholds for GRSG that have been noted and referenced as having the highest densities of GRSG and other criteria important for the persistence of the species.

Table X
Land Management in the Great Basin Planning Area

Surface Land Management	NV/NE CA	ID/SW MT	Utah	Oregon	Great Basin Total
BLM	45,359,000	12,449,000	20,387,200	12,615,900	**90,811,100**
Forest Service	9,719,900	13,252,400	7,396,300	6,454,800	**36,823,400**
Private	11,857,800	13,637,700	10,818,200	10,907,900	**47,221,600**
Bureau of Indian Affairs (tribal)	922,000	343,600	1,140,000	191,900	**2,975,500**
USFWS	805,900	121,900	121,900	482,500	**1,491,700**

2. DECISION

2.1 Summary of the Approved Management Decisions

The decision is hereby made to approve the Great Basin Region Greater Sage-Grouse ARMPAs for the Great Basin Region Greater Sage-Grouse Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah (attachments A, B, C, and D). This ROD serves as the final decision establishing the land use plan amendment decisions outlined in the ARMPAs and is effective on the date it is signed. No further administrative remedies are available for these land use plan decisions.

The decisions included in this ROD and attached ARMPAs amend the land use plans described in Sections 1.1 of attachments A, B, C, and D. This ROD and ARMPAs become effective on the date this ROD is signed. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

The land use decisions provide conservation measures to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Land use plan decisions are expressed as goals and~~,~~ objectives (desired outcomes), and allocations, allowable uses, and management decisions anticipated to achieve desired outcomes. Although decisions identified in the ARMPAs are final and effective upon signing of this ROD, they generally require additional implementation decision steps before on-the-ground activities can begin. Subsequent NEPA analysis will be conducted, as necessary, for such implementation decisions.

2.2 What the Record of Decision and Approved Resource Management Plan Amendments Provide

The ARMPAs include GRSG and GRSG habitat land use plan level management decisions in the form of:

- Goals
- Objectives (Desired Future Conditions)
- Land Use Allocations and Allowable Uses
- Management Actions

Goals are the broad statements of desired outcomes, and are usually not quantifiable.

Objectives are specific desired conditions, usually quantifiable and measurable, and may have timeframes for achievement.

Land use allocations specify locations within the planning area that are available or not for certain uses. These include decisions such as what lands are available for livestock grazing, mineral material use, oil and gas leasing, and locatable mineral development, what lands may be available for disposal via exchange and/ or sale, and what lands are open, closed, or limited to motorized travel (please note that all acreages presented in the Approved Plan are estimations even when presented to the nearest acre).

Comment [KK8]: They are also places where we will prioritize certain conservation and restoration management actions . . . .

Management actions include those provisions that help in meeting the established goals and objectives and include measures that will be applied to guide day-to-day activities on public lands, including but not limited to stipulations, guidelines, best management practices (BMPs), and required design features.

Comment [KK9]: Really, we are considing BMPs protestable RMP-level decisions?

The ARMPAs' management decisions were crafted to alleviate identified threats to ~~Greater Sage-grouse~~GRSG and their habitats (see **Section 1.X**).

2.3 What the Record of Decision and Approved Resource Management Plan Amendments Do Not Provide

The attached ARMPAs do not contain decisions for public lands outside of GRSG habitat management areas, except for travel management decisions in the Idaho and Southwestern Montana ARMPA.

The ARMPAs do not affect valid existing rights.

The ARMPAs do not contain decisions for the mineral estates of lands located in the planning area for lands under the jurisdiction of other Federal agencies such as the Forest Service, or for private or State-owned lands and minerals that are not administered by the BLM. ARMPA decisions for surface estate only apply to BLM managed lands. In addition, many decisions are not appropriate at this level of planning and are not included in the ROD. Examples of these types of decisions include:

Comment [KK10]: This is a "what the ROD & ARMPA does provide" not what it doesn't – and it would be helpful to have the same "what the subsurface decisions do apply to" sentence.

- *Statutory requirements.* The decision will not change the BLM's responsibility to comply with applicable laws, rules, and regulations.
- *National policy.* The decision will not change BLM's obligation to conform to current or future National policy.
- *Funding levels and budget allocations.* These are determined annually at the National level and are beyond the control of the State/District of Field offices.

Implementation decisions (or activity-level decisions) are management actions tied to a specific location. Implementation decisions generally constitute the BLM's final approval allowing on-the-ground actions to proceed and require appropriate site-specific planning and NEPA analysis. Such decisions may be incorporated into implementation plans (activity or project plans) or may exist as stand-alone decisions. These ARMPAs do not contain implementation decisions. Future activity-level plans will address the implementation of the ARMPAs. Implementation decisions and management actions that require additional site-specific project planning, as funding becomes available, will require further environmental analysis.

2.4 Modifications and Clarifications

During preparation of the ARMPAs for all four sub-regions, minor changes were made to the Proposed RMP Amendments to correct errors and to clarify decisions. Clarifications and corrections made since the Proposed RMP Amendments were published on May 29, 2015 ~~and~~ are hereby adopted by this ROD.

2.4.1 Modifications and Clarifications by Sub-region

Modifications and clarifications are summarized below for each of the sub-regional ARMPAs.

Idaho and Southwestern Montana

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Nevada and Northeastern California

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Oregon

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Utah

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

2.4.2 Protest Resolution

BLM's planning regulations at 43 CFR 1610.5-2 allow any person who participated in the planning process and has an interest that may be adversely affected by BLM's planning decisions to protest proposed planning decisions within 30 days from the date the Notice of Availability of the Proposed RMPA/Final EIS was published in the Federal Register (May 29, 2015). Below are descriptions of the protest resolution process for each of the four sub-regional PRMPAs/FEISs.

These decisions are final for the Department of the Interior. With the exception of the granted protest issues, the Director concluded that the BLM followed the applicable laws, regulations, and policies and considered all relevant resource information and public input in developing the Proposed Land Use Plan Amendments/Final EISs. Each protesting party will be notified in writing of the Director's findings and the disposition of their protests. The BLM Director resolved the protests without making significant changes to the Proposed Land Use Plan Amendments/Final EISs, though minor clarifications were made and are summarized in Section 2.5.1.

Idaho and Southwestern Montana

For the Idaho and Southwestern Montana GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Idaho and Southwestern Montana GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Nevada and Northeastern California

For the Nevada and Northeaster California GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Nevada and Northeastern California Sub-Regional GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Oregon

For the Oregon GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Oregon GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Utah

For the Utah GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Utah GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

2.4.3 Governors Consistency Review

The BLM's planning regulations require that RMPs be "consistent with officially approved or adopted resource-related plans, and the policies and procedures contained therein, of other federal agencies, state and local governments, and Indian tribes, so long as the guidance and RMPs also are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands" (43 CFR 1610.3-2(a)). The general requirement in FLPMA/planning regulations is to coordinate the land use planning process with plans of other agencies, states, and local governments to the extent consistent with law (see FLPMA s. 202(c)(9) and 1610.3-1(a)); and the respective duties to be consistent with both officially approved or adopted plans (to the extent those plans are consistent with federal law, or to maximum extent practical) (see 1610.3-2(a)(b)). In accordance with FLPMA, the BLM was aware of and gave consideration to state, local, and tribal land use plans and provided meaningful public involvement of the Proposed RMP Amendments/Final EISs.

The BLM is aware that there are specific state laws and local plans relevant to aspects of public land management that are discrete from, and independent of, federal law. However, the BLM is bound by federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that BLM's land use plans be consistent with officially-approved state and local plans only if those plans are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands. Where officially-approved state and local plans or policies and programs conflict with the purposes, policies, and programs of federal law applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially-approved state and local policies and programs (as opposed to plans), this consistency provision only applies to the maximum extent practical. While county and federal planning processes, under FLPMA, are required to be as integrated and consistent as practical, the federal agency planning process is not bound by or subject to state or county plans, planning processes, policies, or planning stipulations.

In some instances, modifications to the Proposed RMP Amendments were addressed based on recommendations submitted to the BLM by the applicable states. These modifications to the ARMPAs are summarized below by sub-region and are now part of the attached ARMPAs.

Idaho and Southwestern Montana

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Nevada and Northeastern California

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Oregon

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Utah

Will need to populate the "X" areas towards the end of the GCR process (end of July).

3. ALTERNATIVES

3.1 Alternatives Considered

Each of the Great Basin sub-regional planning efforts analyzed in detail a ~~unique~~ set of alternatives in the draft and final sub-regional EISs. The alternatives were developed to provide direction for resource programs influencing land management for the protection and enhancement of ~~Greater Sage-grouse~~GRSG and its habitat. All management under any of the alternatives complied with federal laws, rules, regulations, and policies.

Each alternative emphasized an altered combination of resource uses, allocations, and restoration measures to address issues and resolve conflicts among uses so that GRSG goals and objectives were met in varying degrees across the alternatives. The alternatives differed in how fast the goals would be met, the degree to which they would be met, the emphasis placed on certain programs and activities, and whether active or passive management would occur.

Comment [KK11]: Does the analysis actually differentiate between alternatives on how fast & to what degree goals would be met? If not, perhaps we don't want to say this. Also, this sentence & the next paragraph seem to be saying the same thing

The action alternatives offered a range of possible management approaches for responding to planning issues and concerns identified through public scoping, and to maintain or increase GRSG abundance and distribution in the planning area. While the land use plan goal was the same across alternatives for each sub-region, each alternative contained a discrete set of objectives and management actions constituting a separate RMP amendment. The goal was met in varying degrees, with the potential for different long-range outcomes and conditions.

The relative emphasis given to particular resources and resource uses differed as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs. When resources or resource uses are mandated by law or are not tied to planning issues, there are typically few or no distinctions between alternatives.

Comment [KK12]: These are amendments, so why would we have any decisions not tied to a planning issue – is this more of a revision thing?

3.1.1 Alternative A – No Action Alternative

Alternative A meets the CEQ requirement that a No Action Alternative be considered. This alternative continues current management direction and prevailing conditions derived from the existing field/district office RMPs, as amended. Goals and objectives for resources and resource uses are based on the most recent RMP decisions, along with associated amendments, activity-and implementation-level plans, and other management decision documents. Laws, regulations, and BLM policies that supersede RMP decisions would apply. ~~Many of the underlying RMPs/MFPs are outdated and~~

Comment [KK13]: What does this mean – that the analysis assumed RFD the same as today?

Comment [KK14]: Really – are their implementation level decisions included in no action?

Goals and objectives for BLM-administered lands and mineral estate would not change. Appropriate and allowable uses and restrictions pertaining to activities such as mineral leasing and development, recreation, construction of utility corridors, and livestock grazing would also remain the same. The BLM would not modify existing or establish additional criteria to guide the identification of site-specific use levels for implementation activities.

This alternative was not selected as the ARMPAs because it did not meet the purpose and need of this plan amendment. This alternative did not include changes that are needed to be made to the existing decisions based on the USFWS 2010 listing petition decision that identified inadequacy of regulatory mechanisms as a significant threat to GRSG and its habitat. This alternative did not incorporate the best available science pertaining to GRSG or its habitat.

3.1.2 Alternative B: National Technical Team Report Alternative

Alternative B was based on the conservation measures contained within the National Technical Team (NTT) Report. The GRSG National Technical Team (NTT), comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed *A Report on National Greater Sage-Grouse Conservation Measures* in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized the importance of~~n~~ standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. The Report can be accessed at: http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

The BLM's Washington Office Instructional Memorandum (IM) Number 2012-044 directed the sub-regional planning efforts to analyze the conservation measures developed by the NTT, as appropriate, through the land use planning process and NEPA.

Alternative B would exclude ROW development in PHMA and avoid development in GHMA, would close PHMA to fluid mineral leasing, mineral material sales, and nonenergy leasable minerals, and would recommend withdrawal from locatable mineral entry in all PHMA. These management actions would reduce surface disturbance in PHMA and would minimize disturbance in GHMA, thereby maintaining GRSG habitat. Management actions for wildfire would focus~~e~~ on suppression in PHMA and GHMA, while limiting certain types of fuels treatments. Vegetation management would emphasize sagebrush restoration. Collectively, vegetation and wildfire management would conserve GRSG habitat. Grazing would continue with similar impacts under Alternative B as under Alternative A. The best management practices (BMPs) proposed in the NTT report would be included as required design features as part of Alternative B and are listed in Appendix X, Required Design Features (RDFs), of this document.

Comment [KK15]: Or of each plan – will this be part of each plan appendix or a standalone appendix that each plan appendix references?

This alternative was not selected in its entirety as the ARMPAs because the majority of the conservation measures in the NTT Report, as appropriate and applicable, were applied primarily to PHMA, and few conservation measures in the Report were provided for in GHMA. As a result, most management actions in GHMA reverted back to the No Action Alternative, which was found to not meet the purpose and need for the Amendments. Alternative B was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

Comment [KK16]: Might need to explain what this means

3.1.3 Alternative C: Citizen Groups' Recommended Alternative One

Alternative C was based on a citizen groups' recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and was applied to all occupied GRSG habitat (PHMA and GHMA. Alternative C limited commodity development in areas of occupied GRSG habitat, and closed or excluded large portions of the planning area to many land uses. This included all PHMA and GHMA as being closed to livestock grazing, recommended for withdrawal from locatable minerals, closed to fluid mineral leasing, closed to salable mineral and non-energy leasable mineral development, and exclusion areas for right-of-ways. The Utah LUPA/Draft EIS combined this alternative with Alternative F (discussed below).

Comment [KK17]: Is this right? What was the withdrawal for?

Alternative C is the most restrictive approach to GRSG conservation. It would eliminate all future ROWs, fluid mineral leasing, nonenergy leasable mineral development, and mineral material sales on GRSG habitat. Alternative C would also recommend withdrawal from locatable mineral entry for all GRSG habitat. It would manage all GRSG habitat as PHMA. This alternative would substantially reduce surface disturbance in all GRSG habitat. Under Alternative C, the BLM would take a passive management approach to vegetation management and fuels treatments. Additionally, all GRSG habitat would be unavailable for livestock grazing.

Comment [KK18]: Seems to be a repeat of last 2 sentences in previous paragraph

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which, based on best available science, is not required ~~by best available science from~~to conserve GRSG and its habitats. Alternative C was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.4 Alternative D: Draft RMP Amendments' Preferred Alternative

Alternative D, which was~~ere~~ identified as the Preferred Alternative in the Draft EISs, balanced opportunities to use and develop the planning area as well as conserving, maintaining, and enhancing GRSG and their habitat. Protective measures were applied to GRSG habitat, while still allowing for anthropogenic disturbances ~~that require~~with stringent mitigation measures. This alternative represents the mix and variety of management actions based on BLM's analysis and judgment, which best resolve the resource issues and management concerns while ~~accommodating~~ meeting laws, regulations, and policies pertaining to BLM management. As a result of public scoping comments, internal review, and cooperating agency coordination on the Draft RMP Amendments/EISs, this alternative was modified to become the Proposed RMP Amendments and analyzed in the FEISs. The Preferred Alternatives, with slight variations, became the Proposed Plans in the FEISs.

In PHMA under Alternative D, there would be limitation on disturbance in GRSG habitat by excluding wind and solar energy development (except for certain counties in Southeastern Oregon where avoidance is applied), avoiding all other ROW development, applying no surface occupancy stipulations to fluid mineral development, and closing PHMA to nonenergy leasable mineral development and mineral material sales. These management actions would protect GRSG habitat, while allowing other activities, subject to conditions. In GHMA under Alternative D, allocation decisions were not consistent across the Great Basin. For example, in the Nevada and Northeastern California Proposed Amendment, nonenergy leasable mineral development and mineral material sales would be closed in GHMA, while in the Oregon, Utah, and Idaho and Southwestern Montana Proposed Amendments, these allocations in GHMA were open.

Comment [KK19]: Can we mention those that are consistent? How about, allocations are less stringent, but still aim to protect GRSG habitat, for example through avoidance areas for wind and solar development, but also providing more flexibility from state to state in the Great Basin.

Under Alternative D, the BLM management would support sagebrush/perennial grass ecosystem ~~enhancements~~restoration, would increase fire suppression in PHMA and GHMA, and would manage livestock grazing to maintain or enhance sagebrush and perennial grass ecosystems.

3.1.5 Alternative E: State/Governor's Alternative

Alternative E is the alternative provided by the State or Governor's offices for inclusion and analysis in the EISs. It incorporates guidance from specific State Conservation strategies, if developed, or recommendations from the state on management of Federal lands and emphasizes management of GRSG seasonal habitats and maintaining habitat connectivity to support population objectives. This alternative was identified as a co-Preferred Alternative in the Idaho and Southwestern Montana Draft EIS. California did not provide the BLM with a state GRSG conservation plan and under this alternative, reverted back to Alternative A, the no-action alternative.

Comment [KK20]: Is this right? – I suggest this because capitalized "State Conservation" implies an actual plan exists, but from the paragraphs below, it seems more like the states made recommendations on how BLM should manage – rather than a statewide, all lands conservation strategy.

For Nevada, Alternative E would apply an avoid, minimize, and mitigate strategy to reduce direct and indirect impacts on GRSG from surface-disturbing activities on BLM-administered lands. Effects on GRSG habitat from certain resource programs, such as grazing, lands and realty, wildfire management, and minerals, would not be directly addressed because allocation decisions were not part of the state's plan.

For Oregon, Alternative E contains GRSG conservation guidelines from Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat. The state plan describes the Oregon Department of Fish and Wildlife's proposed management of GRSG. It also provides guidance for public land management agencies and land managers for GRSG conservation. GRSG conservation guidelines in the state plan are designed to maintain (at a minimum) or enhance the quality (the optimum) of current habitats. The guidelines would also assist resource managers in achieving the population and habitat objectives of the state plan.

Comment [KK21]: Does this plan include private and state lands or just federal lands?

For Idaho, Alternative E incorporates proposed GRSG protection measures recommended by the State of Idaho. Management in Montana would remain unchanged from the current RMPs (Alternative A). Alternative E addresses the following primary threats: fire, invasive weeds, and infrastructure development. It also includes guidance for several secondary GRSG threats such as recreation, improper livestock grazing, and West Nile virus for BLM and Forest Service programs that affect GRSG or its habitat.

For Utah, the planning area includes all occupied GRSG habitat in Utah. Alternative E1 is based on the State of Utah's Conservation Plan for Greater Sage-Grouse in Utah and would apply to all BLM-administered lands in Utah. Alternative E1 was designed to eliminate the threats facing the GRSG while balancing the economic and social needs of the residents of Utah. Conservation measures would be applied to 11 areas that the state identified, called Sage-Grouse Management Areas (SGMAs). Emphasis would be placed on expanding GRSG habitat by aggressively treating areas where there are encroaching conifers or invasive species. Alternative E1 includes a general limit on new permanent disturbance of 5 percent of habitat on state or federally managed lands within any particular SGMAs. Occupied habitat outside of the state-identified SGMAs would not receive new management protection. They would continue to be managed according to the GRSG actions in existing RMPs and conservation measures associated with existing activity-level plans.

This alternative was not selected, in whole, as the ARMPAs because some components of the state's plans were not consistent with the purposes, policies and programs of Federal laws and regulations applicable to public lands. However, many goals, objectives, and management actions in the ARMPA were carried forward.

3.1.6 – Alternative F: Citizen Groups' Recommended Alternative Two

Alternative F is also based on a citizen group recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and defines different restrictions for PHMA and GHMA. Alternative F would limit commodity development in areas of occupied GRSG habitat, and would close or designate portions of the planning area to some land uses. This alternative does not apply to the Utah sub-regional planning effort, as it was combined with Alternative C. Under Alternative F, wildfire suppression would be prioritized in PHMA, while limiting certain types of fuels treatments ~~necessary to protect GRSG habitat~~. Concurrent vegetation management would emphasize sagebrush restoration and enhancement. Alternative F would reduce livestock and wild horse and burro management utilization by 25 percent within PHMA and GHMA.

Comment [KK22]: Opinion?

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which is not required by best available science from GRSG and its habitats. Alternative F was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

Comment [KK23]: According to the paragraph above grazing is not closed, but is reduced by 25% - think we need a different example for this alternative

3.1.7 – Proposed Plan Amendment

As a result of public comments, best science, cooperating agency coordination, and internal review of the Draft RMP Amendments/EISs, the BLM has developed the Proposed Amendments/Final EISs for managing BLM-administered lands. The Proposed Amendments/Final EISs focus on addressing public comments, while continuing to meet the BLM's legal and regulatory mandates. The Proposed Amendments/Final EISs are a variation of the preferred alternatives (Alternative D) and are within the range of alternatives analyzed in the DEISs. The Proposed Plans, with slight variations (as outlined in Section 2.5 of this ROD), became ARMPAs.

3.1.8 Environmentally Preferable Alternative Considered in all Sub-Regions

Council on Environmental Quality (CEQ) regulations require that a ROD state which alternatives were considered to be "environmentally preferable" (40 CFR 1505.2(b)). Question 6A of CEQ's 40 most-asked questions regarding CEQ's NEPA regulations defines that term to ordinarily mean the alternative which best protects, preserves, and enhances historic, cultural, and natural resources.

Under that definition, Alternative C, as presented in each of the sub-regional Proposed RMP Amendments/Final EISs is the most environmentally preferable. However, NEPA expresses a continuing policy of the federal government to "use all practicable means and measures…to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans" (Section 101 of NEPA).

Alternative C is most protective of resources, specifically GRSG habitat in the planning area and thus would be the most "environmentally preferable" as that term is defined in Question 6A of CEQ's 40 asked questions regarding NEPA, but both NEPA and FLPMA recognize resource uses as part of the policy of the United States and under the standard of FLPMA's multiple-use mandate, the Proposed Plan was determined to be the most balanced.

Comment [KK24]: Repeat of first sentence of previous paragraph?

3.2 Alternatives Considered But Not Analyzed in Detail

The alternatives listed below by sub-region were considered but were not carried forward for detailed analysis because of one or more of the following reasons:

- They would not meet the requirements of FLPMA or other existing laws and regulations;
- They did not meet the purpose and need;
- The alternative was already captured within the range of alternative analyzed in the EIS;
- They were already part of an existing plan, policy, or administrative function; or
- They did not fall within the limits of the planning criteria.

For additional rationale as to why each of the alternatives listed below by sub-region were not carried forward for detailed analysis, refer to Section 2.11of each of the sub-regional Proposed Amendments/Final EISs.

Idaho and Southwestern Montana

- USFWS-Listing Alternative
- Elimination of Recreational Hunting Alternative
- Predation Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Consideration of Coal Mining Alternative

Nevada and Northeastern California

- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Elko County Sage-Grouse Plan Alternative
- Increase Grazing Alternative

Oregon

- USFWS-Listing Alternative
- Elimination of Livestock Grazing from all BLM Lands Alternative
- Increase Livestock Grazing Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative

Utah

- USFWS-Listing Alternative
- Increase Livestock Grazing Alternative
- Make GRSG Habitat Available for Oil Shale and Tar Sands Alternative
- Citizen Proposed Alternatives (in their entirety)
- Adoption of the State of Utah's Sage-Grouse Management Areas as PHMA for all Alternatives

- Use of Other Habitat Maps Alternatives
- County Sage-Grouse Management Plans Alternative
- Conservation Objectives Team (COT) Report Alternative
- BLM Policies and Regulations Alternative

4. MANAGEMENT CONSIDERATIONS

The BLM is tasked to provide multiple use management for public lands by the Federal Land Policy and Management Act (FLPMA) and numerous other laws and regulations that govern the management of public lands. Due to the diversity of community needs and stakeholders affected by management of BLM lands, there has been both support and opposition to certain components of the Proposed Plans. BLM's objective in choosing the Proposed Plan Amendments as the ARMPAs was to address diverse needs and concerns in a fair manner and provide a practical and workable framework for management of public lands in ~~Greater Sage-grouse~~GRSG habitat. The BLM is ultimately responsible for preparing these ARMPAs consistent with its legal mandates that reflect collective professional judgment using the best available science. The ARMPAs provide a balance between those reasonable measures necessary to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat to meet the purpose and need of these plan amendments, and the ongoing public need for use of the public lands within the Great Basin Region planning area.

The ARMPAs were selected because they will reduce or eliminate threats to ~~Greater Sage-Grouse~~GRSG at a landscape scale, improve and sustain properly functioning resource conditions, and consider needs and demands for existing or potential resource commodities and values. In the end, ~~Greater Sage-Grouse~~GRSG habitat will be managed by integrating ecological, economic, and social principles in a manner that safeguards the long term sustainability, diversity and productivity of the land.

In 2012, ~~at~~ the FWS convened a Conservation Objectives Team (COT) of state and federal representatives to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The final, peer-reviewed COT Report provided a brief overview of the threats to the greater sage-grouse's survival based upon the FWS 2010 listing decision and an assessment of the extent to which these threats affected remaining GRSG populations. **Table XX** provides a crosswalk between the threats to GRSG and their habitat identified in the COT Report and the key management responses from the ARMPAs that aim to ameliorate these threats.

Table XX
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Comment [KK25]: MOVE TO AMELIORATING THREATS SECTION 12.-1.3?

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs

Table XX

Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Comment [KK25]: MOVE TO AMELIORATING THREATS SECTION 12.-1.3?

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
All threats	• Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met. • Require and ensure mitigation that provides a net conservation gain to GRSG and its habitat. • Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner. • Apply buffers necessary based on project type and location to address impacts on leks when authorizing actions in GRSG habitat. • Apply Required Design Features (RDFs) when authorizing actions that affect GRSG habitat. • Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.
All development threats, including mining, infrastructure, and energy development.	• PHMA: Implement an anthropogenic disturbance cap of 3% within the Biologically Significant Unit and proposed project analysis areas in PHMA (slight variations to this management component in the State of Nevada only) • PHMA: Apply a disturbance density cap of 1 facility per 640 acres (except in the State of Nevada)
Energy development—fluid minerals, including geothermal resources	• PHMA: Open to fluid mineral leasing subject to a No Surface Occupancy (NSO) stipulation without waiver or modification, and with limited exceptions. In SFAs, a NSO stipulation would be applied without waiver, modification, or exception. • GHMA: Open to fluid mineral leasing subject to Controlled Surface Use (CSU) and Timing Limitation (TL) lease stipulations (except in the State of Utah where some portions of GHMA are open with standard lease stipulations)
Energy development—wind energy	• PHMA: Exclusion area (not available for wind energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Avoidance area (may be available for wind energy development with special stipulations) (except in the States of Utah and Idaho, where these areas would open to wind energy development)
Energy development—solar energy	• PHMA: Exclusion area (not available for solar energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Exclusion area (not available for solar energy development under any conditions) (except in the States of Oregon and Montana where these areas are avoidance areas for solar energy development and the State of Idaho, where these areas would open to solar energy development)

Table XX

Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Comment [KK25]: MOVE TO AMELIORATING THREATS SECTION 12.-1.3?

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
Infrastructure—major ROWs	• PHMA: Avoidance area (may be available for major ROWs with special stipulations) • GHMA: Avoidance area (may be available for major ROWs with special stipulations) (except in the State of Utah where GHMA is open)
Infrastructure—minor ROWs	• PHMA: Avoidance area (may be available for minor ROWs with special stipulations)
Mining—locatable minerals	• SFA: Recommend withdrawal from the Mining Law of 1872
Mining—nonenergy leasable minerals	• PHMA: Closed area (not available for nonenergy leasable minerals)
Mining—salable minerals	• PHMA: Closed area (not available for salable minerals) with a limited exception (may remain open to free use permits and expansion of existing active pits if criteria are met)
Livestock grazing	• Prioritize the review and processing of grazing permits/leases in SFAs followed by PHMA. • The NEPA analysis for renewals and modifications of grazing permits/leases will include specific management thresholds, based on the GRSG Habitat Objectives Table, Land Health Standards and ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis. • Prioritize field checks in SFAs followed by PHMA to ensure compliance with the terms and conditions of grazing permits.
Free-roaming equid management	• Prioritize gathers in SFAs, followed by other PHMAs. • Manage Herd Management Areas (HMAs) in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives. • Prioritize rangeland health assessment, gathers and population growth suppression techniques, monitoring, and review and adjustment of AMLs and preparation of Herd Management Area Plans in GRSG habitat.
Range management structures	• Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. • Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas subject to valid existing rights.
Recreation	• PHMA: Do not construct new recreation facilities unless required for health and safety purposes. • Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain.

Table XX

Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Comment [KK25]: MOVE TO AMELIORATING THREATS SECTION 12.-1.3?

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
Fire	• Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection. • Prioritize post-fire treatments in SFAs, other PHMAs and GHMAs.
Nonnative, invasive plant species	• Improve GRSG habitat by treating annual grasses. • Treat sites in PHMA and GHMA that contain invasive species infestations through an integrated pest management approach.
Sagebrush removal	• PHMA: Maintain a minimum of 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover. • All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and/or juniper expansion	• Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.
Agricultural conversion and exurban development	• GRSG habitat will be retained in federal management.

5. MITIGATION MEASURES

In all GRSG habitat, in undertaking BLM management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the GRSG including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. Actions which result in habitat loss and degradation include those identified as threats which contribute to GRSG disturbance as identified by the FWS in its 2010 listing decision (75 FR 13910), COT report, and depicted in the ARMPAs' Monitoring Framework (which can be found in Appendix X of each of the attached ARMPAs). Mitigation will follow the regulations from the CEQ (40 CFR, Part 1508.20; e.g. avoid, minimize, and compensate). If impacts from BLM management actions and authorized third-party actions (which are consistent with the goals, objectives, and management actions in the attached ARMPAs) that result in habitat loss and degradation remain after applying avoidance and minimization measures (i.e., residual impacts), then compensatory mitigation projects would be used to provide a net conservation gain to the species. Any compensatory mitigation would be durable, timely, and in addition to what would have resulted without the compensatory mitigation (see the concepts of durability, timeliness, and additionality as described further in the Mitigation Strategy, which can be found in Appendix X of each of the attached ARMPAs).

All practical means to avoid or minimize environmental harm, specifically to ~~Greater Sage-Grouse~~GRSG and its habitat are encompassed in the attached ARMPAs and associated appendices. Mitigation measures, including the application of required design features have been identified. The ARMPAs also identify the development of regional mitigation strategies, in partnership with the states, to guide and target mitigation to achieve the greatest benefit to GRSG and habitat conservation and restoration.

6. PLAN MONITORING

The BLM's Monitoring framework (Appendix X of each of the attached ARMPAs) describes the process that the BLM will use to monitor implementation and effectiveness of ARMPA decisions. The monitoring framework includes methods, data standards, and intervals of monitoring at broad- and mid-scales; consistent indicators to measure descriptions for each of the scales; analysis and reporting methods; and the incorporation of monitoring results into adaptive management.

The BLM has committed to consistently and systematically monitor the land use plans implementation actions authorized within the designated sage-grouse management areas (e.g., Sagebrush Focal Areas, Priority Habitat Management Areas, General Habitat Management Areas). An annual Implementation Monitoring Report will describe the number and types of authorized actions in each of the sage-grouse management areas and will document whether the authorized actions are in conformance with the applicable land use plan. ~~The reporting structure will be based on the BLM program areas and use the completion date of the decision from the NEPA document in the ePlanning system.~~

Effectiveness monitoring includes monitoring disturbance in habitats, as well as landscape habitat attributes. To monitor habitats, the BLM will measure and track attributes of GRSG habitat management areas at the broad scale, and attributes of habitat availability, patch size, linkage/connectivity habitat, edge effect, and human disturbances at the mid-scale. Disturbance monitoring will measure and track changes in the amount of sagebrush in the landscape and changes in the human footprint, including changes in density of energy development. The framework also includes: (1) methods for analyzing and reporting for field offices, states, and BLM districts; (2) geospatial and tabular data for disturbance mapping (e.g., geospatial footprint of new permitted disturbances) and management action effectiveness.

The monitoring data will also provide the indicator estimates for adaptive management. The BLM will adjust management decisions through an adaptive management process (consistent with and in accordance with applicable law, as described in each of the specific adaptive management strategies outlined in Appendix X of the attached ARMPAs).

Comment [KK26]: What is this?

7. PUBLIC INVOLVEMENT, CONSULTATION AND COORDINATION

The BLM land use planning is conducted in accordance with NEPA requirements, CEQ regulations, and US Department~~s~~ of the Interior ~~and Agriculture~~ policies and procedures implementing NEPA, as well as specific BLM planning and NEPA policies. The NEPA and associated laws, regulations, and policies require the BLM to seek public involvement early in and throughout the planning process, to develop a range of reasonable alternatives to proposed actions, and to prepare environmental documents that disclose the potential impacts of proposed alternatives.

Public involvement and agency consultation and coordination have been at the heart of the planning process leading to these Great Basin Region ARMPAs. These efforts were achieved through Federal Register notices, public formal and informal meetings, individual contacts, media releases, planning

bulletins, and a series of GRSG planning-related Web sites. This section documents the outreach efforts that have occurred to date.

7.1 Public Involvement

The scoping period for the National GRSG Planning Strategy, including the four sub-regional planning areas in the Great Basin Region, began with the publication of the NOI in the Federal Register on December 9, 2011, and ended on March 23, 2012. Beginning in December and ending in February of 2012, the BLM hosted a series of public open house scoping meetings across Northeastern California, Idaho, Southwestern Montana, Nevada, Oregon and Utah. A final National GRSG Planning Strategy Scoping Report was released in May 2012.

A Notice of Availability (NOA) for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Draft RMP Amendments/EISs were published in the Federal Register on November 1, 2013. The Oregon Draft RMP Amendment/EIS was released to the public on November 26, 2013.

For the Great Basin Region GRSG Proposed RMP Amendments/FEIS, Idaho and Southwestern Montana conducted seven public meetings,~~;~~ Nevada and Northeastern California conducted seven public meetings, Oregon conducted seven public meetings, and Utah conducted eight public meetings between November 2013 and January 2014.

Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were considered and incorporated, as appropriate, into the Proposed Plans. The Great Basin Region received approximately 4,990 substantive comments, contained in 74,240 submissions during the four Draft EISs' comment periods. Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were carefully considered and incorporated as appropriate into the Proposed Plan Amendments. Public comments resulted in the addition of clarifying text, but did not significantly change Proposed RMP Amendments.

A Notice of Availability (NOA) for the Great Basin Region GRSG Proposed RMP Amendments and Final EISs for the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah Sub-Regions were released on May 29, 2015. The release of the EPA's NOA initiated a 30 day public protest period and a 60 day governors' consistency review. Refer to **Section 2.5** for a full description of the protest period and governors' consistency review outcomes.

7.2 Cooperating Agencies

A cooperating agency is any federal, state, or local government agency or Native American tribe that enters into a formal agreement with the lead federal agency to help develop an environmental analysis. Cooperating Agencies and tribes "work with the BLM, sharing knowledge and resources, to achieve desired outcomes for public lands and communities within statutory and regulatory frameworks" (BLM 2005). The benefits of enhanced collaboration among agencies in preparing NEPA analyses are:

- Disclosing relevant information early in the analytical process
- Applying available technical expertise and staff support
- Avoiding duplication with other federal, state, tribal, and local procedures
- Establishing a mechanism for addressing intergovernmental issues

The BLM entered into a formal Memorandum of Understanding (MOU) for the National GRSG Planning Strategy with the USFWS and the U.S. Forest Service. In addition, the Great Basin sub-regions' also invited local, state, other federal, and tribal representatives to participate as Cooperating Agencies for these RMP Amendments/EISs. In total, there were 11 MOUs signed with Federal agencies, 10 MOUs signed with state agencies, 55 MOUs signed with counties, and 5 MOUs signed with tribal entities. The MOUs outline the interests, expertise, and jurisdictional responsibilities of both the BLM and its cooperating agency partners and also outlines their respective roles and responsibilities in the planning and NEPA processes. For a full list of these cooperating agencies divided by sub-region, refer to the Cooperating Agencies List at the beginning of this ROD. Additional information can also be found in Chapter 6 of each of the Proposed Amendments/FEISs.

Comment [KK27]: Just in GB or for the whole planning effort? I counted 13 federal agencies (if every state repeat is a separate MOU)

7.2 FWS Section 7 Consultation

Consultation with FWS is required under Section 7(c) of the ESA before the start of any BLM project that may affect any federally listed or endangered species or its habitat. These planning processes are considered a major project, and the four Great Basin sub-regional Final EISs defined potential impacts on threatened and endangered species as a result of management actions proposed in the alternatives analyzed in the FEISs. The FWS is a cooperating agency in this planning process. FWS staff participated in interdisciplinary team meetings and has been provided drafts of alternative decisions and analyses for discussion and input.

The BLM formally initiated Section 7 consultation with a letter to the USFWS prior to the release of the Draft RMP Amendments/EISs, and requested concurrence on which species would require consideration during consultation. Over the ensuing months, regular meetings were held to identify the species that would be analyzed in the biological assessment, to address which actions could affect those species, and to determine whether the implementation of the Proposed Plan Amendments "may affect" the species for which this consultation occurred.

Prior to the release of the Proposed Amendments/FEISs, the BLM formally submitted the biological assessments to the USFWS for review. The USFWS evaluated the biological assessments and concurred with the "no affect" determination via memorandum for Oregon, Nevada and Northeastern California, and Idaho and Southwestern Montana, which are appendices to each of these ARMPAs. For Utah, formal consultation was required with the FWS due to a "likely to adversely affect" determination associated with the threatened listed Utah Prairie Dog. The biological opinion from the FWS is attached to the Utah ARMPA (Appendix X of Attachment X).

[Verify that the above paragraph is applicable to UT once BLM UT hears back from their local FWS.]

7.3 Native American Consultation

In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation efforts related to preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent letters to 65 tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts

related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts.

The Draft RMP Amendments/EISs were provided to the Idaho, Montana, Nevada, California, Oregon, and Utah State Historic Preservation Offices (SHPO) concurrently with its release to the public. The Proposed Plan RMP Amendments/FEISs were also provided to the SHPOs.

[Verify that the above paragraph is applicable to UT.]

8. APPROVAL

Land Use Plan Amendment Decisions

It is the decision of the Bureau of Land Management (BLM) to approve the Great Basin Region Approved Resource Management Plan (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub-regions, as described in this Record of Decision. The Proposed Plan Amendments and related Final Environmental Impact Statements (EIS) were published on May 29, 2015, in the Federal Register (80 FR 30711). I have resolved all protests and, in accordance with BLM regulations 43 CFR 1610.5-2, my decision on the protests is the final decision of the Department of Interior. The approval is effective on the date this Record of Decision is signed.

Approved by:

Neil Kornze Director Bureau of Land Management	Date

Secretarial Approval

I hereby approve the land use plan amendments decisions. My approval of the land use plan decisions constitutes the final decision of the Department of the Interior and, in accordance with regulations at 43 CFR 4.410(a)(3), is not subject to appeal under Department regulations at 43 CFR Part 4. Any challenge to these land use plan decisions must be brought in Federal district court.

Approved by:

Sally Jewell Secretary Department of the Interior	Date

9. ATTACHMENTS

Dear Reader:

Enclosed are the Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). The ROD approves the four Great Basin Region ARMPAs, which are part of seventeen other sub-regional RMP Amendments and RMP revisions associated with the National Greater Sage-Grouse Planning Strategy that was initiated on December 11, 2011.

The Bureau of Land Management (BLM) ARMPAs provide a range wide, comprehensive, science-based, collaborative strategy for addressing previously identified threats to the greater sage-grouse (GRSG) and its habitat. This strategy, while designed to address issues leading to the U.S. Fish and Wildlife Service's (FWS) 2010 "warranted but precluded" decision, was guided by over a decade of research, analysis and recommendations for GRSG conservation produced by the Conservation Objectives Team (COT) Report and the BLM National Technical Team and (NTT). Each of these reports was developed by a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research. Science-based decision-making and collaboration with the FWS, the U.S. Forest Service, and state and other partners were fundamental during the development of ~~the land use plan decisions within~~ these ARMPAs to address the identified threats to GRSG.

Comment [GSD1]: FWS does not capitalize and neither does the Dept in our materials . . .

Comment [MEM2]: Caps is consistent with other BLM planning docs and our tech. guide. May need to discuss.

Comment [KK3]: Culminating in? – COT & NTT didn't really produce the decade of research, and analysis; or ". . . guided by over a decade of research for GRSG conservation and analysis and recommendations provided by the COT . . ."

It is important to note that this ROD and these ARMPAs are specific only to BLM administered lands. Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

The Federal Land Policy Management Act (FLPMA) requires the development and maintenance, and, as appropriate, the revision of land use plans for public lands. The National Environmental Policy Act (NEPA) requires Federal agencies to prepare an Environmental Impact Statement (EIS) for major Federal actions that could significantly affect the environment. In fulfillment of these requirements, the Draft RMP Amendments/Draft EISs incorporating analysis and input provided by the public; local, State, and

other Federal agencies and organizations; Native American tribes; Cooperating Agencies, and BLM personnel were published in the fall of 2013. The 90-day public comment periods ensued, with more than 4,990 substantive comments from 1,348 letters that were submitted. These comments were reviewed, summarized and considered in preparing the Proposed RMP Amendments/Final EISs.

The Proposed RMPAs/Final EISs were made available on May 29, 2015, for a 60-day governor's consistency review and 30-day protest period. The BLM received consistency review letters from X and has worked closely with these states to resolve these inconsistencies. X protest letters were received, of which X were valid protests in need of resolution. Protest issues are addressed and resolved in the Protest Summary Report, available on line at: http://www.blm.gov/nv/st/en/fo/wfo/blm_information/rmp.html.

After much consideration, the BLM now approves the attached ARMPAs as the land use planning documents that will guide greater sage-grouse habitat management in the Great Basin Region for the life of the plan amendment for the benefit of GRSG and over 350 other species of wildlife as well as many other land uses, like grazing and recreation, that depend on ~~a~~ healthy sagebrush-steppe landscapes.

Copies of the ROD and ARMPAs can be obtained from the BLM's National Greater Sage-Grouse webpage at: http://www.blm.gov/wo/st/en/prog/more/sagegrouse.html.

The BLM extends special appreciation to the extensive public involvement and the involvement of groups, organizations, Cooperating Agencies; local, State, and other Federal agencies; and Native American tribal representatives who contributed to the completion of these ARMPAs. This participation informed and improved the planning process and the planning documents. Your continued involvement is encouraged as the ARMPAs are implemented and monitored for the conservation of Greater sage-grouse and their habitat.

Sincerely,
X

Enclosure:
1. Record of Decision and Approved Resource Management Plan Amendments

Summary

This Record of Decision (ROD) is the culmination of an unprecedented effort in public land management to meet the multiple-use and sustained-yield management objectives for public lands administered by the Bureau of Land Management (BLM) in accordance with the Federal Land Policy and Management Act of 1976 (FLPMA).

In response to a 2010 determination by the U.S. Fish and Wildlife Service (FWS) that the greater sage-grouse listing under the Endangered Species Act (ESA) is "warranted but precluded" by other priorities, the BLM, in coordination with the U.S. Department of Agriculture Forest Service (Forest Service), has developed a targeted, multi-tiered, landscape-level management approach, based on the best available science, that offers the highest level of protection for Greater Sage-Grouse (GRSG) in the most important habitat areas to address the specific threats identified in the 2010 U.S. Fish and Wildlife "warranted but precluded" decision and Conservation Objectives Team (COT) report.

This Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon; and Utah includes land use allocations in the ARMPAs that limit or eliminate new surface disturbance in Priority Habitat Management Areas (PHMA), while minimizing disturbance in General Habitat Management Areas (GHMA). In addition to establishing protective land use allocations, the ARMPAs implement a suite of management actions, such as the establishment of disturbance limits, GRSG habitat objectives, mitigation requirements, monitoring protocols, and adaptive management triggers and responses, as well as other conservation measures throughout the range. The cumulative effect of these conservation measures work in concert to protect, improve, and restore GRSG habitat across the remaining range of the species in the Great Basin and provide greater certainty that BLM land and resource management activities in GRSG habitat in the Great

Basin Region can lead to conservation of the GRSG and other sagebrush-steppe associated species in the region.

The targeted land use plan protections presented in this ROD and ARMPAs do not only protect the greater sage-grouse and their habitat, but also the over 350 wildlife species that call the sagebrush-steppe ecosystem home. Reversing the slow degradation of this valuable ecosystem will also benefit local rural economies and a variety of rangeland uses ranging from recreation to grazing and energy development, in a manner that safeguards the long term sustainability, diversity and productivity of the land.

This conservation strategy, developed in collaboration with the 11 states in which the ARMPAs and ARMPs apply, in addition to other state and federal actions underway and in development, represents an unprecedented, collaborative effort among federal land management agencies and the states to manage an entire ecosystem and associated flora and fauna, in order to "conserve the sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future". [Dan Ashe. Transmittal letter to COT report. 2014]

Comment [KK4]: It is hard to understand how energy development is benefitted by reversing the degradation of the sagebrush-steppe ecosystem – what is our rationale for this statement?

Comment [GSD5]: We may want to add some language at the end here from the rollout materials about targeted protections that benefit GRSG, 350+ other species as well as economic activity that depends on a healthy range.

Comment [MEM6]: Added this last paragraph based on Sarah G's suggestion. Will this work or should we flesh out more?

1. INTRODUCTION

This Record of Decision (ROD) approves the Bureau of Land Management's (BLM) attached ARMPAs for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM administered lands. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.), BLM planning regulations (43 Code of Federal Regulations [CFR] §1601 *et seq*.), and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA) and the Council on Environmental Quality's Regulations for implementing the procedural provisions of NEPA (40 CFR §1500.1 *et seq*.).

Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

1.1 Great Basin Region Planning Area

The Great Basin Region is composed of four sub-regions, the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah sub-regions (see **Figure 1-1** – Great Basin Region Greater Sage-Grouse Sub-regions). Four separate National Environmental Policy Act (NEPA) documents were prepared for each of these sub-regions. Each sub-region conducted its own planning effort with input from local cooperators, stakeholders, and members of the public. The sub-regional boundaries were constructed to align with BLM administrative offices, state boundaries, as well as areas that shared common threats to the GRSG and their habitat.

Comment [KK7]: We could add the WAFWA zones here as one additional element used to make the region/subregion boundaries??

[Insert **Figure 1-1** - Great Basin Region Greater Sage-Grouse Sub-regions]

The Great Basin Region planning area boundaries include all lands regardless of jurisdiction (see **Figure 1-2** - Great Basin Region Planning Area, Greater Sage-Grouse Habitat Management Areas). **Table 1-1** outlines the amount of surface acres that are administered by specific Federal agencies, states, local governments, and lands that are privately owned in the four sub regions that make up the Great Basin. The planning area includes other BLM-administered lands that are not allocated as habitat management areas for GRSG. The ARMPAs do not establish any additional management for these lands; these lands will continue to be managed according to the existing land use plan for the areas.

The decision area for the Great Basin Region ARMPAs is BLM-administered lands in GRSG habitat management areas (see **Figure 1-3** - Great Basin Region Decision Area , Greater Sage-Grouse Habitat Management Areas), including surface and split-estate lands with BLM subsurface mineral rights. Any decisions in the Great Basin Region ARMPAs apply only to BLM-administered lands, including split-estate lands within GRSG habitat management areas (the decision area). These decisions are limited to providing land use planning direction specific to conserving GRSG and its habitat.

[Insert **Figure 1-3** - Great Basin Region Decision Area, Greater Sage-Grouse Habitat Management Areas]

1.2 Threats to Greater Sage-Grouse

Currently, GRSG occupy an area that has been estimated to be a reduction of 44% from the historically occupied range. In addition, populations in most or all the range have been demonstrated to have declined from 1965- 2003, the period where data was collected most intensively.

The decline of the GRSG and its sagebrush-steppe habitat has been the focus of fish and wildlife agency and conservationists' concerns for decades. In 1994 the Western Association of Fish and Wildlife Agencies (WAFWA) formed a technical committee to monitor the distribution and abundance of GRSG. WAFWA formalized a program of interstate coordination and cooperation in 1995 to address the issues of GRSG population losses and degradation of sagebrush ecosystems in order to: 1) Maintain the present distribution of GRSG and 2) Maintain the present abundance of GRSG. In 1999 WAFWA amended the objectives to: 1) Maintain and increase where possible the present distribution of GRSG and 2) Maintain and increase where possible the present abundance of GRSG. The Bureau of Land Management, USFWS, and U.S. Forest Service formally joined with WAFWA in range-wide conservation efforts in 2000.

Between May 1999 and December 2003, eight petitions were filed with the U.S. Fish and Wildlife Service (USFWS) to have sage-grouse protected under provisions of the Endangered Species Act (ESA). In 2001 the USFWS determined that greater sage-grouse in the Columbia Basin of Washington state warranted protection under provisions of the ESA. On January 12, 2005, the FWS issued a decision that listing the GRSG for protection under the ESA was not warranted. However, in response to July 14, 2006 Western Watersheds Project filing alleging that the FWS 2005 finding was incorrect and arbitrary, the U.S. District Court of Idaho ruled that the 2005 finding was "arbitrary and capricious" and remanded it to the FWS for further consideration. Ultimately, as a result, in 2010 the FWS issued a finding that listing of the Greater sage-grouse was "warranted but precluded". Subsequent to that finding and in accordance with a settlement agreement [details?] the FWS committed to make a final determination regarding the need to list the GRSG by September 30, 2015. Two factors led to the FWS decision to list the species as "warranted but precluded": threats to habitat and the inadequacy of existing regulatory mechanisms.

The USFWS has identified a number of threats to GRSG in the Great Basin Region, focusing on the present and widespread threats of wildfire and the loss of native habitat to invasive species. Other threats, some of which are more localized by nature, include habitat fragmentation due to anthropogenic disturbances associated with energy development, mining, infrastructure, recreation, urbanization and sagebrush elimination, as well as disturbance associated with free-roaming equids and improper livestock grazing.

Additional information regarding potential threats to the GRSG is contained in the BLM National Technical Team (NTT) report and the Conservation Objectives Team (COT) reports. A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG in the Great Basin Region– as articulated in the COT report – is summarized in **Table 1-2**.

In addition, the FWS found that existing local, state and federal regulatory mechanisms were not sufficient to address threats to the habitat. For the BLM, which manages more than 40 percent of the remaining habitat range wide, regulatory mechanisms are the agency's Resource Management Plans (RMPs).

The BLM initiated this planning effort with the U.S. Forest Service to provide the needed federal regulatory mechanisms to address the individual threats listed in Table 1-3. This ROD approves the BLM's attached ARMPAs for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPAs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM- administered lands. ~~The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).~~

1.3 Early GRSG Conservation

The BLM manages the majority of the GRSG habitat on Federal lands (i.e., the range of GRSG not including the Columbia Basin or Bi-State Distinct Population Segments). Efforts to conserve the habitat of this species did not begin with the 2011 BLM's National GRSG Planning Strategy, but rather, have been ongoing for many years.

The Western Association of Fish and Wildlife Agencies (WAFWA) 2004 *Range-wide Conservation Assessment for Greater Sage-Grouse and Sagebrush Habitats* was the first range-wide assessment of GRSG using the vast amount of population data collected over the previous 60 years, habitat information spanning the previous 100 years, and literature dating back 200 years. The goal of the assessment, contributed to by the BLM, was to present an unbiased and scientific documentation of dominant issues and their effects on GRSG populations and sagebrush habitats.
http://sagemap.wr.usgs.gov/docs/Greater_Sage-grouse_Conservation_Assessment_060404.pdf

In November 2004, the BLM released its *National Sage-Grouse Habitat Conservation Strategy*, which encouraged GRSG habitat conservation through consultation, cooperation, and communication with WAFWA, the U.S. Fish and Wildlife Service (FWS), the Forest Service, the U.S. Geological Survey (USGS), State wildlife agencies, local GRSG working groups, and various other public and private partners.

In 2006, WAFWA completed a *Greater Sage-Grouse Comprehensive Conservation Strategy*, with the assistance of the BLM, the Forest Service, and other contributors. The overall goal of the Strategy was to maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain those populations. The Strategy outlined the critical need to develop the associations among local, state, provincial, tribal, and federal agencies, non-governmental organizations, and individual citizens to design and implement cooperative actions to support robust populations of GRSG and the landscapes and habitats upon which they depend. The catalyst for this effort was widespread concern for declining populations and reduced distribution of GRSG.
http://www.wafwa.org/documents/pdf/GreaterSage-grouseConservationStrategy2006.pdf

In 2008, the BLM created two national teams to investigate possible BLM management options for GRSG conservation as well as summarizing BLM's ongoing conservation efforts. A product of this effort was one of the first range-wide priority habitat maps for GRSG that were referred to as "key habitat". At the time, the primary purpose for the key habitat map was to inform and help prioritize fire suppression efforts in GRSG habitat on BLM lands. An additional outcome of this team was the signing of a Memorandum of Understanding by the WAFWA; the BLM, FWS, USGS in the Department of the Interior; and the US Department of Agriculture Forest Service and NRCS, to provide for cooperation among the participating state and federal land managers and wildlife management and science agencies in the conservation and management of GRSG sagebrush habitats and other sagebrush-dependent wildlife throughout the Western United States and Canada.
http://www.blm.gov/style/medialib/blm/wo/Planning_and_Renewable_Resources/fish__wildlife_and/fwp.Par.95958.File.dat/SagegrouseMOU.pdf

In 2010, BLM commissioned an effort to map breeding densities of GRSG across the West. A conference was convened with the state wildlife agencies to get approval and to coordinate the lek survey data needed for this effort. This modelling project, through an agreement with the FWS, mapped known active leks across the West. This model served as a standard starting point for all states to identify priority habitat.

http://www.blm.gov/wo/st/en/prog/more/fish__wildlife_and/sage-grouse-conservation/bird_density.print.html

In March 2010, the US Fish and Wildlife Service (USFWS) published their 12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered (75 Federal Register 13910, March 23, 2010). In that finding, the USFWS concluded that GRSG was "warranted, but precluded" for listing as a threatened or endangered species. A warranted, but precluded determination is one of three results that may occur after a petition is filed by the public to list a species under the Endangered Species Act (ESA). This finding indicates that immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, the species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

The USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 Federal Register 13910, March 23, 2010). The USFWS identified the principal regulatory mechanisms for the BLM and Forest Service as conservation measures in land use plans.

1.4 National Greater Sage Grouse Planning Strategy

Based on the identified threats to the GRSG, especially inadequate regulatory mechanisms, and the FWS's timeline for making a listing decision on this species, the BLM recognized the need to incorporate explicit objectives and adequate conservation measures into RMPs by 2015 to conserve GRSG habitat and avoid the need to list the species under the Endangered Species Act. In August, 2011, the BLM chartered a planning strategy to evaluate the adequacy of BLM RMPs and address revisions and amendments throughout the range of the GRSG (with the exception of the bi-state population in California and Nevada, and the Washington state distinct population segment, which were addressed through other planning efforts). This Charter established the teams, team membership, and team operating procedures for the BLM's National GRSG Planning Strategy. The BLM's objective for chartering this planning strategy effort was to develop new or revised regulatory mechanisms through RMPs to conserve and restore the GRSG and its habitat on BLM-administered lands on a range-wide basis for the long-term (Figure C).
http://www.blm.gov/style/medialib/blm/wo/Communications_Directorate/public_affairs/sage-grouse_planning/documents.Par.2415.File.dat/Final%20Signed%20GSG%20Planning%20Strategy%20Charter.pdf

Two national teams and numerous other studies were used to help inform the planning efforts. The GRSG National Technical Team (NTT), comprised of BLM, FWS, USGS, NRCS, and State specialists, completed A Report on National Greater Sage-Grouse Conservation Measures in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats in the FWS listing action (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones (Figure 1-4). The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and

emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. ~~These WAFWA Management Zones are identified on **Figure 1-4** below.~~ http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

In 2012, FWS convened the Conservation Objectives Team (COT) of state and federal representatives to produce a peer-reviewed report which identified the principal threats to GRSG survival -- based upon the FWS 2010 listing decision -- and the degree to which these threats need to be reduced or ameliorated to conserve the GRSG so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The COT report also identified Priority Areas for Conservation (PACs) and emphasized that "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". Finally, the COT report identified present and widespread, as well as localized threats by GRSG population across the West. These population specific threats, as specified from the COT report, are outlined in **Table 1-2**. **Figure 1-4** from the COT Report identifies the PACs, GRSG populations (and their names), and WAFWA Management Zones across the West. http://www.fws.gov/greatersagegrouse/documents/COT-Report-with-Dear-Interested-Reader-Letter.pdf

[Insert **Figure 1-4** - GRSG Priority Areas for Conservation, Populations (and names), and WAFWA Management Zones.]

Additional science-based reviews by the US Geological Survey and related scientific literature provided further guidance on specific issues that arose in developing the ARMPAs.

To adequately address the reasons for the 2010 "warranted" determination by the FWS – and specific threats summarized in the COT report -- it was clear to the BLM that additional regulatory measures on federal public lands would be necessary to deal with present or threatened destruction, modification, or curtailment of habitat or range. These measures would need to be incorporated into land use plans that guide management actions on lands within the remaining range of the GRSG administered by the agencies to conserve GRSG such that listing under the ESA was no longer necessary.

In December 2011, the BLM published a Notice of Intent to prepare EISs and Supplemental EISs to incorporate GRSG Conservation Measures into Land Use Plans (LUPs) across the range of the species. A total of 15 sub-regional planning efforts (resulting in eight ARMPAs and nine ARMPs) would amend or revise 78 BLM RMPs ~~and 20 Forest LRMPs~~ across the range of the species.

The federal public land planning strategy reflected several key concepts:

- **Landscape-level**: The planning effort focused on the remaining habitat of the GRSG on public lands, covering 10 western states in the Great Basin and Rocky Mountain regions.
- **Best Available Science** – The ARMPAs/ARMPs are grounded in the best available science, drawn from published literature and input from recognized experts, state agencies, the US Geological Survey, the FWS and other sources. The COT report provided a "blueprint" for GRSG conservation by identifying specific threats to each remaining GRSG population and recommending measures to address each category of threat and the NTT report, prepared by the BLM, provided options for dealing with the most significant threats to the GRSG. A series of reports on how to improve efforts to reduce the threats of rangeland fire and invasive species prepared in collaboration with the Western Association of Fish and Wildlife Agencies also provided crucial guidance in formulating the conservation strategy.
- **Targeted, Multi-Tiered Approach** – The ARMPAs/ARMPs were designed to incorporate a layered management approach to avoid or minimize additional surface disturbance in the most valuable habitat, known as Priority Habitat Management Areas (PHMA), which are largely consistent with PACs identified in the COT Report. Within PHMA, the ARMPAs/ARMPs

Comment [KK10]: In this section we go back to talking about the whole planning area, not just the ARMPAs for Great Basin. Is this necessary? If it is, is it clear to the average reader that we have made that transition & what the difference is between ARMPA and ARMP?

provide an added level of protection to limit or eliminate new surface disturbance through the delineation of Sagebrush Focal Areas (SFA), derived from areas identified by the FWS as "strongholds" essential for the species' survival. In General Habitat Management Areas (GHMA), the ARMPAs/ARMPs seek to minimize disturbance while providing greater flexibility for land use activities.

- **Coordinated**: The BLM ARMPAs/ARMPs were developed through a joint planning process led by the BLM with the Forest Service as partners. The USFWS provided guidance and input throughout the process to aid land managers in understanding the threats and the certainty and effectiveness of proposed land management actions in addressing those threats. The USGS and NRCS also provided key technical and scientific support.
- **Collaborative**: The ARMPAs/ARMPs reflect the input of states and local stakeholders from the outset and were developed with the benefit of input from the individual states and cooperators who signed formal agreements with the BLM to provide input into the planning process. The Western Governors Association Sage Grouse Task Force (SGTF), which is discussed below, was particularly useful in facilitating this kind of collaborative input. The proposed LUPs reflect state and stakeholder developed approaches and economic priorities where consistent with conservation objectives.

Most states across the range provided recommendations for the management of the BLM lands in their state to conserve GRSG. In all cases, this input was incorporated into the range of alternatives analyzed in the Final EISs. Components of these state recommendations were used to develop the ARMPAs/ARMPs where consistent with conservation objectives.

In addition, the ~~Western Governors Association Sage Grouse Task Force~~SGTF was established in 2011 to identify and recommend state and federal conservation actions necessary to preclude the need for the GRSG to be listed under the ESA. This group, which includes designees from the 11 western states where GRSG is found as well as representatives from USFWS, BLM, Natural Resources Conservation Service, US Forest Service, US Geological Survey, and the Department of the Interior, played an integral role throughout this land use planning process.

1.5 Addressing Threats to the Greater Sage-Grouse through the ARMPA s

Comment [GSD11]: I talked to Jim yesterday about using the same three headers/categories we have used on other public and planning documents:

(1) Limiting or Eliminating Disturbance
(2) Improving Habitat Condition
(3) Fire

Comment [MEM12]: Reorganized – please see below.

The 2006 WAFWA *Greater Sage Grouse Comprehensive Conservation Strategy* stated goal for management of the GRSG was to "maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain these populations".[1] The NTT report also endorsed this goal "as a guiding philosophy against which management actions and policies of BLM should be weighed"[2] And, in establishing the COT, with the backing of the SGTF, FWS Director Dan Ashe affirmed the commitment to the goal for GRSG conservation originally articulated in the 2006 WAFWA report -- reversing negative population trends and achieving a neutral or positive population trend -- and emphasized the following,

> "The Service interprets this recommendation to mean that actions and measures should be put in place now that will eventually arrest what has been a continuing declining trend. Conservation

---

[1] WAFWA 2006 Strategy. The 2006 objectives built on an initial framework and commitment made by the WAFWA directors, the BLM and the FWS in 2000 with the signing of an interagency sagebrush/sage-grouse conservation MOU.

[2] Sage-grouse National Technical Team. "A Report on National Greater Sage-Grouse Conservation Measures". December 21, 2011.

> success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels."7

The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT stated, "[m]aintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". To achieve this, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT emphasized an "avoidance first strategy" and stressed that threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

The ARMPAs/ARMPs were developed to remove or reduce identified threats to the species and are an essential component of the effort to conserve GRSG and avoid a listing of the species under ESA. Across ten western States, the Great Basin and Rocky Mountain sub-regional ARMPs/ARMPAs contain updated land use plan direction on approximately 50 percent of the remaining habitat for the species. These ARMPAs/ARMPs are the product of extensive coordination between the BLM and the Forest Service and the active engagement of the USFWS in helping to inform land allocation and related management decisions by the BLM. The plans also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, and circumstances in each.

Comment [KK13]: Why is SGTF 11 if this is 10 – Washington state is included?

Designation of Habitat Management Areas

Comment [MEM14]: Let me know if you think I need to integrate this into this section better. I think it flows ok now.

In order to protect the most important GRSG habitat areas, the conservation strategy began with mapping areas of important habitat across the remaining range of the GRSG and within each state. In collaboration with state fish and wildlife agencies, the BLM identified areas as preliminary priority habitat ~~(PPH)~~ and preliminary general habitat ~~(PGH)~~. Maps were revised and refined as further mapping was conducted and state fish and wildlife agencies – often in collaboration with GRSG experts and researchers – provided more detailed analysis of habitat characteristics and populations. The ARMPAs reflect this input and have generally aligned these habitats with Habitat Management Areas in the ARMPAs. GRSG habitat management areas on BLM-administered lands in the decision area consist of lands allocated as Priority Habitat Management Areas (PHMA) which largely coincide with Priority Areas for Conservation in the COT report, General Habitat Management Areas (GHMA), Other Habitat Management Areas (OHMA, applicable only to the Nevada and Northeastern California), and Important Habitat Management Areas (IHMA, applicable only to Idaho). **Table 1-4** identifies surface acres of PHMA, GHMA, OHMA, and IHMA in the decision area for the Great Basin Region.

PHMA, GHMA, OHMA, and IHMA are defined as follows:

- **PHMA**— BLM-administered lands identified as having the highest value for~~to~~ maintaining sustainable GRSG populations. The boundaries and management strategies for PHMA are derived from and generally follow the Preliminary Priority Habitat boundaries identified in the Draft LUPA/EIS. Areas of PHMA largely coincide with areas identified as Priority Areas for Conservation in the COT report.
- **GHMA**— BLM-administered lands where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMA are derived from and generally follow the Preliminary General Habitat boundaries identified in the Draft RMP/EIS.
- **OHMA** —BLM-administered lands ~~only~~ in Nevada, identified as unmapped habitat in the Proposed RMP/EIS that are within the planning area and contain seasonal or connectivity habitat

areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse Habitat in Nevada and Northeastern California; Coates et al. 2014,) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.

- **IHMA** —BLM-administered lands in Idaho that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. ~~There are no IHMAs designated within southwestern Montana.~~ The IHMA boundaries and management strategies are derived from and generally follow the Preliminary Medial Management Area (PMMA) and Important Habitat Zone (IHZ) boundaries identified in Alternatives D and E, respectively, of the Draft LUPA/EIS, but may be modified based on the objectives of each alternative. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the ARMPA.

Table 1-4
Surface Acres of PHMA, GHMA, OHMA, and IHMA in the Decision Area for the Great Basin Region

BLM administered surface acres	PHMA	GHMA	OHMA	IHMA
Idaho and Southwestern MT	4,627,200	2,179,700	0	2,737,600
Utah	2,023,400	502,500	0	0
Oregon	4,547,000	5,660,150	0	0
Nevada and Northeastern CA	9,309,700	5,720,600	5,876,600	0
Total Acres	**20,507,300**	**14,062,950**	**5,876,600**	**2,737,600**

Source: BLM GIS 2015

The ARMPAs also identify Sagebrush Focal Areas (SFAs) on a portion of the landscape. SFAs are a subset of PHMAs (see **Figure 1-3** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas). Across the Great Basin Region, there are 9,076,948 acres of BLM administered SFAs. SFAs correspond to the areas identified by the FWS as GRSG "strongholds" as detailed in an October 27, 2014 memorandum from the FWS Director to BLM Director and Forest Service Chief in response to a request to "identify a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection" (http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf)

This tiered habitat framework provides for a nested or layered conservation design with the greatest protections and limited new surface disturbance in SFAs, a high degree of certainty that the integrity of PHMAs can be maintained through management decisions to avoid or minimize additional surface disturbance, and protection of remaining habitats in GHMAs, with more flexibility for land use activities that would be designed to minimize impacts on existing GRSG leks. In all GRSG habitat management areas, anthropogenic surface disturbing activities would be mitigated, and degraded landscapes, due to fire or other causes, would be actively restored and protected with a priority on SFAs, then PHMAs, and then GHMAs. The combination of habitat classifications and land allocation decisions in the ARMPAs will provide the greatest protection for those areas identified as SFAs and meet the stated objective for these areas "where it is most important that the BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species."

Comment [KK15]: ?? is this correct

Comment [KK16]: Just to confirm, IHMA & OHMA are never part of this hierarchy?

Major components of the attached ARMPAs ~~developed to~~that address the specific threats to the viability of the GRSG, as identified in the USFWS 2010 listing decision and COT Report (many of which were also identified by the BLM's NTT Report) are listed in **Table 1-3** and summarized below. Throughout the ARMPAs, a particular focus is placed on an "avoidance first strategy" as emphasized in the COT report by limiting new disturbance and maintaining current intact GRSG habitat. This avoidance first strategy is accomplished through identification and allocation of important GRSG habitat and excluding or avoiding surface disturbing activities, appropriately managing grazing, and aggressively suppressing fire that could degrade or fragment remaining GRSG habitat. The plans also include decisions to restore degraded habitat, which although more difficult and requiring a longer time frame, is important to the long-term viability of GRSG. Restoration decisions include specific habitat objectives, and a priority on treating GRSG habitat for invasive species, particularly cheatgrass, and encroaching pinyon and juniper. These decisions are reinforced by Secretarial Order 3336 and the *Integrated Rangeland Fire Management Strategy* which provide a framework, specific actions, and Department-wide priority on managing Federal lands, particularly in the Great Basin, to protect and restore sagebrush-steppe habitat.

Table 1-3
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
All threats	• Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met. • Require and ensure mitigation that provides a net conservation gain to GRSG and its habitat. • Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner. • Apply buffers necessary based on project type and location to address impacts on leks when authorizing actions in GRSG habitat. • Apply Required Design Features (RDFs) when authorizing actions that affect GRSG habitat. • Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.
All development threats, including mining, infrastructure, and energy development.	• PHMA: Implement an anthropogenic disturbance cap of 3% within the Biologically Significant Unit and proposed project analysis areas in PHMA (slight variations to this management component in the State of Nevada only) • PHMA: Apply a disturbance density cap of 1 facility per 640 acres (except in the State of Nevada)
Energy development—fluid minerals, including geothermal resources	• PHMA: Open to fluid mineral leasing subject to a No Surface Occupancy (NSO) stipulation without waiver or modification, and with limited exceptions. In SFAs, a NSO stipulation would be applied without waiver, modification, or exception. In Nevada only, in the portions of the PHMAs outside of SFAs, geothermal projects may be considered for

Table 1-3
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
	authorization if certain criteria is met. • GHMA: Open to fluid mineral leasing subject to Controlled Surface Use (CSU) and Timing Limitation (TL) lease stipulations (except in the State of Utah where some portions of GHMA are open with standard lease stipulations)
Energy development—wind energy	• PHMA: Exclusion area (not available for wind energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Avoidance area (may be available for wind energy development with special stipulations) (except in the States of Utah and Idaho, where these areas would open to wind energy development)
Energy development—solar energy	• PHMA: Exclusion area (not available for solar energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Exclusion area (not available for solar energy development under any conditions) (except in the States of Oregon and Montana where these areas are avoidance areas for solar energy development and the State of Idaho, where these areas would open to solar energy development)
Infrastructure—major ROWs	• PHMA: Avoidance area (may be available for major ROWs with special stipulations) • GHMA: Avoidance area (may be available for major ROWs with special stipulations) (except in the State of Utah where GHMA is open)
Infrastructure—minor ROWs	• PHMA: Avoidance area (may be available for minor ROWs with special stipulations)
Mining—locatable minerals	• SFA: Recommend withdrawal from the Mining Law of 1872
Mining—nonenergy leasable minerals	• PHMA: Closed area (not available for nonenergy leasable minerals)
Mining—salable minerals	• PHMA: Closed area (not available for salable minerals) with a limited exception (may remain open to free use permits and expansion of existing active pits if criteria are met)
Livestock grazing	• Prioritize the review and processing of grazing permits/leases in SFAs followed by PHMA. • The NEPA analysis for renewals and modifications of grazing permits/leases will include specific management thresholds, based on the GRSG Habitat Objectives Table, Land Health Standards and ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis. • Prioritize field checks in SFAs followed by PHMA to ensure compliance

Table 1-3
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
	with the terms and conditions of grazing permits.
Free-roaming equid management	• Prioritize gathers in SFAs, followed by other PHMAs. • Manage Herd Management Areas (HMAs) in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives. • Prioritize rangeland health assessment, gathers and population growth suppression techniques, monitoring, and review and adjustment of AMLs and preparation of Herd Management Area Plans in GRSG habitat.
Range management structures	• Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. • Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas subject to valid existing rights.
Recreation	• PHMA: Do not construct new recreation facilities unless required for health and safety purposes. • Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain. • PHMA & GHMA: OHV use limited to existing routes (routes to be designated through future travel management planning)
Fire	• Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection. • Prioritize post-fire treatments in SFAs, other PHMAs and GHMAs.
Nonnative, invasive plant species	• Improve GRSG habitat by treating annual grasses. • Treat sites in PHMA and GHMA that contain invasive species infestations through an integrated pest management approach.
Sagebrush removal	• PHMA: Maintain a minimum of 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover. • All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and/or juniper expansion	• Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.
Agricultural conversion and exurban development	• GRSG habitat will be retained in federal management.

Comment [KK17]: Matt, I am pointing out that I added this to the table – it was in redline in the last version from me & Jim, but since I moved the table I think the whole table was redline so I just want to be sure you see it.

The ARMPAs were developed based on three range-wide objectives for conserving and protecting habitat: minimizing new and additional surface disturbances, improving habitat conditions, and reducing threats of rangeland fire to GRSG and sagebrush habitat. How the ARMPAs met these objectives is summarized below.

1.5.1 Avoid and Minimize Surface Disturbance

Allocations and Habitat Protection/Surface Disturbance Measures

To avoid or minimize further surface disturbance in PHMAs the ARMPAs either close, exclude, or avoid major new surface disturbing activities. In SFAs, in addition to PHMA decisions described below and shown in **Table 1-3**, ARMPAs apply a no surface occupancy stipulation with no exceptions for oil and gas leasing and recommend these areas for withdrawal from future locatable mineral entry.

The four Great Basin ARMPAs provide land use allocations and management guidance for PHMAs to avoid new disturbance and minimize any disturbance associated with projects that might be developed in PHMA in the future. Allocations to avoid and minimize additional disturbance in PHMA include, fo~~i~~r example, the application of a no surface occupancy (NSO) stipulation associated with any future leasing and development of oil and gas in PHMAs. With the exception of a few areas in Utah and in eastern Nevada, there is low potential for fluid minerals in the Great Basin Region.

Similarly, mineral development is closed in PHMAs for non-energy leasable minerals and saleable minerals, ~~with the exception of~~but not for locatable minerals governed under the 1872 Mining Act. An exception is granted for free use permits and the expansion of existing active pits for ~~mineral~~ saleable minerals ~~material sales~~ and expansion of existing non-energy leasable development. Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses this threat. In Utah, at the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. PHMA is essential habitat for maintaining GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).

In all PHMAs in the Great Basin Region, renewable energy development (solar and wind) is excluded, with the exception of three areas in southeastern Oregon where an avoidance allocation is applied; and new rights of way and development for transmission lines, pipelines, and related infrastructure is avoided through restrictions on land use authorizations. Where the allocation is avoidance, exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs, unless the development results in a net conservation gain to the GRSG or its habitat.

While restrictions on future development in PHMA are intended to avoid or minimize additional surface disturbance, restrictions on development in GHMA are less stringent and can accommodate a limited amount of disturbance. Disturbance associated with oil and gas development, for example, is subject to a controlled surface use and timing limitation stipulation rather than an NSO stipulation see **Table 1-3** for more details on GHMA management decisions. However, any disturbance is subject to mitigation and should seek to first avoid and then minimize any impacts to GRSG or its habitat, while offsetting unavoidable impacts to a standard that produces a net conservation gain for the species. As noted in the COT report, "Conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur. …If development or vegetation manipulation activities

Comment [KK18]: Are these subheaders needed or can we just let this section flow from paragraph to paragraph?

Comment [KK19]: I changed this so we used the same name as the previous sentence & Table 3.

Comment [GSD20]: What is the relevance of this statement, do we not have the coal language in the other plans?

Comment [MEM21]: Because energy development is a present and widespread threat to certain populations in UT, I thin k its important to state this. We can remove if needed.

Comment [GSD22]: Do we need to explain why OR is different here or somewhere else?

Comment [KK23]: Is this three areas or three counties?

Comment [MEM24]: This should be addressed in section 1.6. May need assistance with this rationale.

outside of PACs are proposed, the project proponent should work with federal , state or local agencies and interested stakeholders to ensure consistency with sage-grouse habitat needs."

In addition to areas where uses are closed, excluded or avoided, the ARMPAs direct the BLM to proactively prioritize oil and gas leasing and development outside of identified SFAs, PHMAs, and GHMAs in order to encourage new development in areas that would not conflict with GRSG and thus maximize the potential to limit disturbance to remaining GRSG habitat. This approach will also assist developers in reducing the time and cost associated with oil and gas leasing development by avoiding sensitive areas and decreasing the need for compensatory mitigation.

In general, all forms of new development would be closed, excluded, avoided, or developed only if the resultant effect is a net conservation gain to the GRSG or its habitat, assuring that existing habitat would be protected and providing opportunities through compensatory mitigation to restore degraded habitats. This is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0*, published by the FWS in September 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse." In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation gain for the GRSG.

In addition to major surface disturbing activities such as energy and infrastructure development, the ARMPAs address other activities, including grazing, wild horse and burro management, and recreation. Grazing is the most widespread use of the sagebrush steppe ecosystem in the Great Basin Region. The COT Report recommendation for grazing states, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage-grouse (e.g. shrub cover, nesting cover)." To ensure that grazing continues in a manner consistent with the objective of conserving the GRSG and its habitat, the four Great Basin ARMPAs require the incorporation of GRSG seasonal habitat objectives into grazing permits, consistent with the ecological site potential of the local areas, prioritize the review and monitoring of grazing permits, and take numerous actions to avoid and minimize the impacts of range management structures (see **Table 1-3**).

To address the localized threat due to negative influences of grazing by free-roaming equids (wild horses and burros (WHB)), the BLM will focus on meeting and maintaining WHB Herd Management Areas in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives, including completing rangeland health assessments, prioritizing gathers and population growth suppression techniques, and developing or amending Herd Management Area plans to incorporate GRSG habitat objectives and management considerations. In SFAs and PHMA, the BLM will assess and adjust AMLs through the NEPA process within HMAs when WHBs are identified as a significant causal factor in not meeting land health standards, even if current AML is not being exceeded.

Comment [KK25]: Don't think we can just say maintaining since most are currently over AML

Comment [JRL26]: Should we make note of commitment to bring all SFAs to AML by 2020?

Comment [MEM27]: The 2020 deadline is not mentioned as a management action in the ARMPAs. The language as presented is within all 4 ARMPAs.

To ameliorate the threat from recreational activities, new facilities or expansion of existing facilities (e.g., roads, trails, campgrounds) will not be authorized in PHMA unless the development results in a net conservation gain to GRSG its habitat. In PHMA and GHMA travel would be limited to vehicle routes. Initially, vehicles would be limited to existing routes until implementation travel management planning could be completed to designate routes. Travel management plans, including route inventories, NEPA analysis, and route designation will be completed in a subsequent public planning process.

Disturbance Caps, Density Caps, and Lek Buffers

In addition to the management actions and allocations discussed in detail in the sections above, the ARMPAs limit the amount of anthropogenic disturbances in PHMAs through the use of disturbance caps, density caps and lek buffers. These elements further address threats related to surface disturbances by limiting the amount of habitat impacted and keeping uses away from leks. In general, disturbance caps of 3% were established in accordance with the recommendations contained in the COT report. ~~i~~If the 3% anthropogenic disturbance is exceeded on lands (regardless of land ownership) within PHMA in any given Biologically Significant Unit (BSU), no further discrete anthropogenic disturbances (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.) will be permitted within PHMAs in that Biologically Significant Unit. If the disturbance cap is exceeded on all lands (regardless of land ownership) within a proposed project analysis area in a PHMA, then no further anthropogenic disturbance will be permitted until disturbance in the proposed project analysis area has been reduced to be under the cap (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.). The ARMPAs have a few modifications to the disturbance cap: Oregon does not allow more than 1% new anthropogenic disturbance per decade, not to exceed 3% disturbance at any time. In Nevada, exceeding a 3% disturbance cap can occur at the BSU and/or the project level as long as the outcome results in a net conservation benefit as approved by the BLM in accordance with the process described in **Section 1.6**.

Comment [KK28]: Added a sentence to tie this section back to the threats it is addressing.

~~Limiting Density of Disturbance~~

The ARMPAs incorporate a cap on the density of energy and mining facilities to encourage consolidation of structures and to reduce habitat fragmentation. The cap is set at an average of one facility per 640 acres in PHMA in a project authorization area, consistent with guidance contained in the NTT report. If the disturbance density in the PHMA in a proposed project area is on average less than 1 facility per 640 acres, the analysis will proceed through the NEPA process incorporating mitigation measures into an alternative. If the disturbance density is greater than an average of 1 facility per 640 acres, the proposed project will either be deferred until the density of energy and mining facilities is less than the cap or co-located into an existing disturbed area, subject to applicable laws and regulations, such as the 1872 Mining Law, valid existing rights, etc. The one facility per 640 density decision does not apply to Nevada, as described in **Section 1.6**.

~~Buffering Development Impacts~~

The ARMPAs require that impacts to leks be evaluated for actions requiring NEPA analysis. In addition to any other relevant information determined to be appropriate (e.g. State wildlife agency plans), the BLM will assess and address impacts from certain activities using the lek buffer-distances as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). The lek buffer distances required vary by type of disturbance (road, energy development, infrastructure, etc.) and are fully described in Appendix X of the ARMPAs.

The lek buffer distances will be applied as required conservation measures to fully address the impacts to leks as identified in the NEPA analysis. Impacts should be avoided by locating the action outside of the applicable lek buffer-distance(s) as defined in the ARMPAs. In PHMA, if the action cannot be located outside of the buffer-distance, the BLM may approve actions in PHMAs that are within the applicable lek buffer-distance only if a different buffer distance offers the same or greater level of protection to GRSG and its habitat. In GHMAs actions may be approved within the applicable lek buffer distance only if a different distance offers the same or a greater level of protection to GRSG and its habitat, including conservation of seasonal habitat outside of the analyzed buffer area; or impacts to GRSG and its habitat are minimized such that the project will cause minor or no new disturbance (ex. co-location with existing authorizations) and any residual impacts within the lek buffer-distances are addressed through compensatory mitigation measures sufficient to ensure a net conservation gain.

Required Design Features

Required Design Features (RDFs) and Best Management Practices (BMPs) are required for certain activities in all GRSG habitat, including PHMA, GHMA, IHMA in Idaho and OHMA in Nevada. RDFs establish the minimum specifications for certain activities to help mitigate adverse impacts. However, the applicability and overall effectiveness of each RDF cannot be fully assessed until the project level when the project location and design are known. Because of site-specific circumstances, some RDFs may not apply to some projects (e.g., a resource is not present on a given site) and/or may require slight variations (e.g., a larger or smaller protective area). RDFs and BMPs have been developed for oil and gas development, infrastructure, range developments, and other surface disturbing activities and are fully described in Appendix X of the ARMPAs.

1.5.2 Improving Habitat Conditions

In addition to improving management of resource uses and avoiding further surface disturbance, the ARMPAs identify management actions to promote the restoration and improvement of GRSG habitat. The ARMPAs ~~also~~ describe a mitigation program, which follows the avoid, minimize, and compensate mitigation hierarchy. (See **Section 5** for more information.) Where compensatory mitigation is required to offset unavoidable impacts, habitat restoration activities will be developed in coordination with the states, to provide ~~for habitat restoration activities that produce~~ a net conservation gain for the GRSG.

~~In addition to improving management of resource uses and avoiding further surface disturbance, the ARMPAs identify management actions to promote the restoration and improvement of GRSG habitat~~, Decisions related to improving and restoring habitat particularly address~~ing~~ the threats of invasive species, pinyon and juniper expansion, as well as climate change. As with the management of uses, habitat management, restoration, and improvement action is prioritized first in SFAs, followed by PHMA, and then GHMA.

The ARMPAs ~~also~~ specify habitat objectives necessary for GRSG, used both to evaluate grazing and wild horse and burro management and for restoration purposes. These habitat objectives were developed for each of the GRSG's life history stages based on the ecology within each ARMPA's sub-region. These objectives will be used to meet the applicable land health standard in GRSG habitats. They also include maintaining a minimum of 70% of lands capable of producing sagebrush with 10-30% canopy cover, and address species richness and composition, as well as meeting land health standards considering the ecological potential for the site. These habitat objectives are a core component of the adaptive management and monitoring strategy (see section 6 for more information). The ARMPA adaptive management and monitoring strategy provides for specific monitoring of GRSG and its habitat. The data collected is used to evaluate the effects of authorized uses, restoration, and other activities to determine if unexpected impacts to GRSG are occurring that require changes to management to meet the objectives.

The ARMPAs also include specific decisions to improve habitat conditions and meet the habitat objectives related to treatment and removal of invasive annual grasses and the removal of

Comment [MEM29]: Should we add a reference to adaptive management and monitoring?

Comment [KK30]: This section did not quite flow, so I reworked it a bit

Comment [KK31]: Tying adaptive management and monitoring to this section . . .

encroaching pinyon juniper in SFA, PHMA, and GHMA, and restoration of degraded landscapes, including those impacted by fire events. ~~and post-fire restoration.~~

With regard to the threat of climate change, the proposed ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the *Integrated Rangeland Fire Management Strategy* will further this effort. The Fire and Invasives Assessment Team (FIAT) assessments that inform that ARMPAs and supported the development of the *Integrated Rangeland Fire Management Strategy* are specifically designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). Additionally, by limiting or eliminating anthropogenic surface disturbance, especially in the SFAs, ensuring the integrity of the PHMAs, and restoring habitat through fuels management, post-fire restoration, and mitigation efforts, connectivity and availability of sagebrush habitat are expected to increase thus contributing to increased climate resilience.

1.5.3 Reducing Threats of Rangeland Fire to GRSG and Sagebrush Habitat

To ameliorate the threat from fire, the ARMPAs seek to fight the spread of cheatgrass and other invasive species, position wildland fire management resources for more effective rangeland fire response, and accelerate the restoration of fire-impacted landscapes to native grasses and sagebrush. Prescribed fire will not be used unless necessary to facilitate site preparation for restoration of GRSG habitat. The BLM *Greater Sage Grouse Invasive Annual Grasses & Conifer Expansion Assessment* (FIAT 2014) modeled conifer expansion for PACs to provide an initial stratification to determine where conifer removal would benefit important sagebrush habitats. This information is being used to identify and design projects to change vegetation composition and/or structure to modify potential fire behavior for the purpose of improving fire suppression effectiveness and limiting fire spread and intensity due to invasive grasses and conifer encroachment. Consistent with this assessment, the BLM ARMPAs include management actions to remove invading conifers and other undesirable species, and prioritize vegetation treatments closest to occupied GRSG habitats and near occupied leks. Through guidance in the proposed ARMPAs supplemented by the *Integrated Rangeland Fire Management Strategy*, a commitment has been made to address the invasion and expansion of cheatgrass, medusa head, and other invasive grasses through expanded efforts to treat impacted acres and to accelerate and expand efforts to restore lands impacted by fire with native grasses and sagebrush seedlings. Efforts are underway to increase the acreages to be treated with chemical and biological agents to kill and stem the spread of invasive species and to accelerate the registration of other biologicals useful in addressing the threat of cheatgrass invasion.

In addition to and complementing the ARMPAs described in this ROD, Secretarial Order 3336 on Rangeland Fire made clear that "**protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, priority GRSG habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department".** (emphasis added) The strategy places a Departmental priority on activities to prevent, suppress, and restore fire-impacted landscapes in areas identified by the Fire and Invasives Assessment Tool (FIAT) in priority habitat, using recent information derived from a report prepared by WAFWA to assist in addressing the threat of rangeland fire. The FIAT process, applying recent science, identified highly resistant and resilient landscapes to target fire management activities to these most important lands. In addition, through the issuance of a Leaders' Intent letter, signed by the Secretaries of Agriculture and the Interior, rangeland fire was identified as an "additional priority" for the firefighting community in making strategic decisions with regard to the allocation of resources for firefighting in 2015. Additional resources have been allocated and will be targeted to fuel treatments (including invasive species control), suppression (through the prepositioning of fire-fighting resources and the training of additional Rural Fire Protection Associations, local volunteer firefighters, and veteran fire fighters), and habitat restoration in these areas. Firefighting assets (aircraft, firefighters and related equipment) will be located near areas of high priority for rangeland fire.

1.6 Unique Aspects of the Great Basin ARMPAs

Comment [MEM32]: Still need input from Sarah G here related to the rationale as to why these differences exists.

The ARMPAs and their associated environmental impact statements were developed through four ~~separate~~ planning efforts across the Great Basin Region (as described in **Section 1.1**). A landscape approach was used to create cohesive management across the range of GRSG, while also using the subregional plans to accommodate differences in resource conditions, degree of threats, and state management approaches. ~~BLM's land use planning process is a highly collaborative process, involving local cooperating agencies, stakeholders, and members of the public. As a result of conducting four separate planning efforts, each sub-region received unique comments and feedback from their differing cooperating agencies, stakeholders, and interested members of the public. These comments were used to develop the ARMPAs and as a result, the management direction presented in each of the attached ARMPAs addresses sub-regional conditions and management. In addition, a~~As a result of the varying subregional threats, ~~that were presented to local populations~~ (refer to Table 1-2), conditions, and management, each sub-region, in collaboration with their local cooperators and considering public comments, adapted the range-wide landscape approach to address these differences while ~~crafting different approaches to~~ meeting the overall purpose~~d~~ and need to conserve, enhance, and restore GRSG and their habitats. Below is a brief description of the unique aspects of each of the Great Basin sub-regional ARMPAs.

Idaho and Southwestern Montana

The Idaho and Southwestern Montana ARMPA adopted specific aspects of the State of Idaho's Conservation Plan for GRSG. The most important varying aspect adopted from the State's plan is a third tier of habitat management area, Important Habitat Management Areas (IHMA). IHMA are BLM-administered and National Forest System lands that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. This three-tiered approach also serves as the foundation for an adaptive management approach that includes habitat and population hard and soft triggers in areas most valuable to the GRSG and the shifting of IHMA to PHMA when triggers are hit. The Idaho ARMPA also includes a slightly different disturbance calculation, as described in Appendix X of the attached Idaho and Southwestern Montana ARMPA. The ARMPA ~~also~~ applies land use planning allocation decisions for certain distances from leks, which is a deviation from the other Great Basin ARMPAs.

Comment [KK33]: I think we should be more explicit about this & state clearly how it differs; this sentence is a bit opaque

Nevada and Northeastern California

The Nevada portion of the Nevada and Northeastern California ARMPA adopts key elements of the State of Nevada Greater Sage-Grouse Conservation Plan (State of Nevada 2014) and the State of Nevada Conservation Credit System (Nevada Natural Heritage Program and Sagebrush Ecosystem Technical Team 2014) by establishing conservation measures and focusing restoration efforts in the same key areas most valuable to the GRSG. Additionally, other unique aspects of the Nevada and Northeastern California ARMPA includes an NSO exception to geothermal leasing and development and a separate Disturbance Management Protocol (DMP) that is intended to provide for a 3% limitation on disturbance, except in situations where a biological analysis indicates a net conservation gain to the species will be achieved, with concurrence from the BLM, State of Nevada, and FWS. The Nevada and Northeastern California ARMPA also does not have density cap, which is present in the three other Great Basin Region ARMPAs.

Utah

The Utah ARMPA adopts the key elements of the GRSG conservation plans or directives developed by the State of Utah (Conservation Plan for Greater Sage-Grouse in Utah) and the State of Wyoming (Executive Orders 2011-05 and 2013-3), which establishes unique conservation measures for protecting GRSG and also focuses restoration within key areas most valuable to GRSG. Additionally, within GHMA, the Utah ARMPA allows for wind energy and high voltage transmission ROW development (consistent with the mitigation framework for the ARMPA), as well as oil and gas development, which is open with standard constraints. Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses this threat. In Utah, at the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. PHMA is essential habitat for maintaining GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).

Oregon

The Oregon ARMPA adopts key elements of the Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat (Hagen 2011) which establishes unique conservation measures for protecting GRSG and also focuses restoration within key areas most valuable to GRSG. Also, three areas in southeastern Oregon within PHMA are not designated as exclusion areas to solar and wind energy development, but are instead avoidance areas to these types of development.

Comment [KK34]: Counties?

1.7 Summary of the BLM's National GRSG Planning and Conservation Strategy

Pending

Comment [MEM35]: Deciphering whether or not this is needed. If needed, Jim will formulate based on the LR summary.

2. DECISION

2.1 Summary of the Approved Management Decisions

The decision is hereby made to approve the Great Basin Region Greater Sage-Grouse ARMPAs for the Great Basin Region Greater Sage-Grouse Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah (attachments A, B, C, and D). This ROD serves as the final decision establishing the land use plan amendment decisions outlined in the ARMPAs and is effective on the date it is signed. No further administrative remedies are available for these land use plan decisions.

The decisions included in this ROD and attached ARMPAs amend the land use plans described in **Sections 1.1** of attachments A, B, C, and D. This ROD and ARMPAs become effective on the date this ROD is signed. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

The land use decisions provide conservation measures to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Land use plan decisions are expressed as goals and objectives (desired outcomes), and allocations, allowable uses, and management decisions anticipated to achieve desired outcomes. Although decisions identified in the ARMPAs are final and effective upon signing of this ROD, they generally require additional implementation decision steps before on-the-ground activities can begin. Subsequent NEPA analysis will be conducted, as necessary, for such implementation decisions.

2.2 What the Record of Decision and Approved Resource Management Plan Amendments Provide

The ARMPAs include GRSG and GRSG habitat land use plan level management decisions in the form of:

- Goals
- Objectives (Desired Future Conditions)
- Land Use Allocations and Allowable Uses
- Management Actions

Goals are the broad statements of desired outcomes, and are usually not quantifiable.

Objectives are specific desired conditions, usually quantifiable and measurable, and may have timeframes for achievement.

Land use allocations specify locations within the planning area that are available or not for certain uses and are also used prioritize conservation and restoration management actions. These include decisions such as what lands are available for livestock grazing, mineral material use, oil and gas leasing, and locatable mineral development, what lands may be available for disposal via exchange and/ or sale, and what lands are open, closed, or limited to motorized travel (please note that all acreages presented in the Approved Plan are estimations even when presented to the nearest acre).

Management actions include those provisions that help in meeting the established goals and objectives and include measures that will be applied to guide day-to-day activities on public lands..

The ARMPAs' management decisions were crafted to alleviate identified threats to GRSG and their habitats (see **Section 1.5**).

2.3 What the Record of Decision and Approved Resource Management Plan Amendments Do Not Provide

The attached ARMPAs do not contain decisions for public lands outside of GRSG habitat management areas, except for travel management decisions in the Idaho and Southwestern Montana ARMPA.

The ARMPAs do not affect valid existing rights.

The ARMPAs do not contain decisions for the mineral estates of lands located in the planning area for lands under the jurisdiction of other Federal agencies such as the Forest Service, or for private or State-owned lands and minerals that are not administered by the BLM. In addition, many decisions are not appropriate at this level of planning and are not included in the ROD. Examples of these types of decisions include:

- *Statutory requirements.* The decision will not change the BLM's responsibility to comply with applicable laws, rules, and regulations.
- *National policy.* The decision will not change BLM's obligation to conform to current or future National policy.
- *Funding levels and budget allocations.* These are determined annually at the National level and are beyond the control of the State/District of Field offices.

Implementation decisions (or activity-level decisions) are management actions tied to a specific location. Implementation decisions generally constitute the BLM’s final approval allowing on-the-ground actions to proceed and require appropriate site-specific planning and NEPA analysis. Such decisions may be incorporated into implementation plans (activity or project plans) or may exist as stand-alone decisions. These ARMPAs do not contain implementation decisions. Future activity-level plans will address the implementation of the ARMPAs. Implementation decisions and management actions that require additional site-specific project planning, as funding becomes available, will require further environmental analysis.

2.4 Modifications and Clarifications

During preparation of the ARMPAs for all four sub-regions, minor changes were made to the Proposed RMP Amendments to correct errors and to clarify decisions. Clarifications and corrections made since the Proposed RMP Amendments were published on May 29, 2015 are hereby adopted by this ROD.

2.4.1 Modifications and Clarifications by Sub-region

Modifications and clarifications are summarized below for each of the sub-regional ARMPAs.

Idaho and Southwestern Montana

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Nevada and Northeastern California

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Oregon

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Utah

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

2.4.2 Protest Resolution

BLM's planning regulations at 43 CFR 1610.5-2 allow any person who participated in the planning process and has an interest that may be adversely affected by BLM's planning decisions to protest proposed planning decisions within 30 days from the date the Notice of Availability of the Proposed RMPA/Final EIS was published in the Federal Register (May 29, 2015). Below are descriptions of the protest resolution process for each of the four sub-regional PRMPAs/FEISs.

These decisions are final for the Department of the Interior. With the exception of the granted protest issues, the Director concluded that the BLM followed the applicable laws, regulations, and policies and considered all relevant resource information and public input in developing the Proposed Land Use Plan Amendments/Final EISs. Each protesting party will be notified in writing of the Director’s findings and the disposition of their protests. The BLM Director resolved the protests without making significant changes to the Proposed Land Use Plan Amendments/Final EISs, though minor clarifications were made and are summarized in Section 2.5.1.

Idaho and Southwestern Montana

For the Idaho and Southwestern Montana GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director’s decisions on the protests are summarized in the “Director’s Protest Resolution Report, Idaho and Southwestern Montana GRSG Proposed RMP Amendment/Final EIS,” released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Nevada and Northeastern California

For the Nevada and Northeaster California GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Nevada and Northeastern California Sub-Regional GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Oregon

For the Oregon GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Oregon GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Utah

For the Utah GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Utah GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

2.4.3 Governors Consistency Review

The BLM's planning regulations require that RMPs be "consistent with officially approved or adopted resource-related plans, and the policies and procedures contained therein, of other federal agencies, state and local governments, and Indian tribes, so long as the guidance and RMPs also are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands" (43 CFR 1610.3-2(a)). The general requirement in FLPMA/planning regulations is to coordinate the land use planning process with plans of other agencies, states, and local governments to the extent consistent with law (see FLPMA s. 202(c)(9) and 1610.3-1(a)); and the respective duties to be consistent with both officially approved or adopted plans (to the extent those plans are consistent with federal law, or to maximum extent practical) (see 1610.3-2(a)(b)). In accordance with FLPMA, the BLM was aware of and gave consideration to state, local, and tribal land use plans and provided meaningful public involvement of the Proposed RMP Amendments/Final EISs.

The BLM is aware that there are specific state laws and local plans relevant to aspects of public land management that are discrete from, and independent of, federal law. However, the BLM is bound by federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that BLM's land use plans be consistent with officially-approved state and local plans only if those plans are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands. Where officially-approved state and local plans or policies and programs conflict with the purposes, policies, and programs of federal law applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially-approved state and local policies and programs (as opposed to plans), this consistency provision only applies to the maximum extent practical. While county and federal planning processes, under FLPMA, are required to be as integrated and consistent as practical, the federal agency planning process is not bound by or subject to state or county plans, planning processes, policies, or planning stipulations.

In some instances, modifications to the Proposed RMP Amendments were addressed based on recommendations submitted to the BLM by the applicable states. These modifications to the ARMPAs are summarized below by sub-region and are now part of the attached ARMPAs.

Idaho and Southwestern Montana

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Nevada and Northeastern California

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Oregon

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Utah

Will need to populate the "X" areas towards the end of the GCR process (end of July).

3. ALTERNATIVES

3.1 Alternatives Considered

Each of the Great Basin sub-regional planning efforts analyzed in detail a set of alternatives in the draft and final sub-regional EISs. The alternatives were developed to provide direction for resource programs influencing land management for the protection and enhancement of GRSG and its habitat. All management under any of the alternatives complied with federal laws, rules, regulations, and policies.

Each alternative emphasized an altered combination of resource uses, allocations, and restoration measures to address issues and resolve conflicts among uses so that GRSG goals and objectives were met in varying degrees across the alternatives. The action alternatives offered a range of possible management approaches for responding to planning issues and concerns identified through public scoping, and to maintain or increase GRSG abundance and distribution in the planning area. While the land use plan goal was the same across alternatives for each sub-region, each alternative contained a discrete set of objectives and management actions constituting a separate RMP amendment. The goal was met in varying degrees, with the potential for different long-range outcomes and conditions.

The relative emphasis given to particular resources and resource uses differed as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs. When resources or resource uses are mandated by law there are typically few or no distinctions between alternatives.

3.1.1 Alternative A – No Action Alternative

Alternative A meets the CEQ requirement that a No Action Alternative be considered. This alternative continues current management direction derived from the existing field/district office RMPs, as amended. Goals and objectives for resources and resource uses are based on the most recent RMP decisions, along with associated amendments and other management decision documents. Laws, regulations, and BLM policies that supersede RMP decisions would apply.

Goals and objectives for BLM-administered lands and mineral estate would not change. Appropriate and allowable uses and restrictions pertaining to activities such as mineral leasing and development, recreation, construction of utility corridors, and livestock grazing would also remain the same. The BLM would not modify existing or establish additional criteria to guide the identification of site-specific use levels for implementation activities.

This alternative was not selected as the ARMPAs because it did not meet the purpose and need of this plan amendment. This alternative did not include changes that are needed to be made to the existing decisions based on the USFWS 2010 listing petition decision that identified inadequacy of regulatory mechanisms as a significant threat to GRSG and its habitat. This alternative did not incorporate the best available science pertaining to GRSG or its habitat.

3.1.2 Alternative B: National Technical Team Report Alternative

Alternative B was based on the conservation measures contained within the National Technical Team (NTT) Report. The GRSG National Technical Team (NTT), comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed *A Report on National Greater Sage-Grouse Conservation Measures* in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. The Report can be accessed at: http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

The BLM's Washington Office Instructional Memorandum (IM) Number 2012-044 directed the sub-regional planning efforts to analyze the conservation measures developed by the NTT, as appropriate, through the land use planning process and NEPA.

Alternative B would exclude ROW development in PHMA and avoid development in GHMA, would close PHMA to fluid mineral leasing, mineral material sales, and nonenergy leasable minerals, and would recommend withdrawal from locatable mineral entry in all PHMA. These management actions would reduce surface disturbance in PHMA and would minimize disturbance in GHMA, thereby maintaining GRSG habitat. Management actions for wildfire would focus on suppression in PHMA and GHMA, while limiting certain types of fuels treatments. Vegetation management would emphasize sagebrush restoration. Collectively, vegetation and wildfire management would conserve GRSG habitat. Grazing would continue with similar impacts under Alternative B as under Alternative A. The best management practices (BMPs) proposed in the NTT report would be included as required design features as part of Alternative B and are listed in Appendix X, Required Design Features (RDFs), of each of the attached ARMPAs.

This alternative was not selected in its entirety as the ARMPAs because the majority of the conservation measures in the NTT Report, as appropriate and applicable, were applied primarily to PHMA, and few conservation measures in the Report were provided for in GHMA. As a result, most management actions in GHMA reverted back to the No Action Alternative, which was found to not meet the purpose and need for the Amendments.

3.1.3 Alternative C: Citizen Groups' Recommended Alternative One

Alternative C was based on a citizen groups' recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and was applied to all occupied GRSG habitat (PHMA and GHMA. Alternative C limited commodity development in areas of occupied GRSG habitat, and closed or excluded large portions of the planning area to many land uses. This included all PHMA and GHMA as being closed to livestock grazing, recommended for withdrawal from locatable mineral entry, closed to fluid mineral leasing, closed to salable mineral and non-energy leasable mineral development, and exclusion areas for right-of-ways. The Utah LUPA/Draft EIS combined this alternative with Alternative F (discussed below).

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which, based on best available science, is not required to conserve GRSG and its habitats. Alternative C was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.4 Alternative D: Draft RMP Amendments' Preferred Alternative

Alternative D, which was identified as the Preferred Alternative in the Draft EISs, balanced opportunities to use and develop the planning area as well as conserving, maintaining, and enhancing GRSG and their habitat. Protective measures were applied to GRSG habitat, while still allowing for anthropogenic disturbances with stringent mitigation measures. This alternative represents the mix and variety of management actions based on BLM's analysis and judgment, which best resolve the resource issues and management concerns while meeting laws, regulations, and policies pertaining to BLM management. As a result of public scoping comments, internal review, and cooperating agency coordination on the Draft RMP Amendments/EISs, this alternative was modified to become the Proposed RMP Amendments and analyzed in the FEISs. The Preferred Alternatives, with slight variations, became the Proposed Plans in the FEISs.

In PHMA under Alternative D, there would be limitation on disturbance in GRSG habitat by excluding wind and solar energy development (except for certain counties in Southeastern Oregon where avoidance is applied), avoiding all other ROW development, applying no surface occupancy stipulations to fluid mineral development, and closing PHMA to nonenergy leasable mineral development and mineral material sales. These management actions would protect GRSG habitat, while allowing other activities, subject to conditions. In GHMA under Alternative D, allocations are less stringent, but still aim to protect GRSG habitat (for example, applying moderate constraints and stipulations to fluid minerals in GHMA).

Under Alternative D, the BLM management would support sagebrush/perennial grass ecosystem restoration, would increase fire suppression in PHMA and GHMA, and would manage livestock grazing to maintain or enhance sagebrush and perennial grass ecosystems.

3.1.5 Alternative E: State/Governor's Alternative

Alternative E is the alternative provided by the State or Governor's offices for inclusion and analysis in the EISs. It incorporates guidance from specific state conservation strategies, if developed or recommendations from the state on management of Federal lands and emphasizes management of GRSG seasonal habitats and maintaining habitat connectivity to support population objectives. This alternative was identified as a co-Preferred Alternative in the Idaho and Southwestern Montana Draft EIS. California did not provide the BLM with a state GRSG conservation plan and under this alternative, reverted back to Alternative A, the no-action alternative.

For Nevada, Alternative E would apply an avoid, minimize, and mitigate strategy to reduce direct and indirect impacts on GRSG from surface-disturbing activities on BLM-administered lands. Effects on GRSG habitat from certain resource programs, such as grazing, lands and realty, wildfire management, and minerals, would not be directly addressed because allocation decisions were not part of the state's plan.

For Oregon, Alternative E contains GRSG conservation guidelines from Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat. This document describes the Oregon Department of Fish and Wildlife's proposed management of GRSG on Federal lands. It also provides guidance for public land management agencies and land managers for GRSG conservation. GRSG conservation guidelines in the state plan are designed to maintain (at a minimum) or enhance the quality (the optimum) of current habitats. The guidelines would also assist resource managers in achieving the population and habitat objectives of the state plan.

For Idaho, Alternative E incorporates proposed GRSG protection measures recommended by the State of Idaho. Management in Montana would remain unchanged from the current RMPs (Alternative A). Alternative E addresses the following primary threats: fire, invasive weeds, and infrastructure development. It also includes guidance for several secondary GRSG threats such as recreation, improper livestock grazing, and West Nile virus for BLM and Forest Service programs that affect GRSG or its habitat.

For Utah, the planning area includes all occupied GRSG habitat in Utah. Alternative E1 is based on the State of Utah's Conservation Plan for Greater Sage-Grouse in Utah and would apply to all BLM-administered lands in Utah. Alternative E1 was designed to eliminate the threats facing the GRSG while balancing the economic and social needs of the residents of Utah. Conservation measures would be applied to 11 areas that the state identified, called Sage-Grouse Management Areas (SGMAs). Emphasis would be placed on expanding GRSG habitat by aggressively treating areas where there are encroaching conifers or invasive species. Alternative E1 includes a general limit on new permanent disturbance of 5 percent of habitat on state or federally managed lands within any particular SGMAs. Occupied habitat outside of the state-identified SGMAs would not receive new management protection. They would continue to be managed according to the GRSG actions in existing RMPs and conservation measures associated with existing activity-level plans.

This alternative was not selected, in whole, as the ARMPAs because some components of the state's plans were not consistent with the purposes, policies and programs of Federal laws and regulations applicable to public lands. However, many goals, objectives, and management actions in the ARMPA were carried forward.

3.1.6 – Alternative F: Citizen Groups' Recommended Alternative Two

Alternative F is also based on a citizen group recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and defines different restrictions for PHMA and GHMA. Alternative F would limit commodity development in areas of occupied GRSG habitat, and would close or designate portions of the planning area to some land uses. This alternative does not apply to the Utah sub-regional planning effort, as it was combined with Alternative C. Under Alternative F, wildfire suppression would be prioritized in PHMA. Concurrent vegetation management would emphasize sagebrush restoration and enhancement. Alternative F would reduce livestock and wild horse and burro management utilization by 25 percent within PHMA and GHMA.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. Alternative F was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.7 – Proposed Plan Amendment

As a result of public comments, best science, cooperating agency coordination, and internal review of the Draft RMP Amendments/EISs, the BLM has developed the Proposed Amendments/Final EISs for managing BLM-administered lands. The Proposed Amendments/Final EISs focus on addressing public comments, while continuing to meet the BLM's legal and regulatory mandates. The Proposed Amendments/Final EISs are a variation of the preferred alternatives (Alternative D) and are within the range of alternatives analyzed in the DEISs. The Proposed Plans, with slight variations (as outlined in Section 2.5 of this ROD), became ARMPAs.

3.1.8 Environmentally Preferable Alternative Considered in all Sub-Regions

Council on Environmental Quality (CEQ) regulations require that a ROD state which alternatives were considered to be "environmentally preferable" (40 CFR 1505.2(b)). Question 6A of CEQ's 40 most-asked questions regarding CEQ's NEPA regulations defines that term to ordinarily mean the alternative which best protects, preserves, and enhances historic, cultural, and natural resources.

Under that definition, Alternative C, as presented in each of the sub-regional Proposed RMP Amendments/Final EISs is the most environmentally preferable. However, NEPA expresses a continuing policy of the federal government to "use all practicable means and measures…to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans" (Section 101 of NEPA).

3.2 Alternatives Considered But Not Analyzed in Detail

The alternatives listed below by sub-region were considered but were not carried forward for detailed analysis because of one or more of the following reasons:

- They would not meet the requirements of FLPMA or other existing laws and regulations;
- They did not meet the purpose and need;
- The alternative was already captured within the range of alternative analyzed in the EIS;
- They were already part of an existing plan, policy, or administrative function; or
- They did not fall within the limits of the planning criteria.

For additional rationale as to why each of the alternatives listed below by sub-region were not carried forward for detailed analysis, refer to Section 2.11of each of the sub-regional Proposed Amendments/Final EISs.

<u>Idaho and Southwestern Montana</u>

- USFWS-Listing Alternative
- Elimination of Recreational Hunting Alternative
- Predation Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Consideration of Coal Mining Alternative

<u>Nevada and Northeastern California</u>

- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Elko County Sage-Grouse Plan Alternative
- Increase Grazing Alternative

<u>Oregon</u>

- USFWS-Listing Alternative
- Elimination of Livestock Grazing from all BLM Lands Alternative
- Increase Livestock Grazing Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative

<u>Utah</u>

- USFWS-Listing Alternative
- Increase Livestock Grazing Alternative
- Make GRSG Habitat Available for Oil Shale and Tar Sands Alternative
- Citizen Proposed Alternatives (in their entirety)

- Adoption of the State of Utah's Sage-Grouse Management Areas as PHMA for all Alternatives
- Use of Other Habitat Maps Alternatives
- County Sage-Grouse Management Plans Alternative
- Conservation Objectives Team (COT) Report Alternative
- BLM Policies and Regulations Alternative

4. MANAGEMENT CONSIDERATIONS

The BLM is tasked to provide multiple use management for public lands by the Federal Land Policy and Management Act (FLPMA) and numerous other laws and regulations that govern the management of public lands. Due to the diversity of community needs and stakeholders affected by management of BLM lands, there has been both support and opposition to certain components of the Proposed Plans. BLM's objective in choosing the Proposed Plan Amendments as the ARMPAs was to address diverse needs and concerns in a fair manner and provide a practical and workable framework for management of public lands in GRSG habitat. The BLM is ultimately responsible for preparing these ARMPAs consistent with its legal mandates that reflect collective professional judgment using the best available science. The ARMPAs provide a balance between those reasonable measures necessary to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat to meet the purpose and need of these plan amendments, and the ongoing public need for use of the public lands within the Great Basin Region planning area.

The ARMPAs were selected because they will reduce or eliminate threats to GRSG at a landscape scale, improve and sustain properly functioning resource conditions, and consider needs and demands for existing or potential resource commodities and values. In the end, GRSG habitat will be managed by integrating ecological, economic, and social principles in a manner that safeguards the long term sustainability, diversity and productivity of the land.

In 2012, the FWS convened a Conservation Objectives Team (COT) of state and federal representatives to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The final, peer-reviewed COT Report provided a brief overview of the threats to the greater sage-grouse's survival based upon the FWS 2010 listing decision and an assessment of the extent to which these threats affected remaining GRSG populations. A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG in the Great Basin Region– as articulated in the COT report – is summarized in **Table 1-2**. **Table 1-3** provides a crosswalk between the threats to GRSG and their habitat identified in the COT Report and the key management responses from the ARMPAs that aim to ameliorate these threats.

5. MITIGATION MEASURES

In all GRSG habitat, in undertaking BLM management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the GRSG including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. Actions which result in habitat loss and degradation include ~~those identified as~~ threats which contribute to GRSG disturbance as identified by the FWS in its 2010 listing decision (75 FR 13910), COT report, and depicted in the ARMPAs' Monitoring Framework (which can be found in Appendix X of each of the attached ARMPAs). Mitigation will follow the regulations from the CEQ (40 CFR, Part 1508.20; e.g. avoid, minimize, and compensate). If impacts from BLM management actions and authorized third-party actions (which are consistent with the goals, objectives, and management actions in the attached ARMPAs) that result in habitat loss and degradation remain after applying avoidance and minimization measures (i.e., residual impacts), then compensatory mitigation projects would be used to provide a net conservation gain to the species. Any compensatory mitigation would be durable, timely, and in addition to what would have resulted without the compensatory mitigation (see the concepts of durability, timeliness, and additionality as described further in the Mitigation Strategy, which can be found in Appendix X of each of the attached ARMPAs).

All practical means to avoid or minimize environmental harm, specifically to GRSG and its habitat are encompassed in the attached ARMPAs and associated appendices. Mitigation measures, including the application of required design features have been identified.

The ARMPAs also identify the development of regional mitigation strategies, in partnership with the states, to guide and target mitigation to achieve the greatest benefit to GRSG and habitat conservation and restoration. Within 90 days of the issuance of the Record of Decision~~s~~, the BLM will establish a WAFWA Management Zone GRSG Conservation Team to develop a WAFWA Management Zone Regional Mitigation Strategy that will inform the NEPA decision making process including the application of the mitigation hierarchy for actions and third party authorizations that result in habitat loss and degradation. A robust and transparent Regional Mitigation Strategy will contribute to GRSG habitat conservation by reducing, eliminating, or minimizing threats and compensating for residual impacts to GRSG and its habitat. The mitigation strategy will be developed within one year of the issuance of the Record of Decision~~s~~.

6. PLAN MONITORING AND ADAPTIVE MANAGEMENT

Comment [MEM36]: Moved content from the original Section 1.5.3 to here. The CEQ regs do not state that "monitoring" needs to be a standalone, so I think we are ok here.

Plan Monitoring

Monitoring tied to the ARMPAs has two parts: (1) implementation monitoring (i.e., are decisions being implemented in a timely manner, are actions taken consistent with the plan decisions), and (2) effectiveness monitoring (i.e., are the decisions and implementation actions achieving the desired conservation goals). Through effectiveness monitoring, BLM can assess how decisions and actions impact GRSG habitat. Understanding the effectiveness and validating results of ARMPAs and management decisions is an important part of measuring performance under the Government Performance Results Act. For example, riparian condition is a primary measure for ARMPA effectiveness (see WO IM 2010-101). Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, size of patches, etc.). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by state wildlife agencies and other partners, will allow linking real or potential habitat changes (from both natural events and management actions) to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to ameliorate negative effects with appropriate conservation actions.

The BLM Assessment, Inventory, and Monitoring (AIM) Strategy (Toevs et al. 2011 and IB2012-080) describes a vision for integrated, cross-program assessment, inventory, and monitoring of resources at multiple scales of management. Following the AIM Strategy, the BLM is modernizing its resource monitoring approach to more efficiently and effectively meet local, regional, and national resource information needs. The AIM Strategy provides a process for the BLM to collect quantitative information on the condition, trend, amount, location, and spatial pattern of natural resources on the public lands. Each AIM-Monitoring survey, at any scale of inquiry (from the plot level to west-wide deployments), uses a set of core indicators, standardized field methods, remote sensing, and a statistically-valid study design to provide nationally-consistent and scientifically-defensible information to determine conditions (e.g., rangeland health) and trends on public lands.

Comment [KK37]: I think this can all be deleted and the first sentence can just flow into the next paragraph

The National-scale deployment of AIM, known as the Landscape Monitoring Framework (LMF), commenced in 2011 in coordination with NRCS, with the collection of 1,000 plots of field-collected monitoring data across the Western U.S. LMF aims to provide non-biased estimates of vegetation and soil condition and trend using a statistically balanced sample design across BLM lands. A group of GRSG habitat and sagebrush plant community subject matter experts from BLM, USFWS, WAFWA, NRCS, ARS, state wildlife agencies, and academia identified those vegetation indicators collected at LMF sampling points that inform GRSG habitat needs. The common indicators that were identified include: species composition, foliar cover, height of the tallest sagebrush and herbaceous plant, inter-canopy gap, percent of invasive species, sagebrush shape, and bare ground. To increase the precision of estimates of sagebrush conditions within the range of GRSG, additional plot locations in occupied GRSG habitat (Sage-grouse Intensification) were added in 2013. The common indicators are also collected on sampling locations in the NRCS Rangeland Monitoring Survey. The GRSG baseline data will be collected over a five year period and an annual report will be prepared describing the status of the indicators. Beginning in year six, the annual status report will be accompanied with a trend report which will be available on an annual basis thereafter contingent upon continuation of the current monitoring budget. This information, in combination with mapping information, mid-scale habitat suitability indicator measures, and sagebrush availability information will be used to assess the effectiveness of the planning strategy.

The BLM has made significant commitments in the ARMPAs to monitoring actions to conserve GRSG habitats at multiple scales. The results from the monitoring will inform the agencies of the effectiveness of efforts to reduce disturbance and restore seasonal habitats in priority areas, and of the status of the triggers set in the proposed LUPs for adaptive management. The BLM will report annually on the results of the monitoring efforts.

The BLM's Monitoring Framework can be found in Appendix X of each of the attached ARMPAs.

Adaptive Management

The ARMPAs include an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are not specific to any particular project, but identify habitat and population thresholds. Triggers are based on the two key metrics that are being monitored - habitat loss and/or population declines. Adaptive Management with specific triggers provide additional certainty that the regulatory mechanisms included in the ARMPAs are robust and able to respond to a variety of conditions and circumstances quickly and effectively to conserve GRSG habitat.

Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the ~~proposed LUPs~~ARMPAs, the BLM's response is to apply more conservative or restrictive conservation measures to mitigate for the specific causal factor in the decline of populations and/or habitats, with consideration of local knowledge and conditions. In each ARMPA, a soft trigger begins a dialogue between the state, FWS, and the BLM to see if the causal factor can be determined and what implementation-level activities can be used to reverse any trend. These adjustments will be made to preclude tripping a "hard" trigger (which signals more severe habitat loss or population declines).

Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the attached ARMPAs. In the event that new scientific information becomes available demonstrating that the hard trigger would be insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM ARMPAs, the BLM will immediately assess what further actions may be needed to protect GRSG and its habitat and ensure that conservation options are not foreclosed. This could include a formal directive such as an IM or a plan amendment, which, to the extent that it is supported scientifically, may be drawn from the range of alternatives analyzed in the development of the ARMPAs. ARMPA specific strategies can be found in Appendix X of each of the attached ARMPAs.

7. PUBLIC INVOLVEMENT, CONSULTATION AND COORDINATION

The BLM land use planning is conducted in accordance with NEPA requirements, CEQ regulations, and US Department of the Interior policies and procedures implementing NEPA, as well as specific BLM planning and NEPA policies. The NEPA and associated laws, regulations, and policies require the BLM to seek public involvement early in and throughout the planning process, to develop a range of reasonable alternatives to proposed actions, and to prepare environmental documents that disclose the potential impacts of proposed alternatives.

Public involvement and agency consultation and coordination have been at the heart of the planning process leading to these Great Basin Region ARMPAs. These efforts were achieved through Federal Register notices, public formal and informal meetings, individual contacts, media releases, planning bulletins, and a series of GRSG planning-related Web sites. This section documents the outreach efforts that have occurred to date.

7.1 Public Involvement

The scoping period for the National GRSG Planning Strategy, including the four sub-regional planning areas in the Great Basin Region, began with the publication of the NOI in the Federal Register on December 9, 2011, and ended on March 23, 2012. Beginning in December and ending in February of 2012, the BLM hosted a series of public open house scoping meetings across Northeastern California, Idaho, Southwestern Montana, Nevada, Oregon and Utah. A final National GRSG Planning Strategy Scoping Report was released in May 2012.

A Notice of Availability (NOA) for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Draft RMP Amendments/EISs were published in the Federal Register on November 1, 2013. The Oregon Draft RMP Amendment/EIS was released to the public on November 26, 2013.

For the Great Basin Region GRSG Proposed RMP Amendments/FEIS, Idaho and Southwestern Montana conducted seven public meetings, Nevada and Northeastern California conducted seven public meetings, Oregon conducted seven public meetings, and Utah conducted eight public meetings between November 2013 and January 2014.

Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were considered and incorporated, as appropriate, into the Proposed Plans. The Great Basin Region received approximately 4,990 substantive comments, contained in 74,240 submissions during the four Draft EISs' comment periods. Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were carefully considered and incorporated as appropriate into the Proposed Plan Amendments. Public comments resulted in the addition of clarifying text, but did not significantly change Proposed RMP Amendments.

A Notice of Availability (NOA) for the Great Basin Region GRSG Proposed RMP Amendments and Final EISs for the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah Sub-Regions were released on May 29, 2015. The release of the EPA's NOA initiated a 30 day public protest period and a 60 day governors' consistency review. Refer to **Section 2.5** for a full description of the protest period and governors' consistency review outcomes.

7.2 Cooperating Agencies

A cooperating agency is any federal, state, or local government agency or Native American tribe that enters into a formal agreement with the lead federal agency to help develop an environmental analysis. Cooperating Agencies and tribes "work with the BLM, sharing knowledge and resources, to achieve desired outcomes for public lands and communities within statutory and regulatory frameworks" (BLM 2005). The benefits of enhanced collaboration among agencies in preparing NEPA analyses are:

- Disclosing relevant information early in the analytical process
- Applying available technical expertise and staff support
- Avoiding duplication with other federal, state, tribal, and local procedures
- Establishing a mechanism for addressing intergovernmental issues

The BLM entered into a formal Memorandum of Understanding (MOU) for the National GRSG Planning Strategy with the USFWS and the U.S. Forest Service. In addition, the Great Basin sub-regions' also invited local, state, other federal, and tribal representatives to participate as Cooperating Agencies for these RMP Amendments/EISs. In total, there were 13 MOUs signed with Federal agencies, 10 MOUs signed with state agencies, 55 MOUs signed with counties, and 5 MOUs signed with tribal entities. The MOUs outline the interests, expertise, and jurisdictional responsibilities of both the BLM and its cooperating agency partners and also outlines their respective roles and responsibilities in the planning and NEPA processes. For a full list of these cooperating agencies divided by sub-region, refer to the Cooperating Agencies List at the beginning of this ROD. Additional information can also be found in Chapter 6 of each of the Proposed Amendments/FEISs.

7.2 FWS Section 7 Consultation

Consultation with FWS is required under Section 7(c) of the ESA before the start of any BLM project that may affect any federally listed or endangered species or its habitat. These planning processes are considered a major project, and the four Great Basin sub-regional Final EISs defined potential impacts on threatened and endangered species as a result of management actions proposed in the alternatives analyzed in the FEISs. The FWS is a cooperating agency in this planning process. FWS staff participated in interdisciplinary team meetings and has been provided drafts of alternative decisions and analyses for discussion and input.

The BLM formally initiated Section 7 consultation with a letter to the USFWS prior to the release of the Draft RMP Amendments/EISs, and requested concurrence on which species would require consideration during consultation. Over the ensuing months, regular meetings were held to identify the species that would be analyzed in the biological assessment, to address which actions could affect those species, and to determine whether the implementation of the Proposed Plan Amendments "may affect" the species for which this consultation occurred.

Prior to the release of the Proposed Amendments/FEISs, the BLM formally submitted the biological assessments to the USFWS for review. The USFWS evaluated the biological assessments and concurred with the "no affect" determination via memorandum for Oregon, Nevada and Northeastern California, and Idaho and Southwestern Montana, which are appendices to each of these ARMPAs. For Utah, formal consultation was required with the FWS due to a "likely to adversely affect" determination associated with the threatened listed Utah Prairie Dog. The biological opinion from the FWS is attached to the Utah ARMPA (Appendix X of Attachment X).

[Verify that the above paragraph is applicable to UT once BLM UT hears back from their local FWS.]

7.3 Native American Consultation

In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation efforts related to preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent letters to 65 tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts.

The Draft RMP Amendments/EISs were provided to the Idaho, Montana, Nevada, California, Oregon, and Utah State Historic Preservation Offices (SHPO) concurrently with its release to the public. The Proposed Plan RMP Amendments/FEISs were also provided to the SHPOs.

[Verify that the above paragraph is applicable to UT.]

7. REFERENCES

Comment [MEM38]: Need to ask EMPSi if they can formulate.

8. APPROVAL

Land Use Plan Amendment Decisions

It is the decision of the Bureau of Land Management (BLM) to approve the Great Basin Region Approved Resource Management Plan (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub-regions, as described in this Record of Decision.

The Proposed Plan Amendments and related Final Environmental Impact Statements (EIS) were published on May 29, 2015, in the Federal Register (80 FR 30711). I have resolved all protests and, in accordance with BLM regulations 43 CFR 1610.5-2, my decision on the protests is the final decision of the Department of Interior. The approval is effective on the date this Record of Decision is signed.

Approved by:

Neil Kornze Director Bureau of Land Management	Date

Secretarial Approval

I hereby approve the land use plan amendments decisions. My approval of the land use plan decisions constitutes the final decision of the Department of the Interior and, in accordance with regulations at 43 CFR 4.410(a)(3), is not subject to appeal under Department regulations at 43 CFR Part 4. Any challenge to these land use plan decisions must be brought in Federal district court.

Approved by:

Sally Jewell Secretary Department of the Interior	Date

(WO210)(1610)

Dear Reader:

Enclosed are the Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). The ROD approves the four Great Basin Region ARMPAs, which are part the National Greater Sage-Grouse Planning Strategy that was initiated on December 11, 2011. The conservation strategy was initiated by the Bureau of Land Management (BLM) in response to the U.S. Fish and Wildlife Service's (FWS) March 2010 "warranted, but precluded" Endangered Species Act (ESA) listing petition decision. In this decision, the FWS identified the inadequacy of regulatory mechanisms as a significant threat to GRSG. RMP conservation measures were identified as the BLM's principal regulatory mechanism.

The BLM's ARMPAs provide a landscape-level, science-based, coordinated, collaborative strategy for addressing threats to the Greater Sage-Grouse (GRSG) and its habitat. This strategy was designed to address issues identified in the FWS 2010 "warranted but precluded" decision. In addition, the strategy was guided by over a decade of research, analyses and recommendations for GRSG conservation including the Conservation Objectives Team (COT) Report and the BLM National Technical Team (NTT) Report. Each of these reports was developed through a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research. Science-based decision-making and collaboration with the FWS, the U.S. Forest Service, and state and other partners were fundamental to the development of these ARMPAs.

It is important to note that this ROD and these ARMPAs apply only to BLM-administered lands, including BLM sub-surface mineral estate. Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. These Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs for the Great Basin sub-regions included proposed GRSG management direction for National Forest System lands (in Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah). However, the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

The Federal Land Policy and Management Act (FLPMA) require the development and maintenance, and, as appropriate, the revision of land use plans for management of public lands. The National Environmental Policy Act (NEPA) requires Federal agencies to prepare an Environmental Impact Statement (EIS) for major Federal actions significantly affecting the quality of the human environment. In fulfillment of these requirements, the Draft RMP Amendments/Draft EISs incorporated analysis and input provided by the public; local, State, and other Federal agencies and organizations; Native American tribes; Cooperating Agencies, and BLM resource specialists, and were published in the fall of 2013. Ninety -day public comment periods ensued, with more than 4,990 substantive comments from 1,348 unique letters submitted on all four sub-regional proposed LUPAs/Final EISs in the Great Basin Region. These comments were reviewed, summarized and considered in preparing the Proposed RMP Amendments/Final EISs.

The Proposed RMPAs/Final EISs were made available on May 29, 2015, for a 60-day governor's consistency review and 30-day protest period. The BLM received consistency review letters from the States of California, Idaho, Montana, Nevada, Oregon, and Utah in the Great Basin Region and has worked closely with these states to address their concerns and to resolve inconsistencies where possible. Across all four sub-regions in the Great Basin Region, 133 protest submission letters were received from government entities, private citizens, NGOs, and other stakeholders; 124 of these submissions contained valid protest issues pursuant to 43 CFR 1610.5-2 and were addressed in the Director's Protest Resolution Reports. These reports are available on line at: http://www.blm.gov/nv/st/en/fo/wfo/blm_information/rmp.html.

The BLM now approves the attached ARMPAs as the land use plans that will guide future land and resource management within GRSG habitat in the Great Basin Region for the life of the plan amendments. The ARMPAs will benefit GRSG and over 350 other species of wildlife as well as other multiple uses, including grazing and recreation, which depend on healthy sagebrush-steppe landscapes.

Copies of the ROD and ARMPAs can be obtained from the BLM's National Greater Sage-Grouse webpage at: http://www.blm.gov/wo/st/en/prog/more/sagegrouse.html.

The BLM extends special appreciation to the public, local, state, and other federal agencies, Native American tribal representatives, and the Cooperating Agencies, all of whom contributed to the completion of these ARMPAs. This participation informed and improved the planning process and the planning documents. Your continued involvement is encouraged as the ARMPAs are implemented.

Sincerely,
X

Enclosure:
1. Record of Decision and Approved Resource Management Plan Amendments

Summary

This Record of Decision (ROD) is the culmination of an unprecedented effort to conserve Greater Sage-Grouse habitat on public lands administered by the Bureau of Land Management (BLM), consistent with the BLM's multiple use and sustained-yield mission and the joint objective established by federal and state leadership through the Greater Sage Grouse Task Force to conserve GRSG habitat on federal, state, and private land such that additional protections under the Endangered Species Act (ESA) can be avoided.

In response to a 2010 determination by the FWS that the listing of the GRSG under the ESA was "warranted but precluded" by other priorities, the BLM, in coordination with the U.S. Department of Agriculture Forest Service (Forest Service), has developed a targeted, multi-tiered, coordinated, collaborative landscape-level management strategy, based on the best available science, that offers the highest level of protection for GRSG in the most important habitat areas to address the specific threats identified in the 2010 FWS "warranted but precluded" decision and the FWS 2013 Conservation Objectives Team (COT) report.

This ROD and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah include management direction avoids and minimizes additional disturbance in GRSG habitat management areas as well as targets restoration and improvements to the most important areas of habitat. The management direction in the ARMPAs is accomplished through land use allocations that generally apply to GRSG habitat. These allocations (1) eliminate most new surface disturbance in the most highly-valued sagebrush ecosystem areas identified as Sagebrush Focal Areas (SFAs); (2) avoid or limit new surface disturbance in Priority Habitat Management Areas (PHMAs), of which SFAs are a subset; and (3) minimize surface disturbance in General Habitat Management Areas (GHMA). In addition to protective land use allocations in habitat management areas, the ARMPAs include a suite of management actions, such as the establishment of disturbance limits, GRSG habitat objectives, mitigation requirements, monitoring protocols, and adaptive management triggers and responses, and other conservation measures that apply throughout designated habitat management areas. The cumulative effect of these measures is to conserve, enhance, and restore GRSG habitat across the remaining range of the species in the Great Basin and provide greater certainty that BLM land use plan decisions in GRSG habitat in the Great Basin Region can lead to conservation of the GRSG and other sagebrush-steppe associated species in the region.

The targeted land use plan protections presented in this ROD and ARMPAs not only protect the GRSG and its habitat, but also over 350 wildlife species associated with the sagebrush-steppe ecosystem, which is widely recognized as one of the most endangered ecosystems in North America. Reversing the slow degradation of this valuable ecosystem will also benefit local rural economies and a variety of rangeland uses in addition to habitat protection, including recreation and grazing, in a manner that safeguards the long term sustainability, diversity and productivity of these important and iconic landscapes.

This conservation strategy has been developed in conjunction with the 10 states in which the ARMPAs in the Great Basin and the plans in the Rocky Mountain Region apply. In combination with additional state and federal actions underway and in development, represents an unprecedented, collaborative effort among federal land management agencies and the states to manage an entire ecosystem and associated flora and fauna in order to achieve the COT Report objective of "conserv[ing] the sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future". [Dan Ashe. Transmittal letter to COT Report. 2013].

1. INTRODUCTION

This Record of Decision (ROD) approves the BLM's attached approved resource management plan amendments (ARMPAs) for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern

Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPAs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM-administered lands. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.), BLM planning regulations (43 Code of Federal Regulations [CFR] §1601 et seq.), and other applicable laws. The BLM prepared Environmental Impact Statements (EISs) in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA) and the Council on Environmental Quality's Regulations for implementing the procedural provisions of NEPA (40 CFR §1500.1 et seq.).

Throughout the GRSG planning process, the Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs included proposed GRSG management direction for National Forest System lands. The Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities for the Great Basin Region, which is available at http://www.fs.usda.gov/r4/.

This ROD, in conjunction with the ARMPs and ARMPAs approved through the Rocky Mountain ROD, constitute land use planning decisions of the BLM to conserve the GRSG and its habitats throughout that portion of the remaining range of the species that is administered by the BLM under authority of FLPMA. The efforts of the BLM, in coordination with the U.S. Forest Service on National Forest System lands within the remaining range of the species, constitutes a coordinated strategy for conserving the GRSG and the sagebrush-steppe ecosystem on the majority of Federal lands on which the species depends. These decisions complement those implemented by federal agencies through the Rangeland Fire Strategy and the Sage Grouse Initiative as well as those implemented by state and local governments as well as private land owners and other partners.

1.1 Great Basin Region Planning Area

The Great Basin Region planning area is composed of four sub-regions: the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah. (see **Figure 1-1** – Great Basin Region Greater Sage-Grouse Sub-regions). A separate EIS was prepared for each of these sub-regions. Each sub-region conducted its own planning effort with input from local cooperators, stakeholders, and members of the public. The sub-regional boundaries were constructed to align with BLM administrative offices, state boundaries, as well as areas that shared common threats to the GRSG and their habitat. The boundaries for these sub-regions largely coincide with zones III, IV, and V identified by the Western Association of Fish and Wildlife Agencies (WAFWA) Greater Sage-Grouse Conservation Strategy to delineate management zones with similar ecological and biological issues.

[Insert **Figure 1-1** - Great Basin Region Greater Sage-Grouse Sub-regions]

The Great Basin Region planning area boundaries include all lands regardless of jurisdiction (see **Figure 1-2** - Great Basin Region Planning Area). **Table 1-1** outlines the amount of surface acres that are administered by specific Federal agencies, states, local governments, and privately owned lands within the four sub-regions that make up the Great Basin. The planning area also includes other BLM-administered lands that are not identified as habitat management areas for GRSG. The ARMPAs generally do not establish any additional management for these lands outside of GRSG habitat management areas and they will continue to be managed according to the existing land use plans for these planning areas.

[Insert **Figure 1-2** - Great Basin Region Planning Area]

Acres have been rounded to the nearest hundredth.

The decision area for the Great Basin Region ARMPAs is BLM-administered lands in GRSG habitat management areas (see **Figure 1-3** - Great Basin Region Decision Area , Greater Sage-Grouse Habitat Management Areas (BLM-administered)), including surface and split-estate lands where the BLM has subsurface mineral rights. For a description of these habitat management areas, refer to **Section 1-5**.

[Insert **Figure 1-3** - Great Basin Region Decision Area, Greater Sage-Grouse Habitat Management Areas (BLM-administered)]

1.2 Early GRSG Conservation Efforts

Currently, GRSG occupy an estimated 66% of the historically occupied range. The BLM manages the majority of the GRSG habitat on Federal lands (i.e., the range of GRSG not including the Columbia Basin or Bi-State populations). Efforts to conserve GRSG habitat by the BLM and other wildlife conservation agencies and organizations have been ongoing for many years. These efforts provide an important foundation for the GRSG conservation strategy that guides these plans.

The WAFWA 2004 *Range-wide Conservation Assessment for Greater Sage-Grouse and Sagebrush Habitats* was the first range-wide assessment of GRSG using the vast amount of population data collected over the previous 60 years, habitat information spanning the previous 100 years, and literature dating back 200 years. The goal of the assessment, which includes contributions from the BLM, was to present an unbiased and scientific assessment of dominant issues and their effects on GRSG populations and sagebrush habitats.

http://sagemap.wr.usgs.gov/docs/Greater_Sage-grouse_Conservation_Assessment_060404.pdf

In November 2004, the BLM released its *National Sage-Grouse Habitat Conservation Strategy*, which encouraged GRSG habitat conservation through consultation, cooperation, and communication with WAFWA, the FWS, the Forest Service, the U.S. Geological Survey (USGS), State wildlife agencies, local GRSG working groups, and various other public and private partners.

In 2006, WAFWA completed a *Greater Sage-Grouse Comprehensive Conservation Strategy*, with the assistance of the BLM, the Forest Service, and other contributors. The overall goal of the Strategy was to maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain those populations. The Strategy outlined the critical need to develop the associations among local, state, provincial, tribal, and federal agencies, non-governmental organizations, and individual citizens to design and implement cooperative actions to support robust populations of GRSG and the landscapes and habitats upon which they depend. The catalyst for this effort was widespread concern for declining populations and reduced distribution of GRSG. http://www.wafwa.org/documents/pdf/GreaterSage-grouseConservationStrategy2006.pdf

In 2008, the BLM created two national teams to investigate possible BLM management options for GRSG conservation and summarize the BLM's ongoing conservation efforts. A product of this effort was one of the first range-wide priority habitat maps for GRSG that were referred to as "key habitat". At the time, the primary purpose for the key habitat map was to inform and help prioritize fire suppression efforts in GRSG habitat on BLM lands. An additional outcome of this team was the signing of a Memorandum of Understanding by the WAFWA; the BLM, FWS, USGS in the Department of the Interior; and the US Department of Agriculture Forest Service and NRCS, to provide for cooperation among the participating state and federal land managers and wildlife management and science agencies in the conservation and management of GRSG sagebrush habitats and other sagebrush-dependent wildlife throughout the Western United States.

http://www.blm.gov/style/medialib/blm/wo/Planning_and_Renewable_Resources/fish__wildlife_and/fwp.Par.95958.File.dat/SagegrouseMOU.pdf

In 2010, the BLM commissioned an effort to map and model breeding densities of GRSG across the West. A conference was convened with state wildlife agencies to coordinate the lek survey data needed for this effort. This modelling project, through an agreement with the FWS, mapped known active leks across the West. This model served as a standard starting point for all states to identify priority habitat for the species.

http://www.blm.gov/wo/st/en/prog/more/fish__wildlife_and/sage-grouse-conservation/bird_density.print.html

In March 2010, the US Fish and Wildlife Service (USFWS) published its 12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered (75 Federal Register 13910 (March 23, 2010)). In that finding, the USFWS concluded that GRSG was "warranted, but precluded" under the Endangered Species Act (ESA). This finding indicates that, although the species meets the criteria for listing, immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, the species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

As part of their 2010 finding, the USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 Federal Register 13910 (March 23, 2010)). In addition, the FWS found that existing local, state and federal regulatory mechanisms were not sufficient to address threats to the habitat. For the BLM, which manages approximately 66 million acres of the remaining habitat for the species (See **Figure 1-4**.), the USFWS has identified the agency's Resource Management Plans (RMPs) as the primary regulatory mechanisms.

1.3 Threats to Greater Sage-Grouse in the Great Basin Region

The FWS identified a number of specific threats to GRSG in the Great Basin Region in the context of its 2010 finding. The primary threats identified are the widespread present and potential impacts of wildfire, the loss of native habitat to invasive species, and conifer encroachment. Other threats, some of which are more localized by nature, include habitat fragmentation due to anthropogenic disturbances associated with energy development, mining, infrastructure, recreation, urbanization and sagebrush elimination, as well as impacts to habitat associated with free-roaming equids and improper livestock grazing.

In 2011, the BLM established the GRSG National Technical Team (NTT), comprised of BLM, USGS, NRCS, and State Agency specialists. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable GRSG populations focused on the threats identified in the FWS listing determination (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones (Figure 1-4). The NTT produced *A Report on National Greater Sage-grouse Conservation Measures* (The NTT Report) which proposed conservation measures based on habitat requirements and other life history requirements for GRSG. The NTT Report described the scientific basis for the conservation measures proposed within each program area. The NTT Report also emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. To view the NTT Report, go to:

http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

In 2012, the USFWS, with the support of the Western Governors Association Sage Grouse Task Force, convened the Conservation Objectives Team (COT), comprising state and federal representatives, to produce a peer-reviewed report identifying the principal threats to GRSG survival and the degree to which these threats need to be reduced or ameliorated to conserve the GRSG so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The COT Report, released in March 2013, also identified Priority Areas for Conservation (PACs) and emphasized that "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". Finally, the COT report identified present and widespread, as well as localized threats by GRSG population across the West (**Table 1-2)**. The BLM also identified and explained additional threats in the Final EISs that were published with proposed plans on May 29, 2015. **Figure 1-4** identifies the PACs, GRSG populations (and their names), and WAFWA Management Zones across the West. To view the COT Report, go to: http://www.fws.gov/greatersagegrouse/documents/COT-Report-with-Dear-Interested-Reader-Letter.pdf

[Insert **Figure 1-4** - GRSG Priority Areas for Conservation, Populations, and WAFWA Management Zones.]

A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG in the Great Basin Region– as highlighted in the 2013 COT report – is provided in **Table 1-2**.

1.4 National Greater Sage Grouse Conservation Strategy

Based on the identified threats to the GRSG, especially inadequate regulatory mechanisms, and the FWS's timeline for making a listing decision on this species, the BLM recognized the need to incorporate explicit objectives and concrete conservation measures into Resource Management Plans (RMPs) to conserve GRSG habitat and provide robust regulatory mechanisms. In August, 2011, the BLM chartered a strategy to revise and amend existing RMPs throughout the range of the GRSG to incorporate management actions intended to conserve, enhance, and restore the species and the habitat on which it depends. Separate planning efforts were initiated to address the conservation needs of the Bi-State population in California and Nevada, and the Washington State distinct population segment.

In light of the 2010 “warranted” determination by the FWS, and specific threats summarized in the COT Report, the BLM found that additional management direction and specific conservation measures on federal public lands would be necessary to address the present and anticipated threats to GRSG habitat and to restore habitat where possible. The BLM proposed to incorporate the management direction and conservation measures into the BLM’s land use plans. The goal of incorporating these specific measures into BLM land use plans is to conserve, enhance, and restore GRSG and its habitat and to provide sufficient regulatory certainty such that the need for listing the species under the ESA may be avoided.

In December 2011, the BLM published a Notice of Intent to prepare EISs and Supplemental EIS to incorporate GRSG Conservation Measures into Land Use Plans (LUPs) across the range of the species. A total of 15 sub-regional planning efforts and associated EISs were intiated to analyze the alternatives developed for each of the plan amendments and revisions across the range of the species. [1] **Figure 1-5**

---

[1] The National GRSG Conservation Strategy consisted of 15 separate EISs. The Bighorn Basin RMP has been split between the two field offices that make up the Bighorn Basin planning area, the Cody Field Office ARMP and the Worland Field Office ARMP. The Billings and Pompeys Pillar National Monument RMP has also been split between the Billings Field Office ARMP and Pompeys Pillar National Monument ARMP. This results in a total of 17 ARMPs and ARMPAs.

illustrates the regional and sub-regional planning area boundaries, along with BLM-administered PHMAs and GHMAs across the Western United States.

[Insert **Figure 1-5** – Regional and Sub-Regional Boundaries with GRSG Habitat Management Areas (BLM-Administered Lands)]

The planning efforts associated with the National GRSG Conservation Strategy have been coordinated under two administrative planning regions: the Rocky Mountain Region and the Great Basin Region. The regions were drawn roughly to correspond with the threats identified by USFWS in the 2010 listing decision, along with the WAFWA Management Zones (MZs) framework (Stiver et al. 2006). Due to differences in the ecological characteristics of sagebrush across the range of the greater sage-grouse, WAFWA delineated seven Management Zones (MZs I-VII) based primarily on floristic provinces. Vegetation found within a MZ is similar and sage-grouse and their habitats within these areas are likely to respond similarly to environmental factors and management actions.

The Rocky Mountain Region is comprised of BLM planning efforts (which includes plan revisions and plan amendments) in the states of Montana, North Dakota, South Dakota, Wyoming, Colorado, and portions of Utah. This region falls within WAFWA MZs I (Great Plains), II (Wyoming Basin) and a portion of VII (Colorado Plateau). The Great Basin Region is comprised of planning efforts (plan amendments) in California, Nevada, Oregon, Idaho, and portions of Utah and Montana. This region falls within WAFWA MZs III (Southern Great Basin), IV (Snake River Plain), and V (Northern Great Basin).

Both the Rocky Mountain and Great Basin regions are further divided into sub-regions. The NEPA EIS analyses were done at the sub-regional level. These sub-regions are based on the identified threats to the GRSG and the WAFWA MZs from the FWS 2010 listing decision with additional detail regarding threats to individual populations and sub-regions from the FWS COT report. In the Rocky Mountain Region, some sub-regions correspond to BLM field/district office boundaries, specifically for planning efforts that are incorporating GRSG conservation measures through plan revisions that were initiated prior to the start of the National GRSG Conservation Strategy in December 2011.

The BLM used the best available science, including additional review from the USGS on specific issues that arose in developing the ARMPAs. Additionally, the BLM considered state GRSG conservation strategies where they existed, as well as state recommendations for measures to conserve GRSG on BLM-administered lands, where relevant, in the planning effort. These are reflected in the approved plans to the extent compatible with GRSG conservation objectives to conserve, enhance and restore GRSG habitat to address the threats identified in the FWS 2010 listing determination and the 2013 COT Report.

1.5 How the Approved Resource Management Plan Amendments Address the Identified Threats to the Conservation of the GRSG

The 2006 WAFWA *Greater Sage Grouse Comprehensive Conservation Strategy* stated goal for management of the GRSG was to “maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain these populations". The NTT Report also endorsed this goal "as a guiding philosophy against which management actions and policies of BLM should be weighed".

In establishing the COT, with the backing of the Sage Grouse Task Force, FWS Director Dan Ashe affirmed the commitment to the goal for GRSG conservation originally articulated in the 2006 WAFWA report -- reversing negative population trends and achieving a neutral or positive population trend -- and emphasized the following:

> "The Service interprets this recommendation to mean that actions and measures should be put in place now that will eventually arrest what has been a continuing declining trend. Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels. (WAFWA 2006 Strategy)"

The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT stated, "[m]aintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". To achieve this, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT emphasized an "avoidance first strategy" and stressed those threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

The plans were developed to address specific, identified threats to the species in order to conserve GRSG such that the need to list the species under ESA may be avoided. Across ten western States, the Great Basin and Rocky Mountain sub-regional ARMPs/ARMPAs contain land use plan direction on approximately 66 million acres of the remaining habitat for the species (See **Figure 1-5**.). These plans are the product of extensive coordination between the BLM and the Forest Service and the active engagement of the FWS which informed the BLM and Forest Service land allocation and related management decisions. The plans also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, priorities and approaches in each.

In order to protect the most important GRSG habitat areas, the planning effort began with mapping areas of important habitat across the range of the GRSG. In collaboration with state fish and wildlife agencies, the BLM identified areas as preliminary priority habitat (PPH) and preliminary general habitat (PGH). In Utah, all occupied GRSG habitat was identified as PPH. The draft land use plans used PPH and PGH to analyze the impacts of the decisions the BLM was proposing in the plans. PPH and PGH were identified as Priority Habitat Management Areas (PHMA) and General Habitat Management Areas (GHMA) in the Proposed RMP Amendments/Final EISs to identify the management decisions which apply to those areas (except for Nevada and Utah). The designated GRSG Habitat Management Areas on BLM-administered lands in the decision area include: PHMA, which largely coincide with Priority Areas for Conservation (PACs) identified in the COT Report (except for PACs in Nevada and Utah, as specified on page 13 of the COT Report) (See **Figure 1-4**); GHMA; Other Habitat Management Areas (OHMA, applicable only to the Nevada and Northeastern California); and Important Habitat Management Areas (IHMA, applicable only to Idaho). **Table 1-4** identifies surface acres of PHMA, GHMA, OHMA, and IHMA in the decision area for the Great Basin Region.

Habitat maps were based initially on state key habitat maps which identified areas necessary for sage-grouse conservation derived from various data sources including breeding bird density maps and lek counts, nesting areas, sightings, and habitat distribution data including occupied suitable seasonal habitats, nesting and brood rearing areas, and connectivity areas or corridors. This information served as the basis for the development of BLM preliminary priority habitat (PPH) and preliminary general habitat (PGH) maps and, subsequently, for the identification of Priority Habitat Management Areas (PHMAs) and General Habitat Management Areas, respectively. The COT also used state key habitat maps as a basis for identifying Priority Areas for Conservation (PACs). The COT report notes that there is substantial overlap between PACs and BLM PPH areas, with the exception of areas in Nevada and Utah [COT Report, p 13].

PHMA, GHMA, OHMA, and IHMA are defined as follows:

- **PHMA**— BLM-administered lands identified as having highest habitat value for maintaining sustainable GRSG populations. The boundaries and management strategies for PHMAs are derived from and generally follow the Preliminary Priority Habitat boundaries. Areas of PHMAs largely coincide with areas identified as Priority Areas for Conservation (PACs) in the COT report (except for PACs in Nevada and Utah, as specified on page 13 of the COT Report).
- **GHMA**— BLM-administered lands that are occupied seasonal or year-round habitat outside of PHMA where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMAs are derived from and generally follow the Preliminary General Habitat boundaries.
- **OHMA** —BLM-administered lands in Nevada, identified as unmapped habitat in the Proposed RMP/EIS that are within the planning area and contain seasonal or connectivity habitat areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse Habitat in Nevada and Northeastern California; Coates et al. 2014,) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.
- **IHMA** —BLM-administered lands in Idaho that provide a management buffer for PHMAs and connect patches of PHMAs. IHMAs encompasses areas of generally moderate to high habitat value habitat and/or populations, but that are not as important as PHMAs. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the ARMPA.

Table 1-3

Surface Acres of PHMA, GHMA, OHMA, and IHMA in the Decision Area for the Great Basin Region

BLM administered surface acres	PHMA	GHMA	OHMA	IHMA
Idaho and Southwestern MT	4,627,200	2,179,700	0	2,737,600
Utah*	2,023,400	502,500	0	0
Oregon	4,547,000	5,660,150	0	0
Nevada and Northeastern CA	9,309,700	5,720,600	5,876,600	0

Total Acres	**20,507,300**	**14,062,950**	**5,876,600**	**2,737,600**

Source: BLM GIS 2015

*41,200 acres of National Forest System lands in the Anthro Mountain area of Utah would be managed as neither PHMA nor GHMA. These areas would be identified as "Occupied – Anthro Mountain." In the Utah ARMPA, these areas are considered split-estate, where the BLM administers the mineral estate.

The ARMPAs also identify Sagebrush Focal Areas (SFAs) on a portion of the landscape. SFAs are a subset of PHMAs (see **Figure 1-3** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas). Across the Great Basin Region, there are 8,385,280 acres of BLM administered SFAs. SFAs correspond to the areas identified by the FWS as GRSG "strongholds" and which represent "a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection". (http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf).

SFAs are areas of highest habitat value for GRSG and are managed to avoid new surface disturbance, to the extent permitted by law, given that they contain high-quality sagebrush habitat; highest breeding densities; have been identified as essential to conservation and persistence of the species; represent a preponderance of current federal ownership and, in some cases, are adjacent to protected areas that serve to anchor the conservation importance of the landscape. SFA management is consistent with the recommendations provided by FWS that these are the areas "where it is most important that the BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species."

This tiered habitat management area framework, in associated with the land use plan allocation decisions (explained more fully in Section 1.6.2 of this ROD) in the ARMPs and ARMPAs provide a high degree of certainty that the integrity of PHMAs can be maintained through management decisions to avoid or minimize additional surface disturbance.

Remaining habitats in GHMAs and IHMAs (applicable only to BLM-administered lands in Idaho) would be managed consistent with the COT Report recommendation to recognize "that important habitats outside of PACs be conserved to the extent possible". Thus, land allocations in GHMAs and IHMAs provide for more flexibility for land use activities while minimizing impacts on existing GRSG leks.

Major components of the attached ARMPAs that address the specific threats to GRSG and its habitat, as identified in the USFWS 2010 listing decision and 2013 COT Report (many of which were also identified by the BLM's 2011 NTT Report) are listed and summarized in **Table 1-4**.

Table 1-4
Key Responses from the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat	Key Management Responses from the Great Basin Region GRSG ARMPAs

(from COT Report)	
All threats	● Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met. ● Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner.
All development threats, including mining, infrastructure, and energy development.	● PHMA: Implement an anthropogenic disturbance cap of 3% within the Biologically Significant Unit and proposed project analysis areas in PHMA (slight variations to this management component in the State of Nevada only) ● PHMA and IHMA: Apply a disturbance density cap of 1 energy and mining facility per 640 acres (except in the State of Nevada) ● IHMA: Implement the 3% disturbance cap. Apply Anthropogenic Disturbance Development Criteria. ● Apply buffers based on project type and location to address impacts on leks when authorizing actions in GRSG habitat. ● Apply Required Design Features (RDFs) when authorizing actions in GRSG habitat. ● Effects of infrastructure projects, including siting, will be minimized using the best available science, updated as monitoring information on current infrastructure projects becomes available. ● Consider the potential for the development of valid existing rights when authorizing new projects in PHMA. ● When authorizing third-party actions that result in habitat loss and degradation, require and ensure mitigation that provides a net conservation gain to the species.
Energy development—fluid minerals, including geothermal resources	● PHMA: Open to fluid mineral leasing subject to a No Surface Occupancy (NSO) stipulation without waiver or modification, and with limited exceptions. In SFAs, a NSO stipulation would be applied without waiver, modification, or exception. In Nevada only, in the portions of the PHMAs outside of SFAs, geothermal projects may be considered for authorization if certain criteria are met. ● IHMA: Open to fluid mineral leasing subject to NSO stipulation without waiver or modification, and with limited exception. ● GHMA: Open to fluid mineral leasing subject to Controlled Surface Use (CSU) and Timing Limitation (TL) lease stipulations (except in the State of Utah where some portions of GHMA are open with standard lease stipulations) ● Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.

Energy development—wind energy	● PHMA: Exclusion area (not available for wind energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) ● IHMA: Avoidance area (may be available for wind energy development with special stipulations) ● GHMA: Avoidance area (may be available for wind energy development with special stipulations) (except in the States of Utah and Idaho, where these areas are open to wind energy development)
Energy development—solar energy	● PHMA: Exclusion area (not available for solar energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) ● IHMA: Avoidance area (may be available for solar energy development with special stipulations) ● GHMA: Exclusion area (not available for solar energy development under any conditions) (except in the States of Oregon and Montana where these areas are avoidance areas for solar energy development and the State of Idaho, where these areas are open to solar energy development)
Infrastructure—major ROWs	● PHMA: Avoidance area (may be available for major ROWs with special stipulations) ● IHMA: Avoidance area (may be available for major ROWs with special stipulations) ● GHMA: Avoidance area (may be available for major ROWs with special stipulations) (except in the State of Utah where GHMA is open)
Infrastructure—minor ROWs	● PHMA: Avoidance area (may be available for minor ROWs with special stipulations) ● IHMA: Avoidance area (may be available for minor ROWs with special stipulations)
Mining—locatable minerals	● SFA: Recommend withdrawal from the Mining Law of 1872
Mining—nonenergy leasable minerals	● PHMA: Closed area (not available for nonenergy leasable minerals, however, expansion of existing operations could be considered if the disturbance is within the cap and subject to compensatory mitigation.
Mining—salable minerals	● PHMA: Closed area (not available for salable minerals) with a limited exception (may remain open to free use permits and expansion of existing active pits if criteria are met)
Improper Livestock grazing	● Prioritize the review and processing of grazing permits/leases in SFAs followed by PHMA. • The NEPA analysis for renewals and modifications of grazing permits/leases will include specific management thresholds, based on the GRSG Habitat Objectives Table, Land Health Standards and

	ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis. ● Prioritize field checks in SFAs followed by PHMA to ensure compliance with the terms and conditions of grazing permits.
Free-roaming equid management	● Prioritize gathers in SFAs, followed by other PHMAs. ● Manage Herd Management Areas (HMAs) in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives. ● Prioritize rangeland health assessment, gathers and population growth suppression techniques, monitoring, and review and adjustment of AMLs and preparation of Herd Management Area Plans in GRSG habitat.
Range management structures	● Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. ● Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas.
Recreation	● PHMA and IHMA: Do not construct new recreation facilities unless required for health and safety purposes or if the construction will result in a net conservation gain to the species. ● Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain. ● PHMA & GHMA: OHV use limited to existing routes (routes to be designated through future travel management planning). The Utah ARMPA does retain two areas as open to OHV use in PHMA.
Fire	● Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection. ● Restrict the use of prescribed fire for fuel treatments. ● Prioritize post-fire treatments in SFAs, other PHMAs, IHMAs, and GHMAs.
Nonnative, invasive plant species	● Improve GRSG habitat by treating annual grasses. ● Treat sites in PHMA, IHMA, and GHMA that contain invasive species infestations through an integrated pest management approach.
Sagebrush removal	● PHMA: Maintain all lands capable of producing sagebrush with a minimum of 15 percent sagebrush canopy cover, or as consistent with specific ecological site conditions. ● All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and/or juniper	● Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.

expansion	
Agricultural conversion and exurban development	- GRSG habitat will be retained in federal management unless: (1) the agency can demonstrate that disposal (including exchanges) of the lands will provide a net conservation gain to the Greater Sage-Grouse or (2) the agency can demonstrate that the disposal (including exchanges) of the lands will have no direct or indirect adverse impact on conservation of the Greater Sage-Grouse.

1.6 Key Components of the BLM Greater Sage-Grouse Conservation Strategy

The ARMPAs were developed to meet the purpose and need to conserve, enhance, and restore GRSG and their habitat by eliminating or minimizing threats to GRSG habitat identified in the 2010 listing decision and highlighted in the "background and purpose" section of the COT report. Consequently, consistent with guidance contained in the COT and NTT Reports, four essential components of the GRSG conservation strategy were identified: 1) avoiding or minimizing new and additional surface disturbances, 2) improving habitat conditions, 3) reducing threats of rangeland fire to GRSG and sagebrush habitat in the Great Basin, and 4) monitoring and evaluating the effectiveness of conservation measures and implementing adaptive management as needed.

The land allocations and management actions included in the ARMPAs incorporate these components and are summarized below.

1.6.1 Avoid and Minimize Surface Disturbance

Land Allocations and Habitat Protection/Surface Disturbance Measures

The four Great Basin ARMPAs build on the designated habitat management areas described in **Section 1.5** by applying management actions to these areas to avoid and minimize disturbance associated with proposed projects as described below and shown in **Table 1.4**. Land use plan allocations specify locations within the planning area that are available or unavailable for certain uses and also prioritize conservation and restoration management actions applied to habitat management areas.

~~Through this ROD, the BLM adopts those portions of the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah EISs applicable to National Forest System lands, pursuant to the provisions of 40 CFR 1506.3(c). The EISs sufficiently disclose and analyze all environmental issues associated with mineral leasing and provides support to the BLM to authorize mineral leasing in USFS administered lands, should consent be provided by or consultation be required with the USFS prior to issuance of a lease, in compliance with applicable mineral leasing and NEPA regulations, and subject to further site-specific environmental analysis where applicable.~~

The COT report notes that “loss and fragmentation of sagebrush habitats is a primary cause of the decline of sage-grouse populations”. (COT, p 9). While ~~S~~surface disturbance associated with development in the Great Basin is not yet as significant a threat to GRSG and its habitat as rangeland fire and invasive species~~. Nevertheless~~, the BLM ARMPAs include land allocations and management actions that avoid and minimize surface disturbance in PHMA for identified threats (e.g., energy, mining, infrastructure, improper grazing, free-roaming equids, recreation and urbanization). These land allocations and management actions are necessary because the location and extent of habitat loss to fire is difficult to predict and much of the habitat due to low precipitation in the Great Basin is difficult to restore once lost. Further, even a small amount of development in the wrong place could have an outsized impact in these landscapes.

Comment [JRL1]: Should include this in the RM ROD as this point as well.

Formatted: Font: (Default) Times New Roman

The most restrictive allocations include requirements to avoid and minimize additional disturbance in SFAs, which are subset of PHMA, where surface disturbance from fluid mineral development is avoided by NSO without waiver, modification, or exception. In addition, these areas will be recommended for withdrawal to address the risk of disturbance due to mining.

In PHMAs outside of SFAs new fluid mineral leasing would be subject to NSO with no waivers or modifications. Exceptions would be granted only if the proposed action would not have direct, indirect, or cumulative effects on GRSG or its habitat; or, if the action is proposed to be undertaken as an alternative to a similar action occurring on a nearby parcel, and would provide a clear conservation gain to GRSG. This is fully consistent with guidance in the NTT report which states, “Do not allow new surface occupancy on federal lands within priority habitats” (NTT, p. 23).

Similarly, PHMA is closed to non-energy and salable mineral development (this does not apply to locatable minerals governed under the 1872 Mining Law). An exception may be granted for free-use permits and the expansion of existing active pits for salable minerals and expansion of existing non-energy leasable development under certain conditions. This exception is included because of the importance of these materials to local communities and their limited disturbance which will be offset by the mitigation requirements. Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses the potential disturbance threat from coal development. In Utah, at the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. PHMA is essential habitat for maintaining GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).

All PHMAs will be managed as exclusion areas for commercial renewable energy development (solar and wind) with the exception of areas outside of SFAs in three counties in southeastern Oregon. The three counties in Oregon will be managed as avoidance areas. In these counties, the BLM will encourage new renewable energy development in non-habitat areas first. New rights-of-ways and development for transmission lines, pipelines, and related infrastructure would be avoided through restrictions on land use authorizations. In avoidance areas, exceptions would only be granted if it can be demonstrated that adverse impacts will be avoided or that residual impacts will be mitigated.

Comment [JRL2]: This was a part of the agreement that needs to be reflected in the plan and the ROD.

High voltage transmission lines will be avoided in PHMA. However, the planning, siting, and environmental review of a limited number of priority transmission lines (Transwest Express and portions (that are co-located with Transwest Express) of Gateway South, Gateway West and Boardman to Hemingway), which have been underway for a several years and are deemed critical to expanding access to renewable sources of energy and to improving the reliability of the western grid, will proceed through NEPA analysis of these proposed lines under separate authorization processes. Conservation measures for GRSG are being analyzed as part of those NEPA processes, which should achieve a net conservation benefit for GRSG.

While restrictions on future development in PHMA are intended to avoid or minimize additional surface disturbance, restrictions on development in GHMA are tailored to allow disturbance but with restrictions to ensure compatibility with GRSG habitat needs. In addition, mitigation to avoid, minimize, and compensate for unavoidable impacts will be required for proposed projects in GHMA. Disturbance associated with oil and gas development, for example, is subject to a controlled surface use and timing limitation stipulation rather than an NSO stipulation. (See **Table 1-3** for more details on GHMA management decisions.) Any disturbance is subject to mitigation, with the objective of first avoiding and minimizing potential impacts to GRSG or its habitat and then compensating for unavoidable impacts to GRSG or its habitat, to a net conservation gain standard for the species. This is consistent with guidance in the COT Report which states: "Conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur. …If development or vegetation manipulation activities outside of PACs are proposed, the project proponent should work with federal, state or local agencies and interested stakeholders to ensure consistency with sage-grouse habitat needs."

In addition to allocations that limit disturbance in PHMA and GHMA, the ARMPAs prioritize oil and gas leasing and development outside of identified PHMAs, and GHMAs to further limit future surface disturbance and encourage new development in areas that would not conflict with GRSG. This objective is intended to guide development to lower conflict areas and as such, reduce the time and cost associated with oil and gas leasing development by avoiding sensitive areas, reducing the complexity of environmental review and analysis of potential impacts to sensitive species, and decreases the need for compensatory mitigation.

Additionally, new recreation facilities would not be authorized in PHMAs, unless the development results in a net conservation gain to the GRSG or its habitat, or, unless required for health and safety purposes.

In PHMA and GHMA, travel is limited to existing routes until routes are designated through the implementation travel management planning process. Travel management plans, including route inventories, NEPA analysis, and route designation will be completed in a subsequent public planning processes.

In general, all forms of new development in PHMAs and GHMAs would either be closed, excluded, avoided, or developed only if the resultant effect is a net conservation gain to the GRSG or its habitat, ensuring that existing habitat would be protected and providing opportunities, through compensatory mitigation.

While improper livestock grazing can be a threat to GRSG habitat, grazing is not considered a discrete surface disturbing activity for purposes of monitoring and calculating disturbance. The plans address grazing management for the conservation of GRSG and its habitat by incorporating terms and conditions to achieve habitat objectives into permits and by prioritizing assessment and the review of grazing permits (see Section 1.6.2).

Disturbance Caps, Density Caps, Lek Buffers, and Required Design Features

In addition to the management actions and allocations discussed above, the ARMPAs provide further assurance that anthropogenic disturbances in PHMAs will be limited through the use of disturbance caps, density caps, and lek buffers.

A 3% anthropogenic disturbance cap in PHMA has been established in accordance with the recommendations contained in the NTT Report, and peer-reviewed literature from the Great Basin (Knick 2013). Disturbance will be calculated at two scales: first at a Biologically Significant Unit (BSU) scale determined in coordination with the state and second, for the proposed project area. BSUs are geographic units of PHMA that contain relevant and important GRSG habitat. In Oregon for example, BSUs are synonymous with PACs. These BSUs are used solely for the calculation of anthropogenic disturbance cap and in some ARMPAs, the adaptive management habitat triggers.

If 3% anthropogenic disturbance cap is exceeded on lands (regardless of land ownership) within PHMA in any given BSU, no further discrete anthropogenic disturbances (subject to valid existing rights) will be permitted on BLM-managed lands within PHMAs in that BSU until restoration of disturbed lands brings the BSU below the cap. If the 3% anthropogenic disturbance cap is exceeded on all lands (regardless of land ownership) within a proposed project analysis area in a PHMA, then no further anthropogenic disturbance will be permitted by BLM until disturbance in the proposed project analysis area has been reduced to maintain the area under the cap.

An exception to the 3% disturbance cap is provided in designated utility corridors for purposes of achieving a net conservation gain to the species. This exception is limited to projects which fulfill the use for which the corridors were designated (e.g., transmission lines and pipelines) within the designated width of a corridor. This exception will concentrate future ROW surface disturbance in areas of existing disturbance and avoid new development of infrastructure corridors in PHMAs consistent with guidance in the COT report. In addition, the Oregon and Nevada/Northeast California ARMPAs include variations to the disturbance cap: Oregon does not allow more than 1% new anthropogenic disturbance per decade, not to exceed 3% disturbance at any time. In Nevada, permit exceedances of the 3% disturbance cap at the BSU and/or the project level can occur provided that the outcome results in a net conservation benefit to the species with the concurrence of the BLM, Nevada Department of Wildlife, and FWS in each exception.

In ~~For~~ Southwest Montana (the BLM's Dillon Field Office), the BLM will limit~~permit~~ disturbance to 3% until the State of Montana's Sage Grouse Plan's ~~a 5% cap, consistent with the State of Montana's Plan, once their~~ disturbance calculation methodology is instituted and is in effect at which time disturbance will be permitted up to a 5% cap. This is to recognize, as with the Wyoming Core Area Strategy, the importance of the all-lands-all-disturbances strategy that Montana plans to institute for sage grouse conservation.

Appendix E of each of the attached ARMPAs includes additional information about the methodology for calculating anthropogenic disturbance at the BSU and project scales.

The ARMPAs also incorporate a cap on the density of energy and mining facilities to encourage co-location of structures to reduce habitat fragmentation. The limit is an average of one facility per 640 acres in PHMA in a project authorization area, consistent with guidance contained in the NTT Report. If the disturbance density in the PHMA in a proposed project area is, on average, less than 1 facility per 640 acres, the project can proceed through the NEPA analysis incorporating mitigation measures into an alternative. If the disturbance density in the proposed project area is greater than an average of 1 facility per 640 acres, the proposed project will either be deferred until the density of energy and mining facilities is less than the cap or redesigned so facilities are co-located into an existing disturbed area, subject to applicable laws and regulations, such as the 1872 Mining Law and valid existing rights. The one facility per 640 density decision does not apply to Nevada, as described in **Section 1.7**.

In addition to any other relevant information determined to be appropriate, the BLM will further assess and address impacts from certain activities using the lek buffer-distances as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). Lek buffer distances will be applied at the project specific level as required conservation measures to address the impacts to leks as identified in the NEPA analysis. The lek buffer distances vary by type of disturbance (road, energy development, infrastructure, etc.) and justifiable departures may be appropriate as fully described in Appendix B of the ARMPAs. In both PHMA and GHMA, impacts should be avoided first by locating the action outside of the applicable lek buffer-distance(s) as defined in the ARMPAs. In PHMA, the BLM will ensure that any impacts within the buffer distance from a lek are fully addressed. In GHMA, the BLM will minimize and compensate for any unavoidable impacts to the extent possible. This approach to determining relevant lek buffer distances is consistent with the COT recommendation that "conservation plans should be based on the best available science and use local data on threats and ecological conditions."

Additionally, Required Design Features (RDFs) are required for certain activities in all GRSG habitat, including oil and gas development, infrastructure, and other surface disturbing activities and are fully described in Appendix C of the attached ARMPAs. RDFs establish the minimum specifications for certain activities to help mitigate adverse impacts to GRSG and its habitat from threats (such as those posed by standing water that can facilitate West Nile virus or tall structures that can serve as perches for predators). However, the applicability and overall effectiveness of each RDF cannot be fully assessed until the project level when the project location and design are known. Because of site-specific circumstances, some RDFs may not apply to some projects (e.g., a resource is not present on a given site) and/or may require slight variations (e.g., a larger or smaller protective area). In Nevada and Northeastern California, RDFs are also applied to their identified OHMAs.

1.6.2 Improving Habitat Condition

In addition to prescribing land use allocations and managing resource uses in order to minimize and avoid further surface disturbance, the ARMPAs identify management actions to restore and improve GRSG habitat.

The ARMPAs contain an overall habitat management objective that "In all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain all lands ecologically capable of producing sagebrush (but no less than 70%) with a minimum of 15% sagebrush canopy cover or as consistent with specific ecological site conditions." To move toward this goal, the ARMPAs specify GRSG habitat objectives to be incorporated into land management programs, including wild horse and burros, grazing, and habitat restoration. These habitat objectives were developed for each of the GRSG's life history stages within each ARMPA's sub-region. These objectives will be used to meet the applicable land health standard in GRSG habitats.

The ARMPAs also include specific decisions to improve habitat conditions and meet the habitat objectives through treatment of invasive annual grasses and the removal of encroaching conifers in SFA, PHMA, and GHMA, and restoration of degraded landscapes, including those impacted by fire events (See **Section 1.6.3**.)

The BLM recognizes that improper grazing is a threat to GRSG and its habitat. Because grazing is the most widespread use of the sagebrush steppe ecosystem, the ARMPAs address improper grazing. The COT Report recommendation for grazing states, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage-grouse (e.g. shrub cover, nesting cover)." To ensure that grazing continues in a manner consistent with the objective of conserving the GRSG and its habitat, the Great Basin ARMPAs include requirements for the incorporation of terms and conditions informed by GRSG habitat objectives into grazing permits, consistent with the ecological site potential of the local areas, prioritize the review and processing of authorizations and field checks of grazing permits, and take numerous actions to avoid and minimize the impacts of range management structures (**see Table 1-4**).

The BLM will prioritize reviews and processing of grazing authorizations, as well as field checks of grazing permits in the habitat that is most important to GRSG populations: first in SFAs, then PHMAs, followed by GHMA, focusing first on riparian and wet meadows. The decision to prioritize in this way does not indicate that grazing is more of a threat or is an incompatible use in any given area, but rather reflects a decision to prioritize resources to ensure permittees and the BLM manage grazing properly in those areas most important to GRSG. If the BLM finds that relevant habitat objectives are not being met due to improper grazing, the BLM will work with the permittee to ensure progress towards habitat objectives.

To address the localized threat due to negative influences of grazing by free-roaming equids (wild horses and burros (WHB)), the BLM will focus on maintaining WHB Herd Management Areas in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives, including completing rangeland health assessments, prioritizing gathers and population growth suppression techniques, and developing or amending Herd Management Area (HMA) plans to incorporate GRSG habitat objectives and management considerations. The BLM will prioritize WHB management first in SFAs, then the remainder of PHMA, and then GHMA. In SFAs and PHMA, the BLM will assess and adjust AMLs through the NEPA process within HMAs when WHBs are identified as a significant causal factor in not meeting land health standards, even if current AML is not being exceeded.

During the implementation of the ARMPAs, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in GRSG habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain (the actual benefit or gain above baseline conditions) to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for unavoidable impacts by applying beneficial conservation actions to offset remaining impacts associated with the action. This standard is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0* published by the FWS in September, 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse"**.** Mitigation will follow the regulations from the White House Council on Environmental Quality (CEQ) (40 CFR 1508.20; e.g. avoid, minimize, and compensate) and be implemented on BLM-managed lands in a manner consistent with Departmental guidance for landscape mitigation pursuant to Secretarial Order 3330. If impacts from BLM management actions and authorized third party actions result in habitat loss and degradation that remain after applying avoidance and minimization measures (i.e. residual impacts), then compensatory mitigation projects will be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation.

To help achieve the mitigation goal of net conservation gain across the range, the BLM will establish GRSG Conservation Teams based on WAFWA Management Zones, including members from the respective states, Forest Service, FWS, and NRCS. These Conservation Teams will facilitate cross-state issues, such as regional mitigation and adaptive management monitoring and response. These Teams will convene to advise on these specific tasks and will utilize existing coordination and management structures to the extent possible.

With regard to the threat of climate change, the ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the *Integrated Rangeland Fire Management Strategy* will further these goals and objectives. The Fire and Invasives Assessment Team (FIAT) assessments that informed the ARMPAs and supported the development of the Integrated Rangeland Fire

Formatted: Font: Italic

Management Strategy were designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). Additionally, by limiting or eliminating anthropogenic surface disturbance, especially in the SFAs, ensuring the integrity of the PHMAs, and restoring habitat through fuels management, post-fire restoration, and mitigation efforts, connectivity and availability of sagebrush habitat will increase, thus contributing to increased climate resilience. The SFAs in particular, were identified as key areas to conserve as climate changes. The Oregon ARMPA commits to use climate change science concerning projected changes in species ranges and changes in site capability to adjust expected and desired native species compositions as that information becomes available.

1.6.3 Reducing Threats of Rangeland Fire to GRSG and Sagebrush Habitat

The COT emphasized that "rangeland fire (both lightning-caused and human-caused fire) in sagebrush ecosystems is one of the primary risks to the greater sage-grouse, especially as part of the positive feedback loop between exotic invasive annual grasses and fire frequency". For this reason, the ARMPAs seek to fight the spread of cheatgrass and other invasive species, position wildland fire management resources for more effective rangeland fire response, and accelerate the restoration of fire-impacted landscapes to native grasses and sagebrush. Prescribed fire will not be used except under the following conditions: the NEPA analysis for the Burn Plan provides a clear rationale for why alternative techniques were not selected as a viable option, how GRSG habitat management goals and objectives would be met by its use, how the COT Report objectives would be addressed and met, and a risk assessment is prepared to address how potential threats to GRSG habitat would be minimized.

The cornerstone of the FIAT protocol is recent scientific research on resistance and resilience of Great Basin ecosystems (Chambers, et al., 2014b). The final FIAT process report was completed in June 2014 by the Fire and Invasive Assessment Team. The BLM, the Forest Service, FWS, and other cooperating agencies agreed to incorporate this approach into the ARMPAs. This information is being used to identify and design projects to change vegetation composition and/or structure to modify potential fire behavior for the purpose of improving fire suppression effectiveness and limiting fire spread and intensity due to invasive grasses and conifer encroachment. The BLM *Greater Sage Grouse Invasive Annual Grasses & Conifer Expansion Assessment* (FIAT 2014) modeled conifer expansion for PACs to provide an initial stratification to determine where conifer removal would benefit important sagebrush habitats.

Consistent with this assessment, the BLM ARMPAs include management actions to remove invading conifers and other undesirable species, and prioritize vegetation treatments closest to occupied GRSG habitats and near occupied leks. Through guidance in the ARMPAs supplemented by the *Integrated Rangeland Fire Management Strategy*, a commitment has been made to address the invasion and expansion of cheatgrass, medusa head, and other invasive grasses through expanded efforts to treat impacted acres and to accelerate and expand efforts to restore lands impacted by fire with native grasses and sagebrush seedlings. Efforts are underway to increase the acreages to be treated with chemical and biological agents to kill and stem the spread of invasive species and to accelerate the registration of other biologicals useful in addressing the threat of cheatgrass invasion.

In addition to and complementing the ARMPAs described in this ROD, Secretarial Order 3336 on Rangeland Fire made clear that "**protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, priority GRSG habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department"** (emphasis added). The strategy places a Departmental priority on activities to prevent, suppress, and restore fire-impacted landscapes, which are identified by the Fire and Invasives Assessment Tool (FIAT) for the Great Basin Region, using recent information derived from a report prepared by WAFWA to assist in addressing the threat of rangeland fire. The FIAT Assessments provide a list of findings, recommendations, and considerations to protect, maintain, and enhance GRSG habitat. The Assessments also apply recent science and identify highly resistant and resilient landscapes to target fire management activities to these most important lands. In addition, through the issuance of a Leaders' Intent letter, signed by the Secretaries of Agriculture and the Interior, rangeland fire was identified as an "additional priority" for the firefighting community in making strategic decisions with regard to the allocation of resources for firefighting in 2015. Additional resources have been allocated and will be targeted to fuel treatments (including invasive species control), suppression (through the prepositioning of fire-fighting resources and the training of additional Rangeland Fire Protection Associations, local volunteer firefighters, and veteran fire fighters), and habitat restoration in these areas. Firefighting assets (aircraft, firefighters and related equipment) will be located near areas of high priority for rangeland fire.

Comment [JRL3]: Not "Rural"?

1.6.4 Monitoring, Evaluation, and Adaptive Management

The COT Report noted that "a monitoring program is necessary to track the success of conservation plans and proactive conservation activities. Without this information, the actual benefit of conservation activities cannot be measured and there is no capacity to adapt if current management actions are determined to be ineffective." The NTT further notes that "Monitoring is necessary to provide an objective appraisal of the effects of potentially positive conservation actions, and to assess the relative negative effects of management actions to sage-grouse populations and their habitats."

A rangewide monitoring and evaluation framework will be established and implemented as described in the Monitoring Framework (Appendix D of each attached ARMPA). This monitoring strategy has two parts: (1) implementation monitoring (i.e., are decisions being implemented in a timely manner, are actions taken consistent with the plan decisions), and (2) effectiveness monitoring (i.e., are the decisions and implementation actions achieving the desired conservation goals). Through effectiveness monitoring, BLM can determine how management decisions and actions implemented through the ARMPAs affect GRSG habitat to determine if the desired management objectives (e.g. avoiding and minimizing additional surface disturbance in PHMAs) have been achieved. Understanding the effectiveness and validating results of ARMPA management decisions is an essential part of the GRSG conservation strategy and provides the means for determining if desired outcomes are being achieved.

Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, size of patches, etc.). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by state wildlife agencies and other partners, will allow linking real or potential habitat changes (from both natural events and management actions) to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to ameliorate negative effects with appropriate conservation actions. The WAFWA Zone GRSG Conservation Team (as described in Section 1.6.2) will also be used to advise regional monitoring strategies and data analysis as described in the plans.

Each ARMPA includes an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are habitat and population thresholds and are based on the two key metrics that are being monitored - habitat condition and/or population numbers. At a minimum, the BLM will assess annually whether hard and soft trigger thresholds have been met when the population or habitat information becomes available, beginning after the issuance or signature of this ROD.

Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the ARMPAs, the BLM will implement more conservative or restrictive conservation measures on a project-by-project basis to mitigate for the specific causal factor in the decline of populations and/or habitats, with consideration of local knowledge and conditions. In each ARMPA, a soft trigger begins a dialogue between the state, FWS, and the BLM to see if the causal factor can be determined and what implementation-level activities can be used to reverse any trend. These adjustments will be made to preclude tripping a “hard” trigger (which signals more severe habitat loss or population declines).

Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the BLM ARMPAs. In the event that a hard trigger is tripped, the BLM will implement plan-level decisions, such as allocation changes, to immediately institute greater protection for GRSG and its habitat. If a hard trigger is tripped in a PAC that crosses state boundaries, the WAFWA Management Zone GRSG Conservation Team will convene to discuss causes and ~~advise on~~ identify potential responses.

Comment [JRL4]: They need to act, not simply “advise”.

In the event that new scientific information becomes available demonstrating that the hard trigger response is insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM ARMPAs, the BLM will immediately assess what further actions may be needed to protect GRSG and its habitat and ensure that conservation options are not foreclosed. This could include a formal directive such as an Instruction Memorandum (IM) or a plan amendment.

1.7 Unique Aspects of the Great Basin ARMPAs

The ARMPs and ARMPAs and their associated EISs were developed through four planning efforts across the Great Basin Region (as described in Section 1.1). To develop these plans, the BLM employed a landscape-scale approach to achieve a common set of management objectives across the range of GRSG recognizing, in particular, implementing measures to limit anthropogenic disturbance in important habitats. Within this framework, management actions were developed and incorporated into the plans that are tailored to achieve these objectives and accommodate differences in resource conditions, severity of threats, and state-specific management approaches.

This flexible landscape approach provided the opportunity to incorporate recommendations resulting from collaboration with local cooperators and public comments in each planning area. The plans and their future implementation is strengthened by the contributions of local partners and their knowledge, expertise, and experience.

Measures incorporated into the plans remain consistent with the range-wide objective of conserving, enhancing, and restoring GRSG habitat by reducing, eliminating, or minimizing threats to GRSG habitat, such that the need for additional protections under the ESA may be avoided.

Below is a brief description of the unique aspects of each of the Great Basin Region's ARMPAs.

Idaho and Southwestern Montana

The Idaho and Southwestern Montana ARMPA adopted specific aspects of the State of Idaho's Conservation Plan for GRSG. The most significant aspect adopted from the State's plan is a third category of habitat referred to as Important Habitat Management Areas (IHMA). IHMA are BLM-administered and National Forest System lands that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations. In a landscape that is most threatened by fire and invasive species, this three-tiered approach allows land managers to focus suppression and restoration resources on those areas of highest importance while providing an acceptable additional level of flexibility in IHMA and GHMA since surface disturbance due to development is not as great a threat to habitat in the sub-region. The three tiers also serve as the foundation for an adaptive management approaches that includes habitat and population hard and soft triggers. The adaptive management approach requires that when a hard trigger is reached, IHMA will be managed as PHMA to maintain sufficient PHMA to support GRSG populations.

The Idaho portion of the Idaho and Southwestern Montana GRSG ARMPA also includes a unique approach to calculating disturbance to account for effective habitat, as described in Appendix E of the attached Idaho and Southwestern Montana ARMPA, which was developed by the BLM in concert with the Idaho Department of Fish and Game, Forest Service, and FWS. The Idaho and Southwestern Montana ARMPA also includes additional Required Design Features (RDFs) based on lek avoidance distances, which were developed in coordination with the Idaho Department of Fish and Game and the local FWS office. Examples include avoiding building new wire fences within 2 km of occupied leks and placing new, taller structures out of line of sight or at least one kilometer from occupied leks. The BLM will also work with the state of Idaho in setting priorities for the review and processing of grazing permits/leases in SFAs consistent with the methodology recommended by the State of Idaho in its proposed plan for the management of BLM-administered lands in the state.

On August 7, 2015, the Sawtooth National Recreation Area and Jerry Peak Wilderness Act (H.R. 1138) was signed into law. In accordance with the Wilderness Act (16 U.S.C. 1131 *et seq*.), certain Federal lands in the Challis National Forest and Challis District of the Bureau of Land Management in the State of Idaho, were designated as wilderness, as a component of the National Wilderness Preservation System, known as the Jim McClure-Jerry Peak Wilderness. Approximately 12,430 acres of this wilderness area fall within BLM-administered PHMA (as a subset of SFA). The ARMPA decisions for this area will be managed consistent with the Wilderness Act. As specified in the Sawtooth National Recreation Area and Jerry Peak Wilderness Act, a wilderness management plan will be developed within 5-years of the signing of the Act and it will outline specific management guidance for the new wilderness area.

This bill also released the Jerry Peak West, Corral-Horse Basin, and Boulder Creek Wilderness Study Areas (WSAs) and they are no longer subject to management pursuant to Section 603(c) of the FLPMA. The acres released as WSA include approximately X acres of PHMA, X acres of IHMA, and X acres of GHMA. The ARMPA decisions for these areas will not change as a result of the release.

Finally, in accordance with the Recreation and Public Purposes Act, the Sawtooth National Recreation Area and Jerry Peak Wilderness Act also conveyed public lands to Blaine County, Custer County, the City of Challis, the City of Clayton, and the City of Stanley. This conveyance included approximately 35 acres of PHMA, 10 acres of IHMA, and 828 acres of GHMA that are reflected in the ARMPA as being administered by the BLM. Through future plan maintenance, the BLM will adjust the maps and acres as they appear in the ARMPA to depict that these lands are not subject to the management decisions outlined in the Idaho and Southwestern Montana GRSG ARMPA.

The decisions affecting Southwestern Montana in the ARMPA consistent with the objectives of the Montana Sage Grouse Habitat Conservation Program (Montana Office of the Governor Executive Order No. 10-2014) by establishing conservation measures and strategies to minimize disturbance and habitat loss, particularly as a result of surface disturbance from energy exploration and development. The BLM plan will permit the disturbance limit to go from a 3% to a 5% disturbance cap, consistent with the Montana Plan when the process for implementing their disturbance calculation methodology is instituted and effective. Additionally, if the BLM finds that the State of Montana is implementing an effective GRSG habitat conservation program, the BLM would review their management actions to determine if additional sage-grouse related management actions should be adjusted with coordination from the State of Montana and the FWS to achieve consistent and effective conservation across all lands, regardless of ownership.

Nevada and Northeastern California

The Nevada portion of the Nevada and Northeastern California ARMPA is unique from other Great Basin ARMPAs because of how the sub-regional habitat map was developed. The ARPMA uses the "2014 Coates Maps", developed locally using the best available science, and included "Other Habitat Management Areas", where required design features will be applied at the project level. Decisions for BLM-administered lands in the State of California include allocations and management direction that is generally similar to other ARMPAs in the Great Basin, while carrying forward some decisions identified in the Sage Steppe Ecosystem Restoration FEIS (BLM 2008).

Decisions for BLM-administered lands in the State of Nevada incorporate key elements of the State of Nevada Greater Sage-Grouse Conservation Plan (State of Nevada 2014) including consideration of the State of Nevada Conservation Credit System (Nevada Natural Heritage Program and Sagebrush Ecosystem Technical Team 2014) as the ARMPA is implemented and as projects are proposed within the planning area. This mitigation strategy focuses restoration efforts in the key areas most valuable to the GRSG. The ARMPA adopts a Disturbance Management Protocol (DMP) to provide for a 3% limitation on disturbance, except in situations where a biological analysis indicates a net conservation gain to the species, with concurrence from the BLM, State of Nevada, and FWS. The plan provides for this exception due to the development of mitigation tools in Nevada, including the Conservation Credit System, in collaboration with the FWS. Furthermore, given the concurrence of the Nevada Department of Wildlife and FWS in each exception, this approach is consistent with conservation objectives. The Disturbance Management Protocol in BLM-administered lands in Nevada was also deemed sufficient such that the Nevada ARMPA does not utilize a disturbance density cap, which is required in the three other Great Basin Region ARMPAs.

In coordination with the FWS, the Nevada ARMPA also allows for an exception to the geothermal NSO which is an energy development priority for the state and is projected to create very limited disturbance in predictable areas over the life of the plan. For those reasons, this exception is consistent with overall conservation objectives.

Utah

The Utah ARMPA incorporates a number of key strategies for GRSG conservation developed by the State of Utah (Conservation Plan for Greater Sage-Grouse in Utah) and the State of Wyoming (Executive Orders 2011-05 and 2013-3), which establishes conservation measures for protecting GRSG and also focuses conservation and restoration within key areas deemed most valuable to GRSG. The Utah ARMPA also integrates the state's strategic focus on increasing areas available to GRSG through vegetation treatments and reducing threats from wildfire. The ARMPA provides additional flexibility for development in GHMA because 96% of the breeding GRSG in Utah are within PHMAs where conservation measures are applied in a more targeted manner at the project-implementation stage through the use of lek buffers and required design features as well as requiring that compensatory mitigation achieve a net conservation benefit outcome. As such, the Utah ARMPA designates GHMA as open to wind energy and high voltage transmission ROW development (consistent with the net-conservation-gain mitigation framework for the ARMPA). The Utah ARMPA also designates GHMA open to oil and gas development with standard constraints.

Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses this threat.

Oregon

The Oregon ARMPA incorporates key elements of the Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat (Hagen 2011) which establishes unique conservation measures for protecting GRSG and also focuses restoration within key areas most valuable to GRSG. The BLM plan adopts the unique disturbance cap approach developed with the State of Oregon in which disturbance is capped at 1% per decade, in addition to the 3% cap in BSUs and project analysis areas.

The BLM Oregon plans provide additional flexibility for wind development in PHMA in Harney, Lake, and Malheur counties by allowing avoidance rather than exclusion within PHMAs that are outside of the SFAs. The BLM provided this flexibility after recognizing the extent of high and medium potential wind areas in these counties that is in PHMAs, the fact that wind energy is excluded in SFAs in these counties, and, after coordination with the USFWS, determining that the more rigorous disturbance cap (in which disturbance is capped at 1% per decade) and adaptive management triggers adopted by the Oregon plan would compensate for the limited wind development likely to occur in these areas. In addition, the plan encourages development of wind energy ROWs outside of PHMA first, or in non-habitat areas within PHMA, before development is permitted in higher value habitat areas. Due to these factors, the BLM finds these limited areas of flexibility for wind development are not inconsistent with overall conservation objectives of the plan. In addition, the Oregon ARMPA identifies strategic areas where habitat enhancement and restoration activities are encouraged, as well as other strategic areas to address the impacts associated with climate change.

For additional information regarding the unique aspects of each plan, refer to Table 1-6 of the attached Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah ARMPAs, which provides a crosswalk regarding how the ARMPAs address specific threats to GRSG identified in the COT Report through these state-specific management prescriptions.

1.8 Decision Rationale

The ARMPAs provide a comprehensive and effective conservation strategy for addressing the threats identified by the FWS such that the need for additional protections under the ESA may be avoided. The ARMPAs contain objectives which strive to conserve the GRSG and its habitat on BLM-administered lands across the remaining range of the species consistent with measures identified or recommended in the NTT or COT reports.

In combination with the sage-grouse conservation actions taken by the individual states within the remaining range of the species and separate but connected initiatives to address the threat of rangeland fire to curb the continuing spread of non-native invasive grasses, and to promote conservation measures to benefit the Greater sage-grouse on private lands, the BLM and Forest Service proposed ARMPAs are an essential component of the effort to conserve the GRSG and its habitat. Combined, all of the ARMPAs associated with the BLM's National GRSG Conservation Strategy would affect approximately 66 million acres of the remaining habitat for the species.

The BLM Greater Sage-Grouse Conservation Strategy is built upon the following key concepts:

- **Landscape-level**: The planning effort encompasses the remaining habitat of the GRSG on BLM-administered public lands, covering 10 western states in the Great Basin and Rocky Mountain regions. As such, the strategy provides a coherent framework across the BLM RMPs to implement landscape-level conservation for GRSG while allowing for flexibility essential to effectively address threats to the GRSG in the context of the agency's multiple use and sustained yield mandates under FLPMA. The conservation measures included as part of this landscape-level conservation effort ~~appropriately~~ address identified threats to the species, recognizing local ecological conditions, and incorporating existing conservation efforts where they are consistent with the overall objective of conserving the ~~species~~ Greater sage-grouse across its remaining range.
- **Best Available Science** – The ARMPAs are grounded in the best available science, drawn from published literature and input from recognized experts, state agencies, the US Geological Survey, the FWS and other sources. The COT Report provided a "blueprint" for GRSG conservation by identifying specific threats to each remaining GRSG population and recommending measures to address each category of threat. The BLM National Technical Team (NTT) Report provided additional guidance for addressing the most significant threats to the GRSG. A series of subsequent reports on how to improve efforts to reduce the threats of rangeland fire and invasive species prepared in collaboration with the WAFWA, as well as a report to the Secretary of the Interior entitled "An Integrated Rangeland Fire Management Strategy" also informed the GRSG conservation.
- **Targeted, Multi-Tiered Approach** – The ARMPAs were designed to incorporate a layered management approach to target habitat protection and restoration efforts to the most important habitat management areas as determined by state and federal sage grouse experts, largely consistent with the Priority Areas for Conservation (PACs) identified in the COT Report, where land allocations and management direction avoid and minimize additional surface disturbance. These areas are designated as Priority Habitat Management Areas (PHMAs). Within PHMA, the ARMPAs/ARMPs provide an added level of protection to eliminate most surface disturbance through the delineation of Sagebrush Focal Areas (SFA), derived from areas identified by the FWS as "strongholds" essential for the species' survival. General Habitat Management Areas (GHMAs), recognize the potential value of habitat areas outside of PACs -- as recommended by the COT -- where surface disturbance is minimized ~~to~~ while providinge ~~greater~~ flexibility for other land resource use ~~activitie~~s.
- **Coordinated**: The ARMPAs were developed through a joint planning process between the BLM and the Forest Service (as a cooperating agency). As a result, federally-administered lands ~~are~~ essential to the conservation of the GRSG are managed in a coordinated manner. The FWS provided guidance and input throughout the process to aid land managers in understanding the

Comment [JRL5]: Important element in both "rationales".

threats to the GRSG and its habitat. The USGS and NRCS also provided key technical and scientific support.

- **Collaborative**: The ARMPAs reflected extensive input from the relevant states, collaborators, and stakeholders and the public from the outset. The ARMPAs were developed with the benefit of input from the individual states and cooperators who signed formal agreements with the BLM to provide input into the planning process. The Western Governors Association Sage Grouse Task Force (SGTF) was particularly useful in facilitating this kind of collaborative input. The ARMPAs incorporate state and local conservation measures where they are consistent with the overall objective of implementing land use plan conservation measures for the GRSG consistent with the multiple-use and sustained-yield mission of the BLM.

The conservation measures in the ARMPAs reflect over a decade of research, analysis and recommendations for GRSG conservation including those produced by the WAFWA, the NTT, and the COT. Each of these entities produced a strategy or report that was developed through a collaborative effort of state and federal biologists and scientists with extensive experience and expertise in GRSG management and research.

The COT Report –which identified threats to GRSG habitat as well as the most important habitat to protect--provided an important framework for development of the conservation strategy embodied in the sub-regional ARMPAs. The COT, consisting of state and federal scientists, wildlife biologists, ~~and~~ resource managers, and policy advisors, was tasked by the Director of the FWS "with development of range-wide conservation objectives for the sage-grouse to define the degree to which threats need to be reduced or ameliorated to conserve sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future."

In addition, the Fire and Invasives Assessment Team (FIAT) Report and the USGS compilation and summary of published scientific studies that evaluate the influence of anthropogenic activities and infrastructure on GRSG populations -- *Conservation Buffer Distance Estimates for Greater Sage-Grouse—A Review*, and the *Integrated Rangeland Fire Management Strategy: Final report to the Secretary* (Manier et al, 2014; DOI 2015b) provided important guidance in the development of critical aspects of the proposed ARMPAs/ARMPs and the overall GRSG landscape-level conservation strategy. Beyond these range-wide reports, each of the sub-regional plans used local science, where available, to tailor plan elements to reflect local ecological conditions, threats, and GRSG experience where consistent with the overall GRSG management objectives.

The BLM ARMPAs are the product of extensive coordination, including the active engagement of the FWS in helping to inform land allocation and related management decisions by the land management agencies to ensure they limit or eliminate new surface disturbance as well as improve habitat condition in the most important habitat areas. The ARMPAs/ARMPs also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, approaches, and priorities in each. While the effort to incorporate state-developed conservation measures in each of the sub-regional plans has added complexity in developing the overall conservation strategy, the body of local knowledge and expertise regarding conservation measures for the GRSG is extensive and, ultimately, strengthened the plans. Incorporating these measures in the plans is also likely to increase the commitment of all partners to the difficult task of implementing the plans upon completion.

In his transmittal letter accompanying the final COT report, FWS Director Dan Ashe reaffirmed his charge, "I asked the team to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. … Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels."

The ARMPAs are designed to directly address the specific threats to the species identified by the FWS in its 2010 listing determination as more fully explained in the COT Report~~,~~ and the BLM NTT Report~~, and coordination with state and local working groups~~. As previously noted, the COT Report stated, "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation." Specifically, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT further recommended an "avoidance first strategy" and stressed that "threats in PACs must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

Comment [JRL6]: Strike as explained in RM ROD.

In order to address the identified threats and meet the recommendations of the COT, the plans are based first on the identification of important habitat areas for GRSG in which the plans protect remaining habitat and target habitat restoration and improvement actions. Specifically, the plans identify PHMA which align closely with PACs identified in the COT Report (except for PACs in Nevada and Utah, as specified on page 13 of the COT Report). Within PHMA, the plans identify SFAs based on the FWS analysis of strongholds for the species based on population density, habitat integrity, and resilience to climate change among other factors. The SFAs serve as a landscape-level anchor for the conservation strategy and are closed or excluded from discretionary surface disturbances. SFAs are also used to prioritize fire protection, habitat restoration, and other habitat management actions (e.g., prioritizing reductions in wild horse and burro populations to achieve AML). This approach will allow the BLM to target limited resources to those areas identified by the FWS which are most important to long-term ecosystem health and species persistence.

PHMA and GHMA boundaries are based on Preliminary Priority Habitat (PPH) and Preliminary General Habitat (PGH) (except in Utah, where PPH was derived from occupied habitat). Consistent with BLM's Instruction Memorandum 2012-044, PPH and PGH are based on data and maps developed through a collaborative effort between the BLM and the respective state wildlife agency. PPH and PGH (PHMA and GHMA in the Final EISs and now the ARMPAs) were developed using the best available data. Criteria for delineating PPH included breeding bird density (Doherty 2010), sage grouse proportionality, density of leks, and key seasonal habitats, such as known winter concentration areas. PGH (now GHMA) are areas of occupied seasonal, connectivity, or year-round habitat outside of PPH.

Allocations and management actions are targeted to habitat management areas to limit or eliminate surface disturbance. All forms of new development in PHMA – from energy, to transmission lines, to recreation facilities and grazing structures are excluded, avoided, or allowed only if the resultant effect is neutral or beneficial to the GRSG. In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated with habitat protection or restoration activities that produce a net conservation benefit for the GRSG. The ARMPAs/ARMPs will also prioritize future oil and gas leasing and development outside of identified GRSG habitat management areas (i.e., SFAs, PHMAs, and GHMAs) to reduce the potential for future conflict with GRSG.

In addition, the ARMPs and ARMPAs include measures to limit surface disturbance in PHMA through the establishment of disturbance limits or "caps" and density restrictions of on average 1 energy facility per 640 acres, as well as lek buffers. These requirements reflect recommendations contained in the NTT Report and are consistent with certain state strategies that were already in place before the initiation of the BLM's National GRSG Conservation Strategy. As described in Section 1.6.1, BLM determined the appropriate lek buffers to analyze based on the USGS report *Conservation Buffer Distance Estimates for GRSG – A Review* (Manier et al, 2014) based on best available science.

The plans also include actions meant to improve habitat condition to the most important areas for conservation through additional, targeted efforts to protect and restore habitat first in SFAs, then in PHMAs, and finally in areas designated as GHMAs.

Mitigation for activities adversely impacting GRSG or GRSG habitat in PHMA or GHMA will be designed to a net conservation gain standard consistent with the recommendation included in the September 2013 FWS document, *Greater Sage-Grouse Range-Wide Mitigation Framework*. According to the authors, the Framework was prepared …

> "to communicate some of the factors the Service is likely to consider in evaluating the efficacy of mitigation practices and programs in reducing threats to GRSG. The recommendations provided here are consistent with the information and conservation objectives provided in the 2013 Conservation Objectives Team (COT) Report for sage-grouse".

Grazing, which is the most widespread use of the sagebrush ecosystem, will continue in a manner consistent with the objective of conserving the GRSG. Land health standards will incorporate GRSG habitat objectives and vegetative management objectives consistent with the ecological potential of the landscape as recommended by the COT to …

> "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for GRSG (e.g. shrub cover, nesting cover)."

The ARMPAs also address the adverse impacts of free-roaming equids (wild horses and burros) on GRSG habitat by prioritizing gathers and removal of wild horses and burros to achieve AMLs in SFAs, PHMAs, and GHMAs (in that order). The BLM has been working with the National Academy of Sciences to conduct new research of methods to reduce wild horse and burro reproduction rates. Through a combination of targeted gathers and the development of an effective agent for controlling future free-roaming equid reproductive rates, over time, this threat to GRSG may be effectively managed.

Since the interaction of fire and invasive species represents the greatest threat to GRSG survival in the Great Basin region, the ARMPAs provide specific guidance for improving efforts to reduce the risk of GRSG habitat loss to wildfire, including fire prevention and the restoration of habitats impacted by fire. The Department took a series of actions over 2014 and 2015 to develop a more complete and comprehensive strategy for dealing with this threat that led to Secretarial Order (S.O.) 3336 and subsequent report, *An Integrated Rangeland Fire Management Strategy: Final Report to the Secretary of the Interior*.

http://www.forestsandrangelands.gov/rangeland/documents/IntegratedRangelandFireManagementStrategy_FinalReportMay2015.pdf

In accordance with the S.O. and subsequent rangeland fire management strategy, substantial changes in policy and management direction affecting all aspects of the rangeland fire management program – from better coordination between resource managers and fire management officers; to the identification and prioritization of prevention, suppression, and restoration efforts in SFAs, PHMAs, and GHMAs; to the commitment of additional equipment and crews for rangeland firefighting; to additional funding and policy direction to improve post-fire restoration; to the completion of an initiative to collect, store, and better utilize native seed and sagebrush in post-fire restoration of sagebrush steppe ecosystems. This effort, and the initiative to fight the spread of non-native invasive species that contributes to higher rangeland fire risk (e.g. cheatgrass) discussed below, has fundamentally changed how rangeland fire is managed to benefit sagebrush ecosystems and GRSG habitat.

The COT report – and other more recent research and analysis – amplify concern for the contribution of cheatgrass and other invasive annual species to the loss of GRSG habitat associated with increased fire frequency and intensity. Work initiated by the WAFWA and based on recent research by Chambers (Chambers et al, 2014b) led to the development of the Fire and Invasives Assessment Tool (FIAT) and a subsequent assessment that identified areas of resistance and resilience to fire within SFAs, PHMAs, and GHMAs. Through use of the FIAT Assessment/Tool, land managers can more efficiently allocate and use fire resources at initial attack, to stop fire early and prevent catastrophic habitat loss as well as target restoration to those areas important to the species where success is more likely. The BLM is also committed to and accelerating the registration and use of chemical and biological agents to stem the spread of cheatgrass and other invasive annual species.

Even prior to completion of the FIAT assessment, BLM shifted funding for fuels management to protect landscapes of importance to the GRSG. Under the FY2014 Omnibus Appropriation, BLM prioritized the funding of treatments and activities within each state that benefit GRSG (See **Figure 1-6)**.

In addition, the Sage Grouse Initiative (SGI) launched by the Natural Resources Conservation Service in 2010 also contributes to the effort to protect and restore important GRSG habitat. In collaboration with the states and private landowners on private lands, as well as with the BLM and USFS on federally-administered public lands, NRCS has worked to reduce the encroachment of pinyon-juniper trees and restore rangeland habitat on private and BLM-administered lands.

[Insert Figure 1-6. FY 2015 FIAT Priority Project Planning Areas with Focus on Invasive Annual Grasses and Conifer Expansion Assessments.]

To further supplement these efforts, the Department has recently committed $7.5 million to projects in

GRSG habitat to create more resilient landscapes and BLM has allocated $12 million to increase firefighting resources aimed at stopping fires while they are small in the Great Basin. The Department has identified required policy changes to increase the commitment, flexibility and timeframe for use of Emergency Stabilization and Burned Area Restoration (ES & BAR) funding on priority sagebrush-steppe habitats.

Consistent with recommendations contained in the 2006 WAFWA *Greater Sage-Grouse Range-wide Conservation Strategy,* the BLM and Forest Service conservation strategy places heavy reliance on monitoring and evaluation to assess the success and effectiveness of implementing the management decisions in the ARMPAs. Monitoring plans will be developed in coordination with relevant state and federal agencies and will incorporate evaluation of GRSG population trends by the states and changes in habitat condition by the federal land management agencies. As the WAFWA report states …

> Monitoring provides the "currency" necessary to evaluate management decisions and to assess progress or problems. Adequate monitoring should be considered an integral and inseparable component of all management actions, and there, not optional. Lack of proper monitoring will undoubtedly hinder this large-scale conservation effort.

In addition, the ARMPAs incorporate an adaptive management framework that provides an "early warning system" of "soft triggers" to alert resource managers to the need to evaluate the effectiveness of their management strategies should changes in population levels or habitat conditions occur. If the project-level management responses to soft triggers do not adequately address the causes for population or habitat declines and "hard triggers" are reached, the ARMPAs identify measures that will be put in place, including plan-level responses, in an effort to reverse the declines.

In summary, the ARMPAs emphasize an "avoidance first strategy" consistent with the recommendations in the COT Report by limiting new disturbance and maintaining current intact GRSG habitat. This avoidance first strategy is accomplished through identification of important GRSG habitat areas and then applying allocations that exclude or avoid surface disturbing activities, appropriately managing grazing, and aggressively suppressing fire that could degrade or fragment remaining GRSG habitat. The plans also include decisions to restore degraded habitat, which although more difficult and requiring a longer time frame, are important to the long-term conservation of GRSG. Restoration decisions include specific habitat objectives, and a priority on treating GRSG habitat for invasive species, particularly cheatgrass, and encroaching pinyon and juniper. These decisions are reinforced by Secretarial Order 3336 and the *Integrated Rangeland Fire Management Strategy* as well as NRCS' Sage Grouse Initiative (SGI) investments in private landowners' conservation efforts. This strategy reflects a high level of commitment by federal partners to conserve the GRSG and its habitat. These actions on over half of the most important lands for GRSG conservation will serve as an anchor and complement the significant actions being taken by state and local governments as well as private landowners to conserve the species and its habitat.

The landscape-level strategy consisting of new conservation actions that will go into effect through the BLM ARMPAs as well as actions being implemented currently to conserve the species, reflect a significant change in management direction and philosophy for both resource management agencies since

2010 and a long-term commitment to assure the conservation of the species consistent with the objectives set in the 2006 WAFWA conservation strategy and embraced by both the NTT and the COT.

This change represents a new paradigm in managing the sagebrush landscape for the BLM and amplifies the need for collaboration among federal, state, tribal, and private partners to conserve the GRSG consistent with direction articulated in the NTT report:

"Land uses, habitat treatments, and anthropogenic disturbances will need to be managed below threshold necessary to conserve not only local sage-grouse populations, but sagebrush communities and landscapes as well. Management priorities will need to be shifted and balanced to maximize benefits to sage grouse habitats and populations in priority habitats. Adequacy of management adjustments will be measured by science-based effectiveness monitoring of the biological response of sagebrush landscapes and populations. Ultimately, success will be measured by the maintenance and enhancement of sage-grouse populations well into the future."

The conservation benefits to the sagebrush ecosystem and GRSG habitats resulting from the BLM ARMPs and ARMPAs provide an essential foundation for conserving the GRSG which, in conjunction with the amended Forest Service LRMPs, affect nearly two-thirds of GRSG habitat across the remaining range of the species. In conjunction with similar conservation efforts by other federal and state agencies, private landowners, and local partners, the BLM National GRSG Conservation Strategy constitutes an historic conservation effort that will benefit more than 350 species and the sagebrush ecosystem upon which they depend. It is through ~~These~~ collaborative efforts to conserve the ~~vulnerable~~ imperiled sagebrush ecosystem that ~~can best achieve~~ conservation of the GRSG and other sagebrush obligate species can best be achieved and the listing of the Greater sage-grouse under the ESA may be avoided.

Comment [JRL7]: I suggest this closing paragraph for both RODs. Makes the point that ecosystem conservation is the best chance to avoid a listing… without saying it will.

1.9 Implementation

1.9.1 Additional Implementation Guidance and Considerations

Continued commitment to research and use of best available science: Through implementation of this strategy, new management issues and questions are likely to arise that may warrant additional guidance and/or study by technical experts, scientists, and researchers. The BLM is committed to continue to work with individuals and institutions with expertise in relevant fields in order to ensure that land and resource management affecting conservation of the Greater sage-grouse and the sagebrush ecosystem continues to be guided by sound, peer-reviewed research and the best available science. [May want to link to DOI and/or BLM science policy]

Implementation, after a BLM RMP or RMP amendment is approved, is a continuous and active process. Decisions presented as Management Decisions can be characterized as *immediate* or *one-time future* decisions.

Immediate Decisions: These decisions are the lands use planning decisions that go into effect upon signature of the ROD. These include goals, objectives, allowable uses and management direction, such as the allocation of lands as open or closed for saleable mineral sales, lands open with stipulations for oil and gas leasing, and OHV area designations. These decisions require no additional analysis and guide future land management actions and subsequent site specific implementation decisions in the planning area. Proposals for future actions such as oil and gas leasing, land adjustments, and other allocation-based actions will be reviewed against these land use plan decisions to determine if the proposal is in conformance with the plan.

One-Time Future Decisions: These types of decisions include those that are not implemented until additional decision-making and site-specific analysis is completed. Examples are implementation of the recommendations to withdraw lands from locatable mineral entry or development of travel management plans. Future one-time decisions require additional analysis and decision-making and are prioritized as part of the BLM budget process. Priorities for implementation of "one-time" RMP decisions will be based on several criteria, including:

- Current and projected resource needs and demands,
- National BLM management direction, and
- Available resources.

General Implementation Schedule of "One-Time" Decisions: Future Decisions discussed in the attached ARMPAs will be implemented over a period of years depending on budget and staff availability. After issuing the ROD, BLM will prepare implementation plans that establish tentative timeframes for completion of "one-time" decisions identified in these ARMPs and ARMPAa. These actions require additional site specific decision-making and analysis.

This schedule will assist BLM managers and staff in preparing budget requests and in scheduling work. However, the proposed schedule must be considered tentative and will be affected by future funding, changing program priorities, non-discretionary workloads, and cooperation by partners and external publics. Yearly review of the plan will provide consistent tracking of accomplishments and provide information that can be used to develop annual budget requests to continue implementation.

1.9.1 Additional Implementation Guidance and Considerations

Instructional Memoranda – Additional instruction and management direction will be necessary to implement certain land allocation decisions and management direction included in the ARMPAs. For example, additional guidance will be provided to clarify how the Bureau will implement the objective of prioritizing future oil and gas leasing and development outside of GRSG habitat. Instructional Memoranda (IM) and related guidance will be completed by the BLM-Washington office. Presently, IMs for the following management direction are anticipated: oil and gas leasing and development prioritization, livestock grazing, monitoring, and mitigation. Issuance of this national guidance will supersede any related national and field level guidance currently in effect. Additional national, state and field level guidance will be developed as necessary to implement the decisions in the plans.

Transmission lines -- Although future high voltage transmission lines will be avoided in PHMA, the planning, siting, and environmental review of a limited number of Presidential priority lines (Gateway West, Boardman to Hemingway, and Transwest Express, including those portions of Gateway South that are co-located) have been underway for a several years. These lines are critical to expanding access to renewable sources of energy (especially wind) and to improving the reliability of the Western grid, and therefore, planning for these lines is proceeding through NEPA analysis in a separate authorization process. Conservation measures for GRSG are being analyzed as part of those NEPA processes, which should achieve a net conservation benefit for GRSG. Conservation measures to achieve this may include micro-siting to adjust the route to avoid important habitat and leks, transmission tower design to minimize the potential for adverse impacts to GRSG such as perching for predators, and compensatory mitigation measures, such as habitat restoration and pre-suppression activities to reduce the risk of habitat loss due to fire, to offset any unavoidable impacts to a conservation gain standard.

Wild horses and burros – Recognizing the potential for free-roaming equids to adversely impact sage-grouse habitat, the decisions emphasizes the need to focus on maintaining WHB Herd Management Areas in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve habitat management objectives, focusing first in SFAs and PHMAs.

Grazing – Changes in grazing management will occur when authorizations are renewed or modified to meet land health standards, including sage-grouse habitat standards. Changes will be made in accordance with regulatory processes. Therefore, there will be no immediate change in grazing management or modification of term grazing permits and leases upon signing this ROD. As stated in the ARMPAs and ARMPs, the BLM will prioritize review of livestock grazing management in SFAs and PHMAs and implement changes as needed. All BLM grazing use authorizations will contain terms and conditions regarding the actions needed to meet or make significant progress toward meeting the habitat objectives. If an evaluation of monitoring and assessment information shows that the objectives are being met or there is a trend towards meeting the objectives, then no adjustments to the current use and management is required. If the evaluation shows the habitat objectives are not met nor is there progress towards meeting them, then the cause for not meeting the objectives will be identified. If it is determined that the current authorized livestock management or level of use is a significant cause, the use will be adjusted in accordance with the response specified in the instrument that authorized the use, or as described in a NEPA document. The BLM will prioritize the review of grazing authorizations in SFA and PHMA in particular, focusing on those containing important riparian habitats and those not meeting Land Health Standards, to determine if modification is necessary prior to renewal of the authorization. Renewed or modified grazing authorizations in SFA and PHMA will include terms and conditions specifically designed to meet objectives identified in the GRSG Habitat Objectives Table based on ecological site potential and Land Health Standards. One or more defined responses to exceeding specific management thresholds will be subjected to NEPA analysis during the grazing authorization renewal or modification process, which will allow the authorized officer to make adjustments to livestock grazing that have already been subjected to NEPA analysis. The BLM will include additional management direction for implementing grazing management actions in the ARMPs in an Instructional Memorandum.

GRSG Seasonal Habitats – PHMA was designed to include breeding bird density, sage-grouse proportionality, density of leks, and key seasonal habitats, such as known winter concentration areas, and GHMA was designed to include the areas of occupied seasonal, connectivity, or year-round habitat outside of PHMA. As additional important habitats are identified, the BLM will map, and incorporate these habitats for GRSG, consistent with best available science, through subsequent plan revisions or amendments, as appropriate. Priority should be given to ensuring that wintering habitat is identified and captured in all changes in habitat maps subsequent to this decision.

Climate Change Effects on GRSG Conservation – As identified by the FWS 2010 decision and the COT report, climate change can impact efforts to conserve the GRSG and its habitat in a number of ways. While several ARMPAs acknowledge the potential impact of climate change on GRSG habitat and conservation efforts, specific strategies to address the impacts of climate change are limited. The BLM and Forest Service, in coordination with the FWS, will continue to assess the potential impacts of climate change on GRSG and its habitat and develop strategies to mitigate anticipated effects on GRSG conservation efforts. Changes to management decisions will require a plan revision or amendment, as appropriate.

Training -- Given the nature and complexity of the management direction in these ARMPAs, the BLM, in collaboration with the Forest Service and the FWS, will develop and implement a schedule of trainings for key functions, actions, and decisions associated with these plans. In this manner, the BLM will seek to better inform its personnel, partners, cooperators, and stakeholders of the changes in management that will result from this new management paradigm.

2. DECISION

2.1 Summary of the Approved Management Decisions

The decision is hereby made to approve the Great Basin Region Greater Sage-Grouse ARMPAs for the Great Basin Region Greater Sage-Grouse Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah (attachments 1 through 4). This ROD serves as the final decision establishing the land use plan amendment decisions outlined in the ARMPAs and is effective on the date it is signed.

The decisions included in this ROD and attached ARMPAs amend the land use plans described in **Sections 1.3** of attachments 1 through 4.

The land use decisions conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Land use plan decisions are expressed as goals and objectives (desired outcomes), and allocations, allowable uses, and management decisions anticipated to achieve desired outcomes. Although decisions identified in the ARMPAs are final and effective upon signing of this ROD, they generally require additional implementation decision steps before on-the-ground activities can begin. Subsequent NEPA analysis will be conducted, as necessary, for such implementation decisions.

2.2 What the Record of Decision and Approved Resource Management Plan Amendments Provide

The ARMPAs include GRSG and GRSG habitat land use plan level management decisions in the form of:

- Goals
- Objectives (Desired Future Conditions)
- Land Use Allocations and Allowable Uses
- Management Actions

Goals are the broad statements of desired outcomes, and are usually not quantifiable.

Objectives are specific desired conditions, usually quantifiable and measurable, and may have timeframes for achievement.

Land use allocations specify locations within the planning area that are available or not available for certain uses and are also used to prioritize conservation and restoration management actions. These include decisions such as what lands are available for livestock grazing, mineral material use, oil and gas leasing, and locatable mineral development, what lands may be available for disposal via exchange and/or sale, and what lands are open, closed, or limited to motorized travel (please note that all acreages presented in the Approved Plan are estimations even when presented to the nearest acre).

Management decisions/actions include those provisions that help in meeting the established goals and objectives and include measures that will be applied to guide day-to-day activities on public lands, including but not limited to stipulations, guidelines, best management practices (BMPs), and required design features.

The ARMPAs' management decisions were crafted to incorporate conservation measures into LUPs to conserve, enhance, and restore GRSG habitat by reducing, eliminating, or minimizing identified threats to GRSG and their habitats (see **Section 1.3**).

2.3 What the Record of Decision and Approved Resource Management Plan Amendments Do Not Provide

The attached ARMPAs do not contain decisions for public lands outside of GRSG habitat management areas, except for land use plan level travel management area decisions in the Idaho and Southwestern Montana ARMPA.

The ARMPAs and ARMPs do not violate valid existing rights.

The ARMPAs do not contain decisions for the mineral estates that is not administered by the BLM. ARMPA decisions for surface estate only apply to BLM managed lands. In addition, many decisions are not appropriate at this level of planning and are not included in the ROD. Examples of these types of decisions include:

- *Statutory requirements.* The decision will not change the BLM's responsibility to comply with applicable laws, rules, and regulations.
- *National policy.* The decision will not change BLM's obligation to conform to current or future National policy.
- *Funding levels and budget allocations.* These are determined annually at the National level and are beyond the control of the State/District of Field offices.

Implementation decisions (or activity-level decisions) are management actions tied to a specific location. Implementation decisions generally constitute the BLM’s final approval allowing on-the-ground actions to proceed and require appropriate site-specific planning and NEPA analysis. Such decisions may be incorporated into implementation plans (activity or project plans) or may exist as stand-alone decisions. These ARMPAs do not contain implementation decisions. Future activity-level plans will address the implementation of the ARMPAs. Implementation decisions and management actions that require additional site-specific project planning, as funding becomes available, will require further environmental analysis.

2.4 Modifications and Clarifications

The ARMPAs in the Great Basin Region include minor modifications and clarifications to the Proposed RMPs and RMP Amendments. These minor modifications and clarifications were made as a result of internal reviews, response to protests, and recommendations provided to the BLM during the Governors’ consistency review. These modifications and clarifications are hereby adopted by this ROD.

The following modifications/clarifications were made to all of the ARMPAs in the Great Basin Region.

- ARMPA Formatting: The plans were reformatted between the Proposed RMPA and ARMPA planning stages for consistency across the Great Basin Region; the order of management actions and the prefixes for the goals, objectives, and management actions were changed in the ARMPAs to provide consistency among the amendments and revisions for GRSG goals and objectives.

- U.S Forest Service References (applicable only to the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah ARMPAs): All references to National Forest System lands in both text and on maps have been removed from the ARMPAs. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plan Amendment under their planning authorities.
- Fire: Management actions/decisions were modified to stress that the protection of human life is the single, overriding priority for fire and fuels management activities.
- Livestock Grazing: The following statement, "This does not apply to or impact grazing preference transfers, which are addressed in 43 CFR 4110.2-3," was added to the management action/decision which reads, "At the time a permittee or lessee voluntarily relinquishes a permit or lease, the BLM will consider whether the public lands where that permitted use was authorized should remain available for livestock grazing or be used for other resource management objectives, such as reserve common allotments or fire breaks."
- Glossary: Numerous glossary definitions were deleted due to the fact that the terms were not used/referenced in the ARMPAs. If not already contained in the Proposed RMPAs' glossary, the following terms and definitions were added to the glossary for clarification:
  - Grazing Relinquishment: the voluntary and permanent surrender by an existing permittee or lessee, (with concurrence of any base property lienholder(s)), of their priority (preference) to use a livestock forage allocation on public land as well as their permission to use this forage. Relinquishments do not require the consent or approval by BLM. The BLM's receipt of a relinquishment is not a decision to close areas to livestock grazing.
  - Transfer of Grazing Preference: the BLM's approval of an application to transfer grazing preference from one party to another or from one base property to another, or both. Grazing preference means a superior or priority position against others for the purposes of receiving a grazing permit or lease. This priority is attached to base property owned or controlled by the permittee or lessee.
  - Valid Existing Right: Documented, legal rights or interests in the land that allow a person or entity to use said land for a specific purpose and that are still in effect. Such rights include but are not limited to fee title ownership, mineral rights, rights-of-way, easements, permits, and licenses. Such rights may have been reserved, acquired, leased, granted, permitted, or otherwise authorized over time.
  - Mining Claim: A parcel of land that a miner takes and holds for mining purposes, having acquired the right of possession by complying with the Mining Law and local laws and rules. A mining claim may contain as many adjoining locations as the locator may make or buy. There are four categories of mining claims: lode, placer, millsite, and tunnel site.
  - Energy or Mining Facility: Human constructed assets designed and created to serve a particular function and to afford a particular convenience or service that is

affixed to a specific locations, such as oil and gas well pads and associated infrastructure.

- GRSG Habitat Mapping: Information was added to the ARMPAs to specify that when new information becomes available about GRSG habitat, including seasonal habitats, in coordination with the state wildlife agency and FWS, and based on best available scientific information, the BLM may revise the GRSG habitat management area maps and associated management decisions through plan maintenance or plan amendment/revision, as appropriate.
- Adaptive Management: The Greater Sage-Grouse Adaptive Management Strategy was revised to include a commitment that the hard and soft trigger data will be evaluated as soon as it becomes available after the signing of the ROD and then at a minimum, analyzed annually thereafter.
- Vegetation: The desired condition for maintaining a minimum of 70% of lands capable of producing sagebrush with 10 to 30% sagebrush canopy cover in SFAs and PHMAs was modified to read as follows: "In all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain all lands ecologically capable of producing sagebrush (but no less than 70%) with a minimum of 15% sagebrush canopy cover or as consistent with specific ecological site conditions. The attributes necessary to sustain these habitats are described in Interpreting Indicators of Rangeland Health (BLM Tech Ref 1734-6)."
- GRSG Habitat Objectives: For clarification purposes, within each of the ARMPA GRSG Habitat Objectives Tables, native bunchgrasses was provided as an example of a perennial grass cover and the inclusion of residual grasses was added to the perennial grass cover and height objective.
- Sagebrush Focal Areas: Examples of the types of vegetation and conservation actions that will be prioritized within SFAs were provided for clarity in the management action/decision. These examples include land health assessments and wild horse and burro management and habitat restoration actions.
- Required Design Features: One of the criteria for demonstrating that a variation to an RDF is warranted was modified to include the following statement, "An alternative RDF, a state-implemented conservation measure or plan-level protection is determined to provide equal or better protection for GRSG or its habitat."
- Lands and Realty: The following management actions/decisions and objectives were calrified:
  - Effects of infrastructure projects, including siting, will be minimized using the best available science, updated as monitoring information on current infrastructure projects becomes available.
  - Within existing designated utility corridors, the 3% disturbance cap may be exceeded at the project scale if the site specific NEPA analysis indicates that a net conservation gain to the species will be achieved. This exception is limited to projects which fulfill the use for which the corridors were designated (ex., transmission lines, pipelines) and the designated width of a corridor will not be exceeded as a result of any project co-location.
- Land Tenure: Management action associated with land disposals was clarified to include land exchanges as a means of disposal.
- WAFWA GRSG Conservation Team. Additional clarification was added to ARMPAs related to the WAFWA GRSG Conservation Teams that were identified in the Proposed RMPAs: "WAFWA management zones will be used to facilitate cross-state issues, such as regional

mitigation and adaptive management monitoring and response, through WAFWA GRSG Conservation Teams (Teams). These Teams will convene to advise on these specific tasks and will utilize existing coordination and management structures to the extent possible."

- Cheatgrass: The following management action was included consistent with the purpose and need and objectives of the ARMPAs: "Treat areas that contain cheatgrass and other invasive or noxious species to minimize competition and favor establishment of desired species."
- Valid Existing Rights: The following management action was added to the ARMPs and ARMPAs: "Consider the potential for the development of not-yet-constructed valid existing rights of surface disturbing activities as defined in Table 2 of the Monitoring Framework prior to authorizing new projects in PHMA."

Additional modifications and clarifications specific to each sub-region ARMPA are summarized below.

2.4.1 Idaho and Southwestern Montana

General Changes

- All exception language that was in the FEIS in various places was grouped into a stipulation appendix and added it to the ARMPA as Appendix G Stipulations.
- Appendix G Anthropogenic Disturbance and Adaptive Management from the Proposed RMPA, which is now Appendix E in the ARMPA was modified to delete the reference to Tables 2 to 7. Tables 2 to 7 were deleted from the FEIS Appendix G before it was made available to the public for protest, but the reference was not deleted in text of the Appendix. This discrepancy was identified during protest resolution and by the Governor during the Governor's Consistency Review. These values will be calculated after the signing of the ROD (see Adaptive Management below).
- Many editorial changes including, deleting repeated numbers, spelling errors, etc, were made when finalizing the ARMPA.
- On August 7, 2015, President Barack Obama signed into law the Sawtooth National Recreation Area and Jerry Peak Wilderness Act (H.R. 1138). In accordance with the Wilderness Act (16 U.S.C. 1131 et seq.), certain Federal lands in the Challis National Forest and Challis District of the Bureau of Land Management in the State of Idaho, comprising approximately 116,898 acres, were designated as wilderness, as a component of the National Wilderness Preservation System, known as the Jim McClure-Jerry Peak Wilderness. This bill also released the Jerry Peak West, Corral-Horse Basin, and Boulder Creek Wilderness Study Areas and they are no longer subject to section 603(c) of the FLPMA. In accordance with the Recreation and Public Purposes Act, this law also conveyed public lands to Blaine County, Custer County, the City of Challis, the City of Clayton, and the City of Stanley. The new wilderness area, the release of the WSAs, and the lands that were conveyed by this law were not within the decision area of the Idaho and Southwestern Montana ARMPA, therefore, no changes to the ARMPA have been made as a result of the passage of this law.

Special Status Species

- Deleted the Seasonal Timing Restrictions from Appendix C FEIS to reduce redundancy because these restrictions were already in the Required Design Features Appendix.

Livestock Grazing

- Livestock Grazing RM-16 and RM 18, which are now MD LG 15 and MD LG 17 respectively in the ARMPA, had the following sentence added as an accepted recommendation made by the Governor during the Governor's Consistency Review to clarify management and conservation action prioritization in SFAs and: "Management and conservation action prioritization will occur at the Conservation Area (CA) scale and be based on GRSG population and habitat trends: Focusing management and conservation actions first in SFAs followed by areas of PHMA outside SFAs."

Lands and Realty

- Lands and Realty LR-14 from the Proposed RMPA, which is now MD LR 13 in the ARMPA, was modified to remove the statement that lands in PHMA, IHMA, and GHMA would only be available for disposal through exchange. This was removed because it was not consistent with BLM policy and the net conservation gain clause in MD LR-13 will provide assurance that disposals through any method would be beneficial to GRSG.

2.4.2 Nevada and Northeastern California

General Changes

- Editorial changes such as changing 'should' to 'shall', and 'would' to 'will' to reflect the final decision language.
- Re-categorizing some of the Management Decisions into other common resource programs. For example, all of the Fire and Fuels management decisions are all numbered under FIRE, and are not split into different sub-category names.
- Re-lettering of the critical Appendices, and deletion of those that are no longer applicable for the ARMPA.

Special Status Species

- Added clarity to MD SSS 2 A 3, by describing what energy and mining facilities to which this decision would apply; taken directly from the Disturbance Appendix E.
- Added clarity to MD SSS 3A, by including references to valid existing rights and applicable law for the requirement of a 'net conservation gain'.
- Specified in MD SSS 8 that this activity would be coordinated with NDOW or CDFW, and that breeding activity surveys would be for actions involving mineral activities and rights-of-ways.

- Deleted Action PR 4 from the Proposed LUPA because BLM does not manage landfills and transfer stations.

Adaptive Management

- Moved the Adaptive Management Strategy section out of Chapter 2 and made it into Appendix J; moved the Adaptive Management decisions under MD SSS 17 – MD SSS 22.
- Clarified under MD SSS 21 that BLM will coordinate with NDOW, and that the decision was specific to mineral activities and rights-of-way actions.

Fire and Fuels Management

- Deleted ‘field offices and districts’ from MD FIRE 3, as there will be a multi-layer approach to coordination, including BLM State Offices.
- In Objective FIRE 3, added ‘in SFAs first’ to provide more emphasis to the SFA over the rest of the PHMA for this action.
- Modified MD FIRE 26 to delete ‘Districts’, as there will be a multi-layer approach to identifying treatment needs for wildfire and invasive species management across the state.
- Added ‘FWS’ as a coordination entity to MD FIRE 31, when ensuring that proposed sagebrush treatments are coordinated with the BLM and State fish and wildlife agencies.

Livestock Grazing

- Management Decision LG 1 was modified for clarity and to include the fact that BLM would conduct appropriate consultation, cooperation and coordination
- Management Decision LG 5 was modified to add supplementary management actions and clarifies that the potential modifications include, “but are not limited to” to actions on the list.
- Management Decision LG 5 was modified to make it clear that the management strategies listed are not limited to just those listed under LG 5 by adding “but are not limited to”. This was added to clarify a misunderstanding in a protest letter.
- Management Decision LG 7 was clarified to state that “AUMs cannot be applied to another pasture that is already being used by livestock or is being purposefully rested.”
- Management Decision LG 15 was modified to state that removing or modifying water developments must be done “In accordance with state water law and…”

Mineral Resources

- Management Decision MR 18 was modified to provide the Barrick Enabling Agreement as an example of appropriate mitigation that can be considered in the future, and the last sentence was removed because it only repeated BLM regulations, and is unnecessary.

Lands and Realty

- In order to resolve a protest, MD LR 3 was modified to state that corridors will be 3,500 feet in width… "or a different width is specified for congressional designated corridors". This is in response to the Lincoln County Conservation Recreation Development Act (2204) which included congressionally designated corridors that were not included in the plan amendment or the corridor map. The corridor map (Figure 2-10) was also modified to reflect the corridors tied to this Act.
- Action LR-LUA 21 from the Proposed Plan was deleted because the Federal Highway Administration and the Nevada Department of Transportation already have valid existing rights associated with their easements and ROWs, and this planning effort would not change the terms and conditions of their existing easements or ROWs. Making this a Management Action is repetitive and unnecessary.

Travel and Transportation

- Due to confusion that was outlined in protest letters and in the Governor's Consistency Review, MD TTM 2 was clarified that limiting off-highway travel to existing routes in PHMAs and GHMAs would be "subject to valid existing rights, such as for a mine under a plan of operations".
- Additional language was added to MD TTM 3 to make it clear that the bulleted "guidelines will be considered when undertaking future implementation-level travel planning". This was in response to protest misunderstandings. In addition, bullet three was amended by deleting "developed in this plan amendment", as the criteria is not developed through the plan amendment.

Mitigation

- In order to provide consistency across the Great Basin Regional Planning area, the two Mitigation management decisions were removed from the Adaptive Management, Monitoring, and Mitigation section of Chapter 2 in the Proposed LUPA (which are now separate Appendices) and inserted as management decisions independently under the Mitigation section.

2.4.3 Oregon

Lands and Realty

- A typographical error in the socioeconomic analysis of the proposed RMPA was identified during the Protest period. Correction to this error in Section 4.20.3, page 4-345, is as follows: Paragraph beginning "Restrictions to ROW development under Alternatives B, C, D,E, F, and the Proposed Plan…" is replaced with: "Proposed management under Alternatives B, C, D, E, F, and the Proposed Plan could require investors to consider

> alternative power line ROW alignments or designs that could increase the costs of constructing new infrastructure. A 2012 WECC study, for example, provides information on transmission line construction costs per mile, which range from $927,000 to $2,967,000 depending on voltage and whether lines are single or double circuit lines. The same study provides cost multipliers for difficult terrains, reaching up to 2.25 in the case of forested lands (WECC 2012). Utilities and other infrastructure investors typically pass these costs on to consumers. Where the rate base is smaller, such as in rural areas, per-customer rate impacts associated with constructing a 10-mile, 230kV transmission line, for example, would be greater compared to the economic impacts on rate payers served by a larger metropolitan utility proposing the same line. Under Alternatives B, C, D, E, and the Proposed Plan, rate payers serviced by local utility providers with small rate bases would be impacted more by costs associated with added route lengths or infrastructure design requirements compared with rate payers serviced by larger, multi-state providers. Where technically and financially feasible, Alternatives B, D, and the Proposed Plan identify burial of power lines as a design option to mitigate impacts on GRSG. New construction costs of underground transmission lines can be between 4 and 14 times higher compared to new overhead construction (PSC 2011), depending on terrain. In rural areas, burial of new distribution lines would be more than double the cost of new overhead construction. Burying existing distribution lines would likely cost between $400,000 and $500,000 per mile in rural areas (EIA 2012). Under all alternatives, where burying new lines would be technically unfeasible or result in costs that could not be absorbed by the rate payers, infrastructure investors would explore other route or design options that avoid impacts to GRSG habitat."

Special Status Species (Greater Sage-Grouse)

- Objective SSS 6 was modified to clarify that the BLM will coordinate with the State of Oregon regarding proposed management changes, the implementation of conservation measures, mitigation, and site-specific monitoring related to adaptive management and anthropogenic disturbances. This modification was recommended by the Governor during the Governor's Consistency Review.

Leasable Mineral Resources

- Based on internal review, MLS 7 from the proposed RMPA, which is now MD MR 7 in the ARMPA, was modified to include all fluid mineral lease development, including geothermal permits to drill.

2.4.4 Utah

General Changes

- Throughout the Proposed RMP Amendment, the use of words like “would,” “could,” “should,” and “may” were generally removed or revised to reflect the active management direction of an ARMPA rather than potential management presented when the Proposed RMP Amendment was one of many alternatives the agency could select.
- Language was added to Objective SSS-3 (Objective GRSG-3 in the Proposed RMP Amendment), MA-SSS-4 (MA-GRSG-4 in the Proposed RMP Amendment), MA-SSS-6 (MA-GRSG-6 in the Proposed RMP Amendment), Objective VEG-1, MA-VEG-1, MA-FIRE-3 and MA-FIRE-4 to clarify that landscapes that include populations of both GRSG and Utah prairie dog (UPD), a federally listed species, be managed for the benefit of both species. This addition is included to ensure that this objective is applied to all applicable objectives and management actions, not just the five actions in the Proposed RMP Amendment where this concept and language was already present.
- Throughout the Proposed RMPA there were a number of references to coordinating with the State of Utah, Division of Wildlife Resources, or state biologists. These were all revised to note that such coordination would be with “the appropriate State of Utah agency.” This clarification was made at the request of the Governor during the Governor’s Consistency Review.
- The Proposed RMP Amendment introduced the term “biologically significant units” (BSU) for adaptive management and the disturbance cap to provide a consistent approach for managing and monitoring across the GRSG range. In the Utah Sub-Region, the BSU concept is the same as PHMA within population areas. As part of resolving protests, the ARMP was revised to note that “BSUs” are PHMA within population areas. Whenever the term BSU was used, it was replaced with the more descriptive text, with a parenthetical reference to BSUs for the purposes of coordinating across state lines.

Special Status Species (formerly Greater Sage-Grouse)

- Objective GRSG-1 from the Proposed RMP Amendment, which is now Objective SSS-1 in the ARMPA, was changed to remove reference to WAFWA management zones when addressing designation of PHMA. This change was made during the Governor’s Consistency Review to more closely reflect the management in the State of Utah’s Conservation Plan for Greater Sage-Grouse in Utah (2013).
- MA-GRSG-1 from the Proposed RMP Amendment, which is now MA-SSS-1 in the ARMPA was revised to include the following text: “The BLM will apply these goals, objectives, and management actions where the agency has discretion to implement them; the actions do not apply in areas where the BLM does not administer the surface or mineral estate.” This is consistent with the planning criteria contained in the sixth bullet on page 1-20 of the Final EIS. This language was added based on an accepted recommendation made by the Governor during the Governor’s Consistency Review.
- The language of MA-GRSG-1 from the Proposed RMP Amendment, which is now MA-SSS-1 in the ARMPA, regarding non-habitat areas within PHMA and GHMA was revised to clarify the intent of the action. This revision was made as a result of internal reviews to ensure the text more accurately reflected the intent behind the management action.

- The introductory language of MA-GRSG-3 from the Proposed RMP Amendment, which is now MA-SSS-3 in the ARMPA, was revised to clarify the intent of the action. This revision was made as a result of internal reviews to ensure the text accurately reflects the intent behind the management action and to focus on land uses that have been identified as threats to GRSG.
- The language of MA-GRSG-3e from the Proposed RMP Amendment, which is now MA-SSS-3e in the ARMPA, was revised to clarify the intent of the noise restrictions. This revision was made as a result of internal reviews to ensure the text accurately reflects the intent behind the management action to focus on land uses that have been identified as threats to GRSG. Further, language was added to identify when "ambient" noise levels would be assessed to avoid managing for continual, incremental increases in noise levels.
- The language of MA-GRSG-6 from the Proposed RMP Amendment, which is now MA-SSS-6 in the ARMPA, was revised to clarify the intent of GRSG management outside PHMA/GHMA. This revision was made as a result of internal reviews to ensure the text accurately reflects the intent behind the management action. The purpose of this action is to provide direction regarding management of areas outside PHMA/GHMA that have been treated to improve GRSG habitat. The change was necessary to avoid implication of changing allocations or altering PHMA/GHMA boundaries outside a planning process while minimizing conflicting land uses in areas where an investment in increasing GRSG habitat have been made.

Livestock Grazing

- The language of MA-GRA-6 from the Proposed RMP Amendment, which is now MA-LG-6 in the ARMPA, was revised. The concepts and intent did not change, but the text was revised to align with similar concepts and intent that was present in the livestock grazing sections in GRSG amendments throughout the Great Basin.

2.5 Protest Resolution

BLM's planning regulations at 43 CFR 1610.5-2 allow any person who participated in the planning process and has an interest that may be adversely affected by BLM's planning decisions to protest proposed planning decisions within 30 days from the date the Notice of Availability of the Proposed RMP/Final EIS was published in the Federal Register (May 29, 2015). Below are descriptions of the protest resolution process for each of the four Great Basin Region PRMPAs/FEISs.

The Director concluded that the BLM followed all applicable laws, regulations, and policies and considered all relevant resource information and public input in developing the Proposed Land Use Plan Amendments/Final EISs. Each protesting party has been notified in writing of the Director's findings and the disposition of their protests. The BLM Director resolved the protests without making significant changes to the Proposed Land Use Plan Amendments/Final EISs, though minor clarifications were made and are summarized in Section 2.4.1. The BLM Director's decisions on the protests are summarized in each of the PRMPAs/FEISs Director's Protest Resolution Reports, which are available on the following

BLM website:
http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

2.5.1 Idaho and Southwestern Montana

For the Idaho and Southwestern Montana GRSG Proposed LUPA/Final EIS, the BLM Director received 20 timely protest submissions. All of the protesting parties had standing; however, one submission was dismissed as it did not contain any valid protest points pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report included:

- compliance with FLPMA,
- compliance with NEPA,
- compliance with ESA,
- density and disturbance,
- adaptive management,
- GRSG habitat objectives,
- livestock grazing,
- mitigation,
- compliance with APA,
- compliance with the Energy Policy Act of 2005,
- ACECs,
- fire and fuels management,
- fluid minerals,
- solid minerals,
- special status species,
- lands and realty, and
- travel and transportation management.

2.5.2 Nevada and Northeastern California

For the Nevada and Northeastern California GRSG Proposed LUPA/Final EIS, the BLM Director received 40 timely protest submissions. All of the protesting parties had standing; however, two submissions were dismissed as they did not contain any valid protest points pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report included:

- compliance with FLPMA,
- compliance with NEPA,
- compliance with ESA,
- density and disturbance,
- adaptive management,
- GRSG habitat objectives,
- livestock grazing,
- mitigation,
- compliance with APA,

- compliance with the Energy Policy Act of 2005,
- Air Quality,
- Climate Change,
- Noise,
- ACECs,
- solid minerals,
- special status species,
- lands with wilderness characteristics,
- lands and realty,
- tribal issues,
- wild horse and burros, and
- travel and transportation management.

2.5.3 Oregon

For the Oregon GRSG Proposed LUPA/Final EIS, the BLM Director received 30 timely protest submissions. All of the protesting parties had standing; however, three submissions were dismissed as they did not contain any valid protest points pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report included:

- compliance with FLPMA,
- compliance with NEPA,
- compliance with ESA,
- density and disturbance,
- monitoring,
- ACECs,
- fire and fuels management,
- solid minerals,
- special status species, and
- travel and transportation management.

2.5.4 Utah

For the Utah GRSG Proposed LUPA/Final EIS, the BLM Director received 43 timely protest submissions. All of the protesting parties had standing; however, three submissions were dismissed as they did not contain any valid protest points pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report included:

- compliance with FLPMA,
- compliance with NEPA,
- compliance with ESA,
- density and disturbance,
- adaptive management,
- land use allocations,

- GRSG habitat objectives,
- livestock grazing,
- mitigation,
- compliance with APA,
- compliance with the Energy Policy Act of 2005,
- air quality,
- climate change,
- noise,
- ACECs,
- fire and fuels management,
- fluid minerals,
- solid minerals,
- special status species,
- lands and realty,
- travel and transportation management, and
- reasonable foreseeable development scenarios.

2.6 Governor's Consistency Review

The BLM's planning regulations require that RMPs be "consistent with officially approved or adopted resource-related plans, and the policies and procedures contained therein, of other federal agencies, state and local governments, and Indian tribes, so long as the guidance and resource management plans also are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands" (43 CFR 1610.3-2(a)). The general requirement in FLPMA/planning regulations is to coordinate the land use planning process with plans of other agencies, states, and local governments to the extent consistent with law (see FLPMA s. 202(c)(9) and 1610.3-1(a)); and the respective duties to be consistent with both officially approved or adopted plans (to the extent those plans are consistent with federal law, or to maximum extent practical) (see 1610.3-2(a)(b)). In accordance with FLPMA, the BLM was aware of and gave consideration to state, local, and tribal land use plans and provided meaningful public involvement throughout the development of the Proposed RMP Amendments/Final EISs.

The BLM is aware that there are specific state laws and local plans relevant to aspects of public land management that are discrete from, and independent of, federal law. However, the BLM is bound by federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that BLM's land use plans be consistent with officially-approved state and local plans only if those plans are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands. Where officially-approved state and local plans or policies and programs conflict with the purposes, policies, and programs of federal laws and regulations applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially-approved state and local policies and programs (as opposed to plans), this consistency provision only applies to the maximum extent practical. While county and federal planning processes, under FLPMA, are required to be as integrated and consistent as practical, the federal agency planning process is not bound by or subject to state or county plans, planning processes, policies, or planning stipulations.

The 60-day Governor's consistency review period ended on July 29, 2015. In the Great Basin Region, the Governors of Idaho, Nevada, Oregon, and Utah submitted letters to their respective BLM State Directors identifying inconsistencies between the BLM's proposed RMP amendments and their state's or local governments' resource-related plans, policies and/or procedures, as well as other concerns that they had with the proposed planning documents. The BLM State Directors notified the Governors as to whether their recommendations were accepted or rejected on August 6, 2015. These Governors were then provided with 30-days to appeal the BLM State Director's decisions to the BLM Director. By September 8, 2015, the BLM Director received appeals from.

In some instances, modifications to the ARMPAs were addressed based on recommendations submitted to the BLM by the applicable Governors. These modifications to the ARMPAs were made and are summarized in Section 2.4.1.

3. ALTERNATIVES

3.1 Alternatives Considered

Each of the Great Basin sub-regional planning efforts analyzed in detail a set of alternatives in the draft and final sub-regional EISs. The alternatives were developed to provide direction for resource programs in order to meet in the purpose and need of this effort to identify and incorporate appropriate management direction in LUPs to conserve, enhance, and restore GRSG habitat by reducing, eliminating, or minimizing threats to GRSG habitat. All management considered under any of the alternatives complied with federal laws, rules, regulations, and policies.

Each alternative emphasized an altered combination of resource uses, allocations, and restoration measures to address issues and resolve conflicts among uses so that GRSG goals and objectives were met in varying degrees across the alternatives. The action alternatives offered a range of possible management approaches for responding to planning issues and concerns identified through public scoping, and to maintain or increase GRSG abundance and distribution in the planning area. While the land use plan goal was the same across alternatives for each sub-region, each alternative contained a discrete set of objectives and management actions constituting a separate RMP amendment. The goal was met in varying degrees, with the potential for different long-range outcomes and conditions.

The relative emphasis given to particular resources and resource uses differed as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs. When resources or resource uses are mandated by law there are typically few or no distinctions between alternatives.

3.1.1 Alternative A – No Action Alternative

Alternative A meets the CEQ requirement that a No Action Alternative be considered. This alternative continues current management direction derived from the existing field/district office RMPs, as amended. Goals and objectives for resources and resource uses are based on the most recent RMP decisions, along with associated amendments and other management decision documents. Laws, regulations, and BLM policies that supersede RMP decisions would apply.

Goals and objectives for BLM-administered lands and mineral estate would not change. Appropriate and allowable uses and restrictions pertaining to activities such as mineral leasing and development, recreation, construction of utility corridors, and livestock grazing would also remain the same. The BLM would not modify existing or establish additional criteria to guide the identification of site-specific use levels for implementation activities.

This alternative was not selected as the ARMPAs because it did not meet the purpose and need of this plan amendment. This alternative did not include changes that are needed to be made to the existing decisions based on the FWS 2010 listing petition decision that identified inadequacy of regulatory mechanisms as a significant threat to GRSG and its habitat. This alternative did not incorporate the best available science pertaining to GRSG or its habitat.

3.1.2 Alternative B: National Technical Team Report Alternative

Alternative B was based on the conservation measures contained within the National Technical Team (NTT) Report. The GRSG National Technical Team (NTT), comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed *A Report on National Greater Sage-Grouse Conservation Measures* in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. The Report can be accessed at: http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

The BLM's Washington Office Instructional Memorandum (IM) Number 2012-044 directed the sub-regional planning efforts to analyze the conservation measures developed by the NTT, as appropriate, through the land use planning process and NEPA.

Alternative B would exclude ROW development in PHMA and avoid development in GHMA, would close PHMA to fluid mineral leasing, mineral material sales, and nonenergy leasable minerals, and would recommend withdrawal from locatable mineral entry in all PHMA. These management actions would reduce surface disturbance in PHMA and would minimize disturbance in GHMA, thereby maintaining GRSG habitat. Management actions for wildfire would focus on suppression in PHMA and GHMA, while limiting certain types of fuels treatments. Vegetation management would emphasize sagebrush restoration. Collectively, vegetation and wildfire management would conserve GRSG habitat. Grazing would continue with similar impacts under Alternative B as under Alternative A. The best management practices (BMPs) proposed in the NTT report would be included as required design features as part of Alternative B and are listed in Appendix C, Required Design Features (RDFs), of each of the attached ARMPAs.

This alternative was not selected in its entirety as the ARMPAs because the majority of the conservation measures in the NTT Report, as appropriate and applicable, were applied primarily to PHMA, and few conservation measures in the Report were provided for in GHMA. As a result, this alternative did not provide adequate conservation in GHMA. .

3.1.3 Alternative C: Citizen Groups' Recommended Alternative One

Alternative C was based on a citizen groups' recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and was applied to all occupied GRSG habitat (PHMA and GHMA. Alternative C limited commodity development in areas of occupied GRSG habitat, and closed or excluded large portions of the planning area to many land uses. This included all PHMA and GHMA as being closed to livestock grazing, recommended for withdrawal from locatable mineral entry, closed to fluid mineral leasing, closed to salable mineral and non-energy leasable mineral development, and exclusion areas for right-of-ways. The Utah LUPA/Draft EIS combined this alternative with Alternative F (discussed below) and included two sub-alternatives under Alternative C for a reduction in livestock grazing and wild horses and burros management.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which, based on best available science, is not required to conserve GRSG and its habitats. Alternative C was also not selected in its entirety because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.4 Alternative D: Draft RMP Amendments' Preferred Alternative

Alternative D, which was identified as the Preferred Alternative in the Draft EISs, balanced opportunities to use and develop the planning area as well as conserving, maintaining, and enhancing GRSG and their habitat. Protective measures were applied to GRSG habitat, while still allowing for anthropogenic disturbances with stringent mitigation measures. This alternative represents the mix and variety of management actions based on BLM's analysis and judgment, which best resolve the resource issues and management concerns while meeting laws, regulations, and policies pertaining to BLM management. As a result of public scoping comments, internal review, and cooperating agency coordination on the Draft RMP Amendments/EISs, this alternative was modified to become the Proposed RMP Amendments and analyzed in the FEISs. The Preferred Alternatives, with slight variations, became the Proposed Plans in the FEISs.

In PHMA under Alternative D, there would be limitation on disturbance in GRSG habitat by excluding wind and solar energy development (except for certain counties in Southeastern Oregon where avoidance is applied), avoiding all other ROW development, applying no surface occupancy stipulations to fluid mineral development, and closing PHMA to nonenergy leasable mineral development and mineral material sales. These management actions would protect GRSG habitat, while allowing other activities, subject to conditions. In GHMA under Alternative D, allocations are less stringent, but still aim to protect GRSG habitat (for example, applying moderate constraints and stipulations to fluid minerals in GHMA).

Under Alternative D, the BLM management would support sagebrush/perennial grass ecosystem restoration, would increase fire suppression in PHMA and GHMA, and would manage livestock grazing to maintain or enhance sagebrush and perennial grass ecosystems.

3.1.5 Alternative E: State/Governor's Alternative

Alternative E is the alternative based on information provided by the State or Governor's offices for inclusion and analysis in the EISs. In many instances, the BLM had to adjust what was provided by the States and Governors to fit BLM language, decision-making constructs, etc. This alternative incorporates guidance from specific state conservation strategies, if developed or recommendations from the state on management of Federal lands and emphasizes management of GRSG seasonal habitats and maintaining habitat connectivity to support population objectives. This alternative was identified as a co-Preferred Alternative in the Idaho and Southwestern Montana Draft EIS. California did not provide the BLM with a state GRSG conservation plan and under this alternative, reverted back to Alternative A, the no-action alternative.

For Nevada, Alternative E would apply an avoid, minimize, and mitigate strategy to reduce direct and indirect impacts on GRSG from surface-disturbing activities on BLM-administered lands. Effects on GRSG habitat from certain resource programs, such as grazing, lands and realty, wildfire management, and minerals, would not be directly addressed because allocation decisions were not part of the state's plan.

For Oregon, Alternative E contains GRSG conservation guidelines from Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat. This document describes the Oregon Department of Fish and Wildlife's proposed management of GRSG on Federal lands. It also provides guidance for public land management agencies and land managers for GRSG conservation. GRSG conservation guidelines in the state plan are designed to maintain (at a minimum) or enhance the quality (the optimum) of current habitats. The guidelines would also assist resource managers in achieving the population and habitat objectives of the state plan.

For Idaho, Alternative E incorporates proposed GRSG protection measures recommended by the State of Idaho. Management in Montana would remain unchanged from the current RMPs (Alternative A). Alternative E addresses the following primary threats: fire, invasive weeds, and infrastructure development. It also includes guidance for several secondary GRSG threats such as recreation, improper livestock grazing, and West Nile virus for BLM and Forest Service programs that affect GRSG or its habitat.

For Utah, Alternative E1 is based on the State of Utah's Conservation Plan for Greater Sage-Grouse in Utah and would apply to all BLM-administered lands in Utah. In alternative E1 conservation measures would be applied to 11 areas that the state identified, called Sage-Grouse Management Areas (SGMAs). Emphasis would be placed on expanding GRSG habitat by aggressively treating areas where there are encroaching conifers or invasive species. Alternative E1 includes a general limit on new permanent disturbance of 5 percent of habitat on state or federally managed lands within any particular SGMAs. Occupied habitat outside of the state-identified SGMAs would not receive new management protection. They would continue to be managed according to the GRSG actions in existing RMPs and conservation measures associated with existing activity-level plans.

This alternative was not selected in its entirety as the ARMPAs because some components of the state's plans were not consistent with the purposes, policies and programs of Federal laws and regulations applicable to public lands. However, many goals, objectives, and management actions in the alternative were carried forward.

3.1.6 – Alternative F: Citizen Groups' Recommended Alternative Two

Alternative F is also based on a citizen group recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and defines different restrictions for PHMA and GHMA. Alternative F would limit commodity development in areas of occupied GRSG habitat, and would close or designate portions of the planning area to some land uses. This alternative does not apply to the Utah sub-regional planning effort, as it was combined with Alternative C. Under Alternative F, wildfire suppression would be prioritized in PHMA. Concurrent vegetation management would emphasize sagebrush restoration and enhancement. Alternative F would reduce livestock and wild horse and burro management utilization by 25 percent within PHMA and GHMA. While the Utah Draft EIS did not include an Alternative F, it did create two sub-alternatives under Alternative C for livestock grazing and wild horses and burros to consider and analyze a similar reduction.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture.

3.1.7 – Proposed Plan Amendment

As a result of public comments, best science, cooperating agency coordination, and internal review of the Draft RMP Amendments/EISs, the BLM developed the Proposed Amendments/Final EISs for managing BLM-administered lands. The Proposed Amendments/Final EISs focused on addressing public comments, while continuing to meet the BLM's legal and regulatory mandates. The Proposed Amendments/Final EISs are a variation of the preferred alternatives (Alternative D) and are within the range of alternatives analyzed in the DEISs. The Proposed Plans, with slight variations (as outlined in Section 2.5 of this ROD), became ARMPAs.

3.1.8 Environmentally Preferable Alternative

Council on Environmental Quality (CEQ) regulations require that a ROD state which alternatives were considered to be "environmentally preferable" (40 CFR 1505.2(b)). Question 6A of CEQ’s 40 most-asked questions regarding CEQ’s NEPA regulations defines that term to ordinarily mean the alternative which best protects, preserves, and enhances historic, cultural, and natural resources.

Under that definition, Alternative B, as presented in each of the sub-regional Proposed RMP Amendments/Final EISs is the most environmentally preferable. However, NEPA expresses a continuing policy of the federal government to "use all practicable means and measures…to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans" (Section 101 of NEPA).

3.2 Alternatives Considered But Not Analyzed in Detail

The alternatives listed below by sub-region were considered but were not carried forward for detailed analysis because of one or more of the following reasons:

- They would not meet the requirements of FLPMA or other existing laws and regulations;
- They did not meet the purpose and need;
- The alternative was already captured within the range of alternative analyzed in the EIS;
- They were already part of an existing plan, policy, or administrative function; or
- They did not fall within the limits of the planning criteria.

For additional rationale as to why each of the alternatives listed below by sub-region were not carried forward for detailed analysis, refer to Section 2.11of each of the sub-regional Proposed Amendments/Final EISs.

Idaho and Southwestern Montana

- FWS-Listing Alternative
- Elimination of Recreational Hunting Alternative
- Predation Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Consideration of Coal Mining Alternative

Nevada and Northeastern California

- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Elko County Sage-Grouse Plan Alternative
- Increase Grazing Alternative

Oregon

- FWS-Listing Alternative
- Elimination of Livestock Grazing from all BLM Lands Alternative
- Increase Livestock Grazing Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative

Utah

- FWS-Listing Alternative
- Increase Livestock Grazing Alternative
- Make GRSG Habitat Available for Oil Shale and Tar Sands Alternative
- Citizen Proposed Alternatives (in their entirety)
- Adoption of the State of Utah's Sage-Grouse Management Areas as PHMA for all Alternatives
- Use of Other Habitat Maps Alternatives
- County Sage-Grouse Management Plans Alternative
- Conservation Objectives Team (COT) Report Alternative
- BLM Policies and Regulations Alternative

4. PUBLIC INVOLVEMENT, CONSULTATION AND COORDINATION

BLM land use planning is conducted in accordance with NEPA requirements, CEQ regulations, and US Department of the Interior policies and procedures implementing NEPA, as well as specific BLM planning and NEPA policies. The NEPA and associated laws, regulations, and policies require the BLM to seek public involvement early in and throughout the planning process, to develop a range of reasonable alternatives to proposed actions, and to prepare environmental documents that disclose the potential impacts of proposed management.

Public involvement and agency consultation and coordination have been at the heart of the planning process leading to these Great Basin Region ARMPAs. These efforts were achieved through Federal Register notices, public formal and informal meetings, individual contacts, media releases, planning bulletins, and a series of GRSG planning-related Web sites. This section documents the outreach efforts that have occurred to date. For more plan specific information related to the public involvement, consultation, and coordination processes that the BLM conducted, please refer to Chapter 3 of the attached ARMPAs.

4.1 Public Involvement

The scoping period for the National GRSG Planning Strategy, including the four sub-regional planning areas in the Great Basin Region, began with the publication of the NOI in the Federal Register on December 9, 2011, and ended on March 23, 2012. Beginning in December and ending in February of 2012, the BLM hosted a series of public open house scoping meetings across Northeastern California, Idaho, Southwestern Montana, Nevada, Oregon and Utah. A final National GRSG Planning Strategy Scoping Report was released in May 2012.

A Notice of Availability (NOA) for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Draft RMP Amendments/EISs were published in the Federal Register on November 1, 2013. The Oregon Draft RMP Amendment/EIS was released to the public on November 26, 2013.

For the Great Basin Region GRSG Draft RMPAs/DEIS, Idaho and Southwestern Montana conducted seven public meetings, Nevada and Northeastern California conducted seven public meetings, Oregon conducted seven public meetings, and Utah conducted eight public meetings between November 2013 and January 2014.

Comments on the Draft RMPAs/Draft EISs received from the public and internal BLM review were considered and incorporated, as appropriate, into the Proposed Plan Amendments. The Great Basin Region received approximately 4,990 substantive comments, contained in 74,240 submissions during the four Draft RMPAs/Draft EISs' comment periods. Comments on the Draft RMPAs/Draft EISs received from the public and internal BLM review were carefully considered and incorporated as appropriate into the Proposed Plan Amendments. Public comments resulted in the addition of clarifying text, but did not significantly change Proposed RMPAs.

A Notice of Availability (NOA) for all of the Great Basin Region GRSG Proposed RMPAs and Final EISs for the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah Sub-Regions were released on May 29, 2015. The release of the EPA's NOA initiated a 30 day public protest period and a 60 day governor'' consistency review. Refer to **Section 2.5 and 2.6** for a full description of the protest period and governor's consistency review outcomes.

4.2 Cooperating Agencies

A cooperating agency is any federal, state, or local government agency or Native American tribe that enters into a formal agreement with the lead federal agency to help develop an environmental analysis. Cooperating Agencies and tribes "work with the BLM, sharing knowledge and resources, to achieve desired outcomes for public lands and communities within statutory and regulatory frameworks" (BLM 2005). The benefits of enhanced collaboration among agencies in preparing NEPA analyses are:

- Disclosing relevant information early in the analytical process
- Applying available technical expertise and staff support

- Avoiding duplication with other federal, state, tribal, and local procedures
- Establishing a mechanism for addressing intergovernmental issues

The BLM entered into a formal Memorandum of Understanding (MOU) for the National GRSG Planning Strategy with the FWS and the U.S. Forest Service. In addition, the Great Basin sub-regions also invited local, state, other federal, and tribal representatives to participate as Cooperating Agencies for these RMP Amendments/EISs. In total, there were 13 MOUs signed with Federal agencies, 10 MOUs signed with state agencies, 55 MOUs signed with counties, and 5 MOUs signed with tribal entities. The MOUs outline the interests, expertise, and jurisdictional responsibilities of both the BLM and its cooperating agency partners and also outlines their respective roles and responsibilities in the planning and NEPA processes. Additional information can also be found in Chapter 6 of each of the Proposed Amendments/FEISs. These cooperating agencies divided by sub-region are provided below:

Great Basin Region-Wide
US Fish and Wildlife Service
US Forest Service

Idaho and Southwestern Montana
Beaverhead County Commissioners
Bingham County Commissioners
Blaine County Commissioners
Cassia County Commissioners
Clark County Commissioners
Craters of the Moon National Monument
Custer County Commissioners
Fremont County Commissioners
Idaho Association of Counties
Idaho Department of Fish and Game
Idaho Governor's Office of Species Conservation
Idaho National Guard
Jefferson County Commissioners
Lemhi County Commissioners
Madison County Commissioners
Montana Fish, Wildlife and Parks
Natural Resources Conservation Service
Owyhee County Commissioners
Power County Commissioners
Twin Falls County Commissioners
US Department of Defense
US Department of Energy (INL)

Nevada and Northeastern California
Churchill County

Elko County
Eureka County
Humboldt County
Lander County
Lassen County
Lincoln County
Mineral County
Modoc County
Natural Resources Conservation Service
Nevada Department of Transportation
Nevada Department of Wildlife
Nevada Department of Conservation and Natural Resources
Nye County
Pershing County
Pyramid Lake Paiute Tribe
Storey County
Summit Lake Paiute Tribe
Susanville Indian Rancheria
US Department of Defense
US Federal Highway Planning Administration
Washoe County
Washoe Tribe
White Pine County

Oregon
Crook County
Deschutes County
Harney County
Harney Soil and Water Conservation District US
Lake County
Malheur County
Natural Resources Conservation Service
Oregon Department of Fish and Wildlife
Oregon State University
US Federal Energy Regulatory Commission

Utah
Beaver County
Box Elder County
Carbon County
Confederated Tribes of the Goshute Indian Reservation
Duchesne County

Emery County
Garfield County
Grand County
Iron County
Kane County
Lincoln County (WY)
Millard County
Rich County
Sanete County
Sevier County
State of Utah (PLPCO)
State of Wyoming
Sweetwater County (WY)
Sweetwater County Conservation District (WY)
Tooele County
Uinta County (WY)
Uintah County (UT)
Utah County
US Department of Defense
Wayne County
Natural Resources Conservation Service

4.3 FWS Section 7 Consultation

Consultation with FWS is required under Section 7(c) of the ESA before the start of any BLM project that may affect any federally listed or endangered species or its habitat. These planning processes are considered a major project, and the four Great Basin sub-regional Final EISs defined potential impacts on threatened and endangered species as a result of management actions proposed in the alternatives analyzed in the FEISs. The FWS is a cooperating agency in this planning process. FWS staff participated in interdisciplinary team meetings and has been provided drafts of alternative decisions and analyses for discussion and input.

The BLM formally initiated Section 7 consultation with a letter to the FWS prior to the release of the Draft RMP Amendments/EISs, and requested concurrence on which species would require consideration during consultation. Over the ensuing months, regular meetings were held to identify the species that would be analyzed in the biological assessment, to address which actions could affect those species, and to determine whether the implementation of the Proposed Plan Amendments "may affect" the species for which this consultation occurred.

Prior to the release of the Proposed Amendments/FEISs, the BLM formally submitted the biological assessments to the FWS for review. The USFWS evaluated the biological assessments and concurred with the either a "no affect" or "may effect, but will not adversely affect" determination via memorandum for

Oregon, Nevada and Northeastern California, and Idaho and Southwestern Montana, which are appendices to each of these ARMPAs. For Utah, formal consultation was required with the FWS due to a "likely to adversely affect" determination associated with the Utah Prairie Dog, a threatened species under the ESA. The biological opinion from the FWS is attached to the Utah ARMPA (Appendix K).

4.4 Native American and State Historic Preservation Office Consultation

In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation efforts related to preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent 65 letters to tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts.

In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation efforts related to preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent letters to 65 tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts.

As part of the NEPA scoping and consultation process, and as an opportunity to provide comment pursuant to Section 106 of the NHPA, the BLM notified and/or invited the Idaho, Montana, Nevada, California, and Oregon State Historic Preservation Officers (SHPOs) seeking information regarding concerns with historic properties and land use planning direction included in these ARMPAs, to participate in the planning process. The BLM sought information about historic properties in consideration of land use planning decisions included in these ARMPAs in accordance with the National Programmatic Agreement (PA) between the BLM, Advisory Council on Historic Preservation, and National Conference of State Historic Preservation Officers and the Idaho, Montana, and Oregon State Protocol Agreement between the BLM and these SHPOs. The BLM incorporated the information it received from SHPOs and Tribes into the Proposed RMPAs and considered such information in making the land use plan amendment decisions. The BLM has met its obligations under Section 106 of the NHPA, 54 U.S.C. § 306108, as outlined in the National PA and the State Protocols.

For the Utah ARMPA, the BLM completed consultation with the Utah SHPO in accordance with the 36 CFR Part 800. In July 2015, the BLM submitted a formal letter, concluding that the land use plan amendments would not adversely affect cultural properties and seeking input and concurrence on those findings and received a concurrence letter from the Utah SHPO on July 30, 2015. The BLM will satisfy the requirements of NHPA Section 106 for future implementation-level decisions, such as project proposals, including adequate consultation with SHPOs, Tribal Historic Preservation Officers (THPOs), Native American Tribes, and other interested parties, consistent with the alternative procedures set forth in the National PA and relevant State Protocol or where applicable the Section 106 regulations.

6. APPROVAL

Land Use Plan Amendment Decisions

It is the decision of the Bureau of Land Management (BLM) to approve the Great Basin Region Approved Resource Management Plan (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub-regions, as described in this Record of Decision. Notices of the public availability of the Proposed Plan Amendments and related Final Environmental Impact Statements (EIS) were published in the Federal Register on May 29, 2015. in the (80 FR 30711). I have resolved all protests and, in accordance with BLM regulations 43 CFR 1610.5-2, my decision on the protests is the final decision of the Department of the Interior. The approval is effective on the date this Record of Decision is signed.

Approved by:

Neil Kornze Date
Director
Bureau of Land Management

Secretarial Approval

I hereby approve the land use plan amendment decisions. My approval of the land use plan decisions constitutes the final decision of the Department of the Interior and, in accordance with regulations at 43 CFR 4.410(a)(3), is not subject to appeal under Department regulations at 43 CFR Part 4. Any challenge to these land use plan decisions must be brought in Federal district court.

Approved by:

Janice Schneider Date
Assistant Secretary for Land and Minerals
Management
Department of the Interior

(WO210)(1610)

Dear Reader:

Enclosed are the Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). The ROD approves the four Great Basin Region ARMPAs, which are part the National Greater Sage-Grouse Planning Strategy that was initiated on December 11, 2011. The conservation strategy was initiated by the Bureau of Land Management (BLM) in response to the U.S. Fish and Wildlife Service's (FWS) March 2010 "warranted, but precluded" Endangered Species Act (ESA) listing petition decision. In this decision, the FWS identified the inadequacy of regulatory mechanisms as a significant threat to GRSG. RMP conservation measures were identified as the BLM's principal regulatory mechanism.

The BLM's ARMPAs provide a landscape-level, science-based, coordinated, collaborative strategy for addressing threats to the Greater Sage-Grouse (GRSG) and its habitat. This strategy was designed to address issues identified in the FWS 2010 "warranted but precluded" decision. In addition, the strategy was guided by over a decade of research, analyses and recommendations for GRSG conservation including the Conservation Objectives Team (COT) Report and the BLM National Technical Team (NTT) Report. Each of these reports was developed through a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research. Science-based decision-making and collaboration with the FWS, the U.S. Forest Service, and state and other partners were fundamental to the development of these ARMPAs.

It is important to note that this ROD and these ARMPAs apply only to BLM-administered lands, including BLM sub-surface mineral estate. Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. These Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs for the Great Basin sub-regions included proposed GRSG management direction for National Forest System lands (in Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah). However, the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

The Federal Land Policy and Management Act (FLPMA) require the development and maintenance, and, as appropriate, the revision of land use plans for management of public lands. The National Environmental Policy Act (NEPA) requires Federal agencies to prepare an Environmental Impact Statement (EIS) for major Federal actions significantly affecting the quality of the human environment. In fulfillment of these requirements, the Draft RMP Amendments/Draft EISs incorporated analysis and input provided by the public; local, State, and other Federal agencies and organizations; Native American tribes; Cooperating Agencies, and BLM resource specialists, and were published in the fall of 2013. Ninety -day public comment periods ensued, with more than 4,990 substantive comments from 1,348 unique letters submitted on all four sub-regional proposed LUPAs/Final EISs in the Great Basin Region. These comments were reviewed, summarized and considered in preparing the Proposed RMP Amendments/Final EISs.

The Proposed RMPAs/Final EISs were made available on May 29, 2015, for a 60-day governor's consistency review and 30-day protest period. The BLM received consistency review letters from the States of California, Idaho, Montana, Nevada, Oregon, and Utah in the Great Basin Region and has worked closely with these states to address their concerns and to resolve inconsistencies where possible. Across all four sub-regions in the Great Basin Region, 133 protest submission letters were received from government entities, private citizens, NGOs, and other stakeholders; 124 of these submissions contained valid protest issues pursuant to 43 CFR 1610.5-2 and were addressed in the Director's Protest Resolution Reports. These reports are available on line at: http://www.blm.gov/nv/st/en/fo/wfo/blm_information/rmp.html.

The BLM now approves the attached ARMPAs as the land use plans that will guide future land and resource management within GRSG habitat in the Great Basin Region for the life of the plan amendments. The ARMPAs will benefit GRSG and over 350 other species of wildlife as well as other multiple uses, including grazing and recreation, which depend on healthy sagebrush-steppe landscapes.

Formatted: Font: Times New Roman

Copies of the ROD and ARMPAs can be obtained from the BLM's National Greater Sage-Grouse webpage at: http://www.blm.gov/wo/st/en/prog/more/sagegrouse.html.

The BLM extends special appreciation to the public, local, state, and other federal agencies, Native American tribal representatives, and the Cooperating Agencies, all of whom contributed to the completion of these ARMPAs. This participation informed and improved the planning process and the planning documents. Your continued involvement is encouraged as the ARMPAs are implemented.

Sincerely,
X

Enclosure:
1. Record of Decision and Approved Resource Management Plan Amendments

Summary

This Record of Decision (ROD) is the culmination of an unprecedented effort to conserve Greater Sage-Grouse habitat on public lands administered by the Bureau of Land Management (BLM), consistent with the BLM's multiple use and sustained-yield mission and the joint objective established by federal and state leadership through the Greater Sage Grouse Task Force to conserve GRSG habitat on federal, state, and private land such that additional protections under the Endangered Species Act (ESA) can be avoided.

Formatted: Font: Times New Roman

In response to a 2010 determination by the FWS that the listing of the GRSG under the ESA was "warranted but precluded" by other priorities, the BLM, in coordination with the U.S. Department of Agriculture Forest Service (Forest Service), has developed a targeted, multi-tiered, coordinated, collaborative landscape-level management strategy, based on the best available science, that offers the highest level of protection for GRSG in the most important habitat areas to address the specific threats identified in the 2010 FWS "warranted but precluded" decision and the FWS 2013 Conservation Objectives Team (COT) report.

This ROD and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah include management direction that avoids and minimizes additional disturbance in GRSG habitat management areas as well as targets restoration and improvements to the most important areas of habitat. The management direction in the ARMPAs is accomplished through land use allocations that ~~generally~~ apply to GRSG habitat. These allocations (1) eliminate most new surface disturbance in the most highly-valued sagebrush ecosystem areas identified as Sagebrush Focal Areas (SFAs); (2) avoid or limit new surface disturbance in Priority Habitat Management Areas (PHMAs), of which SFAs are a subset; and (3) minimize surface disturbance in General Habitat Management Areas (GHMA). In addition to protective land use allocations in habitat management areas, the ARMPAs include a suite of management actions, such as the establishment of disturbance limits, GRSG habitat objectives, mitigation requirements, monitoring protocols, and adaptive management triggers and responses, and other conservation measures that apply throughout designated habitat management areas. The cumulative effect of these measures is to conserve, enhance, and restore GRSG habitat across the remaining range of the species in the Great Basin and provide greater certainty that BLM land use plan decisions in GRSG habitat in the Great Basin Region can lead to conservation of the GRSG and other sagebrush-steppe associated species in the region.

The targeted land use plan protections presented in this ROD and ARMPAs not only protect the GRSG and its habitat, but also over 350 wildlife species associated with the sagebrush-steppe ecosystem, which is widely recognized as one of the most endangered ecosystems in North America. Reversing the slow degradation of this valuable ecosystem will also benefit local rural economies and a variety of rangeland uses in addition to habitat protection, including recreation and grazing, in a manner that safeguards the long term sustainability, diversity and productivity of these important and iconic landscapes.

This conservation strategy has been developed in conjunction with the 10 states in which the ARMPAs in the Great Basin and the plans in the Rocky Mountain Region apply. In combination with additional state and federal actions underway and in development, the strategy represents an unprecedented, coordinated, and collaborative effort among federal land management agencies and the states to manage an entire ecosystem and associated flora and fauna in order to achieve the COT Report objective of "conserv[ing] the sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future". [Dan Ashe. Transmittal letter to COT Report. 2013].

1. INTRODUCTION

Formatted: Font color: Auto

This Record of Decision (ROD) approves the BLM's attached approved resource management plan amendments (ARMPAs) for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPAs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM-administered lands. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.), BLM planning regulations (43 Code of Federal Regulations [CFR] §1601 et seq.), and other applicable laws. The BLM prepared Environmental Impact Statements (EISs) in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA) and the Council on Environmental Quality's Regulations for implementing the procedural provisions of NEPA (40 CFR §1500.1 et seq.).

Formatted: No Spacing

Formatted: Font: Times New Roman

Throughout the GRSG planning process, the Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs included proposed GRSG management direction for National Forest System lands. The Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities for the Great Basin Region, which is available at ~~http://www.fs.usda.gov/r4/~~ http://www.fs.usda.gov/r4/.

Formatted: Font: Times New Roman

This ROD, in conjunction with the ARMPs and ARMPAs approved through the Rocky Mountain ROD, constitute land use planning decisions of the BLM to conserve the GRSG and its habitats throughout that portion of the remaining range of the species that is administered by the BLM under authority of FLPMA. The efforts of the BLM, in coordination with the U.S. Forest Service on National Forest System lands within the remaining range of the species, constitutes a coordinated strategy for conserving the GRSG and the sagebrush-steppe ecosystem on the majority of Federal lands on which the species depends. These decisions complement those implemented by federal agencies through ~~the~~ An Integrated Rangeland Fire Strategy: Final Report to the Secretary of the Interior and the Sage Grouse Initiative as well as those implemented by state and local governments as well as private land owners and other partners.

1.1 Great Basin Region Planning Area

Formatted: Font color: Auto

The Great Basin Region planning area is composed of four sub-regions: the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah. (see **Figure 1-1** – Great Basin Region Greater Sage-Grouse Sub-regions). A separate EIS was prepared for each of these sub-regions. Each sub-region conducted its own planning effort with input from local cooperators, stakeholders, and members of the public. The sub-regional boundaries were constructed to align with BLM administrative offices, state boundaries, as well as areas that shared common threats to the GRSG and their habitat. The boundaries for these sub-regions largely coincide with zones III, IV, and V identified by the Western Association of Fish and Wildlife Agencies (WAFWA) Greater Sage-Grouse Conservation Strategy to delineate management zones with similar ecological and biological issues.

[Insert **Figure 1-1** - Great Basin Region Greater Sage-Grouse Sub-regions]

The Great Basin Region planning area boundaries include all lands regardless of jurisdiction (see **Figure 1-2** - Great Basin Region Planning Area). **Table 1-1** outlines the amount of surface acres that are administered by specific Federal agencies, states, local governments, and privately--owned lands within the four sub-regions that make up the Great Basin. The planning area also includes other BLM-administered lands that are not identified as habitat management areas for GRSG. The ARMPAs generally do not establish any additional management for these lands outside of GRSG habitat management areas and they will continue to be managed according to the existing land use plans for these planning areas.

[Insert **Figure 1-2** - Great Basin Region Planning Area]

Table 1-1
Land Management in the Great Basin Planning Area

Surface Land Management	NV/NE CA	ID/SW MT	Utah	Oregon	Great Basin Total

1.2 Early GRSG Conservation Efforts

Formatted: Font color: Auto

Currently, GRSG occupy an estimated 66% of the historically occupied range. The BLM manages the majority of the GRSG habitat on Federal lands (i.e., the range of GRSG not including the Columbia Basin or Bi-State populations). Efforts to conserve GRSG habitat by the BLM and other wildlife conservation agencies and organizations have been ongoing for many years. These efforts provide an important foundation for the GRSG conservation strategy that guides these plans.

Formatted: Font: Times New Roman

The WAFWA 2004 *Range-wide Conservation Assessment for Greater Sage-Grouse and Sagebrush Habitats* was the first range-wide assessment of GRSG using the vast amount of population data collected over the previous 60 years, habitat information spanning the previous 100 years, and literature dating back 200 years. The goal of the assessment, which includes contributions from the BLM, was to present an unbiased and scientific assessment of dominant issues and their effects on GRSG populations and sagebrush habitats.

http://sagemap.wr.usgs.gov/docs/Greater_Sage-grouse_Conservation_Assessment_060404.pdf

In November 2004, the BLM released its *National Sage-Grouse Habitat Conservation Strategy*, which encouraged GRSG habitat conservation through consultation, cooperation, and communication with WAFWA, the FWS, the Forest Service, the U.S. Geological Survey (USGS), State wildlife agencies, local GRSG working groups, and various other public and private partners.

In 2006, WAFWA completed a *Greater Sage-Grouse Comprehensive Conservation Strategy*, with the assistance of the BLM, the Forest Service, and other contributors. The overall goal of the Strategy was to maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain those populations. The Strategy outlined the critical need to develop the associations among local, state, provincial, tribal, and federal agencies, non-governmental organizations, and individual citizens to design and implement cooperative actions to support robust populations of GRSG and the landscapes and habitats upon which they depend. The catalyst for this effort was widespread concern for declining populations and reduced distribution of GRSG. http://www.wafwa.org/documents/pdf/GreaterSage-grouseConservationStrategy2006.pdf

In 2008, the BLM created two national teams to investigate possible BLM management options for GRSG conservation and summarize the BLM's ongoing conservation efforts. A product of this effort was one of the first range-wide priority habitat maps for GRSG that were referred to as "key habitat". At the time, the primary purpose for the key habitat map was to inform and help prioritize fire suppression efforts in GRSG habitat on BLM lands. An additional outcome of this team was the signing of a Memorandum of Understanding by the WAFWA; the BLM, FWS, USGS in the Department of the Interior; and the US Department of Agriculture Forest Service and NRCS, to provide for cooperation among the participating state and federal land managers and wildlife management and science agencies in the conservation and management of GRSG sagebrush habitats and other sagebrush-dependent wildlife throughout the Western United States.

http://www.blm.gov/style/medialib/blm/wo/Planning_and_Renewable_Resources/fish__wildlife_and/fwp.Par.95958.File.dat/SagegrouseMOU.pdf

In 2010, the BLM commissioned an effort to map and model breeding densities of GRSG across the West. A conference was convened with state wildlife agencies to coordinate the lek survey data needed for this effort. This modelling project, through an agreement with the FWS, mapped known active leks across the West. This model served as a standard starting point for all states to identify priority habitat for the species.

http://www.blm.gov/wo/st/en/prog/more/fish__wildlife_and/sage-grouse-conservation/bird_density.print.html

In March 2010, the US Fish and Wildlife Service (USFWS) published its 12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered (75 Federal Register 13910 (March 23, 2010)). In that finding, the USFWS concluded that GRSG was "warranted, but precluded" under the Endangered Species Act (ESA). This finding indicates that, although the species meets the criteria for listing, immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, the species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

As part of their 2010 finding, the USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 Federal Register 13910 (March 23, 2010)). In addition, the FWS found that existing local, state and federal regulatory mechanisms were not sufficient to address threats to the habitat. For the BLM, which manages approximately 66 million acres of the remaining habitat for the species (See **Figure 1-4**.), the USFWS has identified the agency's Resource Management Plans (RMPs) as the primary regulatory mechanisms.

Formatted: Font: Times New Roman

Formatted: Line spacing: single

Formatted: Font: Times New Roman

1.3 Threats to Greater Sage-Grouse in the Great Basin Region

Formatted: Font color: Auto

The FWS identified a number of specific threats to GRSG in the Great Basin Region in the context of its 2010 finding. The primary threats identified are the widespread present and potential impacts of wildfire, the loss of native habitat to invasive species, and conifer encroachment. Other threats, some of which are more localized by nature, include habitat fragmentation due to anthropogenic disturbances associated with energy development, mining, infrastructure, recreation, urbanization and sagebrush elimination, as well as impacts to habitat associated with free-roaming equids and improper livestock grazing.

Formatted: Font: Times New Roman

In 2011, the BLM established the GRSG National Technical Team (NTT), comprised of BLM, USGS, NRCS, and State ~~Agency~~ specialists. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable GRSG populations focused on the threats identified in the FWS listing determination (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones (Figure 1-4). The NTT produced *A Report on National Greater Sage-grouse Conservation Measures* (The NTT Report) which proposed conservation measures based on habitat requirements and other life history requirements for GRSG. The NTT Report described the scientific basis for the conservation measures proposed within each program area. The NTT Report also emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. ~~To view the NTT Report, go to: http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf~~

http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

In 2012, the USFWS, with the support of the Western Governors Association Sage Grouse Task Force, convened the Conservation Objectives Team (COT), comprising state and federal representatives, to produce a peer-reviewed report identifying the principal threats to GRSG survival and the degree to which these threats need to be reduced or ameliorated to conserve the GRSG so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The COT Report, released in March 2013, also identified Priority Areas for Conservation (PACs) and emphasized that "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". Finally, the COT report identified present and widespread, as well as localized threats by GRSG population across the West (**Table 1-2)**. The BLM also identified and explained additional threats in the Final EISs that were published with proposed plans on May 29, 2015. **Figure 1-4** identifies the PACs, GRSG populations (and their names), and WAFWA Management Zones across the West. ~~To view the COT Report, go to:~~ http://www.fws.gov/greatersagegrouse/documents/COT-Report-with-Dear-Interested-Reader-Letter.pdf

[Insert **Figure 1-4** - GRSG Priority Areas for Conservation, Populations, and WAFWA Management Zones.]

A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG in the Great Basin Region– as highlighted in the 2013 COT report – is provided in **Table 1-2**.

1.4 National Greater Sage Grouse Conservation Strategy

Formatted: Font color: Auto

Based on the identified threats to the GRSG, especially inadequate regulatory mechanisms, and the FWS's timeline for making a listing decision on this species, the BLM recognized the need to incorporate explicit objectives and concrete conservation measures into Resource Management Plans (RMPs) to conserve GRSG habitat and provide robust regulatory mechanisms. In August, 2011, the BLM chartered a strategy to revise and amend existing RMPs throughout the range of the GRSG to incorporate management actions intended to conserve, enhance, and restore the species and the habitat on which it depends. Separate planning efforts were initiated to address the conservation needs of the Bi-State population in California and Nevada, and the Washington State distinct population segment.

In light of the 2010 “warranted” determination by the FWS, and specific threats summarized in the COT Report, the BLM found that additional management direction and specific conservation measures on federal public lands would be necessary to address the present and anticipated threats to GRSG habitat and to restore habitat where possible. The BLM proposed to incorporate the management direction and conservation measures into the BLM’s land use plans. The goal of incorporating these specific measures into BLM land use plans is to conserve, enhance, and restore GRSG and its habitat and to provide sufficient regulatory certainty such that the need for listing the species under the ESA may be avoided.

In December 2011, the BLM published a Notice of Intent to prepare EISs and Supplemental EIS to incorporate GRSG Conservation Measures into Land Use Plans (LUPs) across the range of the species. A total of 15 sub-regional planning efforts and associated EISs were intiated to analyze the alternatives developed for each of the plan amendments and revisions across the range of the species. [1] **Figure 1-5** illustrates the regional and sub-regional planning area boundaries, along with BLM-administered PHMAs and GHMAs across the Western United States.

Formatted: Font: Times New Roman

[Insert **Figure 1-5** – Regional and Sub-Regional Boundaries with GRSG Habitat Management Areas (BLM-Administered Lands)]

Formatted: Font: Times New Roman

Formatted: No Spacing

The planning efforts associated with the National GRSG Conservation Strategy have been coordinated under two administrative planning regions: the Rocky Mountain Region and the Great Basin Region. The regions were drawn roughly to correspond with the threats identified by USFWS in the 2010 listing decision, along with the WAFWA Management Zones (MZs) framework (Stiver et al. 2006). Due to differences in the ecological characteristics of sagebrush across the range of the greater sage-grouse, WAFWA delineated seven Management Zones (MZs I-VII) based primarily on floristic provinces.

---

[1] The National GRSG Conservation Strategy consisted of 15 separate EISs. The Bighorn Basin RMP has been split between the two field offices that make up the Bighorn Basin planning area, the Cody Field Office ARMP and the Worland Field Office ARMP. The Billings and Pompeys Pillar National Monument RMP has also been split between the Billings Field Office ARMP and Pompeys Pillar National Monument ARMP. This results in a total of 17 ARMPs and ARMPAs.

Formatted: Footnote Reference, Font: Times New Roman, Not Superscript/ Subscript

Formatted: Footnote Text

Formatted: Font: Times New Roman

Vegetation found within a MZ is similar and sage-grouse and their habitats within these areas are likely to respond similarly to environmental factors and management actions.

Formatted: Font: Times New Roman

The Rocky Mountain Region is comprised of BLM planning efforts (which includes plan revisions and plan amendments) in the states of Montana, North Dakota, South Dakota, Wyoming, Colorado, and portions of Utah. This region falls within WAFWA MZs I (Great Plains), II (Wyoming Basin) and a portion of VII (Colorado Plateau). The Great Basin Region is comprised of planning efforts (plan amendments) in California, Nevada, Oregon, Idaho, and portions of Utah and Montana. This region falls within WAFWA MZs III (Southern Great Basin), IV (Snake River Plain), and V (Northern Great Basin).

Formatted: No Spacing

Formatted: Font: Times New Roman

Both the Rocky Mountain and Great Basin regions are further divided into sub-regions. The NEPA EIS analyses were done at the sub-regional level. These sub-regions are based on the identified threats to the GRSG and the WAFWA MZs from the FWS 2010 listing decision with additional detail regarding threats to individual populations and sub-regions from the FWS COT report. In the Rocky Mountain Region, some sub-regions correspond to BLM field/district office boundaries, specifically for planning efforts that are incorporating GRSG conservation measures through plan revisions that were initiated prior to the start of the National GRSG Conservation Strategy in December 2011.

Formatted: Font: Times New Roman

The BLM used the best available science, including additional review from the USGS on specific issues that arose in developing the ARMPAs. Additionally, the BLM considered state GRSG conservation strategies where they existed, as well as state recommendations for measures to conserve GRSG on BLM-administered lands, where relevant, in the planning effort. These are reflected in the approved plans to the extent compatible with GRSG conservation objectives to conserve, enhance and restore GRSG habitat to address the threats identified in the FWS 2010 listing determination and the 2013 COT Report.

1.5 How the Approved Resource Management Plan Amendments Address the Identified Threats to the Conservation of the GRSG

Formatted: Font color: Auto

The 2006 WAFWA *Greater Sage Grouse Comprehensive Conservation Strategy* stated goal for management of the GRSG was to “maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain these populations”. The NTT Report also endorsed this goal “as a guiding philosophy against which management actions and policies of BLM should be weighed”.

Formatted: Font: Times New Roman

In establishing the COT, with the backing of the Sage Grouse Task Force, FWS Director Dan Ashe affirmed the commitment to the goal for GRSG conservation originally articulated in the 2006 WAFWA report -- reversing negative population trends and achieving a neutral or positive population trend -- and emphasized the following:

> “The Service interprets this recommendation to mean that actions and measures should be put in place now that will eventually arrest what has been a continuing declining trend. Conservation success will be achieved by removing or reducing threats to the species now, such that population

> trends will eventually be stable or increasing, even if numbers are not restored to historic levels. (WAFWA 2006 Strategy)"

The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT stated, "[m]aintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". To achieve this, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT emphasized an "avoidance first strategy" and stressed those threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

The plans were developed to address specific, identified threats to the species in order to conserve GRSG such that the need to list the species under ESA may be avoided. Across ten western States, the Great Basin and Rocky Mountain sub-regional ARMPs/ARMPAs contain land use plan direction on approximately 66 million acres of the remaining habitat for the species (See **Figure 1-5**.). These plans are the product of extensive coordination between the BLM and the Forest Service and the active engagement of the FWS which informed the BLM and Forest Service land allocation and related management decisions. The plans also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, priorities and approaches in each.

In order to protect the most important GRSG habitat areas, the planning effort began with mapping areas of important habitat across the range of the GRSG. In collaboration with state fish and wildlife agencies, the BLM identified areas as preliminary priority habitat (PPH) and preliminary general habitat (PGH). In Utah, all occupied GRSG habitat was identified as PPH. The draft land use plans used PPH and PGH to analyze the impacts of the decisions the BLM was proposing in the plans. PPH and PGH were identified as Priority Habitat Management Areas (PHMA) and General Habitat Management Areas (GHMA) in the Proposed RMP Amendments/Final EISs to identify the management decisions which apply to those areas (except for Nevada and Utah). The designated GRSG Habitat Management Areas on BLM-administered lands in the decision area include: PHMA, which largely coincide with Priority Areas for Conservation (PACs) identified in the COT Report (except for PACs in Nevada and Utah, as specified on page 13 of the COT Report) (See **Figure 1-4**); GHMA; Other Habitat Management Areas (OHMA, applicable only to the Nevada and Northeastern California); and Important Habitat Management Areas (IHMA, applicable only to Idaho). **Table 1-4** identifies surface acres of PHMA, GHMA, OHMA, and IHMA in the decision area for the Great Basin Region.

Formatted: Font: Times New Roman

Habitat maps were based initially on state key habitat maps which identified areas necessary for sage-grouse conservation derived from various data sources including breeding bird density maps and lek counts, nesting areas, sightings, and habitat distribution data including occupied suitable seasonal habitats, nesting and brood rearing areas, and connectivity areas or corridors. This information served as the basis for the development of BLM preliminary priority habitat (PPH) and preliminary general habitat (PGH) maps and, subsequently, for the identification of Priority Habitat Management Areas (PHMAs) and General Habitat Management Areas~~,~~ (GHMA), respectively. The COT also used state key habitat maps as a basis for identifying Priority Areas for Conservation (PACs). The COT report notes that there is substantial overlap between PACs and BLM PPH areas, with the exception of areas in Nevada and Utah [COT Report, p 13].

Formatted: Font: Times New Roman

PHMA, GHMA, OHMA, and IHMA are defined as follows:

- **PHMA**— BLM-administered lands identified as having highest habitat value for maintaining sustainable GRSG populations. The boundaries and management strategies for PHMAs are derived from and generally follow the Preliminary Priority Habitat boundaries. Areas of PHMAs largely coincide with areas identified as Priority Areas for Conservation (PACs) in the COT report (except for PACs in Nevada and Utah, as specified on page 13 of the COT Report).
- **GHMA**— BLM-administered lands that are occupied seasonal or year-round habitat outside of PHMA where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMAs are derived from and generally follow the Preliminary General Habitat boundaries.
- **OHMA** —BLM-administered lands in Nevada, identified as unmapped habitat in the Proposed RMP/EIS that are within the planning area and contain seasonal or connectivity habitat areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse Habitat in Nevada and Northeastern California; Coates et al. 2014,) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.
- **IHMA** —BLM-administered lands in Idaho that provide a management buffer for PHMAs and connect patches of PHMAs. IHMAs encompasses areas of generally moderate to high habitat value habitat and/or populations, but that are not as important as PHMAs. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the ARMPA.

Source: BLM GIS 2015

*41,200 acres of National Forest System lands in the Anthro Mountain area of Utah would be managed as neither PHMA nor GHMA. These areas would be identified as "Occupied – Anthro Mountain." In the Utah ARMPA, these areas are considered split-estate, where the BLM administers the mineral estate.

Formatted: Font: Times New Roman

Formatted: Font: 9 pt

The ARMPAs also identify Sagebrush Focal Areas (SFAs) on a portion of the landscape. SFAs are a subset of PHMAs (see **Figure 1-3** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas). Across the Great Basin Region, there are 8,385,280 acres of BLM administered SFAs. SFAs correspond to the areas identified by the FWS as GRSG "strongholds" and which represent "a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection”. (http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf).

Formatted: Font: Times New Roman

SFAs are areas of highest habitat value for GRSG and are managed to avoid new surface disturbance~~, to the extent permitted by law~~, given that they contain high-quality sagebrush habitat; highest breeding densities; have been identified as essential to conservation and persistence of the species; represent a preponderance of current federal ownership and, in some cases, are adjacent to protected areas that serve to anchor the conservation importance of the landscape. SFA management is consistent with the recommendations provided by FWS that these are the areas “where it is most important that the BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species.”

Formatted: Font: Times New Roman

This tiered habitat management area framework, in associated with the land use plan allocation decisions (explained more fully in Section 1.6.2 of this ROD) in the ARMPs and ARMPAs provide a high degree of certainty that the integrity of PHMAs can be maintained through management decisions to avoid or minimize additional surface disturbance.

Formatted: Font: Times New Roman

Remaining habitats in GHMAs and IHMAs (applicable only to BLM-administered lands in Idaho) would be managed consistent with the COT Report recommendation to recognize “that important habitats outside of PACs be conserved to the extent possible”. Thus, land allocations in GHMAs and IHMAs provide for more flexibility for land use activities while minimizing impacts on existing GRSG leks.

Formatted: Font: Times New Roman

Major components of the attached ARMPAs that address the specific threats to GRSG and its habitat, as identified in the USFWS 2010 listing decision and 2013 COT Report (many of which were also identified by the BLM’s 2011 NTT Report) are listed and summarized in **Table 1-4**.

Table 1-4
Key Responses from the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses from the Great Basin Region GRSG ARMPAs
All threats	• Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met. • Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner.
All development	• PHMA: Implement an anthropogenic disturbance cap of 3% within the Biologically Significant Unit and proposed project analysis areas in

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses from the Great Basin Region GRSG ARMPAs
threats, including mining, infrastructure, and energy development.	PHMA (slight variations to this management component in the State of Nevada only) ● PHMA and IHMA: Apply a disturbance density cap of 1 energy and mining facility per 640 acres (except in the State of Nevada) ● IHMA: Implement the 3% disturbance cap. Apply Anthropogenic Disturbance Development Criteria. ● Apply buffers based on project type and location to address impacts on leks when authorizing actions in GRSG habitat. ● Apply Required Design Features (RDFs) when authorizing actions in GRSG habitat. ● Effects of infrastructure projects, including siting, will be minimized using the best available science, updated as monitoring information on current infrastructure projects becomes available. ● Consider the potential for the development of valid existing rights when authorizing new projects in PHMA. ● When authorizing third-party actions that result in habitat loss and degradation, require and ensure mitigation that provides a net conservation gain to the species.
Energy development—fluid minerals, including geothermal resources	● PHMA: Open to fluid mineral leasing subject to a No Surface Occupancy (NSO) stipulation without waiver or modification, and with limited exceptions. In SFAs, a NSO stipulation would be applied without waiver, modification, or exception. In Nevada only, in the portions of the PHMAs outside of SFAs, geothermal projects may be considered for authorization if certain criteria are met. ● IHMA: Open to fluid mineral leasing subject to NSO stipulation without waiver or modification, and with limited exception. ● GHMA: Open to fluid mineral leasing subject to Controlled Surface Use (CSU) and Timing Limitation (TL) lease stipulations (except in the State of Utah where some portions of GHMA are open with standard lease stipulations) ● Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.
Energy development—wind energy	● PHMA: Exclusion area (not available for wind energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) ● IHMA: Avoidance area (may be available for wind energy development with special stipulations)

Table 1-4
Key Responses from the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses from the Great Basin Region GRSG ARMPAs
	ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis. ● Prioritize field checks in SFAs followed by PHMA to ensure compliance with the terms and conditions of grazing permits.
Free-roaming equid management	● Prioritize gathers in SFAs, followed by other PHMAs. ● Manage Herd Management Areas (HMAs) in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives. ● Prioritize rangeland health assessment, gathers and population growth suppression techniques, monitoring, and review and adjustment of AMLs and preparation of Herd Management Area Plans in GRSG habitat.
Range management structures	● Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. ● Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas.
Recreation	● PHMA and IHMA: Do not construct new recreation facilities unless required for health and safety purposes or if the construction will result in a net conservation gain to the species. ● Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain. ● PHMA & GHMA: OHV use limited to existing routes (routes to be designated through future travel management planning). The Utah ARMPA does retain two areas as open to OHV use in PHMA.
Fire	● Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection. ● Restrict the use of prescribed fire for fuel treatments. ● Prioritize post-fire treatments in SFAs, other PHMAs, IHMAs, and GHMAs.
Nonnative, invasive plant species	● Improve GRSG habitat by treating annual grasses. ● Treat sites in PHMA, IHMA, and GHMA that contain invasive species infestations through an integrated pest management approach.
Sagebrush removal	● PHMA: Maintain all lands capable of producing sagebrush (but no less than 70%) with a minimum of 15 percent sagebrush canopy cover, ~~or as~~

	consistent with specific ecological site conditions. ● All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and/or juniper expansion	● Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.
Agricultural conversion and exurban development	● GRSG habitat will be retained in federal management unless: (1) the agency can demonstrate that disposal (including exchanges) of the lands will provide a net conservation gain to the Greater Sage-Grouse or (2) the agency can demonstrate that the disposal (including exchanges) of the lands will have no direct or indirect adverse impact on conservation of the Greater Sage-Grouse.

1.6 Key Components of the BLM Greater Sage-Grouse Conservation Strategy

The ARMPAs were developed to meet the purpose and need to conserve, enhance, and restore GRSG and their habitat by eliminating or minimizing threats to GRSG habitat identified in the 2010 listing decision and highlighted in the "background and purpose" section of the COT report. Consequently, consistent with guidance contained in the COT and NTT Reports, four essential components of the GRSG conservation strategy were identified: 1) avoiding or minimizing new and additional surface disturbances, 2) improving habitat conditions, 3) reducing threats of rangeland fire to GRSG and sagebrush habitat in the Great Basin, and 4) monitoring and evaluating the effectiveness of conservation measures and implementing adaptive management as needed.

The land allocations and management actions included in the ARMPAs incorporate these components and are summarized below.

1.6.1 Avoid and Minimize Surface Disturbance

Land Allocations and Habitat Protection/Surface Disturbance Measures

The four Great Basin ARMPAs build on the designated habitat management areas described in **Section 1.5** by applying management actions to these areas to avoid and minimize disturbance associated with proposed projects as described below and shown in **Table 1.4**. Land use plan allocations specify

locations within the planning area that are available or unavailable for certain uses and also prioritize conservation and restoration management actions applied to habitat management areas.

Formatted: Font: Times New Roman

Through this ROD, the BLM adopts those portions of the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah EISs applicable to National Forest System lands, pursuant to the provisions of 40 CFR 1506.3(c). The EISs sufficiently disclose and analyze all environmental issues associated with mineral leasing and provides support to the BLM to authorize mineral leasing in USFS administered lands, should consent be provided by or consultation be required with the USFS prior to issuance of a lease, in compliance with applicable mineral leasing and NEPA regulations, and subject to further site-specific environmental analysis where applicable.

The COT ~~report~~Report notes that "loss and fragmentation of sagebrush habitats is a primary cause of the decline of sage-grouse populations". ~~(COT, p 9).~~ While surface disturbance associated with development in the Great Basin is not ~~yet~~ as significant a threat to GRSG and its habitat as rangeland fire and invasive species~~,~~, the BLM ARMPAs include land allocations and management actions that avoid and minimize surface disturbance in PHMA for identified threats (e.g., energy, mining, infrastructure, improper grazing, free-roaming equids, recreation and urbanization). These land allocations and management actions are necessary because the location and extent of habitat loss to fire is difficult to predict and much of the habitat due to low precipitation in the Great Basin is difficult to restore once lost. Further, even a small amount of development in the wrong place could have an outsized impact in these landscapes.

Comment [JRL3]: Should include this in the RM ROD as this point as well.

Formatted: Font: Calibri

The most restrictive allocations include requirements to avoid and minimize additional disturbance in SFAs, which are a subset of PHMA, where surface disturbance from fluid mineral development is avoided by NSO without waiver, modification, or exception. In addition, these areas will be recommended for withdrawal to address the risk of disturbance due to mining.

Formatted: Font: Times New Roman

In PHMAs outside of SFAs new fluid mineral leasing would be subject to NSO with no waivers or modifications. Exceptions would be granted only if the proposed action would not have direct, indirect, or cumulative effects on GRSG or its habitat; or, if the action is proposed to be undertaken as an alternative to a similar action occurring on a nearby parcel, and would provide a clear conservation gain to GRSG. This is fully consistent with guidance in the NTT report which states, "Do not allow new surface occupancy on federal lands within priority habitats" (NTT, p. 23).

Formatted: Font: Times New Roman

Similarly, PHMA is closed to non-energy and salable mineral development (this does not apply to locatable minerals governed under the 1872 Mining Law). An exception may be granted for free-use permits and the expansion of existing active pits for salable minerals and expansion of existing non-energy leasable development under certain conditions. This exception is included because of the importance of these materials to local communities and their limited disturbance which will be offset by the mitigation requirements. Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses the potential disturbance threat from coal development. In Utah, at the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. PHMA is essential habitat for maintaining GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).

All PHMAs will be managed as exclusion areas for commercial renewable energy development (solar and wind) with the exception of areas outside of SFAs in three counties in southeastern Oregon. The three counties in Oregon will be managed as avoidance areas. ~~In these counties, the BLM will encourage new renewable energy development in non-habitat areas first.~~ New rights-of-ways and development for transmission lines, pipelines, and related infrastructure would be avoided through restrictions on land use authorizations. In avoidance areas, exceptions would only be granted if it can be demonstrated that adverse impacts will be avoided or that residual impacts will be mitigated.

Comment [JRL4]: This was a part of the agreement that needs to be reflected in the plan and the ROD.

Formatted: Font: Times New Roman

High voltage transmission lines will be avoided in PHMA. However, the planning, siting, and environmental review of a limited number of priority transmission lines (Transwest Express and portions (that are co-located with Transwest Express) of Gateway South, Gateway West and Boardman to Hemingway), which have been underway for a several years and are deemed critical to expanding access to renewable sources of energy and to improving the reliability of the western grid, will proceed through NEPA analysis of these proposed lines under separate authorization processes. Conservation measures for GRSG are being analyzed as part of those NEPA processes, which should achieve a net conservation benefit for GRSG.

Formatted: Font: Times New Roman

While restrictions on future development in PHMA are intended to avoid or minimize additional surface disturbance, restrictions on development in GHMA are tailored to allow disturbance but with restrictions to ensure compatibility with GRSG habitat needs. In addition, mitigation to avoid, minimize, and compensate for unavoidable impacts will be required for proposed projects in GHMA. Disturbance associated with oil and gas development, for example, is subject to a controlled surface use and timing limitation stipulation rather than an NSO stipulation. (See **Table 1-3** for more details on GHMA management decisions.) Any disturbance is subject to mitigation, with the objective of first avoiding and minimizing potential impacts to GRSG or its habitat and then compensating for unavoidable impacts to GRSG or its habitat, to a net conservation gain standard for the species. This is consistent with guidance in the COT Report which states: "Conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur. …If development or vegetation manipulation activities outside of PACs are proposed, the project proponent should work with federal, state or local agencies and interested stakeholders to ensure consistency with sage-grouse habitat needs."

In addition to allocations that limit disturbance in PHMA and GHMA, the ARMPAs prioritize oil and gas leasing and development outside of identified PHMAs, and GHMAs to further limit future surface disturbance and encourage new development in areas that would not conflict with GRSG. This objective is intended to guide development to lower conflict areas and as such, reduce the time and cost associated with oil and gas leasing development by avoiding sensitive areas, reducing the complexity of environmental review and analysis of potential impacts to sensitive species, and decreases the need for compensatory mitigation.

Formatted: Font: Times New Roman

Additionally, new recreation facilities would not be authorized in PHMAs, unless the development results in a net conservation gain to the GRSG or its habitat, or, unless required for health and safety purposes.

In PHMA and GHMA, travel is limited to existing routes until routes are designated through the implementation travel management planning process. Travel management plans, including route inventories, NEPA analysis, and route designation will be completed in a subsequent public planning processes.

Formatted: Font: Times New Roman

In general, all forms of new development in PHMAs and GHMAs would either be closed, excluded, avoided, or developed only if the resultant effect is a net conservation gain to the GRSG or its habitat, ensuring that existing habitat would be protected and providing opportunities, through compensatory mitigation.

Formatted: Font: Times New Roman

While improper livestock grazing can be a threat to GRSG habitat, grazing is not considered a discrete surface disturbing activity for purposes of monitoring and calculating disturbance. The plans address grazing management for the conservation of GRSG and its habitat by incorporating terms and conditions into permits to achieve habitat objectives ~~into permits~~ and by prioritizing assessment and the review of grazing permits (see Section 1.6.2).

Formatted: Font: Times New Roman, Underline

Disturbance Caps, Density Caps, Lek Buffers, and Required Design Features

In addition to the management actions and allocations discussed above, the ARMPAs provide further assurance that anthropogenic disturbances in PHMAs will be limited through the use of disturbance caps, density caps, and lek buffers.

A 3% anthropogenic disturbance cap in PHMA has been established in accordance with the recommendations contained in the NTT Report, and peer-reviewed literature from the Great Basin (Knick 2013). Disturbance will be calculated at two scales: first at a Biologically Significant Unit (BSU) scale determined in coordination with the state and second, for the proposed project area. BSUs are geographic units of PHMA that contain relevant and important GRSG habitat. In Oregon for example, BSUs are synonymous with PACs. These BSUs are used solely for the calculation of anthropogenic disturbance cap and in some ARMPAs, the adaptive management habitat triggers.

If 3% anthropogenic disturbance cap is exceeded on lands (regardless of land ownership) within PHMA in any given BSU, no further discrete anthropogenic disturbances (subject to valid existing rights) will be permitted on BLM-managed lands within PHMAs in that BSU until restoration of disturbed lands brings the BSU below the cap. If the 3% anthropogenic disturbance cap is exceeded on all lands (regardless of land ownership) within a proposed project analysis area in a PHMA, then no further anthropogenic disturbance will be permitted by BLM until disturbance in the proposed project analysis area has been reduced to maintain the area under the cap.

Formatted: Font: Times New Roman

An exception to the 3% disturbance cap is provided in designated utility corridors for purposes of achieving a net conservation gain to the species. This exception is limited to projects which fulfill the use for which the corridors were designated (e.g., transmission lines and pipelines) within the designated width of a corridor. This exception will concentrate future ROW surface disturbance in areas of existing disturbance and avoid new development of infrastructure corridors in PHMAs consistent with guidance in the COT report. In addition, the Oregon and Nevada/Northeast California ARMPAs include variations to the disturbance cap: Oregon does not allow more than 1% new anthropogenic disturbance per decade, not to exceed 3% disturbance at any time. In Nevada, permit exceedances of the 3% disturbance cap at the BSU and/or the project level can occur provided that the outcome results in a net conservation benefit to the species with the concurrence of the BLM, Nevada Department of Wildlife, and FWS in each exception.

In Southwest Montana (the BLM's Dillon Field Office), the BLM will limit disturbance to 3% until the State of Montana's Sage Grouse Plan's disturbance calculation methodology is instituted and is in effect at which time disturbance will be permitted up to a 5% cap. This is to recognize, as with the Wyoming Core Area Strategy, the importance of the all-lands-all-disturbances strategy that Montana plans to institute for sage-grouse conservation.

Appendix E of each of the attached ARMPAs includes additional information about the methodology for calculating anthropogenic disturbance at the BSU and project scales.

Formatted: Font: Times New Roman

The ARMPAs also incorporate a cap on the density of energy and mining facilities to encourage co-location of structures to reduce habitat fragmentation. The limit is an average of one facility per 640 acres in PHMA in a project authorization area, consistent with guidance contained in the NTT Report. If the disturbance density in the PHMA in a proposed project area is, on average, less than 1 facility per 640 acres, the project can proceed through the NEPA analysis incorporating mitigation measures into an alternative. If the disturbance density in the proposed project area is greater than an average of 1 facility per 640 acres, the proposed project will either be deferred until the density of energy and mining facilities is less than the cap or redesigned so facilities are co-located into an existing disturbed area, subject to applicable laws and regulations, such as the 1872 Mining Law and valid existing rights. The one facility per 640 density decision does not apply to Nevada, as described in **Section 1.7**.

In addition to any other relevant information determined to be appropriate, the BLM will further assess and address impacts from certain activities using the lek buffer-distances as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). Lek buffer distances will be applied at the project specific level as required conservation measures to address the impacts to leks as identified in the NEPA analysis. The lek buffer distances vary by type of disturbance (road, energy development, infrastructure, etc.) and justifiable departures may be appropriate as fully described in Appendix B of the ARMPAs. In both PHMA and GHMA, impacts should be avoided first by locating the action outside of the applicable lek buffer-distance(s) as defined in the ARMPAs. In PHMA, the BLM will ensure that any impacts within the buffer distance from a lek are fully addressed. In GHMA, the BLM will minimize and compensate for any unavoidable impacts to the extent possible. This approach to determining relevant lek buffer distances is consistent with the COT recommendation that "conservation plans should be based on the best available science and use local data on threats and ecological conditions."

Additionally, Required Design Features (RDFs) are required for certain activities in all GRSG habitat, including oil and gas development, infrastructure, and other surface disturbing activities and are fully described in Appendix C of the attached ARMPAs. RDFs establish the minimum specifications for certain activities to help mitigate adverse impacts to GRSG and its habitat from threats (such as those posed by standing water that can facilitate West Nile virus or tall structures that can serve as perches for predators). However, the applicability and overall effectiveness of each RDF cannot be fully assessed until the project level when the project location and design are known. Because of site-specific circumstances, some RDFs may not apply to some projects (e.g., a resource is not present on a given site) and/or may require slight variations (e.g., a larger or smaller protective area). In Nevada and Northeastern California, RDFs are also applied to their identified OHMAs.

1.6.2 Improving Habitat Condition

Formatted: Font color: Auto

In addition to prescribing land use allocations and managing resource uses in order to minimize and avoid further surface disturbance, the ARMPAs identify management actions to restore and improve GRSG habitat.

The ARMPAs contain an overall habitat management objective that "In all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain all lands ecologically capable of producing sagebrush (but no less than 70%) with a minimum of 15% sagebrush canopy cover or as consistent with specific ecological site conditions." To move toward this goal, the ARMPAs specify GRSG habitat objectives to be incorporated into land management programs, including wild horse and burros, grazing, and habitat restoration. These habitat objectives were developed for each of the GRSG's life history stages within each ARMPA's sub-region. These objectives will be used to meet the applicable land health standard in GRSG habitats.

The ARMPAs also include specific decisions to improve habitat conditions and meet the habitat objectives through treatment of invasive annual grasses and the removal of encroaching conifers in SFA, PHMA, and GHMA, and restoration of degraded landscapes, including those impacted by fire events (See **Section 1.6.3**.)

The BLM recognizes that improper grazing is a threat to GRSG and its habitat. Because grazing is the most widespread use of the sagebrush steppe ecosystem, the ARMPAs address improper grazing. The COT Report recommendation for grazing states, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage-grouse (e.g. shrub cover, nesting cover)." To ensure that grazing continues in a manner consistent with the objective of conserving the GRSG and its habitat, the Great Basin ARMPAs include requirements for the incorporation of terms and conditions informed by GRSG habitat objectives into grazing permits, consistent with the ecological site potential of the local areas, prioritize the review and processing of authorizations and field checks of grazing permits, and take numerous actions to avoid and minimize the impacts of range management structures (**see Table 1-4**).

Formatted: Font: Times New Roman

The BLM will prioritize reviews and processing of grazing authorizations, as well as field checks of grazing permits in the habitat that is most important to GRSG populations: first in SFAs, then PHMAs, followed by GHMA, focusing first on riparian and wet meadows. The decision to prioritize in this way does not indicate that grazing is more of a threat or is an incompatible use in any given area, but rather reflects a decision to prioritize resources to ensure permittees and the BLM manage grazing properly in those areas most important to GRSG. If the BLM finds that relevant habitat objectives are not being met due to improper grazing, the BLM will work with the permittee to ensure progress towards habitat objectives.

To address the localized threat due to negative influences of grazing by free-roaming equids (wild horses and burros (WHB)), the BLM will focus on maintaining WHB Herd Management Areas in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives, including completing rangeland health assessments, prioritizing gathers and population growth suppression techniques, and developing or amending Herd Management Area (HMA) plans to incorporate GRSG habitat objectives and management considerations. The BLM will prioritize WHB management first in SFAs, then the remainder of PHMA, and then GHMA. In SFAs and PHMA, the BLM will assess and adjust AMLs through the NEPA process within HMAs when WHBs are identified as a significant causal factor in not meeting land health standards, even if current AML is not being exceeded.

During the implementation of the ARMPAs, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in GRSG habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain (the actual benefit or gain above baseline conditions) to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for unavoidable impacts by applying beneficial conservation actions to offset remaining impacts associated with the action. This standard is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0* published by the FWS in September, 2014, which states that mitigation "should be strategically designed to result in net overall positive outcomes for sage-grouse"**.** Mitigation will follow the regulations from the White House Council on Environmental Quality (CEQ) (40 CFR 1508.20; e.g. avoid, minimize, and compensate) and be implemented on BLM-managed lands in a manner consistent with Departmental guidance for landscape mitigation pursuant to Secretarial Order 3330. If impacts from BLM management actions and authorized third party actions result in habitat loss and degradation that remain after applying avoidance and minimization measures (i.e. residual impacts), then compensatory mitigation projects will be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation.

Comment [5]: Hotlink documents throughout

Formatted: Font: Times New Roman

To help achieve the mitigation goal of net conservation gain across the range, the BLM will establish GRSG Conservation Teams based on WAFWA Management Zones, including members from the respective states, Forest Service, FWS, and NRCS. These Conservation Teams will facilitate cross-state issues, such as regional mitigation and adaptive management monitoring and response. These Teams will convene to advise on these specific tasks and will utilize existing coordination and management structures to the extent possible.

With regard to the threat of climate change, the ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the *Integrated Rangeland Fire Management Strategy* will further these goals and objectives. The Fire and Invasives Assessment Team (FIAT) assessments that informed the ARMPAs and supported the development of the Integrated Rangeland Fire Management Strategy were designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). Additionally, by limiting or eliminating anthropogenic surface disturbance, especially in the SFAs, ensuring the integrity of the PHMAs, and restoring habitat through fuels management, post-fire restoration, and mitigation efforts, connectivity and availability of sagebrush habitat will increase, thus contributing to increased climate resilience. The SFAs in particular, were identified as key areas to conserve as climate changes. The Oregon ARMPA commits to use climate change science concerning projected changes in species ranges and changes in site capability to adjust expected and desired native species compositions as that information becomes available.

Formatted: Font: Times New Roman

As identified by the FWS 2010 decision and the COT report, climate change can impact efforts to conserve the GRSG and its habitat in a number of ways. While several ARMPAs acknowledge the potential impact of climate change on GRSG habitat and conservation efforts, specific strategies to address the impacts of climate change are limited. The BLM and Forest Service, in coordination with the FWS, will continue to assess the potential impacts of climate change on GRSG and its habitat and develop strategies to mitigate anticipated effects on GRSG conservation efforts. Changes to management decisions will require a plan revision or amendment, as appropriate.

Formatted: Right: 0.21", Line spacing: Multiple 1.03 li

1.6.3 Reducing Threats of Rangeland Fire to GRSG and Sagebrush Habitat

Formatted: Font color: Auto

The COT emphasized that "rangeland fire (both lightning-caused and human-caused fire) in sagebrush ecosystems is one of the primary risks to the greater sage-grouse, especially as part of the positive feedback loop between exotic invasive annual grasses and fire frequency". For this reason, the ARMPAs seek to fight the spread of cheatgrass and other invasive species, position wildland fire management resources for more effective rangeland fire response, and accelerate the restoration of fire-impacted landscapes to native grasses and sagebrush. Prescribed fire will not be used except under the following conditions: the NEPA analysis for the Burn Plan provides a clear rationale for why alternative techniques were not selected as a viable option, how GRSG habitat management goals and objectives would be met by its use, how the COT Report objectives would be addressed and met, and a risk assessment is prepared to address how potential threats to GRSG habitat would be minimized.

Formatted: Font: Times New Roman

The cornerstone of the FIAT protocol is recent scientific research on resistance and resilience of Great Basin ecosystems (Chambers, et al., 2014b). The final FIAT process report was completed in June 2014 by the Fire and Invasive Assessment Team. The BLM, the Forest Service, FWS, and other cooperating agencies agreed to incorporate this approach into the ARMPAs. This information is being used to identify and design projects to change vegetation composition and/or structure to modify potential fire behavior for the purpose of improving fire suppression effectiveness and limiting fire spread and intensity due to invasive grasses and conifer encroachment. The BLM *Greater Sage Grouse Invasive Annual Grasses & Conifer Expansion Assessment* (FIAT 2014) modeled conifer expansion for PACs to provide an initial stratification to determine where conifer removal would benefit important sagebrush habitats.

Formatted: Font: Times New Roman

Consistent with this assessment, the BLM ARMPAs include management actions to remove invading conifers and other undesirable species, and prioritize vegetation treatments closest to occupied GRSG habitats and near occupied leks. Through guidance in the ARMPAs supplemented by the *Integrated Rangeland Fire Management Strategy*, a commitment has been made to address the invasion and expansion of cheatgrass, medusa head, and other invasive grasses through expanded efforts to treat impacted acres and to accelerate and expand efforts to restore lands impacted by fire with native grasses and sagebrush seedlings. Efforts are underway to increase the acreages to be treated with chemical and biological agents to kill and stem the spread of invasive species and to accelerate the registration of other biologicals useful in addressing the threat of cheatgrass invasion.

In addition to and complementing the ARMPAs described in this ROD, Secretarial Order 3336 on Rangeland Fire made clear that "**protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, priority GRSG habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department"** (emphasis added). The strategy places a Departmental priority on activities to prevent, suppress, and restore fire-impacted landscapes, which are identified by the Fire and Invasives Assessment Tool (FIAT) for the Great Basin Region, using recent information derived from a report prepared by WAFWA to assist in addressing the threat of rangeland fire. The FIAT Assessments provide a list of findings, recommendations, and considerations to protect, maintain, and enhance GRSG habitat. The Assessments also apply recent science and identify highly resistant and resilient landscapes to target fire management activities to these most important lands. In addition, through the issuance of a Leaders' Intent letter, signed by the Secretaries of Agriculture and the Interior, rangeland fire was identified as an "additional priority" for the firefighting community in making strategic decisions with regard to the allocation of resources for firefighting in 2015. Additional resources have been allocated and will be targeted to fuel treatments (including invasive species control), suppression (through the prepositioning of fire-fighting resources and the training of additional Rangeland Fire Protection Associations, local volunteer firefighters, and veteran fire fighters), and habitat restoration in these areas. Firefighting assets (aircraft, firefighters and related equipment) will be located near areas of high priority for rangeland fire.

Comment [JRL6]: Not "Rural"?

1.6.4 Monitoring, Evaluation, and Adaptive Management

Formatted: Font color: Auto

The COT Report noted that “a monitoring program is necessary to track the success of conservation plans and proactive conservation activities. Without this information, the actual benefit of conservation activities cannot be measured and there is no capacity to adapt if current management actions are determined to be ineffective.” The NTT further notes that “Monitoring is necessary to provide an objective appraisal of the effects of potentially positive conservation actions, and to assess the relative negative effects of management actions to sage-grouse populations and their habitats.”

Formatted: Font: Cambria Math

Formatted: Font: Times New Roman

A rangewide monitoring and evaluation framework will be established and implemented as described in the Monitoring Framework (Appendix D of each attached ARMPA). This monitoring strategy has two parts: (1) implementation monitoring (i.e., are decisions being implemented in a timely manner, are actions taken consistent with the plan decisions), and (2) effectiveness monitoring (i.e., are the decisions and implementation actions achieving the desired conservation goals). Through effectiveness monitoring, BLM can determine how management decisions and actions implemented through the ARMPAs affect GRSG habitat to determine if the desired management objectives (e.g. avoiding and minimizing additional surface disturbance in PHMAs) have been achieved. Understanding the effectiveness and validating results of ARMPA management decisions is an essential part of the GRSG conservation strategy and provides the means for determining if desired outcomes are being achieved.

Formatted: Font: Times New Roman

Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, size of patches, etc.). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by state wildlife agencies and other partners, will allow linking real or potential habitat changes (from both natural events and management actions) to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to ameliorate negative effects with appropriate conservation actions. The WAFWA Zone GRSG Conservation ~~Team~~Teams (as described in Section 1.6.2) will also be used to advise regional monitoring strategies and data analysis as described in the plans.

Formatted: Font: Times New Roman

Each ARMPA includes an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are habitat and population thresholds and are based on the two key metrics that are being monitored - habitat condition and/or population numbers. At a minimum, the BLM will assess annually whether hard and soft trigger thresholds have been met when the population or habitat information becomes available, beginning after the issuance or signature of this ROD.

Formatted: Font: Times New Roman

Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the ARMPAs, the BLM will implement more conservative or restrictive conservation measures on a project-by-project basis to mitigate for the specific causal factor in the decline of populations and/or habitats, with consideration of local knowledge and conditions. In each ARMPA, a soft trigger begins a dialogue between the state, FWS, and the BLM to see if the causal factor can be determined and what implementation-level activities can be used to reverse any trend. These adjustments will be made to preclude tripping a “hard” trigger (which signals more severe habitat loss or population declines).

Formatted: Font: Times New Roman

Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the BLM ARMPAs. In the event that a hard trigger is tripped, the BLM will implement plan-level decisions, such as allocation changes, to immediately institute greater protection for GRSG and its habitat. If a hard trigger is tripped in a PAC that crosses state boundaries, the WAFWA Management Zone GRSG Conservation Team will convene to discuss causes and identify potential responses.

Comment [JRL7]: They need to act, not simply “advise”.

Formatted: Font: Times New Roman

In the event that new scientific information becomes available demonstrating that the hard trigger response is insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM ARMPAs, the BLM will immediately assess what further actions may be needed to protect GRSG and its habitat and ensure that conservation options are not foreclosed. This could include a formal directive such as an Instruction Memorandum (IM) or a plan amendment.

1.7 Unique Aspects of the Great Basin ARMPAs

Formatted: Font color: Auto

The ARMPs and ARMPAs and their associated EISs were developed through four planning efforts across the Great Basin Region (as described in Section 1.1). To develop these plans, the BLM employed a landscape-scale approach to achieve a common set of management objectives across the range of GRSG recognizing, in particular, implementing measures to limit anthropogenic disturbance in important habitats. Within this framework, management actions were developed and incorporated into the plans that are tailored to achieve these objectives and accommodate differences in resource conditions, severity of threats, and state-specific management approaches.

Formatted: Font: Times New Roman

This flexible landscape approach provided the opportunity to incorporate recommendations resulting from collaboration with the states and local cooperators ~~and~~as well as public comments in each planning area. The plans and their future implementation ~~is~~are strengthened by the contributions of local partners and their knowledge, expertise, and experience.

Formatted: Font: Times New Roman

Measures incorporated into the plans remain consistent with the range-wide objective of conserving, enhancing, and restoring GRSG habitat by reducing, eliminating, or minimizing threats to GRSG habitat, such that the need for additional protections under the ESA may be avoided.

Below is a brief description of the unique aspects of each of the Great Basin Region’s ARMPAs.

Formatted: Font: Times New Roman

Idaho and Southwestern Montana

Comment [8]: Hotlink

The Idaho and Southwestern Montana ARMPA adopted specific aspects of the State of Idaho’s Conservation Plan for GRSG. The most significant aspect adopted from the State’s plan is a third category of habitat referred to as Important Habitat Management Areas (IHMA). IHMA are BLM-administered and National Forest System lands that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations. In a landscape that is most threatened by fire and invasive species, this three-tiered approach allows land managers to focus suppression and restoration resources on those areas of highest importance while providing an acceptable additional level of flexibility in IHMA and GHMA since surface disturbance due to development is not as great a threat to habitat in the sub-region. The three tiers also serve as the foundation for an adaptive management approaches that includes habitat and population hard and soft triggers. The adaptive management approach requires that when a hard trigger is reached, IHMA will be managed as PHMA to maintain sufficient PHMA to support GRSG populations.

The Idaho portion of the Idaho and Southwestern Montana GRSG ARMPA also includes a unique approach to calculating disturbance to account for effective habitat, as described in Appendix E of the attached Idaho and Southwestern Montana ARMPA, which was developed by the BLM in concert with the Idaho Department of Fish and Game, Forest Service, and FWS. The Idaho and Southwestern Montana ARMPA also includes additional Required Design Features (RDFs) based on lek avoidance distances, which were developed in coordination with the Idaho Department of Fish and Game and the local FWS office. Examples include avoiding building new wire fences within 2 km of occupied leks and placing new, taller structures out of line of sight or at least one kilometer from occupied leks. The BLM will also work with the state of Idaho in setting priorities for the review and processing of grazing permits/leases in SFAs consistent with the methodology recommended by the State of Idaho in its proposed plan for the management of BLM-administered lands in the state.

On August 7, 2015, the Sawtooth National Recreation Area and Jerry Peak Wilderness Act (H.R. 1138) was signed into law. In accordance with the Wilderness Act (16 U.S.C. 1131 *et seq*.), certain Federal lands in the Challis National Forest and Challis District of the Bureau of Land Management in the State of Idaho, were designated as wilderness, as a component of the National Wilderness Preservation System, known as the Jim McClure-Jerry Peak Wilderness. Approximately 12,430 acres of this wilderness area fall within BLM-administered PHMA~~ (as a subset of~~, which is all SFA~~). The ARMPA decisions for this~~. This area will now also be managed as Wilderness consistent with the Wilderness Act. As specified in the Sawtooth National Recreation Area and Jerry Peak Wilderness Act, a wilderness management plan will be developed within 5-years of the signing of the Act and it will outline specific management guidance for the new wilderness area.

Formatted: Not Highlight

Formatted: Not Highlight

Formatted: Not Highlight

This bill also released the Jerry Peak West, Corral-Horse Basin, and Boulder Creek Wilderness Study Areas (WSAs) and they are no longer subject to management pursuant to Section 603(c) of the FLPMA. The acres released as ~~WSA~~WSAs include approximately ~~X~~71,194 acres of PHMA, ~~X~~11,923 acres of IHMA, and ~~X~~5,912 acres of GHMA. The ARMPA decisions for these areas will not change as a result of the release.

Comment [MA9]: Getting clarification on this

Finally~~, in accordance with the Recreation and Public Purposes Act,~~ the Sawtooth National Recreation Area and Jerry Peak Wilderness Act also ~~conveyed~~directed the BLM to convey certain public lands to Blaine County, Custer County, the City of Challis, the City of Clayton, and the City of Stanley. ~~This conveyance included~~These conveyances include approximately ~~35~~53 acres of PHMA, 10 acres of IHMA, and 828 acres of GHMA that are reflected in the ARMPA as being administered by the BLM. ~~Through future plan maintenance,~~Once conveyed, the BLM will adjust the maps and acres as they appear in the ARMPA through plan maintenance to depict that these lands are not subject to the management decisions outlined in the Idaho and Southwestern Montana GRSG ARMPA.

The decisions affecting Southwestern Montana in the ARMPA consistent with the objectives of the Montana Sage Grouse Habitat Conservation Program (Montana Office of the Governor Executive Order No. 10-2014) by establishing conservation measures and strategies to minimize disturbance and habitat loss, particularly as a result of surface disturbance from energy exploration and development. The BLM plan will permit the disturbance limit to go from a 3% to a 5% disturbance cap, consistent with the Montana Plan when the process for implementing their disturbance calculation methodology is instituted and effective. Additionally, if the BLM finds that the State of Montana is implementing an effective GRSG habitat conservation program, the BLM would review their management actions to determine if additional sage-grouse related management actions should be adjusted with coordination from the State of Montana and the FWS to achieve consistent and effective conservation across all lands, regardless of ownership.

Formatted: Font: Times New Roman

Formatted: Font: Times New Roman

Formatted: Font: Times New Roman

Nevada and Northeastern California

The Nevada portion of the Nevada and Northeastern California ARMPA is unique from other Great Basin ARMPAs because of how the sub-regional habitat map was developed. The ARPMA uses the “2014 Coates Maps”, developed locally using the best available science, and included “Other Habitat Management Areas”, where required design features will be applied at the project level. Decisions for BLM-administered lands in the State of California include allocations and management direction that is generally similar to other ARMPAs in the Great Basin, while carrying forward some decisions identified in the Sage Steppe Ecosystem Restoration FEIS (BLM 2008).

Decisions for BLM-administered lands in the State of Nevada incorporate key elements of the State of Nevada Greater Sage-Grouse Conservation Plan (State of Nevada 2014) including consideration of the State of Nevada Conservation Credit System (Nevada Natural Heritage Program and Sagebrush Ecosystem Technical Team 2014) as the ARMPA is implemented and as projects are proposed within the planning area. This mitigation strategy focuses restoration efforts in the key areas most valuable to the GRSG. The ARMPA adopts a Disturbance Management Protocol (DMP) to provide for a 3% limitation on disturbance, except in situations where a biological analysis indicates a net conservation gain to the species, with concurrence from the BLM, State of Nevada, and FWS. The plan provides for this exception due to the development of mitigation tools in Nevada, including the Conservation Credit System, in collaboration with the FWS. Furthermore, given the concurrence of the Nevada Department of Wildlife and FWS in each exception, this approach is consistent with conservation objectives. The Disturbance Management Protocol in BLM-administered lands in Nevada was also deemed sufficient such that the Nevada ARMPA does not utilize a disturbance density cap, which is required in the three other Great Basin Region ARMPAs.

In coordination with the FWS, the Nevada ARMPA also allows for an exception to the geothermal NSO which is an energy development priority for the state and is projected to create very limited disturbance in predictable areas over the life of the plan. For those reasons, this exception is consistent with overall conservation objectives.

Formatted: Font: Times New Roman

Utah

The Utah ARMPA incorporates a number of key strategies for GRSG conservation developed by the State of Utah (Conservation Plan for Greater Sage-Grouse in Utah) and the State of Wyoming (Executive Orders 2011-05 and 2013-3), which establishes conservation measures for protecting GRSG and also focuses conservation and restoration within key areas deemed most valuable to GRSG. The Utah ARMPA also integrates the state's strategic focus on increasing areas available to GRSG through vegetation treatments and reducing threats from wildfire. The ARMPA provides additional flexibility for development in GHMA because 96% of the breeding GRSG in Utah are within PHMAs where conservation measures are applied in a more targeted manner at the project-implementation stage through the use of lek buffers and required design features as well as requiring that compensatory mitigation achieve a net conservation benefit outcome. As such, the Utah ARMPA designates GHMA as open to wind energy and high voltage transmission ROW development (consistent with the net-conservation-gain mitigation framework for the ARMPA). The Utah ARMPA also designates GHMA open to oil and gas development with standard constraints.

Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses this threat.

Oregon

The Oregon ARMPA incorporates key elements of the Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat (Hagen 2011) which establishes unique conservation measures for protecting GRSG and also focuses restoration within key areas most valuable to GRSG. The BLM plan adopts the unique disturbance cap approach developed with the State of Oregon in which disturbance is capped at 1% per decade, in addition to the 3% cap in BSUs and project analysis areas.

The BLM Oregon plans provide additional flexibility for wind development in PHMA in Harney, Lake, and Malheur counties by allowing avoidance rather than exclusion within PHMAs that are outside of the SFAs. The BLM provided this flexibility after recognizing the extent of high and medium potential wind areas in these counties that is in PHMAs, the fact that wind energy is excluded in SFAs in these counties, and, after coordination with the USFWS, determining that the more rigorous disturbance cap (in which disturbance is capped at 1% per decade) and adaptive management triggers adopted by the Oregon plan would compensate for the limited wind development likely to occur in these areas. In addition, the plan encourages development of wind energy ROWs outside of PHMA first, or in non-habitat areas within PHMA, before development is permitted in higher value habitat areas. Due to these factors, the BLM finds these limited areas of flexibility for wind development are not inconsistent with overall conservation objectives of the plan. In addition, the Oregon ARMPA identifies strategic areas where habitat enhancement and restoration activities are encouraged, as well as other strategic areas to address the impacts associated with climate change.

For additional information regarding the unique aspects of each plan, refer to Table 1-6 of the attached Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah ARMPAs, which provides a crosswalk regarding how the ARMPAs address specific threats to GRSG identified in the COT Report through these state-specific management prescriptions.

Comment [10]: Hotlink.

1.8 Decision Rationale

Formatted: Font color: Auto

The ARMPAs provide a comprehensive and effective conservation strategy for addressing the threats identified by the FWS such that the need for additional protections under the ESA may be avoided. The ARMPAs contain objectives which strive to conserve the GRSG and its habitat on BLM-administered lands across the remaining range of the species consistent with measures identified or recommended in the NTT or COT reports.

In combination with the sage-grouse conservation actions taken by the individual states within the remaining range of the species and separate but connected initiatives to address the threat of rangeland fire to curb the ~~continuing~~ spread of non-native invasive grasses, and to promote conservation measures to benefit the Greater sage-grouse on private lands, the BLM and Forest Service proposed ARMPAs are an essential component of the effort to conserve the GRSG and its habitat. Combined, all of the ARMPAs associated with the BLM's National GRSG Conservation Strategy would affect approximately 66 million acres of the remaining habitat for the species.

The BLM Greater Sage-Grouse Conservation Strategy is built upon the following key concepts:

- **Landscape-level**: The planning effort encompasses the remaining habitat of the GRSG on BLM-administered public lands, covering 10 western states in the Great Basin and Rocky Mountain regions. As such, the strategy provides a coherent framework across the BLM RMPs to implement landscape-level conservation for GRSG while allowing for flexibility essential to effectively address threats to the GRSG in the context of the agency's multiple use and sustained yield mandates under FLPMA. The conservation measures included as part of this landscape-level conservation effort address identified threats to the species, recognizing local ecological conditions, and incorporating existing conservation efforts where they are consistent with the overall objective of conserving ~~the Greater sage-grouse~~GRSG across its remaining range.
- **Best Available Science** – The ARMPAs are grounded in the best available science, drawn from published literature and input from recognized experts, state agencies, the US Geological Survey, the FWS and other sources. The COT Report provided a "blueprint" for GRSG conservation by identifying specific threats to each remaining GRSG population and recommending measures to address each category of threat. The BLM National Technical Team (NTT) Report provided additional guidance for addressing the most significant threats to the GRSG. A series of

Formatted: Indent: Left: 0.25", Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 2.75" + Indent at: 1" subsequent reports on how to improve efforts to reduce the threats of rangeland fire and invasive species prepared in collaboration with the WAFWA, as well as a report to the Secretary of the Interior entitled "An Integrated Rangeland Fire Management Strategy" also informed the GRSG conservation.

- **Targeted, Multi-Tiered Approach** – The ARMPAs were designed to incorporate a layered management approach to target habitat protection and restoration efforts to the most important habitat management areas as determined by state and federal sage grouse experts, largely consistent with the Priority Areas for Conservation (PACs) identified in the COT Report, where land allocations and management direction avoid and minimize additional surface disturbance. These areas are designated as Priority Habitat Management Areas (PHMAs). Within PHMA, the ARMPAs/ARMPs provide an added level of protection to eliminate most surface disturbance through the delineation of Sagebrush Focal Areas (SFA), derived from areas identified by the FWS as "strongholds" essential for the species' survival. General Habitat Management Areas (GHMAs), recognize the potential value of habitat areas outside of PACs -- as recommended by the COT -- where surface disturbance is minimized -while providing greater flexibility for other land resource uses.
- **Coordinated**: The ARMPAs were developed through a joint planning process between the BLM and the Forest Service (as a cooperating agency). As a result, federally-administered ~~landsessential~~lands essential to the conservation of the GRSG are managed in a coordinated manner. The FWS provided guidance and input throughout the process to aid land managers in understanding the threats to the GRSG and its habitat. The USGS and NRCS also provided key technical and scientific support.
- **Collaborative**: The ARMPAs reflected extensive input from the relevant states, collaborators, and stakeholders and the public from the outset. The ARMPAs were developed with the benefit of input from the individual states and cooperators who signed formal agreements with the BLM to provide input into the planning process. The Western Governors Association Sage Grouse Task Force (SGTF) was particularly useful in facilitating this kind of collaborative input. The ARMPAs incorporate state and local conservation measures where they are consistent with the overall objective of implementing land use plan conservation measures for the GRSG consistent with the multiple-use and sustained-yield mission of the BLM.

Comment [JRL11]: Important element in both "rationales".

The conservation measures in the ARMPAs reflect over a decade of research, analysis and recommendations for GRSG conservation including those produced by the WAFWA, the NTT, and the COT. Each of these entities produced a strategy or report that was developed through a collaborative effort of state and federal biologists and scientists with extensive experience and expertise in GRSG management and research.

The COT Report –which identified threats to GRSG habitat as well as the most important habitat to protect--provided an important framework for development of the conservation strategy embodied in the sub-regional ARMPAs. The COT, consisting of state and federal scientists, wildlife biologists, resource managers, and policy advisors, was tasked by the Director of the FWS "with development of range-wide conservation objectives for the sage-grouse to define the degree to which threats need to be reduced or ameliorated to conserve sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future."

In addition, the Fire and Invasives Assessment Team (FIAT) Report and the USGS compilation and summary of published scientific studies that evaluate the influence of anthropogenic activities and infrastructure on GRSG populations -- *Conservation Buffer Distance Estimates for Greater Sage-Grouse—A Review*, and the *Integrated Rangeland Fire Management Strategy: Final report to the Secretary* (Manier et al, 2014; DOI 2015b) provided important guidance in the development of critical aspects of the proposed ARMPAs/ARMPs and the overall GRSG landscape-level conservation strategy. Beyond these range-wide reports, each of the sub-regional plans used local science, where available, to tailor plan elements to reflect local ecological conditions, threats, and GRSG experience where consistent with the overall GRSG management objectives.

Comment [12]: Hotlink

The BLM ARMPAs are the product of extensive coordination, including the active engagement of the FWS in helping to inform land allocation and related management decisions by the land management agencies to ensure they limit or eliminate new surface disturbance as well as improve habitat condition in the most important habitat areas. The ARMPAs/ARMPs also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, approaches, and priorities in each. While the effort to incorporate state-developed conservation measures in each of the sub-regional plans has added complexity in developing the overall conservation strategy, the body of local knowledge and expertise regarding conservation measures for the GRSG is extensive and, ultimately, strengthened the plans. Incorporating these measures in the plans is also likely to increase the commitment of all partners to the difficult task of implementing the plans upon completion.

In his transmittal letter accompanying the final COT report, FWS Director Dan Ashe reaffirmed his charge, "I asked the team to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. … Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels."

The ARMPAs are designed to directly address the specific threats to the species identified by the FWS in its 2010 listing determination as more fully explained in the COT Report, and the BLM NTT Report. As previously noted, the COT Report stated, "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation." Specifically, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT further recommended an "avoidance first strategy" and stressed that "threats in PACs must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

Comment [JRL13]: Strike as explained in RM ROD.

In order to address the identified threats and meet the recommendations of the COT, the plans are based first on the identification of important habitat areas for GRSG in which the plans protect remaining habitat and target habitat restoration and improvement actions. Specifically, the plans identify PHMA which align closely with PACs identified in the COT Report (except for PACs in Nevada and Utah, as specified on page 13 of the COT Report). Within PHMA, the plans identify SFAs based on the FWS analysis of strongholds for the species based on population density, habitat integrity, and resilience to climate change among other factors. The SFAs serve as a landscape-level anchor for the conservation strategy and are closed or excluded from discretionary surface disturbances. SFAs are also used to prioritize fire protection, habitat restoration, and other habitat management actions (e.g., prioritizing reductions in wild horse and burro populations to achieve AML). This approach will allow the BLM to target limited resources to those areas identified by the FWS which are most important to long-term ecosystem health and species persistence.

PHMA and GHMA boundaries are based on Preliminary Priority Habitat (PPH) and Preliminary General Habitat (PGH) (except in Utah, where PPH was derived from occupied habitat). Consistent with BLM's Instruction Memorandum 2012-044, PPH and PGH are based on data and maps developed through a collaborative effort between the BLM and the respective state wildlife agency. PPH and PGH (PHMA and GHMA in the Final EISs and now the ARMPAs) were developed using the best available data. Criteria for delineating PPH included breeding bird density (Doherty 2010), sage grouse proportionality, density of leks, and key seasonal habitats, such as known winter concentration areas. PGH (now GHMA) are areas of occupied seasonal, connectivity, or year-round habitat outside of PPH.

Allocations and management actions are targeted to habitat management areas to limit or eliminate surface disturbance. All forms of new development in PHMA – from energy, to transmission lines, to recreation facilities and grazing structures are excluded, avoided, or allowed only if the resultant effect is neutral or beneficial to the GRSG. In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated with habitat protection or restoration activities that produce a net conservation benefit for the GRSG. The ARMPAs/ARMPs will also prioritize future oil and gas leasing and development outside of identified GRSG habitat management areas (i.e., SFAs, PHMAs, and GHMAs) to reduce the potential for future conflict with GRSG.

In addition, the ARMPs and ARMPAs include measures to limit surface disturbance in PHMA through the establishment of disturbance limits or "caps" and density restrictions of on average 1 energy facility per 640 acres, as well as lek buffers. These requirements reflect recommendations contained in the NTT Report and are consistent with certain state strategies that were already in place before the initiation of the BLM's National GRSG Conservation Strategy. As described in Section 1.6.1, BLM determined the appropriate lek buffers to analyze based on the USGS report *Conservation Buffer Distance Estimates for GRSG – A Review* (Manier et al, 2014) based on best available science.

Formatted: Font: Times New Roman

The plans also include actions meant to improve habitat condition to the most important areas for conservation through additional, targeted efforts to protect and restore habitat first in SFAs, then in PHMAs, and finally in areas designated as GHMAs.

Formatted: Font: Times New Roman

Mitigation for activities adversely impacting GRSG or GRSG habitat in PHMA or GHMA will be designed to a net conservation gain standard consistent with the recommendation included in the September 2013 FWS document, *Greater Sage-Grouse Range-Wide Mitigation Framework*. According to the authors, the Framework was prepared …

> "to communicate some of the factors the Service is likely to consider in evaluating the efficacy of mitigation practices and programs in reducing threats to GRSG. The recommendations provided here are consistent with the information and conservation objectives provided in the 2013 Conservation Objectives Team (COT) Report for sage-grouse".

Grazing, which is the most widespread use of the sagebrush ecosystem, will continue in a manner consistent with the objective of conserving the GRSG. Land health standards will incorporate GRSG habitat objectives and vegetative management objectives consistent with the ecological potential of the landscape as recommended by the COT to …

> "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for GRSG (e.g. shrub cover, nesting cover)."

The ARMPAs also address the adverse impacts of free-roaming equids (wild horses and burros) on GRSG habitat by prioritizing gathers and removal of wild horses and burros to achieve AMLs in SFAs, PHMAs, and GHMAs (in that order). The BLM has been working with the National Academy of Sciences to conduct new research of methods to reduce wild horse and burro reproduction rates. Through a combination of targeted gathers and the development of an effective agent for controlling future free-roaming equid reproductive rates, over time, this threat to GRSG may be effectively managed.

Since the interaction of fire and invasive species represents the greatest threat to GRSG survival in the Great Basin region, the ARMPAs provide specific guidance for improving efforts to reduce the risk of GRSG habitat loss to wildfire, including fire prevention and the restoration of habitats impacted by fire. The Department took a series of actions over 2014 and 2015 to develop a more complete and comprehensive strategy for dealing with this threat that led to Secretarial Order (S.O.) 3336 and subsequent report, *An Integrated Rangeland Fire Management Strategy: Final Report to the Secretary of the Interior*.

http://www.forestsandrangelands.gov/rangeland/documents/IntegratedRangelandFireManagementStrategy_FinalReportMay2015.pdf

In accordance with the S.O. and subsequent rangeland fire management strategy, substantial changes in policy and management direction affecting all aspects of the rangeland fire management program – from better coordination between resource managers and fire management officers; to the identification and prioritization of prevention, suppression, and restoration efforts in SFAs, PHMAs, and GHMAs; to the commitment of additional equipment and crews for rangeland firefighting; to additional funding and policy direction to improve post-fire restoration; to the completion of an initiative to collect, store, and better utilize native seed and sagebrush in post-fire restoration of sagebrush steppe ecosystems. This effort, and the initiative to fight the spread of non-native invasive species that contributes to higher rangeland fire risk (e.g. cheatgrass) discussed below, has fundamentally changed how rangeland fire is managed to benefit sagebrush ecosystems and GRSG habitat.

The COT report – and other more recent research and analysis – amplify concern for the contribution of cheatgrass and other invasive annual species to the loss of GRSG habitat associated with increased fire frequency and intensity. Work initiated by the WAFWA and based on recent research by

Chambers (Chambers et al, 2014b) led to the development of the Fire and Invasives Assessment Tool (FIAT) and a subsequent assessment that identified areas of resistance and resilience to fire within SFAs, PHMAs, and GHMAs. Through use of the FIAT Assessment/Tool, land managers can more efficiently allocate and use fire resources at initial attack, to stop fire early and prevent catastrophic habitat loss as well as target restoration to those areas important to the species where success is more likely. The BLM is also committed to and accelerating the registration and use of chemical and biological agents to stem the spread of cheatgrass and other invasive annual species.

Even prior to completion of the FIAT assessment, BLM shifted funding for fuels management to protect landscapes of importance to the GRSG. Under the FY2014 Omnibus Appropriation, BLM prioritized the funding of treatments and activities within each state that benefit GRSG (See **Figure 1-6)**.

In addition, the Sage Grouse Initiative (SGI) launched by the Natural Resources Conservation Service in 2010 also contributes to the effort to protect and restore important GRSG habitat. In collaboration with the states and private landowners on private lands, as well as with the BLM and USFS on federally-administered public lands, NRCS has worked to reduce the encroachment of pinyon-juniper trees and restore rangeland habitat on private and BLM-administered lands.

[Insert Figure 1-6. FY 2015 FIAT Priority Project Planning Areas with Focus on Invasive Annual Grasses and Conifer Expansion Assessments.]

Formatted: Font color: Green

Formatted: Font: Times New Roman, Font color: Green

To further supplement these efforts, the Department has recently committed $7.5 million to projects in GRSG habitat to create more resilient landscapes and BLM has allocated $12 million to increase firefighting resources aimed at stopping fires while they are small in the Great Basin. The Department has identified required policy changes to increase the commitment, flexibility and ~~timeframe~~time frame for use of Emergency Stabilization and Burned Area Restoration (ES & BAR) funding on priority sagebrush-steppe habitats.

Consistent with recommendations contained in the 2006 WAFWA *Greater Sage-Grouse Range-wide Conservation Strategy,* the BLM and Forest Service conservation strategy places heavy reliance on monitoring and evaluation to assess the success and effectiveness of implementing the management decisions in the ARMPAs. Monitoring plans will be developed in coordination with relevant state and federal agencies and will incorporate evaluation of GRSG population trends by the states and changes in habitat condition by the federal land management agencies. As the WAFWA report states …

> Monitoring provides the "currency" necessary to evaluate management decisions and to assess progress or problems. Adequate monitoring should be considered an integral and inseparable component of all management actions, and there, not optional. Lack of proper monitoring will undoubtedly hinder this large-scale conservation effort.

In addition, the ARMPAs incorporate an adaptive management framework that provides an "early warning system" of "soft triggers" to alert resource managers to the need to evaluate the effectiveness of their management strategies should changes in population levels or habitat conditions occur. If the project-level management responses to soft triggers do not adequately address the causes for population or habitat declines and “hard triggers” are reached, the ARMPAs identify measures that will be put in place, including plan-level responses, in an effort to reverse the declines.

In summary, the ARMPAs emphasize an “avoidance first” strategy~~”~~ consistent with the recommendations in the COT Report by limiting new disturbance and maintaining current intact GRSG habitat. This avoidance first strategy is accomplished through identification of important GRSG habitat areas and then applying allocations that exclude or avoid surface disturbing activities, appropriately managing grazing, and aggressively suppressing fire that could degrade or fragment remaining GRSG habitat. The plans also include decisions to restore degraded habitat, which although more difficult and requiring a longer time frame, are important to the long-term conservation of GRSG. Restoration decisions include specific habitat objectives, and a priority on treating GRSG habitat for invasive species, particularly cheatgrass, and encroaching pinyon and juniper. These decisions are reinforced by Secretarial Order 3336 and the *Integrated Rangeland Fire Management Strategy* as well as NRCS’ Sage Grouse Initiative (SGI) investments in private landowners’ conservation efforts. This strategy reflects a high level of commitment by federal partners to conserve the GRSG and its habitat. These actions on over half of the most important lands for GRSG conservation will serve as an anchor and complement the significant actions being taken by state and local governments as well as private landowners to conserve the species and its habitat.

The landscape-level strategy consisting of new conservation actions that will go into effect through the BLM ARMPAs as well as actions being implemented currently to conserve the species, reflect a significant change in management direction and philosophy for both resource management agencies since 2010 and a long-term commitment to assure the conservation of the species consistent with the objectives set in the 2006 WAFWA conservation strategy and embraced by both the NTT and the COT.

This change represents a new paradigm in managing the sagebrush landscape for the BLM and amplifies the need for collaboration among federal, state, tribal, and private partners to conserve the GRSG consistent with direction articulated in the NTT report:

“Land uses, habitat treatments, and anthropogenic disturbances will need to be managed below threshold necessary to conserve not only local sage-grouse populations, but sagebrush communities and landscapes as well. Management priorities will need to be shifted and balanced to maximize benefits to sage grouse habitats and populations in priority habitats. Adequacy of management adjustments will be measured by science-based effectiveness monitoring of the biological response of sagebrush landscapes and populations. Ultimately, success will be measured by the maintenance and enhancement of sage-grouse populations well into the future.”

Formatted: Font: Times New Roman

The conservation benefits to the sagebrush ecosystem and GRSG habitats resulting from the BLM ARMPs and ARMPAs provide an essential foundation for conserving the GRSG which, in conjunction with the amended Forest Service LRMPs, affect nearly two-thirds of GRSG habitat across the remaining range of the species. In conjunction with similar conservation efforts by other federal and state agencies, private landowners, and local partners, the BLM National GRSG Conservation Strategy constitutes an historic conservation effort that will benefit more than 350 species and the sagebrush ecosystem upon which they depend. It is through collaborative efforts to conserve the imperiled sagebrush ecosystem that conservation of the GRSG and other sagebrush obligate species can best be achieved and the listing of the ~~Greater sage-grouse~~GRSG under the ESA may be avoided.

Comment [JRL14]: I suggest this closing paragraph for both RODs. Makes the point that ecosystem conservation is the best chance to avoid a listing… without saying it will.

1.9 Implementation

Formatted: Font color: Auto

Formatted: Font: Times New Roman, 14 pt, Font color: Auto

~~1.9.1 Additional Implementation Guidance and Considerations~~

~~*Continued commitment to research and use of best available science:* Through implementation of this strategy, new management issues and questions are likely to arise that may warrant additional guidance and/or study by technical experts, scientists, and researchers. The BLM is committed to continue to work with individuals and institutions with expertise in relevant fields in order to ensure that land and resource management affecting conservation of the Greater sage-grouse and the sagebrush ecosystem continues to be guided by sound, peer-reviewed research and the best available science. [May want to link to DOI and/or BLM science policy]~~

~~Implementation, after a BLM RMP or RMP amendment is approved, is a continuous and active process.~~Future decisions made in conformance with the ARMPAs serve to continuously and actively implement its provisions. Decisions presented as Management Decisions can be characterized as *immediate* or *one-time future* decisions.

Formatted: Line spacing: single

Immediate Decisions: These decisions are the lands use planning decisions that go into effect upon signature of the ROD. These include goals, objectives, allowable uses and management direction, such as the allocation of lands as open or closed for saleable mineral sales, lands open with stipulations for oil and gas leasing, and OHV area designations. These decisions require no additional analysis and guide future land management actions and subsequent site specific implementation decisions in the planning area. Proposals for future actions such as oil and gas leasing, land adjustments, and other allocation-based actions will be reviewed against these land use plan decisions to determine if the proposal is in conformance with the plan.

One-Time Future Decisions: These types of decisions include those that are not implemented until additional decision-making and site-specific analysis is completed. Examples are implementation of the recommendations to withdraw lands from locatable mineral entry or development of travel management plans. Future one-time decisions require additional analysis and decision-making and are prioritized as part of the BLM budget process. Priorities for implementation of "one-time" RMP decisions will be based on several criteria, including:

- Current and projected resource needs and demands,
- National BLM management direction, and
- Available resources.

Formatted: Font: Times New Roman

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 0.75" + Indent at: 0.5"

Formatted: Font: Times New Roman

Formatted: Font: Times New Roman

Formatted: Indent: Hanging: 0.25", Line spacing: single, Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 0.75" + Indent at: 0.5"

Formatted: Font: Times New Roman

Formatted: Don't add space between paragraphs of the same style, Line spacing: single

General Implementation Schedule of "One-Time" Decisions: Future Decisions discussed in the attached ARMPAs will be implemented over a period of years depending on budget and staff availability. After issuing the ROD, BLM will prepare implementation plans that establish tentative timeframes for completion of "one-time" decisions identified in these ARMPs and ARMPAa. These actions require additional site specific decision-making and analysis.

Formatted: Line spacing: single

This schedule will assist BLM managers and staff in preparing budget requests and in scheduling work. However, the proposed schedule must be considered tentative and will be affected by future funding, changing program priorities, non-discretionary workloads, and cooperation by partners and external publics. Yearly review of the plan will provide consistent tracking of accomplishments and provide information that can be used to develop annual budget requests to continue implementation.

1.9.1 Additional Implementation Guidance and Considerations

Formatted: Font color: Auto

Instructional Memoranda – Additional instruction and management direction will be necessary to implement certain land allocation decisions and ~~management~~ direction included in the ARMPAs. For example, additional guidance will be provided to clarify how the Bureau will implement the objective of prioritizing future oil and gas leasing and development outside of GRSG habitat. Instructional Memoranda (IM) and related guidance will be completed by the BLM-Washington office. ~~Presently,~~The BLM intends to complete IMs for the following management direction ~~are anticipated:~~ within 90 days of the RODs: oil and gas leasing and development prioritization~~,~~ and livestock grazing. Other IMs, including, monitoring, and mitigation, will be developed as necessary. Issuance of this national guidance will supersede any related national and field level guidance currently in effect. Additional national, state and field level guidance will be developed as necessary to implement the decisions in the plans.

~~*Transmission lines* – Although future high voltage transmission lines will be avoided in PHMA, the planning, siting, and environmental review of a limited number of Presidential priority lines (Gateway West, Boardman to Hemingway, and Transwest Express, including those portions of Gateway South that are co-located) have been underway for a several years. These lines are critical to expanding access to renewable sources of energy (especially wind) and to improving the reliability of the Western grid, and therefore, planning for these lines is proceeding through NEPA analysis in a separate authorization process. Conservation measures for GRSG are being analyzed as part of those NEPA processes, which should achieve a net conservation benefit for GRSG. Conservation measures to achieve this may include micro-siting to adjust the route to avoid important habitat and leks, transmission tower design to minimize the potential for adverse impacts to GRSG such as perching for predators, and compensatory mitigation measures, such as habitat restoration and pre-suppression activities to reduce the risk of habitat loss due to fire, to offset any unavoidable impacts to a conservation gain standard.~~

~~*Wild horses and burros* – Recognizing the potential for free-roaming equids to adversely impact sage-grouse habitat, the decisions emphasizes the need to focus on maintaining WHB Herd Management Areas in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve habitat management objectives, focusing first in SFAs and PHMAs.~~

~~*Grazing* – Changes in grazing management will occur when authorizations are renewed or modified to meet land health standards, including sage-grouse habitat standards. Changes will be made in accordance~~

~~with regulatory processes. Therefore, there will be no immediate change in grazing management or modification of term grazing permits and leases upon signing this ROD. As stated in the ARMPAs and ARMPs, the BLM will prioritize review of livestock grazing management in SFAs and PHMAs and implement changes as needed. All BLM grazing use authorizations will contain terms and conditions regarding the actions needed to meet or make significant progress toward meeting the habitat objectives. If an evaluation of monitoring and assessment information shows that the objectives are being met or there is a trend towards meeting the objectives, then no adjustments to the current use and management is required. If the evaluation shows the habitat objectives are not met nor is there progress towards meeting them, then the cause for not meeting the objectives will be identified. If it is determined that the current authorized livestock management or level of use is a significant cause, the use will be adjusted in accordance with the response specified in the instrument that authorized the use, or as described in a NEPA document. The BLM will prioritize the review of grazing authorizations in SFA and PHMA in particular, focusing on those containing important riparian habitats and those not meeting Land Health Standards, to determine if modification is necessary prior to renewal of the authorization. Renewed or modified grazing authorizations in SFA and PHMA will include terms and conditions specifically designed to meet objectives identified in the GRSG Habitat Objectives Table based on ecological site potential and Land Health Standards. One or more defined responses to exceeding specific management thresholds will be subjected to NEPA analysis during the grazing authorization renewal or modification process, which will allow the authorized officer to make adjustments to livestock grazing that have already been subjected to NEPA analysis. The BLM will include additional management direction for implementing grazing management actions in the ARMPs in an Instructional Memorandum.~~

Map Adjustment and GRSG Seasonal Habitats – PHMA was designed to include breeding bird density, sage-grouse proportionality, density of leks, and key seasonal habitats, such as known winter concentration areas, and GHMA was designed to include the areas of occupied seasonal, connectivity, or year-round habitat outside of PHMA. As additional important habitats are identified, the BLM will map, and incorporate these -habitats for GRSG, consistent with best available science, through subsequent plan revisions or amendments, as appropriate. Priority should be given to ensuring that wintering habitat is identified and captured in all changes in habitat maps subsequent to this decision. In the interim, the BLM will use the existing maps for all decisions.

~~*Climate Change Effects on GRSG Conservation* – As identified by the FWS 2010 decision and the COT report, climate change can impact efforts to conserve the GRSG and its habitat in a number of ways. While several ARMPAs acknowledge the potential impact of climate change on GRSG habitat and conservation efforts, specific strategies to address the impacts of climate change are limited. The BLM and Forest Service, in coordination with the FWS, will continue to assess the potential impacts of climate change on GRSG and its habitat and develop strategies to mitigate anticipated effects on GRSG conservation efforts. Changes to management decisions will require a plan revision or amendment, as appropriate.~~

Formatted: Right: 0.21", Line spacing: Multiple 1.03 li

Continued Commitment to Research and Use of Best Available Science: Through implementation of this strategy, new management issues and questions are likely to arise that may warrant additional guidance and/or study by technical experts, scientists, and researchers. The BLM is committed to continue to work with individuals and institutions with expertise in relevant fields in order to ensure that land and resource management affecting conservation of the GRSG and the sagebrush ecosystem continues to be guided by sound, peer-reviewed research and the best available science.

Training -- Given the nature and complexity of the management direction in these ARMPAs, the BLM, in collaboration with the Forest Service and the FWS, will develop and implement a schedule of trainings for key functions, actions, and decisions associated with these plans. In this manner, the BLM will seek to better inform its personnel, partners, cooperators, and stakeholders of the changes in management that will result from this new management paradigm.

2. DECISION

2.1 Summary of the Approved Management Decisions

The decision is hereby made to approve the Great Basin Region Greater Sage-Grouse ARMPAs for the Great Basin Region Greater Sage-Grouse Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah (attachments 1 through 4). This ROD serves as the final decision establishing the land use plan amendment decisions outlined in the ARMPAs and is effective on the date it is signed.

The decisions included in this ROD and attached ARMPAs amend the land use plans described in **Sections 1.3** of attachments 1 through 4.

The land use decisions conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Land use plan decisions are expressed as goals and objectives (desired outcomes), and allocations, allowable uses, and management decisions anticipated to achieve desired outcomes. Although decisions identified in the ARMPAs are final and effective upon signing of this ROD, they generally require additional implementation decision steps before on-the-ground activities can begin. Subsequent NEPA analysis will be conducted, as necessary, for such implementation decisions.

2.2 What the Record of Decision and Approved Resource Management Plan Amendments Provide

The ARMPAs include GRSG and GRSG habitat land use plan level management decisions in the form of:

- Goals
- Objectives (Desired Future Conditions)
- Land Use Allocations and Allowable Uses

Formatted: Font color: Auto

Formatted: Font: Times New Roman

Formatted: Font: Times New Roman

Formatted: Font color: Auto

- Management Actions

Goals are the broad statements of desired outcomes, and are usually not quantifiable.

Objectives are specific desired conditions, usually quantifiable and measurable, and may have timeframes for achievement.

Land use allocations specify locations within the planning area that are available or not available for certain uses and are also used to prioritize conservation and restoration management actions. These include decisions such as what lands are available for livestock grazing, mineral material use, oil and gas leasing, and locatable mineral development, what lands may be available for disposal via exchange and/ or sale, and what lands are open, closed, or limited to motorized travel (please note that all acreages presented in the Approved Plan are estimations even when presented to the nearest acre).

Management decisions/actions include those provisions that help in meeting the established goals and objectives and include measures that will be applied to guide day-to-day activities on public lands, including but not limited to stipulations, guidelines, best management practices (BMPs), and required design features.

Formatted: Font: 11 pt

Formatted: para

The ARMPAs' management decisions were crafted to incorporate conservation measures into LUPs to conserve, enhance, and restore GRSG habitat by reducing, eliminating, or minimizing identified threats to GRSG and their habitats (see **Section 1.3**).

2.3 What the Record of Decision and Approved Resource Management Plan Amendments Do Not Provide

Formatted: Font color: Auto

The attached ARMPAs do not contain decisions for public lands outside of GRSG habitat management areas, except for land use plan level travel management area decisions in the Idaho and Southwestern Montana ARMPA.

The ARMPAs and ARMPs do not violate valid existing rights.

Formatted: No Spacing

Formatted: Font: Times New Roman

The ARMPAs do not contain decisions for the mineral estates that is not administered by the BLM. ARMPA decisions for surface estate only apply to BLM managed lands. In addition, many decisions are not appropriate at this level of planning and are not included in the ROD. Examples of these types of decisions include:

Formatted: No Spacing

Formatted: Font: Times New Roman

- *Statutory requirements*. The decision will not change the BLM's responsibility to comply with applicable laws, rules, and regulations.
- *National policy*. The decision will not change BLM's obligation to conform to current or future National policy.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.25" + Indent at: 0.5"

- *Funding levels and budget allocations.* These are determined annually at the National level and are beyond the control of the State/District of Field offices.

Implementation decisions (or activity-level decisions) are management actions tied to a specific location. Implementation decisions generally constitute the BLM's final approval allowing on-the-ground actions to proceed and require appropriate site-specific planning and NEPA analysis. Such decisions may be incorporated into implementation plans (activity or project plans) or may exist as stand-alone decisions. These ARMPAs do not contain implementation decisions. Future activity-level plans will address the implementation of the ARMPAs. Implementation decisions and management actions that require additional site-specific project planning, as funding becomes available, will require further environmental analysis.

2.4 Modifications and Clarifications

The ARMPAs in the Great Basin Region include minor modifications and clarifications to the Proposed RMPs and RMP Amendments. These minor modifications and clarifications were made as a result of internal reviews, response to protests, and recommendations provided to the BLM during the Governors' consistency review. These modifications and clarifications are hereby adopted by this ROD.

The following modifications/clarifications were made to all of the ARMPAs in the Great Basin Region.

- ARMPA Formatting: The plans were reformatted between the Proposed RMPA and ARMPA planning stages for consistency across the Great Basin Region; the order of management actions and the prefixes for the goals, objectives, and management actions were changed in the ARMPAs to provide consistency among the amendments and revisions for GRSG goals and objectives.
- U.S Forest Service References (applicable only to the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah ARMPAs): All references to National Forest System lands in both text and on maps have been removed from the ARMPAs. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plan Amendment under their planning authorities.
- Fire: Management actions/decisions were modified to stress that the protection of human life is the single, overriding priority for fire and fuels management activities.
- Livestock Grazing: The following statement, "This does not apply to or impact grazing preference transfers, which are addressed in 43 CFR 4110.2-3," was added to the management action/decision which reads, "At the time a permittee or lessee voluntarily relinquishes a permit or lease, the BLM will consider whether the public lands where that permitted use was authorized should remain available for livestock grazing or be used for other resource management objectives, such as reserve common allotments or fire breaks."
- Glossary: Numerous glossary definitions were deleted due to the fact that the terms were not used/referenced in the ARMPAs. If not already contained in the Proposed RMPAs' glossary, the following terms and definitions were added to the glossary for clarification:

Comment [SMC15]: These may have minor changes - additional rationale based on the protests and GCR – finalizing this week

Formatted: Font: Times New Roman

Formatted: Font: Times New Roman

    - Grazing Relinquishment: the voluntary and permanent surrender by an existing permittee or lessee, (with concurrence of any base property lienholder(s)), of their priority (preference) to use a livestock forage allocation on public land as well as their permission to use this forage. Relinquishments do not require the consent or approval by BLM. The BLM's receipt of a relinquishment is not a decision to close areas to livestock grazing.
    - Transfer of Grazing Preference: the BLM's approval of an application to transfer grazing preference from one party to another or from one base property to another, or both. Grazing preference means a superior or priority position against others for the purposes of receiving a grazing permit or lease. This priority is attached to base property owned or controlled by the permittee or lessee.
    - Valid Existing Right: Documented, legal rights or interests in the land that allow a person or entity to use said land for a specific purpose and that are still in effect. Such rights include but are not limited to fee title ownership, mineral rights, rights-of-way, easements, permits, and licenses. Such rights may have been reserved, acquired, leased, granted, permitted, or otherwise authorized over time.
    - Mining Claim: A parcel of land that a miner takes and holds for mining purposes, having acquired the right of possession by complying with the Mining Law and local laws and rules. A mining claim may contain as many adjoining locations as the locator may make or buy. There are four categories of mining claims: lode, placer, millsite, and tunnel site.
    - Energy or Mining Facility: Human constructed assets designed and created to serve a particular function and to afford a particular convenience or service that is affixed to a specific locations, such as oil and gas well pads and associated infrastructure.
- GRSG Habitat Mapping: Information was added to the ARMPAs to specify that when new information becomes available about GRSG habitat, including seasonal habitats, in coordination with the state wildlife agency and FWS, and based on best available scientific information, the BLM may revise the GRSG habitat management area maps and associated management decisions through plan maintenance or plan amendment/revision, as appropriate.
- Adaptive Management: The Greater Sage-Grouse Adaptive Management Strategy was revised to include a commitment that the hard and soft trigger data will be evaluated as soon as it becomes available after the signing of the ROD and then at a minimum, analyzed annually thereafter.
- Vegetation: The desired condition for maintaining a minimum of 70% of lands capable of producing sagebrush with 10 to 30% sagebrush canopy cover in SFAs and PHMAs was modified to read as follows: "In all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain all lands ecologically capable of producing sagebrush (but no less than 70%) with a minimum of 15% sagebrush canopy cover or as consistent with specific ecological site conditions. The attributes necessary to sustain these habitats are described in Interpreting Indicators of Rangeland Health (BLM Tech Ref 1734-6)."

Formatted: Font: Times New Roman

Formatted: Bulleted + Level: 1 + Aligned at: 0.25" + Indent at: 0.5"

- GRSG Habitat Objectives: For clarification purposes, within each of the ARMPA GRSG Habitat Objectives Tables, native bunchgrasses was provided as an example of a perennial grass cover and the inclusion of residual grasses was added to the perennial grass cover and height objective.
- Sagebrush Focal Areas: Examples of the types of vegetation and conservation actions that will be prioritized within SFAs were provided for clarity in the management action/decision. These examples include land health assessments and wild horse and burro management and habitat restoration actions.
- Required Design Features: One of the criteria for demonstrating that a variation to an RDF is warranted was modified to include the following statement, "An alternative RDF, a state-implemented conservation measure or plan-level protection is determined to provide equal or better protection for GRSG or its habitat."
- Lands and Realty: The following management actions/decisions and objectives were calrified:
  - Effects of infrastructure projects, including siting, will be minimized using the best available science, updated as monitoring information on current infrastructure projects becomes available.
  - Within existing designated utility corridors, the 3% disturbance cap may be exceeded at the project scale if the site specific NEPA analysis indicates that a net conservation gain to the species will be achieved. This exception is limited to projects which fulfill the use for which the corridors were designated (ex., transmission lines, pipelines) and the designated width of a corridor will not be exceeded as a result of any project co-location.
- Land Tenure: Management action associated with land disposals was clarified to include land exchanges as a means of disposal.
- WAFWA GRSG Conservation Team. Additional clarification was added to ARMPAs related to the WAFWA GRSG Conservation Teams that were identified in the Proposed RMPAs: "WAFWA management zones will be used to facilitate cross-state issues, such as regional mitigation and adaptive management monitoring and response, through WAFWA GRSG Conservation Teams (Teams). These Teams will convene to advise on these specific tasks and will utilize existing coordination and management structures to the extent possible."
- Cheatgrass: The following management action was included consistent with the purpose and need and objectives of the ARMPAs: "Treat areas that contain cheatgrass and other invasive or noxious species to minimize competition and favor establishment of desired species."
- Valid Existing Rights: The following management action was added to the ARMPs and ARMPAs: "Consider the potential for the development of not-yet-constructed valid existing rights of surface disturbing activities as defined in Table 2 of the Monitoring Framework prior to authorizing new projects in PHMA."

Additional modifications and clarifications specific to each sub-region ARMPA are summarized below.

2.4.1 Idaho and Southwestern Montana

General Changes

Formatted: Font: Times New Roman

Formatted: Font: Times New Roman

Formatted: Font: Times New Roman

Formatted: Font color: Auto

Formatted: Font: Times New Roman, Bold, Font color: Auto

Formatted: Font: Times New Roman, Underline

- All exception language that was in the FEIS in various places was grouped into a stipulation appendix and added it to the ARMPA as Appendix G Stipulations.
- Appendix G Anthropogenic Disturbance and Adaptive Management from the Proposed RMPA, which is now Appendix E in the ARMPA was modified to delete the reference to Tables 2 to 7. Tables 2 to 7 were deleted from the FEIS Appendix G before it was made available to the public for protest, but the reference was not deleted in text of the Appendix. This discrepancy was identified during protest resolution and by the Governor during the Governor's Consistency Review. These values will be calculated after the signing of the ROD (see Adaptive Management below).
- Many editorial changes including, deleting repeated numbers, spelling errors, etc, were made when finalizing the ARMPA.
- On August 7, 2015, President Barack Obama signed into law the Sawtooth National Recreation Area and Jerry Peak Wilderness Act (H.R. 1138). In accordance with the Wilderness Act (16 U.S.C. 1131 et seq.), certain Federal lands in the Challis National Forest and Challis District of the Bureau of Land Management in the State of Idaho, comprising approximately 116,898 acres, were designated as wilderness, as a component of the National Wilderness Preservation System, known as the Jim McClure-Jerry Peak Wilderness. This bill also released the Jerry Peak West, Corral-Horse Basin, and Boulder Creek Wilderness Study Areas and they are no longer subject to section 603(c) of the FLPMA. In accordance with the Recreation and Public Purposes Act, this law also conveyed public lands to Blaine County, Custer County, the City of Challis, the City of Clayton, and the City of Stanley. The new wilderness area, the release of the WSAs, and the lands that were conveyed by this law were not within the decision area of the Idaho and Southwestern Montana ARMPA, therefore, no changes to the ARMPA have been made as a result of the passage of this law.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.75" + Indent at: 1"

Formatted: Font: Times New Roman

Special Status Species

Formatted: Font: Times New Roman, Underline

- Deleted the Seasonal Timing Restrictions from Appendix C FEIS to reduce redundancy because these restrictions were already in the Required Design Features Appendix.

Formatted: Indent: Left: 0.75", Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 0.75" + Indent at: 0.5"

Livestock Grazing

Formatted: Font: Times New Roman, Underline

- Livestock Grazing RM-16 and RM 18, which are now MD LG 15 and MD LG 17 respectively in the ARMPA, had the following sentence added as an accepted recommendation made by the Governor during the Governor's Consistency Review to clarify management and conservation action prioritization in SFAs and: "Management and conservation action prioritization will occur at the Conservation Area (CA) scale and be based on GRSG population and habitat trends: Focusing management and conservation actions first in SFAs followed by areas of PHMA outside SFAs."

Formatted: Indent: Left: 0.75", Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 0.75" + Indent at: 0.5"

Lands and Realty

Formatted: Font: Times New Roman, Underline

Formatted: Font: Times New Roman

- Lands and Realty LR-14 from the Proposed RMPA, which is now MD LR 13 in the ARMPA, was modified to remove the statement that lands in PHMA, IHMA, and GHMA would only be available for disposal through exchange. This was removed because it was not consistent with BLM policy and the net conservation gain clause in MD LR-13 will provide assurance that disposals through any method would be beneficial to GRSG.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.75" + Indent at: 1"

2.4.2 Nevada and Northeastern California

Formatted: Font color: Auto

Formatted: Font: Times New Roman, Bold, Font color: Auto

General Changes

Formatted: Font: Times New Roman, Underline

- Editorial changes such as changing 'should' to 'shall', and 'would' to 'will' to reflect the final decision language.
- Re-categorizing some of the Management Decisions into other common resource programs. For example, all of the Fire and Fuels management decisions are all numbered under FIRE, and are not split into different sub-category names.
- Re-lettering of the critical Appendices, and deletion of those that are no longer applicable for the ARMPA.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.75" + Indent at: 1"

Special Status Species

Formatted: Font: Times New Roman

- Added clarity to MD SSS 2 A 3, by describing what energy and mining facilities to which this decision would apply; taken directly from the Disturbance Appendix E.
- Added clarity to MD SSS 3A, by including references to valid existing rights and applicable law for the requirement of a 'net conservation gain'.
- Specified in MD SSS 8 that this activity would be coordinated with NDOW or CDFW, and that breeding activity surveys would be for actions involving mineral activities and rights-of-ways.
- Deleted Action PR 4 from the Proposed LUPA because BLM does not manage landfills and transfer stations.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.75" + Indent at: 1"

- Under the Brood Rearing/Summer category, it was clarified that the objective of the 7 inch deep rooted perennial bunchgrass in upland habitats was only for a 522-foot (200 meter) area around riparian areas and meadows. The additional reference was added for Casazza et al. 2011
- The footnote #7 was replaced. The original footnote stated that the "specific height requirements needed to meet the objective will be set at the time of HAF assessments". This is incorrect, because the height requirements will need to be set well in advance of the HAF assessments.
- The footnote #7 was replaced with "Any one single habitat indicator does not define whether the habitat objective is or is not met. Instead, the preponderance of evidence from all indicators within that seasonal habitat period must be considered when assessing sage-grouse habitat objectives." This addition was for the purpose of clarification.

Adaptive Management

Formatted: Font: Times New Roman, Underline

- Moved the Adaptive Management Strategy section out of Chapter 2 and made it into Appendix J; moved the Adaptive Management decisions under MD SSS 17 – MD SSS 22.
- Clarified under MD SSS 21 that BLM will coordinate with NDOW, and that the decision was specific to mineral activities and rights-of-way actions.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.75" + Indent at: 1"

Fire and Fuels Management

Formatted: Font: Times New Roman

- Deleted 'field offices and districts' from MD FIRE 3, as there will be a multi-layer approach to coordination, including BLM State Offices.
- In Objective FIRE 3, added 'in SFAs first' to provide more emphasis to the SFA over the rest of the PHMA for this action.
- Modified MD FIRE 26 to delete 'Districts', as there will be a multi-layer approach to identifying treatment needs for wildfire and invasive species management across the state.
- Added 'FWS' as a coordination entity to MD FIRE 31, when ensuring that proposed sagebrush treatments are coordinated with the BLM and State fish and wildlife agencies.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.75" + Indent at: 1"

Livestock Grazing

Formatted: Font: Times New Roman, Underline

- Management Decision LG 1 was modified for clarity and to include the fact that BLM would conduct appropriate consultation, cooperation and coordination
- Management Decision LG 5 was modified to add supplementary management actions and clarifies that the potential modifications include, "but are not limited to" to actions on the list.
- Management Decision LG 5 was modified to make it clear that the management strategies listed are not limited to just those listed under LG 5 by adding "but are not limited to". This was added to clarify a misunderstanding in a protest letter.
- Management Decision LG 7 was clarified to state that "AUMs cannot be applied to another pasture that is already being used by livestock or is being purposefully rested."
- Management Decision LG 15 was modified to state that removing or modifying water developments must be done "In accordance with state water law and…"

Formatted: Font color: Auto

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.75" + Indent at: 1"

Mineral Resources

Formatted: Font: Times New Roman, Underline

- Management Decision MR 18 was modified to provide the Barrick Enabling Agreement as an example of appropriate mitigation that can be considered in the future, and the last sentence was removed because it only repeated BLM regulations, and is unnecessary.

Formatted: List Paragraph, Add space between paragraphs of the same style, Bulleted + Level: 1 + Aligned at: 0.75" + Indent at: 1"

Formatted: Font: Times New Roman

Lands and Realty

Formatted: Font: Times New Roman, Underline, Highlight

Formatted: Font: Times New Roman

- In order to resolve a protest, MD LR 3 was modified to state that corridors will be 3,500 feet in width… "or a different width is specified for congressional designated corridors". This is in response to the Lincoln County Conservation Recreation Development Act (2204) which included congressionally designated corridors that were not included in the plan amendment or the corridor map. The corridor map (Figure 2-10) was also modified to reflect the corridors tied to this Act.
- Action LR-LUA 21 from the Proposed Plan was deleted because the Federal Highway Administration and the Nevada Department of Transportation already have valid existing rights associated with their easements and ROWs, and this planning effort would not change the terms and conditions of their existing easements or ROWs. Making this a Management Action is repetitive and unnecessary.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.75" + Indent at: 1"

Travel and Transportation

Formatted: Font: Times New Roman, Underline, Highlight

Formatted: Font: Times New Roman

- Due to confusion that was outlined in protest letters and in the Governor's Consistency Review, MD TTM 2 was clarified that limiting off-highway travel to existing routes in PHMAs and GHMAs would be "subject to valid existing rights, such as for a mine under a plan of operations".
- Additional language was added to MD TTM 3 to make it clear that the bulleted "guidelines will be considered when undertaking future implementation-level travel planning". This was in response to protest misunderstandings. In addition, bullet three was amended by deleting "developed in this plan amendment", as the criteria is not developed through the plan amendment.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.75" + Indent at: 1"

Mitigation

- In order to provide consistency across the Great Basin Regional Planning area, the two Mitigation management decisions were removed from the Adaptive Management, Monitoring, and Mitigation section of Chapter 2 in the Proposed LUPA (which are now separate Appendices) and inserted as management decisions independently under the Mitigation section.

Formatted: Indent: Left: 0.75", Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 0.75" + Indent at: 0.5"

2.4.3 Oregon

Formatted: Font color: Auto

Formatted: Font: Times New Roman, Bold, Font color: Auto

Lands and Realty

Formatted: Font: Times New Roman

- A typographical error in the socioeconomic analysis of the proposed RMPA was identified during the Protest period. Correction to this error in Section 4.20.3, page 4-345, is as follows: Paragraph beginning "Restrictions to ROW development under Alternatives B, C, D,E, F, and the Proposed Plan…" is replaced with: "Proposed management under Alternatives B, C, D, E, F, and the Proposed Plan could require investors to consider alternative power line ROW alignments or designs that could increase the costs of constructing new infrastructure. A 2012 WECC study, for example, provides information on transmission line construction costs per mile, which range from $927,000 to

Formatted: Indent: Left: 0.75", Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 0.75" + Indent at: 0.5"

$2,967,000 depending on voltage and whether lines are single or double circuit lines. The same study provides cost multipliers for difficult terrains, reaching up to 2.25 in the case of forested lands (WECC 2012). Utilities and other infrastructure investors typically pass these costs on to consumers. Where the rate base is smaller, such as in rural areas, per-customer rate impacts associated with constructing a 10-mile, 230kV transmission line, for example, would be greater compared to the economic impacts on rate payers served by a larger metropolitan utility proposing the same line. Under Alternatives B, C, D, E, and the Proposed Plan, rate payers serviced by local utility providers with small rate bases would be impacted more by costs associated with added route lengths or infrastructure design requirements compared with rate payers serviced by larger, multi-state providers. Where technically and financially feasible, Alternatives B, D, and the Proposed Plan identify burial of power lines as a design option to mitigate impacts on GRSG. New construction costs of underground transmission lines can be between 4 and 14 times higher compared to new overhead construction (PSC 2011), depending on terrain. In rural areas, burial of new distribution lines would be more than double the cost of new overhead construction. Burying existing distribution lines would likely cost between $400,000 and $500,000 per mile in rural areas (EIA 2012). Under all alternatives, where burying new lines would be technically unfeasible or result in costs that could not be absorbed by the rate payers, infrastructure investors would explore other route or design options that avoid impacts to GRSG habitat."

Special Status Species (Greater Sage-Grouse)

- Objective SSS 6 was modified to clarify that the BLM will coordinate with the State of Oregon regarding proposed management changes, the implementation of conservation measures, mitigation, and site-specific monitoring related to adaptive management and anthropogenic disturbances. This modification was recommended by the Governor during the Governor's Consistency Review.

Leasable Mineral Resources

- Based on internal review, MLS 7 from the proposed RMPA, which is now MD MR 7 in the ARMPA, was modified to include all fluid mineral lease development, including geothermal permits to drill.

2.4.4 Utah

General Changes

- Throughout the Proposed RMP Amendment, the use of words like "would," "could," "should," and "may" were generally removed or revised to reflect the active management direction of an ARMPA rather than potential management presented when the Proposed RMP Amendment was one of many alternatives the agency could select.

Formatted: Font: Times New Roman

Formatted: Indent: Left: 0.75", Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 0.75" + Indent at: 0.5"

- Language was added to Objective SSS-3 (Objective GRSG-3 in the Proposed RMP Amendment), MA-SSS-4 (MA-GRSG-4 in the Proposed RMP Amendment), MA-SSS-6 (MA-GRSG-6 in the Proposed RMP Amendment), Objective VEG-1, MA-VEG-1, MA-FIRE-3 and MA-FIRE-4 to clarify that landscapes that include populations of both GRSG and Utah prairie dog (UPD), a federally listed species, be managed for the benefit of both species. This addition is included to ensure that this objective is applied to all applicable objectives and management actions, not just the five actions in the Proposed RMP Amendment where this concept and language was already present.
- Throughout the Proposed RMPA there were a number of references to coordinating with the State of Utah, Division of Wildlife Resources, or state biologists. These were all revised to note that such coordination would be with “the appropriate State of Utah agency.” This clarification was made at the request of the Governor during the Governor’s Consistency Review.
- The Proposed RMP Amendment introduced the term “biologically significant units” (BSU) for adaptive management and the disturbance cap to provide a consistent approach for managing and monitoring across the GRSG range. In the Utah Sub-Region, the BSU concept is the same as PHMA within population areas. As part of resolving protests, the ARMP was revised to note that “BSUs” are PHMA within population areas. Whenever the term BSU was used, it was replaced with the more descriptive text, with a parenthetical reference to BSUs for the purposes of coordinating across state lines.

Special Status Species (formerly Greater Sage-Grouse)

Formatted: Font: Times New Roman, Underline

- Objective GRSG-1 from the Proposed RMP Amendment, which is now Objective SSS-1 in the ARMPA, was changed to remove reference to WAFWA management zones when addressing designation of PHMA. This change was made during the Governor’s Consistency Review to more closely reflect the management in the State of Utah’s Conservation Plan for Greater Sage-Grouse in Utah (2013).

Formatted: Indent: Left: 0.75", Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 0.75" + Indent at: 0.5"

- MA-GRSG-1 from the Proposed RMP Amendment, which is now MA-SSS-1 in the ARMPA was revised to include the following text: “The BLM will apply these goals, objectives, and management actions where the agency has discretion to implement them; the actions do not apply in areas where the BLM does not administer the surface or mineral estate.” This is consistent with the planning criteria contained in the sixth bullet on page 1-20 of the Final EIS. This language was added based on an accepted recommendation made by the Governor during the Governor’s Consistency Review.
- The language of MA-GRSG-1 from the Proposed RMP Amendment, which is now MA-SSS-1 in the ARMPA, regarding non-habitat areas within PHMA and GHMA was revised to clarify the intent of the action. This revision was made as a result of internal reviews to ensure the text more accurately reflected the intent behind the management action.
- The introductory language of MA-GRSG-3 from the Proposed RMP Amendment, which is now MA-SSS-3 in the ARMPA, was revised to clarify the intent of the action. This revision was made as a result of internal reviews to ensure the text accurately reflects the

intent behind the management action and to focus on land uses that have been identified as threats to GRSG.

- The language of MA-GRSG-3e from the Proposed RMP Amendment, which is now MA-SSS-3e in the ARMPA, was revised to clarify the intent of the noise restrictions. This revision was made as a result of internal reviews to ensure the text accurately reflects the intent behind the management action to focus on land uses that have been identified as threats to GRSG. Further, language was added to identify when "ambient" noise levels would be assessed to avoid managing for continual, incremental increases in noise levels.
- The language of MA-GRSG-6 from the Proposed RMP Amendment, which is now MA-SSS-6 in the ARMPA, was revised to clarify the intent of GRSG management outside PHMA/GHMA. This revision was made as a result of internal reviews to ensure the text accurately reflects the intent behind the management action. The purpose of this action is to provide direction regarding management of areas outside PHMA/GHMA that have been treated to improve GRSG habitat. The change was necessary to avoid implication of changing allocations or altering PHMA/GHMA boundaries outside a planning process while minimizing conflicting land uses in areas where an investment in increasing GRSG habitat have been made.

Livestock Grazing

Formatted: Font: Times New Roman, Underline

- The language of MA-GRA-6 from the Proposed RMP Amendment, which is now MA-LG-6 in the ARMPA, was revised. The concepts and intent did not change, but the text was revised to align with similar concepts and intent that was present in the livestock grazing sections in GRSG amendments throughout the Great Basin.

Formatted: Indent: Left: 0.75", Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 0.75" + Indent at: 0.5"

2.5 Protest Resolution

Formatted: Font color: Auto

Formatted: Font: Times New Roman, 14 pt, Font color: Auto

BLM's planning regulations at 43 CFR 1610.5-2 allow any person who participated in the planning process and has an interest that may be adversely affected by BLM's planning decisions to protest proposed planning decisions within 30 days from the date the Notice of Availability of the Proposed RMP/Final EIS was published in the Federal Register (May 29, 2015). Below are descriptions of the protest resolution process for each of the four Great Basin Region PRMPAs/FEISs.

The Director concluded that the BLM followed all applicable laws, regulations, and policies and considered all relevant resource information and public input in developing the Proposed Land Use Plan Amendments/Final EISs. Each protesting party has been notified in writing of the Director's findings and the disposition of their protests. The BLM Director resolved the protests without making significant changes to the Proposed Land Use Plan Amendments/Final EISs, though minor clarifications were made and are summarized in Section 2.4.1. The BLM Director's decisions on the protests are summarized in each of the PRMPAs/FEISs Director's Protest Resolution Reports, which are available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

2.5.1 Idaho and Southwestern Montana

Formatted: Font color: Auto

Formatted: Font: Times New Roman, Bold, Font color: Auto

For the Idaho and Southwestern Montana GRSG Proposed LUPA/Final EIS, the BLM Director received 20 timely protest submissions. All of the protesting parties had standing; however, one submission was dismissed as it did not contain any valid protest points pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report included:

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.44" + Indent at: 0.56"

- compliance with FLPMA,
- compliance with NEPA,
- compliance with ESA,
- density and disturbance,
- adaptive management,
- GRSG habitat objectives,
- livestock grazing,
- mitigation,
- compliance with APA,
- compliance with the Energy Policy Act of 2005,
- ACECs,
- fire and fuels management,
- fluid minerals,
- solid minerals,
- special status species,
- lands and realty, and
- travel and transportation management.

2.5.2 Nevada and Northeastern California

Formatted: Font color: Auto

Formatted: Font: Times New Roman, Bold, Font color: Auto

For the Nevada and Northeastern California GRSG Proposed LUPA/Final EIS, the BLM Director received 40 timely protest submissions. All of the protesting parties had standing; however, two submissions were dismissed as they did not contain any valid protest points pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report included:

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.44" + Indent at: 0.56"

- compliance with FLPMA,
- compliance with NEPA,
- compliance with ESA,
- density and disturbance,
- adaptive management,
- GRSG habitat objectives,
- livestock grazing,
- mitigation,
- compliance with APA,
- compliance with the Energy Policy Act of 2005,
- Air Quality,
- Climate Change,

- Noise,
- ACECs,
- solid minerals,
- special status species,
- lands with wilderness characteristics,
- lands and realty,
- tribal issues,
- wild horse and burros, and
- travel and transportation management.

2.5.3 Oregon

For the Oregon GRSG Proposed LUPA/Final EIS, the BLM Director received 30 timely protest submissions. All of the protesting parties had standing; however, three submissions were dismissed as they did not contain any valid protest points pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report included:

- compliance with FLPMA,
- compliance with NEPA,
- compliance with ESA,
- density and disturbance,
- monitoring,
- ACECs,
- fire and fuels management,
- solid minerals,
- special status species, and
- travel and transportation management.

2.5.4 Utah

For the Utah GRSG Proposed LUPA/Final EIS, the BLM Director received 43 timely protest submissions. All of the protesting parties had standing; however, three submissions were dismissed as they did not contain any valid protest points pursuant to 43 CFR 1610.5-2. Valid protest issues addressed in the Director's Protest Resolution Report included:

- compliance with FLPMA,
- compliance with NEPA,
- compliance with ESA,
- density and disturbance,
- adaptive management,
- land use allocations,
- GRSG habitat objectives,
- livestock grazing,
- mitigation,

- climate change,
- noise,
- ACECs,
- fire and fuels management,
- fluid minerals,
- solid minerals,
- special status species,
- lands and realty,
- travel and transportation management, and
- reasonable foreseeable development scenarios.

2.6 Governor's Consistency Review

Formatted: Font color: Auto

Formatted: Font: Times New Roman, 14 pt, Font color: Auto

The BLM's planning regulations require that RMPs be "consistent with officially approved or adopted resource-related plans, and the policies and procedures contained therein, of other federal agencies, state and local governments, and Indian tribes, so long as the guidance and resource management plans also are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands" (43 CFR 1610.3-2(a)). The general requirement in FLPMA/planning regulations is to coordinate the land use planning process with plans of other agencies, states, and local governments to the extent consistent with law (see FLPMA s. 202(c)(9) and 1610.3-1(a)); and the respective duties to be consistent with both officially approved or adopted plans (to the extent those plans are consistent with federal law, or to maximum extent practical) (see 1610.3-2(a)(b)). In accordance with FLPMA, the BLM was aware of and gave consideration to state, local, and tribal land use plans and provided meaningful public involvement throughout the development of the Proposed RMP Amendments/Final EISs.

The BLM is aware that there are specific state laws and local plans relevant to aspects of public land management that are discrete from, and independent of, federal law. However, the BLM is bound by federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that BLM's land use plans be consistent with officially-approved state and local plans only if those plans are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands. Where officially-approved state and local plans or policies and programs conflict with the purposes, policies, and programs of federal laws and regulations applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially-approved state and local policies and programs (as opposed to plans), this consistency provision only applies to the maximum extent practical. While county and federal planning processes, under FLPMA, are required to be as integrated and consistent as practical, the federal agency planning process is not bound by or subject to state or county plans, planning processes, policies, or planning stipulations.

The 60-day Governor's consistency review period ended on July 29, 2015. In the Great Basin Region, the Governors of Idaho, Nevada, Oregon, and Utah submitted letters to their respective BLM State Directors identifying inconsistencies between the BLM's proposed RMP amendments and their state's or local governments' resource-related plans, policies and/or procedures, as well as other concerns that they had with the proposed planning documents. The BLM State Directors notified the Governors as to whether their recommendations were accepted or rejected on August 6, 2015. These Governors were then provided with 30-days to appeal the BLM State Director's decisions to the BLM Director. By September 8, 2015, the BLM Director received appeals from.

Comment [mem16]: Need to update when GCR process is towards completion.

Formatted: Font: Times New Roman, Font color: Green

In some instances, modifications to the ARMPAs were addressed based on recommendations submitted to the BLM by the applicable Governors. These modifications to the ARMPAs were made and are summarized in Section 2.4.1.

Formatted: Font: Times New Roman

Formatted: Font color: Auto

3. ALTERNATIVES

3.1 Alternatives Considered

Each of the Great Basin sub-regional planning efforts analyzed in detail a set of alternatives in the draft and final sub-regional EISs. The alternatives were developed to provide direction for resource programs in order to meet in the purpose and need of this effort to identify and incorporate appropriate management direction in LUPs to conserve, enhance, and restore GRSG habitat by reducing, eliminating, or minimizing threats to GRSG habitat. All management considered under any of the alternatives complied with federal laws, rules, regulations, and policies.

Each alternative emphasized an altered combination of resource uses, allocations, and restoration measures to address issues and resolve conflicts among uses so that GRSG goals and objectives were met in varying degrees across the alternatives. The action alternatives offered a range of possible management approaches for responding to planning issues and concerns identified through public scoping, and to maintain or increase GRSG abundance and distribution in the planning area. While the land use plan goal was the same across alternatives for each sub-region, each alternative contained a discrete set of objectives and management actions constituting a separate RMP amendment. The goal was met in varying degrees, with the potential for different long-range outcomes and conditions.

The relative emphasis given to particular resources and resource uses differed as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs. When resources or resource uses are mandated by law there are typically few or no distinctions between alternatives.

3.1.1 Alternative A – No Action Alternative

Formatted: Font color: Auto

Alternative A meets the CEQ requirement that a No Action Alternative be considered. This alternative continues current management direction derived from the existing field/district office RMPs, as amended. Goals and objectives for resources and resource uses are based on the most recent RMP decisions, along with associated amendments and other management decision documents. Laws, regulations, and BLM policies that supersede RMP decisions would apply.

Goals and objectives for BLM-administered lands and mineral estate would not change. Appropriate and allowable uses and restrictions pertaining to activities such as mineral leasing and development, recreation, construction of utility corridors, and livestock grazing would also remain the same. The BLM would not modify existing or establish additional criteria to guide the identification of site-specific use levels for implementation activities.

This alternative was not selected as the ARMPAs because it did not meet the purpose and need of this plan amendment. This alternative did not include changes that are needed to be made to the existing decisions based on the FWS 2010 listing petition decision that identified inadequacy of regulatory mechanisms as a significant threat to GRSG and its habitat. This alternative did not incorporate the best available science pertaining to GRSG or its habitat.

3.1.2 Alternative B: National Technical Team Report Alternative

Formatted: Font color: Auto

Alternative B was based on the conservation measures contained within the National Technical Team (NTT) Report. The GRSG National Technical Team (NTT), comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed *A Report on National Greater Sage-Grouse Conservation Measures* in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. The Report can be accessed at: http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

The BLM's Washington Office Instructional Memorandum (IM) Number 2012-044 directed the sub-regional planning efforts to analyze the conservation measures developed by the NTT, as appropriate, through the land use planning process and NEPA.

Alternative B would exclude ROW development in PHMA and avoid development in GHMA, would close PHMA to fluid mineral leasing, mineral material sales, and nonenergy leasable minerals, and would recommend withdrawal from locatable mineral entry in all PHMA. These management actions would reduce surface disturbance in PHMA and would minimize disturbance in GHMA, thereby maintaining GRSG habitat. Management actions for wildfire would focus on suppression in PHMA and GHMA, while limiting certain types of fuels treatments. Vegetation management would emphasize sagebrush restoration. Collectively, vegetation and wildfire management would conserve GRSG habitat. Grazing would continue with similar impacts under Alternative B as under Alternative A. The best management practices (BMPs) proposed in the NTT report would be included as required design features as part of Alternative B and are listed in Appendix C, Required Design Features (RDFs), of each of the attached ARMPAs.

This alternative was not selected in its entirety as the ARMPAs because the majority of the conservation measures in the NTT Report, as appropriate and applicable, were applied primarily to PHMA, and few conservation measures in the Report were provided for in GHMA. As a result, this alternative did not provide adequate conservation in GHMA. .

3.1.3 Alternative C: Citizen Groups' Recommended Alternative One

Formatted: Font color: Auto

Alternative C was based on a citizen groups' recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and was applied to all occupied GRSG habitat (PHMA and GHMA. Alternative C limited commodity development in areas of occupied GRSG habitat, and closed or excluded large portions of the planning area to many land uses. This included all PHMA and GHMA as being closed to livestock grazing, recommended for withdrawal from locatable mineral entry, closed to fluid mineral leasing, closed to salable mineral and non-energy leasable mineral development, and exclusion areas for right-of-ways. The Utah LUPA/Draft EIS combined this alternative with Alternative F (discussed below) and included two sub-alternatives under Alternative C for a reduction in livestock grazing and wild horses and burros management.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which, based on best available science, is not required to conserve GRSG and its habitats. Alternative C was also not selected in its entirety because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.4 Alternative D: Draft RMP Amendments' Preferred Alternative

Formatted: Font color: Auto

Alternative D, which was identified as the Preferred Alternative in the Draft EISs, balanced opportunities to use and develop the planning area as well as conserving, maintaining, and enhancing GRSG and their habitat. Protective measures were applied to GRSG habitat, while still allowing for anthropogenic disturbances with stringent mitigation measures. This alternative represents the mix and variety of management actions based on BLM's analysis and judgment, which best resolve the resource issues and management concerns while meeting laws, regulations, and policies pertaining to BLM management. As a result of public scoping comments, internal review, and cooperating agency coordination on the Draft RMP Amendments/EISs, this alternative was modified to become the Proposed RMP Amendments and analyzed in the FEISs. The Preferred Alternatives, with slight variations, became the Proposed Plans in the FEISs.

In PHMA under Alternative D, there would be limitation on disturbance in GRSG habitat by excluding wind and solar energy development (except for certain counties in Southeastern Oregon where avoidance is applied), avoiding all other ROW development, applying no surface occupancy stipulations to fluid mineral development, and closing PHMA to nonenergy leasable mineral development and mineral material sales. These management actions would protect GRSG habitat, while allowing other activities, subject to conditions. In GHMA under Alternative D, allocations are less stringent, but still aim to protect GRSG habitat (for example, applying moderate constraints and stipulations to fluid minerals in GHMA).

Under Alternative D, the BLM management would support sagebrush/perennial grass ecosystem restoration, would increase fire suppression in PHMA and GHMA, and would manage livestock grazing to maintain or enhance sagebrush and perennial grass ecosystems.

3.1.5 Alternative E: State/Governor's Alternative

Formatted: Font color: Auto

Alternative E is the alternative based on information provided by the State or Governor's offices for inclusion and analysis in the EISs. In many instances, the BLM had to adjust what was provided by the States and Governors to fit BLM language, decision-making constructs, etc. This alternative incorporates guidance from specific state conservation strategies, if developed or recommendations from the state on management of Federal lands and emphasizes management of GRSG seasonal habitats and maintaining habitat connectivity to support population objectives. This alternative was identified as a co-Preferred Alternative in the Idaho and Southwestern Montana Draft EIS. California did not provide the BLM with a state GRSG conservation plan and under this alternative, reverted back to Alternative A, the no-action alternative.

For Nevada, Alternative E would apply an avoid, minimize, and mitigate strategy to reduce direct and indirect impacts on GRSG from surface-disturbing activities on BLM-administered lands. Effects on GRSG habitat from certain resource programs, such as grazing, lands and realty, wildfire management, and minerals, would not be directly addressed because allocation decisions were not part of the state's plan.

For Oregon, Alternative E contains GRSG conservation guidelines from Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat. This document describes the Oregon Department of Fish and Wildlife's proposed management of GRSG on Federal lands. It also provides guidance for public land management agencies and land managers for GRSG conservation. GRSG conservation guidelines in the state plan are designed to maintain (at a minimum) or enhance the quality (the optimum) of current habitats. The guidelines would also assist resource managers in achieving the population and habitat objectives of the state plan.

For Idaho, Alternative E incorporates proposed GRSG protection measures recommended by the State of Idaho. Management in Montana would remain unchanged from the current RMPs (Alternative A). Alternative E addresses the following primary threats: fire, invasive weeds, and infrastructure development. It also includes guidance for several secondary GRSG threats such as recreation, improper livestock grazing, and West Nile virus for BLM and Forest Service programs that affect GRSG or its habitat.

For Utah, Alternative E1 is based on the State of Utah's Conservation Plan for Greater Sage-Grouse in Utah and would apply to all BLM-administered lands in Utah. In alternative E1 conservation measures would be applied to 11 areas that the state identified, called Sage-Grouse Management Areas (SGMAs). Emphasis would be placed on expanding GRSG habitat by aggressively treating areas where there are encroaching conifers or invasive species. Alternative E1 includes a general limit on new permanent disturbance of 5 percent of habitat on state or federally managed lands within any particular SGMAs. Occupied habitat outside of the state-identified SGMAs would not receive new management protection. They would continue to be managed according to the GRSG actions in existing RMPs and conservation measures associated with existing activity-level plans.

This alternative was not selected in its entirety as the ARMPAs because some components of the state's plans were not consistent with the purposes, policies and programs of Federal laws and regulations applicable to public lands. However, many goals, objectives, and management actions in the alternative were carried forward.

3.1.6 – Alternative F: Citizen Groups' Recommended Alternative Two

Formatted: Font color: Auto

Alternative F is also based on a citizen group recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and defines different restrictions for PHMA and GHMA. Alternative F would limit commodity development in areas of occupied GRSG habitat, and would close or designate portions of the planning area to some land uses. This alternative does not apply to the Utah sub-regional planning effort, as it was combined with Alternative C. Under Alternative F, wildfire suppression would be prioritized in PHMA. Concurrent vegetation management would emphasize sagebrush restoration and enhancement. Alternative F would reduce livestock and wild horse and burro management utilization by 25 percent within PHMA and GHMA. While the Utah Draft EIS did not include an Alternative F, it did create two sub-alternatives under Alternative C for livestock grazing and wild horses and burros to consider and analyze a similar reduction.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture.

3.1.7 – Proposed Plan Amendment

Formatted: Font color: Auto

As a result of public comments, best science, cooperating agency coordination, and internal review of the Draft RMP Amendments/EISs, the BLM developed the Proposed Amendments/Final EISs for managing BLM-administered lands. The Proposed Amendments/Final EISs focused on addressing public comments, while continuing to meet the BLM's legal and regulatory mandates. The Proposed Amendments/Final EISs are a variation of the preferred alternatives (Alternative D) and are within the range of alternatives analyzed in the DEISs. The Proposed Plans, with slight variations (as outlined in Section 2.5 of this ROD), became ARMPAs.

Formatted: Font color: Auto

3.1.8 Environmentally Preferable Alternative

Council on Environmental Quality (CEQ) regulations require that a ROD state which alternatives were considered to be "environmentally preferable" (40 CFR 1505.2(b)). Question 6A of CEQ's 40 most-asked questions regarding CEQ's NEPA regulations defines that term to ordinarily mean the alternative which best protects, preserves, and enhances historic, cultural, and natural resources.

Under that definition, Alternative B, as presented in each of the sub-regional Proposed RMP Amendments/Final EISs is the most environmentally preferable. However, NEPA expresses a continuing policy of the federal government to "use all practicable means and measures…to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans" (Section 101 of NEPA).

3.2 Alternatives Considered But Not Analyzed in Detail

Formatted: Font color: Auto

The alternatives listed below by sub-region were considered but were not carried forward for detailed analysis because of one or more of the following reasons:

- They would not meet the requirements of FLPMA or other existing laws and regulations;
- They did not meet the purpose and need;
- The alternative was already captured within the range of alternative analyzed in the EIS;
- They were already part of an existing plan, policy, or administrative function; or
- They did not fall within the limits of the planning criteria.

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.25" + Indent at: 0.5"

For additional rationale as to why each of the alternatives listed below by sub-region were not carried forward for detailed analysis, refer to Section 2.11of each of the sub-regional Proposed Amendments/Final EISs.

Idaho and Southwestern Montana

- FWS-Listing Alternative
- Elimination of Recreational Hunting Alternative
- Predation Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Consideration of Coal Mining Alternative

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.25" + Indent at: 0.5"

Nevada and Northeastern California

- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Elko County Sage-Grouse Plan Alternative
- Increase Grazing Alternative

4. PUBLIC INVOLVEMENT, CONSULTATION AND COORDINATION

Formatted: Font color: Auto

BLM land use planning is conducted in accordance with NEPA requirements, CEQ regulations, and US Department of the Interior policies and procedures implementing NEPA, as well as specific BLM planning and NEPA policies. The NEPA and associated laws, regulations, and policies require the BLM to seek public involvement early in and throughout the planning process, to develop a range of reasonable alternatives to proposed actions, and to prepare environmental documents that disclose the potential impacts of proposed management.

Public involvement and agency consultation and coordination have been at the heart of the planning process leading to these Great Basin Region ARMPAs. These efforts were achieved through Federal Register notices, public formal and informal meetings, individual contacts, media releases, planning bulletins, and a series of GRSG planning-related Web sites. This section documents the outreach efforts that have occurred to date. For more plan specific information related to the public involvement, consultation, and coordination processes that the BLM conducted, please refer to Chapter 3 of the attached ARMPAs.

4.1 Public Involvement

Formatted: Font color: Auto

The scoping period for the National GRSG Planning Strategy, including the four sub-regional planning areas in the Great Basin Region, began with the publication of the NOI in the Federal Register on

December 9, 2011, and ended on March 23, 2012. Beginning in December and ending in February of 2012, the BLM hosted a series of public open house scoping meetings across Northeastern California, Idaho, Southwestern Montana, Nevada, Oregon and Utah. A final National GRSG Planning Strategy Scoping Report was released in May 2012.

A Notice of Availability (NOA) for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Draft RMP Amendments/EISs were published in the Federal Register on November 1, 2013. The Oregon Draft RMP Amendment/EIS was released to the public on November 26, 2013.

For the Great Basin Region GRSG Draft RMPAs/DEIS, Idaho and Southwestern Montana conducted seven public meetings, Nevada and Northeastern California conducted seven public meetings, Oregon conducted seven public meetings, and Utah conducted eight public meetings between November 2013 and January 2014.

Comments on the Draft RMPAs/Draft EISs received from the public and internal BLM review were considered and incorporated, as appropriate, into the Proposed Plan Amendments. The Great Basin Region received approximately 4,990 substantive comments, contained in 74,240 submissions during the four Draft RMPAs/Draft EISs' comment periods. Comments on the Draft RMPAs/Draft EISs received from the public and internal BLM review were carefully considered and incorporated as appropriate into the Proposed Plan Amendments. Public comments resulted in the addition of clarifying text, but did not significantly change Proposed RMPAs.

Formatted: Font: Times New Roman

A Notice of Availability (NOA) for all of the Great Basin Region GRSG Proposed RMPAs and Final EISs for the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah Sub-Regions were released on May 29, 2015. The release of the EPA's NOA initiated a 30 day public protest period and a 60 day governor'' consistency review. Refer to **Section 2.5 and 2.6** for a full description of the protest period and governor's consistency review outcomes.

4.2 Cooperating Agencies

Formatted: Font color: Auto

A cooperating agency is any federal, state, or local government agency or Native American tribe that enters into a formal agreement with the lead federal agency to help develop an environmental analysis. Cooperating Agencies and tribes "work with the BLM, sharing knowledge and resources, to achieve desired outcomes for public lands and communities within statutory and regulatory frameworks" (BLM 2005). The benefits of enhanced collaboration among agencies in preparing NEPA analyses are:

- Disclosing relevant information early in the analytical process
- Applying available technical expertise and staff support
- Avoiding duplication with other federal, state, tribal, and local procedures
- Establishing a mechanism for addressing intergovernmental issues

Formatted: Indent: Hanging: 0.25", Outline numbered + Level: 1 + Numbering Style: Bullet + Aligned at: 1.25" + Indent at: 0.5"

The BLM entered into a formal Memorandum of Understanding (MOU) for the National GRSG Planning Strategy with the FWS and the U.S. Forest Service. In addition, the Great Basin sub-regions also invited local, state, other federal, and tribal representatives to participate as Cooperating Agencies for these RMP Amendments/EISs. In total, there were 13 MOUs signed with Federal agencies, 10 MOUs signed with state agencies, 55 MOUs signed with counties, and 5 MOUs signed with tribal entities. The MOUs outline the interests, expertise, and jurisdictional responsibilities of both the BLM and its cooperating agency partners and also outlines their respective roles and responsibilities in the planning and NEPA processes. Additional information can also be found in Chapter 6 of each of the Proposed Amendments/FEISs. These cooperating agencies divided by sub-region are provided below:

Great Basin Region-Wide
US Fish and Wildlife Service
US Forest Service

Idaho and Southwestern Montana
Beaverhead County Commissioners
Bingham County Commissioners
Blaine County Commissioners
Cassia County Commissioners
Clark County Commissioners
Craters of the Moon National Monument
Custer County Commissioners
Fremont County Commissioners
Idaho Association of Counties
Idaho Department of Fish and Game
Idaho Governor's Office of Species Conservation
Idaho National Guard
Jefferson County Commissioners
Lemhi County Commissioners
Madison County Commissioners
Montana Fish, Wildlife and Parks
Natural Resources Conservation Service
Owyhee County Commissioners
Power County Commissioners
Twin Falls County Commissioners
US Department of Defense
US Department of Energy (INL)

Nevada and Northeastern California
Churchill County
Elko County
Eureka County
Humboldt County
Lander County
Lassen County
Lincoln County

Mineral County
Modoc County
Natural Resources Conservation Service
Nevada Department of Transportation
Nevada Department of Wildlife
Nevada Department of Conservation and Natural Resources
Nye County
Pershing County
Pyramid Lake Paiute Tribe
Storey County
Summit Lake Paiute Tribe
Susanville Indian Rancheria
US Department of Defense
US Federal Highway Planning Administration

4.3 FWS Section 7 Consultation

Formatted: Font color: Auto

Consultation with FWS is required under Section 7(c) of the ESA before the start of any BLM project that may affect any federally listed or endangered species or its habitat. These planning processes are considered a major project, and the four Great Basin sub-regional Final EISs defined potential impacts on threatened and endangered species as a result of management actions proposed in the alternatives analyzed in the FEISs. The FWS is a cooperating agency in this planning process. FWS staff participated in interdisciplinary team meetings and has been provided drafts of alternative decisions and analyses for discussion and input.

The BLM formally initiated Section 7 consultation with a letter to the FWS prior to the release of the Draft RMP Amendments/EISs, and requested concurrence on which species would require consideration during consultation. Over the ensuing months, regular meetings were held to identify the species that would be analyzed in the biological assessment, to address which actions could affect those species, and to determine whether the implementation of the Proposed Plan Amendments "may affect" the species for which this consultation occurred.

Prior to the release of the Proposed Amendments/FEISs, the BLM formally submitted the biological assessments to the FWS for review. The USFWS evaluated the biological assessments and concurred with the either a "no affect" or "may effect, but will not adversely affect" determination via memorandum for Oregon, Nevada and Northeastern California, and Idaho and Southwestern Montana, which are appendices to each of these ARMPAs. For Utah, formal consultation was required with the FWS due to a "likely to adversely affect" determination associated with the Utah Prairie Dog, a threatened species under the ESA. The biological opinion from the FWS is attached to the Utah ARMPA (Appendix K).

4.4 Native American and State Historic Preservation Office Consultation

Formatted: Font color: Auto

~~In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in~~In recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation ~~efforts related to~~in preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent 65 individual letters to tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts, and in some cases, as Cooperating Agencies.

Formatted: Font: Times New Roman

Formatted: Space After: 10 pt, Line spacing: Multiple 1.15 li

~~In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation efforts related to preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent letters to 65 tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts.~~

As part of the NEPA scoping and consultation process, ~~and as an opportunity to provide comment pursuant to Section 106 of the NHPA~~, the BLM notified ~~and/or invited~~ the Idaho, Montana, Nevada, California, and Oregon State Historic Preservation Officers (SHPOs) ~~seeking information regarding concerns with~~ of the opportunities to comment on the planning and NEPA documents prepared for these efforts, as they relate to historic properties in the planning areas and the land use ~~planning direction~~plan decisions included in ~~these~~the ARMPAs~~, to participate in the planning process~~. The BLM sought information about historic properties in consideration of land use planning decisions ~~included in these ARMPAs~~ in accordance with the National Programmatic Agreement (PA) between the BLM, Advisory Council on Historic Preservation, ~~and~~ National Conference of State Historic Preservation Officers, and the Idaho, Montana, and Oregon State Protocol Agreement between the BLM and these SHPOs. ~~The~~If the BLM ~~incorporated the~~ received comments and information ~~it received~~ from SHPOs and Tribes~~-~~, that information was considered and incorporated into the Proposed RMPAs~~ and considered such information in making~~/Final EISs and the ~~land use plan amendment decisions~~ARMPAs. The BLM has met its obligations under Section 106 of the NHPA, 54 U.S.C. § 306108, as outlined in the National PA and the State Protocols. The BLM will satisfy the requirements of NHPA Section 106 for future implementation-level decisions, such as project proposals, including adequate consultation with SHPOs, THPOs, Native American Tribes, and other interested parties, consistent with the alternative procedures set forth in the National PA and relevant State Protocol or where applicable the Section 106 regulations.

For the Utah ARMPA, the BLM completed consultation with the Utah SHPO in accordance with the 36 CFR Part 800. In July 2015, the BLM submitted a formal letter, concluding that the land use plan amendments would not adversely affect cultural properties and seeking input and concurrence on those findings and received a concurrence letter from the Utah SHPO on July 30, 2015. The BLM will satisfy the requirements of NHPA Section 106 for future implementation-level decisions, such as project proposals, including adequate consultation with SHPOs, Tribal Historic Preservation Officers (THPOs), Native American Tribes, and other interested parties, consistent with the alternative procedures set forth in the National PA and relevant State Protocol, programmatic agreements, or where applicable the Section 106 regulations.

6. APPROVAL

Land Use Plan Amendment Decisions

It is the decision of the Bureau of Land Management (BLM) to approve the Great Basin Region Approved Resource Management Plan (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub-regions, as described in this Record of Decision. Notices of the public availability of the Proposed Plan Amendments and related Final Environmental Impact Statements (EIS) were published in the Federal Register on May 29, 2015. in the (80 FR 30711). I have resolved all protests and, in accordance with BLM regulations 43 CFR 1610.5-2, my decision on the protests is the final decision of the Department of the Interior. The approval is effective on the date this Record of Decision is signed.

(WO210)(1610)

Dear Reader:

Enclosed are the Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). The ROD approves the four Great Basin Region ARMPAs, which are part of seventeen other sub-regional RMP Amendments and RMP revisions associated with the National Greater Sage-Grouse Planning Strategy that was initiated on December 11, 2011.

The Bureau of Land Management (BLM) ARMPAs provide a ~~range wide~~ landscape-level, ~~comprehensive~~, science-based, collaborative strategy for addressing previously identified threats to the greater sage-grouse (GRSG) and its habitat. This strategy, while designed to address issues leading to the U.S. Fish and Wildlife Service's (FWS) 2010 "warranted but precluded" decision, was guided by over a decade of research, analysis and recommendations for GRSG conservation produced by the Conservation Objectives Team (COT) Report and the BLM National Technical Team and (NTT). Each of these reports was developed by a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research. Science-based decision-making and collaboration with the FWS, the U.S. Forest Service, and state and other partners were fundamental during the development of ~~the land use plan decisions within~~ these ARMPAs to address the identified threats to GRSG.

It is important to note that this ROD and these ARMPAs are specific only to BLM-administered lands. Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

The Federal Land Policy Management Act (FLPMA) requires the development and maintenance, and, as appropriate, the revision of land use plans for public lands. The National Environmental Policy Act (NEPA) requires Federal agencies to prepare an Environmental Impact Statement (EIS) for major Federal actions that could significantly affect the environment. In fulfillment of these requirements, the Draft

Comment [JRL2]: NEED TO CLARIFY WHAT THIS IS AND WHAT TRIGGERED THE "START" OF THE STRATEGY – not referenced in the ROD precisely as "start" of strategy.

Comment [JRL3]: NOT RANGEWIDE, SINCE BLM PLANS DON'T COVER THE ENTIRE RANGE. THEY ARE "LANDSCAPE-LEVEL".

Comment [JRL4]: NOT COMPREHENSIVE SINCE OTHER ACTIVITIES – E.G., IMPLEMENTATION OF THE RANGELAND FIRE STRATEGY IS ALSO A PART OF A "COMPREHENSIVE" STRATEGY – AND NOT PART OF THE DECISIONS COVERED IN THE ARMPAs.

Comment [GSD5]: FWS does not capitalize and neither does the Dept in our materials . . .

Comment [MEM6]: Caps is consistent with other BLM planning docs and our tech. guide. May need to discuss.

Comment [KK7]: Culminating in? – COT & NTT didn't really produce the decade of research, and analysis; or ". . . guided by over a decade of research for GRSG conservation and analysis and recommendations provided by the COT . . ."

Comment [JRL8]: Shouldn't this be "hyphenated" every time?
KK: contractor will take care of editorial items

RMP Amendments/Draft EISs incorporating analysis and input provided by the public; local, State, and other Federal agencies and organizations; Native American tribes; Cooperating Agencies, and BLM personnel were published in the fall of 2013. The 90-day public comment periods ensued, with more than 4,990 substantive comments from 1,348 letters that were submitted. These comments were reviewed, summarized and considered in preparing the Proposed RMP Amendments/Final EISs.

Comment [JRL9]: For all plans or just those in this subregion?
KK: just this subregion

The Proposed RMPAs/Final EISs were made available on May 29, 2015, for a 60-day governor's consistency review and 30-day protest period. The BLM received consistency review letters from X and has worked closely with these states to resolve these inconsistencies. X protest letters were received, of which X were valid protests in need of resolution. Protest issues are addressed and resolved in the Protest Summary Report, available on line at: http://www.blm.gov/nv/st/en/fo/wfo/blm_information/rmp.html.

After much consideration, the BLM now approves the attached ARMPAs as the land use planning documents that will guide greater sage-grouse habitat management and uses that may affect the GRSG and its habitat in the Great Basin Region for the life of the plan amendment for the benefit of GRSG and over 350 other species of wildlife as well as many other land uses, like grazing and recreation, that depend on ~~a~~ healthy sagebrush-steppe landscapes.

Comment [JRL10]: Actually, all land and resource management in the affected area – better to clarify?
KK: suggested edit

Copies of the ROD and ARMPAs can be obtained from the BLM's National Greater Sage-Grouse webpage at: http://www.blm.gov/wo/st/en/prog/more/sagegrouse.html.

The BLM extends special appreciation to the extensive public involvement and the involvement of groups, organizations, Cooperating Agencies; local, State, and other Federal agencies; and Native American tribal representatives who contributed to the completion of these ARMPAs. This participation informed and improved the planning process and the planning documents. Your continued involvement is encouraged as the ARMPAs are implemented and monitored for the conservation of Greater sage-grouse and their habitat.

Sincerely,
X

Enclosure:
1. Record of Decision and Approved Resource Management Plan Amendments

Summary

This Record of Decision (ROD) is the culmination of an unprecedented effort in public land management to meet the multiple-use and sustained-yield management objectives for public lands administered by the Bureau of Land Management (BLM) in accordance with the Federal Land Policy and Management Act of 1976 (FLPMA).

In response to a 2010 determination by the U.S. Fish and Wildlife Service (FWS) that the greater sage-grouse listing under the Endangered Species Act (ESA) is "warranted but precluded" by other priorities, the BLM, in coordination with the U.S. Department of Agriculture Forest Service (Forest Service), has developed a targeted, multi-tiered, landscape-level management approach, based on the best available science, that offers the highest level of protection for Greater Sage-Grouse (GRSG) in the most important habitat areas to address the specific threats identified in the 2010 U.S. Fish and Wildlife "warranted but precluded" decision and Conservation Objectives Team (COT) report.

This Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon; and Utah includes land use allocations in the ARMPAs that limit or eliminate new surface disturbance in Priority Habitat Management Areas (PHMA), while minimizing disturbance in General Habitat Management Areas (GHMA). In addition to establishing protective land use allocations, the ARMPAs implement a suite of management actions, such as the establishment of disturbance limits, GRSG habitat objectives, mitigation requirements, monitoring protocols, and adaptive management triggers and responses, as well as other conservation measures throughout the range. The cumulative effect of these conservation measures work in concert to protect, improve, and restore GRSG habitat across the remaining range of the species in the Great Basin and provide greater certainty that BLM land and resource management activities in GRSG habitat in the Great

Basin Region can lead to conservation of the GRSG and other sagebrush-steppe associated species in the region.

The targeted land use plan protections presented in this ROD and ARMPAs do not only protect the greater sage-grouse and their habitat, but also the over 350 wildlife species that call the sagebrush-steppe ecosystem home. Reversing the slow degradation of this valuable ecosystem will also benefit local rural economies and a variety of rangeland uses in addition to habitat protection, ~~ranging from~~ including recreation and ~~to~~ grazing ~~and energy development~~, in a manner that safeguards the long term sustainability, diversity and productivity of the land.

This conservation strategy, developed in collaboration with the 11 states in which the ARMPAs and ARMPs apply, in addition to other state and federal actions underway and in development, represents an unprecedented, collaborative effort among federal land management agencies and the states to manage an entire ecosystem and associated flora and fauna, in order to "conserve the sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future". [Dan Ashe. Transmittal letter to COT report. 2014]

Comment [GSD11]: We may want to add some language at the end here from the rollout materials about targeted protections that benefit GRSG, 350+ other species as well as economic activity that depends on a healthy range.

Comment [MEM12]: Added this last paragraph based on Sarah G's suggestion. Will this work or should we flesh out more?

1. INTRODUCTION

This Record of Decision (ROD) approves the Bureau of Land Management's (BLM) attached ARMPAs for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM-~~-~~administered lands. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.), BLM planning regulations (43 Code of Federal Regulations [CFR] §1601 *et seq*.), and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA) and the Council on Environmental Quality's Regulations for implementing the procedural provisions of NEPA (40 CFR §1500.1 *et seq*.).

Comment [JRL13]: Hyphen?

Throughout the GRSG planning process, the ~~U.S.~~ Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs included proposed GRSG management direction for National Forest System lands. The ~~U.S.~~ Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Comment [JRL14]: Cited previously, so should reference consistently through here on out.

1.1 Great Basin Region Planning Area

The Great Basin Region is composed of four sub-regions, the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah sub-regions (see **Figure 1-1** – Great Basin Region Greater Sage-Grouse Sub-regions). Four separate National Environmental Policy Act (NEPA) documents were prepared for each of these sub-regions. Each sub-region conducted its own planning effort with input from local cooperators, stakeholders, and members of the public. The sub-regional boundaries were constructed to align with BLM administrative offices, state boundaries, as well as areas that shared common threats to the GRSG and their habitat. The boundaries for these sub-regions largely coincide with zones III, IV, and V identified by the WAFWA Greater Sage-Grouse Conservation Strategy to delineate management zones with ~~similarecological~~similar ecological and biological issues and similarities.

Comment [KK15]: We could add the WAFWA zones here as one additional element used to make the region/subregion boundaries??

[Insert **Figure 1-1** - Great Basin Region Greater Sage-Grouse Sub-regions]

The Great Basin Region planning area boundaries include all lands regardless of jurisdiction (see **Figure 1-2** - Great Basin Region Planning Area, Greater Sage-Grouse Habitat Management Areas). **Table 1-1** outlines the amount of surface acres that are administered by specific Federal agencies, states, local governments, and lands that are privately owned in the four sub regions that make up the Great Basin. The planning area includes other BLM-administered lands that are not allocated as habitat management areas for GRSG. The ARMPAs do not establish any additional management for these lands; these lands will continue to be managed according to the existing land use plan for the areas.

[Insert **Figure 1-2** - Great Basin Region Planning Area, Greater Sage-Grouse Habitat Management Areas]

Table 1-1
Land Management in the Great Basin Planning Area

Surface Land Management	NV/NE CA	ID/SW MT	Utah	Oregon	Great Basin Total
BLM	45,359,000	12,449,000	20,387,200	12,615,900	**90,811,100**
Forest Service	9,719,900	13,252,400	7,396,300	6,454,800	**36,823,400**

The decision area for the Great Basin Region ARMPAs is BLM-administered lands in GRSG habitat management areas (see **Figure 1-3** - Great Basin Region Decision Area , Greater Sage-Grouse Habitat Management Areas), including surface and split-estate lands with BLM subsurface mineral rights. Any decisions in the Great Basin Region ARMPAs apply only to BLM-administered lands, including split-estate lands within GRSG habitat management areas (the decision area). These decisions are limited to providing land use planning direction specific to conserving GRSG and its habitat.

Formatted: Highlight

Formatted: Highlight

Comment [JRL16]: HOW DO THESE DECISIONS DIFFER FROM OTHER LAND USE DECISIONS?
KK: should this sentence be deleted? It just seems to open the door to a debate about whether every decision in the plan really is necessary for conservation. And obviously, since this amendment is for GRSG conservation, all decisions are pertinent to that.

[Insert **Figure 1-3** - Great Basin Region Decision Area, Greater Sage-Grouse Habitat Management Areas]

1.2 Threats to Greater Sage-Grouse

Currently, GRSG occupy an area that has been estimated to be a reduction of 44% from the historically occupied range. In addition, populations in most or all the range have been demonstrated to have declined from 1965- 2003, the period where data was collected most intensively.

The decline of the GRSG and its sagebrush-steppe habitat has been the focus of fish and wildlife agency and conservationists' concerns for decades. In 1994 the Western Association of Fish and Wildlife Agencies (WAFWA) formed a technical committee to monitor the distribution and abundance of GRSG. WAFWA formalized a program of interstate coordination and cooperation in 1995 to address the issues of GRSG population losses and degradation of sagebrush ecosystems in order to: 1) Maintain the present distribution of GRSG and 2) Maintain the present abundance of GRSG. In 1999 WAFWA amended the objectives to: 1) Maintain and increase where possible the present distribution of GRSG and 2) Maintain and increase where possible the present abundance of GRSG. The Bureau of Land Management, USFWS, and U.S. Forest Service formally joined with WAFWA in range-wide conservation efforts in 2000.

Between May 1999 and December 2003, eight petitions were filed with the U.S. Fish and Wildlife Service (USFWS) to have sage-grouse protected under provisions of the Endangered Species Act (ESA). In 2001 the USFWS determined that greater sage-grouse in the Columbia Basin of Washington state warranted protection under provisions of the ESA. On January 12, 2005, the FWS issued a decision that listing the GRSG for protection under the ESA was not warranted. However, in response to July 14, 2006 Western Watersheds Project filing alleging that the FWS 2005 finding was incorrect and arbitrary, the U.S. District Court of Idaho ruled that the 2005 finding was "arbitrary and capricious" and remanded it to the FWS for further consideration. Ultimately, as a result, in 2010 the FWS issued a finding that listing of the Greater sage-grouse was "warranted but precluded". Subsequent to that finding ~~and in accordance with a settlement agreement,~~[details?] the FWS committed to make a final determination regarding the need to list the GRSG by September 30, 2015. Two factors led to the FWS decision to list the species as "warranted but precluded": threats to habitat and the inadequacy of existing regulatory mechanisms.

Comment [JRL17]: Need to address.

Comment [KK18]: I suggest we just delete it – don't think this is necessary for the BLM ROD

Formatted: Highlight

The USFWS has identified a number of threats to GRSG in the Great Basin Region, focusing on the present and widespread threats of wildfire and the loss of native habitat to invasive species. Other threats, some of which are more localized by nature, include habitat fragmentation due to anthropogenic disturbances associated with energy development, mining, infrastructure, recreation, urbanization and sagebrush elimination, as well as disturbance associated with free-roaming equids and improper livestock grazing.

Additional information regarding potential threats to the GRSG is contained in the BLM National Technical Team (NTT) report and the Conservation Objectives Team (COT) reports. A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG in the Great Basin Region– as articulated in the COT report – is summarized in **Table 1-2**.

In addition, the FWS found that existing local, state and federal regulatory mechanisms were not sufficient to address threats to the habitat. For the BLM, which manages more than 40 percent of the remaining habitat range wide, regulatory mechanisms are the agency's Resource Management Plans (RMPs).

Comment [JRL19]: DO WE NEED TO FOOTNOTE SINCE WE USE "RANGE" AS THE BASE HERE AND A DIFFERENT CHARACTERIZATION/REFERENCE IN OTHER PARTS OF THE DOCUMENT?

The BLM initiated this planning effort with the U.S. Forest Service to provide the needed federal regulatory mechanisms to address the individual threats listed in Table 1-3. This ROD approves the BLM's attached ARMPAs for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPAs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM- administered lands. ~~The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).~~

Comment [KK20]: I'm inclined to delete this as unneeded here

Comment [KK21]: Already in the 1st paragraph of the intro

1.3 Early GRSG Conservation

The BLM manages the majority of the GRSG habitat on Federal lands (i.e., the range of GRSG not including the Columbia Basin or Bi-State Distinct Population Segments). Efforts to conserve the habitat of this species by the BLM and other wildlife conservation agencies and organizations ~~did not begin with the 2011 BLM's National GRSG Planning Strategy, but rather,~~ have been ongoing for many years.

The Western Association of Fish and Wildlife Agencies (WAFWA) 2004 *Range-wide Conservation Assessment for Greater Sage-Grouse and Sagebrush Habitats* was the first range-wide assessment of GRSG using the vast amount of population data collected over the previous 60 years, habitat information spanning the previous 100 years, and literature dating back 200 years. The goal of the assessment, contributed to by the BLM, was to present an unbiased and scientific documentation of dominant issues and their effects on GRSG populations and sagebrush habitats.
http://sagemap.wr.usgs.gov/docs/Greater_Sage-grouse_Conservation_Assessment_060404.pdf

In November 2004, the BLM released its *National Sage-Grouse Habitat Conservation Strategy*, which encouraged GRSG habitat conservation through consultation, cooperation, and communication with WAFWA, the U.S. Fish and Wildlife Service (FWS), the Forest Service, the U.S. Geological Survey (USGS), State wildlife agencies, local GRSG working groups, and various other public and private partners.

In 2006, WAFWA completed a *Greater Sage-Grouse Comprehensive Conservation Strategy*, with the assistance of the BLM, the Forest Service, and other contributors. The overall goal of the Strategy was to maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain those populations. The Strategy outlined the critical need to develop the associations among local, state, provincial, tribal, and federal agencies, non-governmental organizations, and individual citizens to design and implement cooperative actions to support robust populations of GRSG and the landscapes and habitats upon which they depend. The catalyst for this effort was widespread concern for declining populations and reduced distribution of GRSG.
http://www.wafwa.org/documents/pdf/GreaterSage-grouseConservationStrategy2006.pdf

In 2008, the BLM created two national teams to investigate possible BLM management options for GRSG conservation as well as summarizing BLM's ongoing conservation efforts. A product of this effort was one of the first range-wide priority habitat maps for GRSG that were referred to as "key habitat". At the time, the primary purpose for the key habitat map was to inform and help prioritize fire suppression efforts in GRSG habitat on BLM lands. An additional outcome of this team was the signing of a Memorandum of Understanding by the WAFWA; the BLM, FWS, USGS in the Department of the Interior; and the US Department of Agriculture Forest Service and NRCS, to provide for cooperation among the participating state and federal land managers and wildlife management and science agencies in the conservation and management of GRSG sagebrush habitats and other sagebrush-dependent wildlife throughout the Western United States and Canada.
http://www.blm.gov/style/medialib/blm/wo/Planning_and_Renewable_Resources/fish__wildlife_and/fwp.Par.95958.File.dat/SagegrouseMOU.pdf

In 2010, BLM commissioned an effort to map breeding densities of GRSG across the West. A conference was convened with the state wildlife agencies to get approval and to coordinate the lek survey data needed for this effort. This modelling project, through an agreement with the FWS, mapped known active leks across the West. This model served as a standard starting point for all states to identify priority habitat.

http://www.blm.gov/wo/st/en/prog/more/fish__wildlife_and/sage-grouse-conservation/bird_density.print.html

In March 2010, the US Fish and Wildlife Service (USFWS) published their 12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered (75 Federal Register 13910, March 23, 2010). In that finding, the USFWS concluded that GRSG was "warranted, but precluded" for listing as a threatened or endangered species. A warranted, but precluded determination is one of three results that may occur after a petition is filed by the public to list a species under the Endangered Species Act (ESA). This finding indicates that immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, the species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

The USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 Federal Register 13910, March 23, 2010). The USFWS identified the principal regulatory mechanisms for the BLM and Forest Service as conservation measures in land use plans.

1.4 National Greater Sage Grouse Planning Strategy

Based on the identified threats to the GRSG, especially inadequate regulatory mechanisms, and the FWS's timeline for making a listing decision on this species, the BLM recognized the need to incorporate explicit objectives and adequate conservation measures into RMPs by 2015 to conserve GRSG habitat and avoid the need to list the species under the Endangered Species Act. In August, 2011, the BLM chartered a planning strategy to evaluate the adequacy of BLM RMPs and address revisions and amendments throughout the range of the GRSG (with the exception of the bi-state population in California and Nevada, and the Washington state distinct population segment, which were addressed through other planning efforts). This Charter established the teams, team membership, and team operating procedures for the BLM's National GRSG Planning Strategy. The BLM's objective for chartering this planning strategy effort was to develop new or revised regulatory mechanisms through RMPs to conserve and restore the GRSG and its habitat on BLM-administered lands on a range-wide basis for the long-term (Figure C).
http://www.blm.gov/style/medialib/blm/wo/Communications_Directorate/public_affairs/sage-grouse_planning/documents.Par.2415.File.dat/Final%20Signed%20GSG%20Planning%20Strategy%20Charter.pdf

Two national teams and numerous other studies were used to help inform the planning efforts. The GRSG National Technical Team (NTT), comprised of BLM, FWS, USGS, NRCS, and State specialists, completed A Report on National Greater Sage-Grouse Conservation Measures in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats in the FWS listing action (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones (Figure 1-4). The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and

emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. ~~These WAFWA Management Zones are identified on **Figure 1-4** below.~~ http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

In 2012, FWS convened the Conservation Objectives Team (COT) of state and federal representatives to produce a peer-reviewed report which identified the principal threats to GRSG survival -- based upon the FWS 2010 listing decision -- and the degree to which these threats need to be reduced or ameliorated to conserve the GRSG so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future.[1] The COT report also identified Priority Areas for Conservation (PACs) and emphasized that "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". Finally, the COT report identified present and widespread, as well as localized threats by GRSG population across the West. These population specific threats, as specified from the COT report, are outlined in **Table 1-2**. **Figure 1-4** from the COT Report identifies the PACs, GRSG populations (and their names), and WAFWA Management Zones across the West. http://www.fws.gov/greatersagegrouse/documents/COT-Report-with-Dear-Interested-Reader-Letter.pdf

[Insert **Figure 1-4** - GRSG Priority Areas for Conservation, Populations (and names), and WAFWA Management Zones.]

Additional science-based reviews by the US Geological Survey and related scientific literature provided further guidance on specific issues that arose in developing the ARMPAs.

To adequately address the reasons for the 2010 "warranted" determination by the FWS – and specific threats summarized in the COT report -- it was clear to the BLM that additional regulatory measures on federal public lands would be necessary to deal with present or threatened destruction, modification, or curtailment of habitat or range. These measures would need to be incorporated into land use plans that guide management actions on lands within the remaining range of the GRSG administered by the agencies to conserve GRSG such that listing under the ESA was no longer necessary.

In December 2011, the BLM published a Notice of Intent to prepare EISs and Supplemental EISs to incorporate GRSG Conservation Measures into Land Use Plans (LUPs) across the range of the species. A total of 15 sub-regional planning efforts (resulting in eight ARMPAs and nine ARMPs) would amend or revise 78 BLM RMPs ~~and 20 Forest LRMPs~~ across the range of the species.

The federal public land planning strategy reflected several key concepts:

- **Landscape-level**: The planning effort focused on the remaining habitat of the GRSG on public lands, covering 10 western states in the Great Basin and Rocky Mountain regions.
- **Best Available Science** – The ARMPAs/ARMPs are grounded in the best available science, drawn from published literature and input from recognized experts, state agencies, the US Geological Survey, the FWS and other sources. The COT report provided a "blueprint" for GRSG conservation by identifying specific threats to each remaining GRSG population and recommending measures to address each category of threat and the NTT report, prepared by the BLM, provided options for dealing with the most significant threats to the GRSG. A series of reports on how to improve efforts to reduce the threats of rangeland fire and invasive species prepared in collaboration with the Western Association of Fish and Wildlife Agencies also provided crucial guidance in formulating the conservation strategy.

Comment [KK22]: In this section we go back to talking about the whole planning area, not just the ARMPAs for Great Basin. Is this necessary? If it is, is it clear to the average reader that we have made that transition & what the difference is between ARMPA and ARMP?

---

[1] The Conservation Objectives Team (COT) report was prepared with the encouragement of the members of the Sage Grouse Task Force, chaired by former Secretary of the Interior Ken Salazar and Governor Meade of Wyoming and Governor Hickenlooper of Colorado.

- **Targeted, Multi-Tiered Approach** – The ARMPAs/ARMPs were designed to incorporate a layered management approach to avoid or minimize additional surface disturbance in the most valuable habitat, known as Priority Habitat Management Areas (PHMA), which are largely consistent with PACs identified in the COT Report. Within PHMA, the ARMPAs/ARMPs provide an added level of protection to limit or eliminate new surface disturbance through the delineation of Sagebrush Focal Areas (SFA), derived from areas identified by the FWS as "strongholds" essential for the species' survival. In General Habitat Management Areas (GHMA), the ARMPAs/ARMPs seek to minimize disturbance while providing greater flexibility for land use activities.
- **Coordinated**: The BLM ARMPAs/ARMPs were developed through a joint planning process led by the BLM with the Forest Service as partners. The USFWS provided guidance and input throughout the process to aid land managers in understanding the threats and the certainty and effectiveness of proposed land management actions in addressing those threats. The USGS and NRCS also provided key technical and scientific support.
- **Collaborative**: The ARMPAs/ARMPs reflected the input of states and local stakeholders from the outset and were developed with the benefit of input from the individual states and cooperators who signed formal agreements with the BLM to provide input into the planning process. The Western Governors Association Sage Grouse Task Force (SGTF), which is discussed below, was particularly useful in facilitating this kind of collaborative input. The ~~proposed LUPs~~ ARMPAs/ARMPs reflect state and stakeholder developed approaches and economic priorities where consistent with conservation objectives.

Most states across the range provided recommendations for the management of the BLM lands in their state to conserve GRSG. In all cases, this input was incorporated into the range of alternatives analyzed in the Final EISs. Components of these state recommendations were used to develop the ARMPAs/ARMPs where consistent with conservation objectives.

In addition, the ~~Western Governors Association Sage Grouse Task Force~~SGTF was established in 2011 to identify and recommend state and federal conservation actions necessary to preclude the need for the GRSG to be listed under the ESA. This group, which includes designees from the 11 western states where GRSG is found as well as representatives from USFWS, BLM, Natural Resources Conservation Service, US Forest Service, US Geological Survey, and the Department of the Interior, played an integral role throughout this land use planning process.

1.5 Addressing Threats to the Greater Sage-Grouse through the ARMPAs~~ s~~

The 2006 WAFWA *Greater Sage Grouse Comprehensive Conservation Strategy* stated goal for management of the GRSG was to "maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain these populations".[2] The NTT report also endorsed this goal "as a guiding philosophy against which management actions and policies of BLM should be weighed"[3] And, in establishing the COT, with the backing of the SGTF, FWS Director Dan Ashe affirmed the commitment to the goal for GRSG conservation originally articulated in the 2006

---

[2] WAFWA 2006 Strategy. The 2006 objectives built on an initial framework and commitment made by the WAFWA directors, the BLM and the FWS in 2000 with the signing of an interagency sagebrush/sage-grouse conservation MOU.

[3] Sage-grouse National Technical Team. "A Report on National Greater Sage-Grouse Conservation Measures". December 21, 2011.

WAFWA report -- reversing negative population trends and achieving a neutral or positive population trend -- and emphasized the following,

> "The Service interprets this recommendation to mean that actions and measures should be put in place now that will eventually arrest what has been a continuing declining trend. Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels."7

The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT stated, "[m]aintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". To achieve this, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT emphasized an "avoidance first strategy" and stressed that threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

The ARMPAs/ARMPs were developed to remove or reduce identified threats to the species and are an essential component of the effort to conserve GRSG and avoid a listing of the species under ESA. Across ten western States, the Great Basin and Rocky Mountain sub-regional ARMPs/ARMPAs contain updated land use plan direction on approximately 50 percent of the remaining habitat for the species. These ARMPAs/ARMPs are the product of extensive coordination between the BLM and the Forest Service and the active engagement of the USFWS in helping to inform land allocation and related management decisions by the BLM. The plans also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, and circumstances in each.

~~Designation of~~ Habitat Management Areas

In order to protect the most important GRSG habitat areas, the conservation strategy began with mapping areas of important habitat across the remaining range of the GRSG and within each state. In collaboration with state fish and wildlife agencies, the BLM identified areas as preliminary priority habitat ~~(PPH)~~ and preliminary general habitat ~~(PGH)~~. Maps were revised and refined as further mapping was conducted and state fish and wildlife agencies – often in collaboration with GRSG experts and researchers – provided more detailed analysis of habitat characteristics and populations. The ARMPAs reflect this input and have generally aligned these habitats with Habitat Management Areas in the ARMPAs. GRSG habitat management areas on BLM-administered lands in the decision area consist of lands allocated as Priority Habitat Management Areas (PHMA) which largely coincide with Priority Areas for Conservation in the COT report, General Habitat Management Areas (GHMA), Other Habitat Management Areas (OHMA, applicable only to the Nevada and Northeastern California), and Important Habitat Management Areas (IHMA, applicable only to Idaho). **Table 1-4** identifies surface acres of PHMA, GHMA, OHMA, and IHMA in the decision area for the Great Basin Region.

PHMA, GHMA, OHMA, and IHMA are defined as follows:

- **PHMA**— BLM-administered lands identified as having the highest value for~~to~~ maintaining sustainable GRSG populations. The boundaries and management strategies for PHMA are derived from and generally follow the Preliminary Priority Habitat boundaries identified in the Draft LUPA/EIS. Areas of PHMA largely coincide with areas identified as Priority Areas for Conservation in the COT report.

Comment [JRL23]: Need to check footnotes – these do not run in order in present draft

Formatted: Highlight

Comment [KK24]: Why is SGTF 11 if this is 10 – Washington state is included?

Comment [JRL25]: I DON'T LIKE THIS NUMBER. WE HAVE BEEN SAYING WE MANAGED NEARLY 60% OF THE REMAINING HABITAT FOR SOME TIME. WE SHOULD NOT BE CHANGING THE NUMBERS NOW UNLESS OR ORIGINAL ANALYSIS WAS WRONG!

KK: we did change to 50% in the landscape report, so this is consistent with that. Did we use something like this in the FEISs?

Comment [MEM26]: Let me know if you think I need to integrate this into this section better. I think it flows ok now.

Comment [JRL27]: THIS SECTION DEALS WITH MORE THAN "DESIGNATION" SO I SUGGEST THE MODIFICATION NOTED.

- **GHMA**— BLM-administered lands where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMA are derived from and generally follow the Preliminary General Habitat boundaries identified in the Draft RMP/EIS.
- **OHMA** —BLM-administered lands ~~only~~ in Nevada, identified as unmapped habitat in the Proposed RMP/EIS that are within the planning area and contain seasonal or connectivity habitat areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse Habitat in Nevada and Northeastern California; Coates et al. 2014,) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.
- **IHMA** —BLM-administered lands in Idaho that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. ~~There are no IHMAs designated within southwestern Montana.~~ The IHMA boundaries and management strategies are derived from and generally follow the Preliminary Medial Management Area (PMMA) and Important Habitat Zone (IHZ) boundaries identified in Alternatives D and E, respectively, of the Draft LUPA/EIS, but may be modified based on the objectives of each alternative. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the ARMPA.

Table 1-4
Surface Acres of PHMA, GHMA, OHMA, and IHMA in the Decision Area for the Great Basin Region

BLM administered surface acres	PHMA	GHMA	OHMA	IHMA
Idaho and Southwestern MT	4,627,200	2,179,700	0	2,737,600
Utah	2,023,400	502,500	0	0
Oregon	4,547,000	5,660,150	0	0
Nevada and Northeastern CA	9,309,700	5,720,600	5,876,600	0
Total Acres	**20,507,300**	**14,062,950**	**5,876,600**	**2,737,600**

Source: BLM GIS 2015

The ARMPAs also identify Sagebrush Focal Areas (SFAs) on a portion of the landscape. SFAs are a subset of PHMAs (see **Figure 1-3** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas). Across the Great Basin Region, there are 9,076,948 acres of BLM administered SFAs. SFAs correspond to the areas identified by the FWS as GRSG "strongholds" as detailed in an October 27, 2014 memorandum from the FWS Director to BLM Director and Forest Service Chief in response to a request to "identify a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection". (http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf)

This tiered habitat framework provides for a nested or layered conservation design with the goal of providing the greatest ~~protections~~ protections for habitat in PHMAs achieved through: ~~and~~ ~~(1)~~ the strongest limits ~~ed~~on- new surface disturbance – ~~achieved through~~such as (1) no surface occupancy with limited exceptions for fluid minerals development, (2) exclusions (with limited exception) for wind and solar development, (3) avoidance for new rights of way, (4) closures for saleable mineral, with limited exceptions, (5) -priority protection from rangeland fire~~, (6) priority for habitat~~

~~restoration.~~, (7) accelerated efforts to reduce grazing impacts from free-ranging equids, and (7) priority review for compliance with cattle grazing standards for public land allotments, as well as priority for habitat restoration.~~ in SFAs,~~

These conservation prescriptions for the PHMAs provide a high degree of certainty that the integrity of PHMAs can be maintained through management decisions to avoid or minimize additional surface disturbance. In SFAs, maximize protection from new surface disturbance would be achieved by (1) requiring NSO without exceptions for fluid minerals, (2) additional limits on disturbance from mining and related activity by recommending~~-~~ withdrawal from new hardrock mining claims~~,~~for areas of PHMA not already closed to hardrock mining, ~~and a commitment to reduce wild horse and burro populations to Appropriate Management Levels (AML) by 2020~~. Given the “existing high quality sage brush habitat for sage grouse … and highest breeding densities of sage grouse” in the SFAs, or strongholds, as identified by the FWS, the decision to recommend withdrawal of SFAs from future hard rock mining is consistent with the COT recommendation to “Avoid new mining activities and/or any associated facilities within occupied habitats, including seasonal habitats; and avoid leasing in sage-grouse habitats until other suitable habitats can be restored to habitats used by sage-grouse.”

~~p~~

Protection of remaining habitats in GHMAs would be managed consistent with the COT report recommendation ~~-~~to recognize “that important habitats outside of PACs be conserved to the extent possible”. ~~,~~Thus, land allocations and management prescriptions for lands in GHMAs provide for ~~with~~ more flexibility for land use activities that would be designed to minimize impacts on existing GRSG leks. In all GRSG habitat management areas, anthropogenic surface disturbing activities would be mitigated, and degraded landscapes, due to fire or other causes, would be actively restored and protected. ~~with a priority on SFAs, then PHMAs, and then GHMAs.~~ The combination of habitat classifications and land allocation decisions in the ARMPAs will provide the greatest protection for those areas identified as SFAs and meet the stated objective for these areas “where it is most important that the BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species.”

Major components of the attached ARMPAs ~~developed to~~that address the specific threats to the viability of the GRSG, as identified in the USFWS 2010 listing decision and COT r~~R~~eport (many of which were also identified by the BLM’s NTT Report) are listed in **Table 1-3** and summarized below. Throughout the ARMPAs, a particular focus is placed on an “avoidance first strategy” as emphasized in the COT report by limiting new disturbance and maintaining current intact GRSG habitat. This avoidance first strategy is accomplished through identification and allocation of important GRSG habitat and excluding or avoiding surface disturbing activities, appropriately managing grazing, and aggressively suppressing fire that could degrade or fragment remaining GRSG habitat. The plans also include decisions to restore degraded habitat, which although more difficult and requiring a longer time frame, is important to the long-term viability of GRSG. Restoration decisions include specific habitat objectives, and a priority on treating GRSG habitat for invasive species, particularly cheatgrass, and encroaching pinyon and juniper. These decisions are reinforced by Secretarial Order 3336 and the *Integrated Rangeland Fire Management Strategy* which provide a framework, specific actions, and Department-wide priority on managing Federal lands, particularly in the Great Basin, to protect and restore sagebrush-steppe habitat.

Comment [KK28]: Moved this down because the rest are surface disturbance, this is not.

Comment [KK29]: This new text is covered in the sections below about surface protection & habitat improvement – this section was supposed to be just about the designations, to provide context for the next sections. By moving it all up here, should we delete all following sections?

Comment [JRL30]: Correctly characterized?

Comment [KK31]: This is not an RMP thing so should not be included.

Comment [KK32]: I recommend moving all of this down to the surface disturbance section

Comment [KK33]: ?? is this correct

Comment [KK34]: Just to confirm, IHMA & OHMA are never part of this hierarchy?

Comment [KK35]: JL has deleted this, not sure why because it seems pertinent to explain the hierarchy.

Table 1-3
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
All threats	• Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met. • Require and ensure mitigation that provides a net conservation gain to GRSG and its habitat. • Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner. • Apply buffers necessary based on project type and location to address impacts on leks when authorizing actions in GRSG habitat. • Apply Required Design Features (RDFs) when authorizing actions that affect GRSG habitat. • Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.
All development threats, including mining, infrastructure, and energy development.	• PHMA: Implement an anthropogenic disturbance cap of 3% within the Biologically Significant Unit and proposed project analysis areas in PHMA (slight variations to this management component in the State of Nevada only) • PHMA: Apply a disturbance density cap of 1 facility per 640 acres (except in the State of Nevada)
Energy development—fluid minerals, including geothermal resources	• PHMA: Open to fluid mineral leasing subject to a No Surface Occupancy (NSO) stipulation without waiver or modification, and with limited exceptions. In SFAs, a NSO stipulation would be applied without waiver, modification, or exception. In Nevada only, in the portions of the PHMAs outside of SFAs, geothermal projects may be considered for authorization if certain criteria is met. • GHMA: Open to fluid mineral leasing subject to Controlled Surface Use (CSU) and Timing Limitation (TL) lease stipulations (except in the State of Utah where some portions of GHMA are open with standard lease stipulations)
Energy development—wind energy	• PHMA: Exclusion area (not available for wind energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Avoidance area (may be available for wind energy development with special stipulations) (except in the States of Utah and Idaho, where these areas would open to wind energy development)
Energy development—solar energy	• PHMA: Exclusion area (not available for solar energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Exclusion area (not available for solar energy development under any conditions) (except in the States of Oregon and Montana where these areas are avoidance areas for solar energy development and the State of Idaho, where these areas would open to solar energy

Table 1-3
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
	development)
Infrastructure—major ROWs	• PHMA: Avoidance area (may be available for major ROWs with special stipulations) • GHMA: Avoidance area (may be available for major ROWs with special stipulations) (except in the State of Utah where GHMA is open)
Infrastructure—minor ROWs	• PHMA: Avoidance area (may be available for minor ROWs with special stipulations)
Mining—locatable minerals	• SFA: Recommend withdrawal from the Mining Law of 1872
Mining—nonenergy leasable minerals	• PHMA: Closed area (not available for nonenergy leasable minerals)
Mining—salable minerals	• PHMA: Closed area (not available for salable minerals) with a limited exception (may remain open to free use permits and expansion of existing active pits if criteria are met)
Livestock grazing	• Prioritize the review and processing of grazing permits/leases in SFAs followed by PHMA. • The NEPA analysis for renewals and modifications of grazing permits/leases will include specific management thresholds, based on the GRSG Habitat Objectives Table, Land Health Standards and ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis. • Prioritize field checks in SFAs followed by PHMA to ensure compliance with the terms and conditions of grazing permits.
Free-roaming equid management	• Prioritize gathers in SFAs, followed by other PHMAs. • Manage Herd Management Areas (HMAs) in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives. • Prioritize rangeland health assessment, gathers and population growth suppression techniques, monitoring, and review and adjustment of AMLs and preparation of Herd Management Area Plans in GRSG habitat.
Range management structures	• Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. • Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas subject to valid existing rights.
Recreation	• PHMA: Do not construct new recreation facilities unless required for health and safety purposes.

Table 1-3
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
	• Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain. • PHMA & GHMA: OHV use limited to existing routes (routes to be designated through future travel management planning)
Fire	• Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection. • Prioritize post-fire treatments in SFAs, other PHMAs and GHMAs.
Nonnative, invasive plant species	• Improve GRSG habitat by treating annual grasses. • Treat sites in PHMA and GHMA that contain invasive species infestations through an integrated pest management approach.
Sagebrush removal	• PHMA: Maintain a minimum of 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover. • All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and/or juniper expansion	• Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.
Agricultural conversion and exurban development	• GRSG habitat will be retained in federal management.

Comment [KK36]: Matt, I am pointing out that I added this to the table – it was in redline in the last version from me & Jim, but since I moved the table I think the whole table was redline so I just want to be sure you see it.

The ARMPAs were developed based on three range-wide objectives for conserving and protecting habitat: minimizing new and additional surface disturbances, improving habitat conditions, and reducing threats of rangeland fire to GRSG and sagebrush habitat. How the ARMPAs met these objectives is summarized below.

1.5.1 Avoid and Minimize Surface Disturbance

Allocations and Habitat Protection/Surface Disturbance Measures

Comment [KK37]: Are these subheaders needed or can we just let this section flow from paragraph to paragraph?

To avoid or minimize further surface disturbance in PHMAs the ARMPAs either close, exclude, or avoid major new surface disturbing activities. In SFAs, in addition to PHMA decisions described below and shown in **Table 1-3**, ARMPAs apply a no surface occupancy stipulation with no exceptions for oil and gas leasing and recommend these areas for withdrawal from future locatable mineral entry.

The four Great Basin ARMPAs provide land use allocations and management guidance for PHMAs to avoid new disturbance and minimize any disturbance associated with projects that might be developed in PHMA in the future. Allocations to avoid and minimize additional disturbance in PHMA include, fo~~i~~r example, the application of a no surface occupancy (NSO) stipulation associated with any future leasing and development of oil and gas in PHMAs. With the exception of a few areas in Utah and in eastern Nevada, there is low potential for fluid minerals in the Great Basin Region.

Similarly, mineral development is closed in PHMAs for non-energy leasable minerals and saleable minerals, ~~with the exception of~~but not for locatable minerals governed under the 1872 Mining Act. An exception is granted for free use permits and the expansion of existing active pits for ~~mineral~~ saleable minerals ~~material sales~~ and expansion of existing non-energy leasable development. Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses this threat. In Utah, at the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. PHMA is essential habitat for maintaining GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).

Comment [KK38]: I changed this so we used the same name as the previous sentence & Table 3.

Comment [GSD39]: What is the relevance of this statement, do we not have the coal language in the other plans?

Comment [MEM40]: Because energy development is a present and widespread threat to certain populations in UT, I thin k its important to state this. We can remove if needed.

In all PHMAs in the Great Basin Region, renewable energy development (solar and wind) is excluded, with the exception of three areas in southeastern Oregon where an avoidance allocation is applied; and new rights of way and development for transmission lines, pipelines, and related infrastructure is avoided through restrictions on land use authorizations. Where the allocation is avoidance, exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs, unless the development results in a net conservation gain to the GRSG or its habitat.

Comment [GSD41]: Do we need to explain why OR is different here or somewhere else?

Comment [KK42]: Is this three areas or three counties?

Comment [MEM43]: This should be addressed in section 1.6. May need assistance with this rationale.

While restrictions on future development in PHMA are intended to avoid or minimize additional surface disturbance, restrictions on development in GHMA are less stringent and can accommodate a limited amount of disturbance. Disturbance associated with oil and gas development, for example, is subject to a controlled surface use and timing limitation stipulation rather than an NSO stipulation see **Table 1-3** for more details on GHMA management decisions. However, any disturbance is subject to mitigation and should seek to first avoid and then minimize any impacts to GRSG or its habitat, while offsetting unavoidable impacts to a standard that produces a net conservation gain for the species. As noted in the COT report, "Conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur. …If development or vegetation manipulation activities outside of PACs are proposed, the project proponent should work with federal , state or local agencies and interested stakeholders to ensure consistency with sage-grouse habitat needs."

In addition to areas where uses are closed, excluded or avoided, the ARMPAs direct the BLM to proactively prioritize oil and gas leasing and development outside of identified SFAs, PHMAs, and GHMAs in order to encourage new development in areas that would not conflict with GRSG and thus maximize the potential to limit disturbance to remaining GRSG habitat. This approach will also assist developers in reducing the time and cost associated with oil and gas leasing development by avoiding sensitive areas and decreasing the need for compensatory mitigation.

Comment [JRL44]: SHOULD WE CITE FINDINGS IN THE WEST STUDY HERE TO HIGHLIGHT HIGH AND MEDIUM OIL AND GAS POTENTIAL OUTSIDE OF HABITAT?

In general, all forms of new development would be closed, excluded, avoided, or developed only if the resultant effect is a net conservation gain to the GRSG or its habitat, assuring that existing habitat would be protected and providing opportunities through compensatory mitigation to restore degraded habitats. This is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0*, published by the FWS in September 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse." In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation gain for the GRSG.

In addition to major surface disturbing activities such as energy and infrastructure development, the ARMPAs address other identified threats~~activities~~, including improper livestock grazing, wild horses and burros overuse ~~management~~, and recreation. Grazing is the most widespread use of the sagebrush steppe ecosystem in the Great Basin Region. The COT r~~R~~eport recommendation for grazing states, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage- grouse (e.g. shrub cover, nesting cover)." To ensure that grazing continues in a manner consistent with the objective of conserving the GRSG and its habitat, the four Great Basin ARMPAs require the incorporation of GRSG seasonal habitat objectives into grazing permits, consistent with the ecological site potential of the local areas, prioritize the review and monitoring of grazing permits, and take numerous actions to avoid and minimize the impacts of range management structures (see **Table 1-3**).

To address the localized threat due to negative influences of grazing by free-roaming equids (wild horses and burros (WHB)), the BLM will focus on meeting and maintaining WHB Herd Management Areas in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives, including completing rangeland health assessments, prioritizing gathers and population growth suppression techniques, and developing or amending Herd Management Area plans to incorporate GRSG habitat objectives and management considerations. In SFAs and PHMA, the BLM will assess and adjust AMLs through the NEPA process within HMAs when WHBs are identified as a significant causal factor in not meeting land health standards, even if current AML is not being exceeded.

Comment [KK45]: Don't think we can just say maintaining since most are currently over AML

Comment [JRL46]: Should we make note of commitment to bring all SFAs to AML by 2020?

Comment [MEM47]: The 2020 deadline is not mentioned as a management action in the ARMPAs. The language as presented is within all 4 ARMPAs.

To ameliorate the threat from recreational activities, new facilities or expansion of existing facilities (e.g., roads, trails, campgrounds) will not be authorized in PHMA unless the development results in a net conservation gain to GRSG its habitat. In PHMA and GHMA travel would be limited to vehicle routes. Initially, vehicles would be limited to existing routes until implementation travel management planning could be completed to designate routes. Travel management plans, including route inventories, NEPA analysis, and route designation will be completed in a subsequent public planning process.

Disturbance Caps, Density Caps, and Lek Buffers

In addition to the management actions and allocations discussed in detail in the sections above, the ARMPAs limit the amount of anthropogenic disturbances in PHMAs through the use of disturbance caps, density caps and lek buffers. These elements further address threats related to surface disturbances by limiting the amount of habitat impacted and keeping resource uses an appropriate distance~~way~~ from leks. In general, disturbance caps of 3% were established in accordance with the recommendations contained in the COT report. ~~i~~If the 3% anthropogenic disturbance is exceeded on lands (regardless of land ownership) within PHMA in any given Biologically Significant Unit (BSU), no further discrete anthropogenic disturbances (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.) will be permitted within PHMAs in that Biologically Significant Unit. If the disturbance cap is exceeded on all lands (regardless of land ownership) within a proposed project analysis area in a PHMA, then no further anthropogenic disturbance will be permitted until disturbance in the proposed project analysis area has been reduced to be under the cap (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.). The ARMPAs have a few modifications to the disturbance cap: Oregon does not allow more than 1% new anthropogenic disturbance per decade, not to exceed 3% disturbance at any time. In Nevada, exceeding a 3% disturbance cap can occur at the BSU and/or the project level as long as the outcome results in a net conservation benefit as approved by the BLM in accordance with the process described in **Section 1.6**.

Comment [KK48]: Added a sentence to tie this section back to the threats it is addressing.

Comment [JRL49]: WHERE DO WE ADDRESS BSUs AND CALCULATION OF DISTURBANCE WITHIN BSUs? NEED TO DO SO WITH A PARAGRAPH OR REFERENCE TO A FOOTNOTE OR APPENDICE HERE.

~~Limiting Density of Disturbance~~

The ARMPAs incorporate a cap on the density of energy and mining facilities to encourage consolidation of structures and to reduce habitat fragmentation. The cap is set at an average of one facility per 640 acres in PHMA in a project authorization area, consistent with guidance contained in the NTT report. If the disturbance density in the PHMA in a proposed project area is on average less than 1 facility per 640 acres, the analysis will proceed through the NEPA process incorporating mitigation measures into an alternative. If the disturbance density is greater than an average of 1 facility per 640 acres, the proposed project will either be deferred until the density of energy and mining facilities is less than the cap or co-located into an existing disturbed area, subject to applicable laws and regulations, such as the 1872 Mining Law, valid existing rights, etc. The one facility per 640 density decision does not apply to Nevada, as described in **Section 1.6**.

~~Buffering Development Impacts~~

The ARMPAs require that impacts to leks be evaluated for actions requiring NEPA analysis. In addition to any other relevant information determined to be appropriate (e.g. State wildlife agency plans), the BLM will assess and address impacts from certain activities using the lek buffer-distances as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). The lek buffer distances required vary by type of disturbance (road, energy development, infrastructure, etc.) and are fully described in Appendix X of the ARMPAs.

The lek buffer distances will be applied as required conservation measures to fully address the impacts to leks as identified in the NEPA analysis. Impacts should be avoided by locating the action outside of the applicable lek buffer-distance(s) as defined in the ARMPAs. In PHMA, if the action cannot be located outside of the buffer-distance, the BLM may approve actions in PHMAs that are within the applicable lek buffer-distance only if a different buffer distance offers the same or greater level of protection to GRSG and its habitat. In GHMAs actions may be approved within the applicable lek buffer distance only if a different distance offers the same or a greater level of protection to GRSG and its habitat, including conservation of seasonal habitat outside of the analyzed buffer area; or impacts to GRSG and its habitat are minimized such that the project will cause minor or no new disturbance (ex. co-location with existing authorizations) and any residual impacts within the lek buffer-distances are addressed through compensatory mitigation measures sufficient to ensure a net conservation gain. This approach to determining relevant lek buffer distances is consistent with the COT recommendation that "conservation plans should be based on the best available science and use local data on threats and ecological conditions."[4]

Required Design Features

Required Design Features (RDFs) and Best Management Practices (BMPs) are required for certain activities in all GRSG habitat, including PHMA, GHMA, IHMA in Idaho and OHMA in Nevada. RDFs establish the minimum specifications for certain activities to help mitigate adverse impacts. However, the applicability and overall effectiveness of each RDF cannot be fully assessed until the project level when the project location and design are known. Because of site-specific circumstances, some RDFs may not apply to some projects (e.g., a resource is not present on a given site) and/or may require slight variations (e.g., a larger or smaller protective area). RDFs and BMPs have been developed for oil and gas

---

[4] COT report. p 34

development, infrastructure, range developments, and other surface disturbing activities and are fully described in Appendix X of the ARMPAs.

1.5.2 Habitat Mitigation and Restoration, Monitoring and Adaptive Management~~Improving Habitat Conditions~~

In addition to ~~improving~~ prescribing land allocations and- managing~~ement of~~ resource uses ~~and~~ to minimize and avoid~~ing~~ further surface disturbance, the ARMPs/ARMPAs identify management actions to promote the ~~restoration and~~ mitigation and restoration ~~improvement~~ of GRSG habitat. ~~The ARMPAs also describe a~~ M~~m~~itigation for habitat disturbing resource uses will ~~program, which~~ follow~~s~~ the avoid, minimize, and compensate mitigation hierarchy. ~~(See **Section 5** for more information.)~~ Where compensatory mitigation is required to offset unavoidable impacts, habitat restoration activities will be developed ~~in coordination with the states,~~ to provide ~~for habitat restoration activities that produce~~ a net conservation gain for the GRSG.

During the implementation of the ARMPs/ARMPAs, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in GRSG habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation; ~~Wyoming will apply a net conservation gain standard to actions in PHMA only~~. This will be achieved by avoiding, minimizing, and compensating for unavoidable impacts by applying beneficial conservation actions to offset remaining impacts associated with the action. This standard is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0* published by the FWS in September, 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse"[5]**.** Mitigation will follow the regulations from the White House Council on Environmental Quality (CEQ) (40 CFR 1508.20; e.g. avoid, minimize, and compensate) and be implemented on BLM-managed lands in a manner consistent with Departmental guidance for landscape mitigation pursuant to Secretarial Order 3330[6]. If impacts from BLM and Forest Service management actions and authorized third party actions result in habitat loss and degradation that remain after applying avoidance and minimization measures (i.e. residual impacts), then compensatory mitigation projects will be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation.

Within 90 days of the issuance of the Record of Decisions, BLM will establish WAFWA Management Zone GRSG Conservation Team, including members from the respective states, Forest Service, USFWS, NRCS, and other local governments. This team that will develop a WAFWA Management Zone Regional Mitigation Strategy to inform the NEPA decision making process including the application of the mitigation hierarchy for BLM and Forest Service actions and third party authorizations that result in habitat loss and degradation. These regional mitigation strategies will contribute to GRSG habitat conservation by reducing, eliminating, or

Comment [MEM50]: Should we add a reference to adaptive management and monitoring?

Comment [KK51]: This section did not quite flow, so I reworked it a bit

Comment [KK52]: I think this reference should stay.

Comment [KK53]: Recommend moving down to mitigation section

---

[5] USFWS. Greater Sage Grouse Range-Wide Mitigation Framework: Version 1.0. September 3, 2014.

[6] Secretarial Order 3330. Improving Mitigation Policies and Practices of the Department of the Interior. October 2013.

minimizing threats and compensating for residual impacts to GRSG and its habitat~~.~~, the BLM will establish a WAFWA Management Zone GRSG Conservation Team to help guide the conservation of GRSG. The zonal mitigation strategy will be developed within one year of the issuance of the Record of Decisions.

Comment [JRL54]: CONFUSING – ONE TEAM DEVELOPS OVERALL STRATEGY THEN TEAMS DEVELOP REGIONAL STRATEGIES? OR ONE TEAM DOES IT ALL? Why are the WAFWA zone teams as opposed to Sage Grouse Management zone teams?

KK: move to mitigation section

~~In addition to improving management of resource uses and avoiding further surface disturbance, the ARMPAs identify management actions to promote the restoration and improvement of GRSG habitat~~, ~~Decisions related to improving and restoring habitat particularly addressing the threats of invasive species, pinyon and juniper expansion, as well as climate change. As with the management of uses, habitat management, restoration, and improvement action is prioritized first in SFAs, followed by PHMA, and then GHMA.~~

Comment [KK55]: Need to get the hierarchy of SFA, PHMA, GHMA into this section somewhere

~~The~~ARMPs/ ARMPAs ~~also~~ specify habitat objectives necessary for GRSG, used both to evaluate grazing and wild horse and burro management and for restoration purposes. These habitat objectives were developed for each of the GRSG's life history stages based on the ecology within each ARMPA's sub-region. These objectives will be used to meet the applicable land health standard in GRSG habitats. They also include maintaining a minimum of 70% of lands capable of producing sagebrush with 10-30% canopy cover, and address species richness and composition, as well as meeting land health standards considering the ecological potential for the site. ~~These habitat objectives are a core component of the adaptive management and monitoring strategy (see section 6 for more information). The ARMPA adaptive management and monitoring strategy provides for specific monitoring of GRSG and its habitat. The data collected is used to evaluate the effects of authorized uses, restoration, and other activities to determine if unexpected impacts to GRSG are occurring that require changes to management to meet the objectives.~~

Comment [JRL56]: DOESN'T WORK FOR ME!

Comment [KK57]: Tying adaptive management and monitoring to this section . . .

The ARMPAs also include specific decisions to improve habitat conditions and meet the habitat objectives related to treatment and removal of invasive annual grasses and the removal of encroaching pinyon juniper in SFA, PHMA, and GHMA, and restoration of degraded landscapes, including those impacted by fire events. ~~and post-fire restoration.~~

The COT identified wildfire and conversion of sagebrush habitat to invasive annual grass-dominated vegetative communities as two of the primary threats to the sustainability of GRSG in the Western portion of the species range (i.e., the Great Basin). The proposed LUPs contain a framework that provides a consistent approach to conduct assessments to identify priority habitat areas and management strategies to reduce the threats to GRSG resulting from impacts of invasive annual grasses, wildfires, and conifer expansion (FIAT 2014). To assist in addressing these threats, the Fire and Invasive Assessment Tool (FIAT) was developed to assess the major threats to the sagebrush-steppe in order to conserve the GRSG and its habitat. The purpose of the FIAT is to identify priority habitat areas and management strategies to reduce the threats to GRSG resulting from impacts of invasive annual grasses, wildfires, and conifer expansion. The FIAT is a process that uses the best available information from many disciplines including ecology, biology, soils, fire science as part of a strategic framework. The cornerstone of the FIAT protocol is recent scientific research on resistance and resilience of Great Basin ecosystems (Chambers, et al., 2014b). The final FIAT process report was completed in June 2014 by the Fire and Invasive Assessment Team. The BLM, the Forest Service, and FWS agreed to incorporate this approach into the final GRSG EISs. The FIAT is also a key element of the

Integrated Rangeland Fire Management Strategy, identifying focal areas for priority actions in fire and fuel management.

The FIAT process:

- Identifies important GRSG occupied habitats and baseline data layers to define and prioritize GRSG habitats.
- Assesses their resistance to invasive annual grasses and resilience after disturbance.
- Prioritizes focal habitats for conservation and restoration.
- Identifies geospatially-explicit management strategies to conserve GRSG habitats.

BLM ARMPs/ describe goals, objectives, and management actions ~~and Forest Service LRMPs describe desired conditions, objectives, standards, and guidelines~~ to conserve GRSG, but do not provide specificity related to project prioritization, extent, and location, which is information important to the 2015 FWS listing decision. As such, FIAT products, in conjunction with the Integrated Rangeland Fire Management Strategy, fulfill a key role by providing quantified descriptions of future conservation actions to inform the GRSG listing decision to increase the efficacy of fire management efforts.

Comment [KK58]: This should probably be largely moved to the fire section below. Although invasive species treatments & PJ removal are not limited to fire priority areas, so I think some of that discussion still belongs here.

~~Also important to responding to the threat of fire and invasive plant species is the FWS-sponsored project with WAFWA that assembled an interdisciplinary team to provide additional information on wildland fire and invasive plants and developed strategies for addressing these issues. (Mayer et al, 2013) The FWS-sponsored project is based, in part, on NRCS soil surveys that include geospatial information on soil temperature and moisture regimes associated with resistance and resiliency properties. While this assessment is applicable across the range of GRSG, the analysis is limited to WAFWA GRSG Management Zones III, IV, and V (roughly the Great Basin region) because of the significant issues associated with invasive annual grasses and the high level of wildfires in this region.~~

Comment [KK59]: Not pertinent to the BLM ROD??

With regard to the threat of climate change, the proposed ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the *Integrated Rangeland Fire Management Strategy* will further this effort. The Fire and Invasives Assessment Team (FIAT) assessments that inform that ARMPAs and supported the development of the *Integrated Rangeland Fire Management Strategy* are specifically designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). Additionally, by limiting or eliminating anthropogenic surface disturbance, especially in the SFAs, ensuring the integrity of the PHMAs, and restoring habitat through fuels management, post-fire restoration, and mitigation efforts, connectivity and availability of sagebrush habitat are expected to increase thus contributing to increased climate resilience.

The COT noted that "a monitoring program is necessary to track the success of conservation plans and proactive conservation activities. Without this information, the actual benefit of conservation activities cannot be measured and there is no capacity to adapt if current management actions are determined to be ineffective." The ARMPAs monitoring strategy has two parts: (1) implementation monitoring (i.e., are decisions being implemented in a timely manner, are actions taken consistent with the plan decisions), and (2) effectiveness monitoring (i.e., are the decisions and implementation actions achieving the desired conservation goals). Through effectiveness monitoring, BLM can answer questions about how decisions and actions impact GRSG habitat. Understanding the effectiveness and validating results of ARMPAs and management decisions is an important part of measuring performance under the Government Performance Results Act. For example, riparian condition is a primary measure for ARMPA effectiveness (see WO IM 2010-101). Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, size of patches, etc.). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by state wildlife agencies and other partners, will allow linking real or potential habitat changes (from both natural events and management actions) to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to ameliorate negative effects with appropriate conservation actions.

Each proposed LUP includes an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are not specific to any particular project, but identify habitat and population thresholds. Triggers are based on the two key metrics that are being monitored - habitat loss and/or population declines.

Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the proposed ~~LUPs~~ARMPAs, the BLM ~~and Forest Service~~ response is to apply more conservative or restrictive conservation measures to mitigate for the specific causal factor in the decline of populations and/or habitats, with consideration of local knowledge and conditions. In each proposed LUP, a soft trigger begins a dialogue between the state, FWS, and the BLM ~~or Forest Service~~ to see if the causal factor can be determined and what implementation-level activities can be used to reverse any trend. These adjustments will be made to preclude tripping a "hard" trigger (which signals more severe habitat loss or population declines). Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the BLM ~~and Forest Service proposed LUPs~~ARMPAs. In the event that new scientific information becomes available demonstrating that the hard trigger would be insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM ~~and Forest Service proposed LUPs~~ARMPAs, the BLM ~~and/or Forest Service~~ will immediately assess what further actions may be needed to protect GRSG and its habitat and ensure that conservation options are not foreclosed. This could include a formal directive such as an IM or a plan amendment, which, to the extent that it is supported scientifically, may be drawn from the range of alternatives analyzed in the development of the ~~proposed LUPs~~ARMPAs.

Comment [KK60]: This whole section needs to move to the monitoring & adaptive management section below – as I understand it from Matt, this needs to be its own section in the ROD.

~~With regard to the threat of climate change, the proposed ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the *Integrated Rangeland Fire Management Strategy* will further this effort. The Fire and Invasives Assessment Team (FIAT) assessments that inform that ARMPAs and supported the development of the *Integrated Rangeland Fire Management Strategy* are specifically designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). ~~fuels management, post-fire restoration, and mitigation efforts, connectivity and availability of sagebrush habitat are expected to increase thus contributing to increased climate resilience.~~

1.5.3 Reducing Threats of Rangeland Fire to GRSG and Sagebrush Habitat

The COT emphasized that " rangeland fire ~~o~~ (both lightning-caused and human-caused fire) in sagebrush ecosystems is one of the primary risks to the greater sage-grouse, especially as part of the positive feedback loop between exotic invasive annual grasses and fire frequency". For this reason, the ARMPAs ~~ameliorate the threat from fire, the ARMPs~~ seek to fight the spread of cheatgrass and other invasive species, position wildland fire management resources for more effective rangeland fire response, and accelerate the restoration of fire-impacted landscapes to native grasses and sagebrush. Prescribed fire will not be used unless necessary to facilitate site preparation for restoration of GRSG habitat. The BLM *Greater Sage Grouse Invasive Annual Grasses & Conifer Expansion Assessment* (FIAT 2014) modeled conifer expansion for PACs to provide an initial stratification to determine where conifer removal would benefit important sagebrush habitats. This information is being used to identify and design projects to change vegetation composition and/or structure to modify potential fire behavior for the purpose of improving fire suppression effectiveness and limiting fire spread and intensity due to invasive grasses and conifer encroachment. Consistent with this assessment, the BLM ARMPAs include management actions to remove invading conifers and other undesirable species, and prioritize vegetation treatments closest to occupied GRSG habitats and near occupied leks. Through guidance in the proposed ARMPAs supplemented by the *Integrated Rangeland Fire Management Strategy*, a commitment has been made to address the invasion and expansion of cheatgrass, medusa head, and other invasive grasses through expanded efforts to treat impacted acres and to accelerate and expand efforts to restore lands impacted by fire with native grasses and sagebrush seedlings. Efforts are underway to increase the acreages to be treated with chemical and biological agents to kill and stem the spread of invasive species and to accelerate the registration of other biologicals useful in addressing the threat of cheatgrass invasion.

In addition to and complementing the ARMPAs described in this ROD, Secretarial Order 3336 on Rangeland Fire made clear that "**protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, priority GRSG habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department".** (emphasis added) The strategy places a Departmental priority on activities to prevent, suppress, and restore fire-impacted landscapes in areas identified by the Fire and Invasives Assessment Tool (FIAT) in priority habitat, using recent information derived from a report prepared by WAFWA to assist in addressing the threat of rangeland fire. The FIAT process, applying recent science, identified highly resistant and resilient landscapes to target fire management activities to these most important lands. In addition, through the issuance of a Leaders' Intent letter, signed by the Secretaries of Agriculture and the Interior, rangeland fire was identified as an "additional priority" for the firefighting community in making strategic decisions with regard to the allocation of resources for firefighting in 2015. Additional resources have been allocated and will be targeted to fuel treatments (including invasive species control), suppression (through the prepositioning of fire-fighting resources and the training of additional Rural Fire Protection Associations, local volunteer firefighters, and veteran fire fighters), and habitat restoration in these areas. Firefighting assets (aircraft, firefighters and related equipment) will be located near areas of high priority for rangeland fire.

1.6 Unique Aspects of the Great Basin ARMPAs

Comment [MEM61]: Still need input from Sarah G here related to the rationale as to why these differences exists.

The ARMPAs and their associated environmental impact statements were developed through four ~~separate~~ planning efforts across the Great Basin Region (as described in **Section 1.1**). A landscape approach was used to create cohesive management across the range of GRSG, while also using the subregional plans to accommodate differences in resource conditions, degree of threats, and state management approaches. ~~BLM's land use planning process is a highly collaborative process, involving local cooperating agencies, stakeholders, and members of the public. As a result of conducting four separate planning efforts, each sub-region received unique comments and feedback from their differing cooperating agencies, stakeholders, and interested members of the public. These comments were used to develop the ARMPAs and as a result, the management direction presented in each of the attached ARMPAs addresses sub-regional conditions and management. In addition, a~~As a result of the varying subregional threats, ~~that were presented to local populations~~ (refer to Table 1-2), conditions, and management, each sub-region, in collaboration with their local cooperators and considering public comments, adapted the range-wide landscape-management strategy ~~approach~~ to address these differences while ~~crafting different approaches to~~ meeting the overall ~~purposed and need~~ objective to conserve, enhance, and restore GRSG and their habitats. Below is a brief description of the unique aspects of each of the Great Basin sub-regional ARMPAs.

Idaho and Southwestern Montana

The Idaho and Southwestern Montana ARMPA adopted specific aspects of the State of Idaho's Conservation Plan for GRSG. The most ~~important varying~~significant aspect adopted from the State's plan is a third tier of habitat management area, Important Habitat Management Areas (IHMA). IHMA are BLM-administered and National Forest System lands that provide a management buffer for PHMA and connect patches of PHMA. I-HMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. In a landscape that is most threatened by fire and invasive species, this three-tiered approach allows land managers to focus suppression and restoration resources on those areas of highest importance while providing an acceptable additional level of flexibility in IHMA and GHMA since development is not as great a threat to habitat in the state. The three tiers ~~This three-tiered approach~~ also serve~~s~~ as the foundation for an adaptive management approach that includes habitat and population hard and soft triggers ~~in areas most valuable to the GRSG~~that when hit require ~~and the~~ shifting ~~of~~ IHMA to PHMA ~~when triggers are hit~~to maintain sufficient PHMA to support populations. The Idaho ARMPA also includes a slightly different disturbance calculation, as described in Appendix X of the attached Idaho and Southwestern Montana ARMPA. The ARMPA ~~also~~ applies land use planning allocation decisions for certain distances from leks, which is a deviation from the other Great Basin ARMPAs.

Nevada and Northeastern California

The Nevada portion of the Nevada and Northeastern California ARMPA adopts key elements of the State of Nevada Greater Sage-Grouse Conservation Plan (State of Nevada 2014) and the State of Nevada Conservation Credit System (Nevada Natural Heritage Program and Sagebrush Ecosystem Technical Team 2014) by establishing conservation measures and focusing restoration efforts in the same key areas most valuable to the GRSG. ~~Ad~~The Nevada plan allows for an exception to geothermal NSO which is an energy development priority for the state and is projected to create very limited disturbance in predictable areas over the life of the plan. For those reasons, after conversation with the USFWS, the BLM determined that this exception is consistent with overall conservation objectives. The ARMPA also adopts a Disturbance Management Protocol (DMP) to provide for a 3% limitation on disturbance, except in situations where a biological analysis indicates a net conservation gain to the species, with concurrence from the BLM, State of Nevada, and FWS. The plan provides for this exception due to unique factors in Nevada including the lower threat posed by development versus fire and invasive species, the extremely

Comment [JRL62]: THESE NEED TO BE INCLUDED AS APPENDICES TO THE ROD TO MAKE IT EASIER TO READ THE ROD AS A COMPLETE DOCUMENT.

KK: they will be attached to the ROD as appendices to each RMP.

Comment [KK63]: I think we should be more explicit about this & state clearly how it differs; this sentence is a bit opaque

Comment [JRL64]: What does this mean?

Comment [KK65]: GSD: don't know how to explain different disturbance calculation & allocation buffers.

Comment [KK66]: GSD: BLM needs to explain why we made limited use of CCS

Comment [KK67]: The list from Stephanie also included :unique disturbance approach – is that different from the DMP? If it is, GSD: BLM needs to explain limited nature of certain habitat types (including wet meadows and riparian areas) located mostly on private land, and the development of strong mitigation tools in the state which may make disturbance on publicly-managed PHMA along with protection for higher value habitat in the conservation interest of the species under certain circumstances. Given those factors and the procedural protections in place, the BLM determined that this approach is consistent with conservation objectives.~~ditionally, other unique aspects of the Nevada and Northeastern California ARMPA includes an NSO exception to geothermal leasing and development and a separate Disturbance Management Protocol (DMP) that is intended to provide for a 3% limitation on disturbance, except in situations where a biological analysis indicates a net conservation gain to the species, with concurrence from the BLM, State of Nevada, and FWS~~. The Nevada and Northeastern California ARMPA also does not have density cap, which is present in the three other Great Basin Region ARMPAs.

Comment [JRL68]: NEED TO EXPLAIN AND JUSTIFY –OTHERWISE MIGHT SEEM "ARBITRARY AND CAPRICIOUS"

KK: see revised text from GSD

Comment [JRL69]: NEED TO EXPLAIN WHY; GSD: BLM needs to explain

Comment [KK70]: Stephanie's list included "updated map" GSD: BLM must explain

Utah

The Utah ARMPA adopts the key elements of the GRSG conservation plans or directives developed by the State of Utah (Conservation Plan for Greater Sage-Grouse in Utah) and the State of Wyoming (Executive Orders 2011-05 and 2013-3), which establishes unique conservation measures for protecting GRSG and also focuses restoration within key areas deemed most valuable to GRSG. Additionally, within GHMA, the Utah ARMPA allows for wind energy and high voltage transmission ROW development (consistent with the mitigation framework for the ARMPA), as well as oil and gas development, which is open with standard constraints. The ARMPA provides additional flexibility for development in GHMA because 95% of the breeding GRSG in Utah are within PHMAs and understanding appropriate protections such as lek buffers and required design features will be analyzed and applied at the project-implementation stage. Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses this threat. In Utah, at the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. PHMA is essential habitat for maintaining GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).

Comment [JRL71]: NEED TO CLARIFY – PERMITTED BY THE MITIGATION FRAMEWORK OR REQUIRING MITIGATION CONSISTENT WITH THE FRAMEWORK?

Comment [KK72]: Stephanie's list included: allocation/habitat exception language for GHMA – if that is different from what is here, GSD: BLM should explain

Comment [JRL73]: NEEDS CLARIFICATION

Oregon

The Oregon ARMPA adopts key elements of the Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat (Hagen 2011) which establishes unique conservation measures for protecting GRSG and also focuses restoration within key areas most valuable to GRSG. In addition, the BLM plan adopts the unique disturbance cap approach developed by the state in which disturbance is capped at 1% per decade. The BLM Oregon plans provide additional flexibility for wind development in PHMA in the three counties that have SFAs by allowing for avoidance rather than exclusion in that part of PHMA that is outside of the SFAs. The BLM adopted this flexibility after coordination with the USFWS because of the priority the State of Oregon has placed on wind development in conjunction with the more rigorous disturbance cap approach and adaptive management triggers adopted by the Oregon plan. Avoidance for solar and wind in three SE counties in PHMA. Due to these factors, the BLM finds these limited areas of flexibility for wind development are consistent with overall conservation objectives.~~Also, three areas in southeastern Oregon within PHMA are not designated as exclusion areas to solar and wind energy development, but are instead avoidance areas to these types of development. This exception would not apply to areas designated as SFAs in this portion of southeastern Oregon.~~.

Comment [KK74]: JL: need to name the 3 counties

Comment [JRL75]: YES, NEED TO NAME

[SUGGEST INSERTION OF A SUMMARY TABLE HERE FROM THE LANDSCAPE REPORT THAT SHOWS DIFFERENCES BETWEEN OVERALL REGIONAL DIRECTION AND STATE-SPECIFIC MODIFICATIONS TO REGIONAL DIRECTION FOR THE 4 SUBREGIONAL PLANS!!!]

Formatted: Font: 14 pt, Bold

1.7 Summary of the BLM's National GRSG Planning and Conservation Strategy

Collectively, the BLM Great Basin subregional ARMPAs provide a landscape-level, science-based, comprehensive, coordinated, collaborative strategy for addressing previously identified threats to the GRSG and a means to remedy the need for "regulatory certainty" leading to the 2010 "warranted but precluded" finding by the FWS. ,

These plans reflect over a decade of research, analysis and recommendations for GRSG conservation produced by the WAFWA, the NTT, and the COT. Each of these reports was developed by a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research.

The COT report provided the primary blueprint for development of the GRSG conservation strategy embodied in the 15 sub-regional ARMPAs/ARMPs that will amend or revise 78 BLM and 20 Forest Service plans. Since the COT was chartered to provide guidance for the development of state and federal land management plans by the FWS with the backing of the Sage Grouse Task Force, this is appropriate.

Comment [JRL76]: ARE THESE NUMBERS CORRECT AND HOW MANY PLANS ARE WE NOW TALKING ABOUT?

In addition to these seminal documents, the Fire and Invasives Assessment Team (FIAT) report[7], the USGS compilation and summary of published scientific studies that evaluate the influence of anthropogenic activities and infrastructure on GRSG populations -- *Conservation Buffer Distance Estimates for Greater Sage-Grouse—A Review*, and the *Integrated Rangeland Fire Management Strategy: Final report to the Secretary* (Manier et al, 2014; DOI 2015b) provided important guidance in the development of critical aspects of the proposed ARMPAs/ARMPs and the overall GRSG landscape-level conservation strategy.

In combination with the sage-grouse conservation actions taken by the individual states within the remaining range of the bird and separate but connected initiatives to address the threat of rangeland fire, to curb the continuing spread of non-native invasive grasses, and to promote conservation measures to benefit the Greater sage-grouse on private lands, the BLM and Forest Service proposed ARMPAs/ARMPs are an essential component of the effort to conserve GRSG and its habitat and obviate the need for a listing of the species under ESA. Combined, the 15 sub-

---

[7] Greater Sage-Grouse Wildfire. Invasive Annual Grasses, and Conifer Expansion Assessment. June 2013.

regional proposed ARMPAs/ARMPs would affect nearly half of the remaining habitat for the species.

Comment [JRL77]: Numbers? CHECK!

The BLM ARMPAs/ARMPs are the product of extensive coordination, including the active engagement of the FWS in helping to inform land allocation and related management decisions by the land management agencies. They also benefit from strong collaboration with the states and reflect the unique landscapes, approaches, and priorities in each. While this has added to the challenge of developing a complete, comprehensive, and coordinated conservation strategy, it has also strengthened the proposed ARMPAs/ARMPs and is likely to increase the commitment of all partners to implementation upon completion.

In the introduction to the COT report, the state and federal partners who authored the report reiterated their charge,

> "… the development of range-wide conservation objectives for the sage-grouse to define the degree to which threats need to be reduced or ameliorated to conserve sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future."

And, in his transmittal letter accompanying the final report, FWS Director Dan Ashe reaffirmed this charge, "I asked the team to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. … Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels."[8]

The BLM ARMPAs/ARMPs were directly address the specific threats to the viability of the species identified in the COT report (many of which were also identified by the BLM NTT).

Land Allocations for Habitat Protection

The COT emphasized the need to avoid or minimize additional disturbance in PACs (which largely coincide with PHMAs in the proposed LUPs). "Stop the bleeding" was the emphatic plea of the COT with regard to the need to protect the highly valued PACs. As previously noted, the COT stated, "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation." Specifically, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT recommended an "avoidance first strategy" and stressed that "threats in PACs must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

In response, the BLM ARMPAs/ARMPs include goals and objectives and land use allocations and management actions for BLM-administered surface and subsurface lands and

---

[8] COT report. Transmittal letter by Dan Ashe. February 2013.

resources in PHMAs to retain areas of existing habitats and to avoid new disturbance. Furthermore, the proposed plans avoid, minimize, and offset any unavoidable impacts associated with disturbance from projects that might be developed in PHMA in the future, subject to valid existing rights.

Land allocations to avoid and minimize additional disturbance in important habitat areas (identified as PHMAs in most ARMPAs/ARMPs) included some closures (primarily in portions of the Lander LUP) but rely primarily on the use of no surface occupancy (NSO) associated with any future development of oil, gas, and geothermal reserves in PHMAs for most proposed LUPs (with the exception of core areas in the Wyoming proposed LUPs and geothermal leasing in Nevada). Renewable energy development (solar and wind) is excluded in the PHMAs, in most proposed LUPs, with avoidance used in some proposed LUPs, particularly in Wyoming and Oregon.

Similarly, mineral development, with the exception of locatable minerals governed under the 1872 Mining Act, is closed in the large majority of PHMAs for non-energy leasable minerals and saleable minerals. An exception was granted for free use permits and the expansion of existing active pits for mineral material sales. The BLM will determine at the time of a new coal lease or lease modification whether the lease application area is "unsuitable" for all or certain coal mining methods recognizing that PHMAs are “essential habitat” for purposes of suitability determinations.

New rights of way for transmission lines, pipelines, and related infrastructure development in PHMAs will be avoided through restrictions on land use authorizations in the proposed LUPs. Exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs unless there is a net conservation gain for GRSG.

In general, all forms of new development – from energy, to transmission lines, to recreation facilities and grazing structures would be excluded, avoided, or developed only if the resultant effect is neutral or beneficial to the GRSG in PHMA. In all instances, whether in PHMA or GHMA (except in Wyoming only in PHMA), any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation benefit for the GRSG.

While the COT report identified PACs as “crucial building blocks of a successful conservation strategy”, the COT also emphasized that “sage-grouse habitats outside of PACs may also be essential… [and therefore] conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities.” Consistent with this guidance, restrictions on development in GHMA are less stringent and can accommodate a limited amount of disturbance. Disturbance associated with oil and gas development, for example, is subject to seasonal and timing restrictions rather than NSO with limited exceptions and GHMA is generally an avoidance area for renewable energy rather than an exclusion area. However, any disturbance is subject to mitigation and should seek to first avoid, then minimize any adverse effects to habitat while offsetting unavoidable impacts to a standard that produces a net conservation gain for the species (except in Wyoming).

The proposed ARMPAs/ARMPs provide an added element of habitat protection for GRSG strongholds identified by the FWS in a memo to Director Kornze and Chief Tidwell in October, 2014[9]. The proposed LUPs designate a subset of PHMA as Sagebrush Focal Areas (SFAs) to be administered by the BLM and the Forest Service. SFAs consist of areas of largely intact priority habitat, primarily under federal management, with greater GRSG bird densities and high resistance and resilience to fire. As the FWS communicated to BLM and Forest Service leadership that "[s]trong, durable, and meaningful protection of federally administered lands in these areas will provide additional certainty and help obtain confidence for long term sage grouse persistence," land allocations for these areas were intended to avoid future surface disturbance to the maximum extent. Land allocations in the SFAs require NSO with no exceptions for oil, gas, and geothermal development. The proposed plans will also include a recommendation that these areas be withdrawn by the Secretary from mineral entry under the 1872 Mining Act (in the RODs of proposed Forest Service plans). SFAs will also be prioritized for restoration and conservation action. While the SFAs have minimal land surface disturbance and, based on existing, available data, limited mineral potential, valid existing rights – as in all habitat – will be recognized and be able to proceed in accordance with their legal rights.

Management Direction, Prioritization, and Mitigation

In addition to land allocations to protect SFAs, PHMAs, and GHMAs, the ARMPAs/ARMPs guide other uses of these landscapes to meet COT objectives consistent with existing, authorized uses of GRSG habitats and the sagebrush landscape.

Grazing is the most widespread use of the sagebrush steppe ecosystem. In order to ensure that grazing continues in a manner consistent with the objective of conserving the GRSG, the proposed LUPs will require the incorporation of GRSG habitat requirements into the vegetative management objectives for proposed actions, including authorizations for grazing allotments, consistent with the ecological potential of the landscape. The COT recommends, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for GRSG (e.g. shrub cover, nesting cover)."

The proposed LUPs place a priority on the review and update of grazing allotment management to incorporate standards, guidelines, and habitat objectives, and to ensure that they are being met consistent with ecological site potential. Priority will be given, first, to the review of allotments in SFAs, then PHMAs, followed by GHMA; focusing first on riparian and wet meadows, and, if the standards, guidelines, or habitat objectives are not being met due to improper grazing, to work with the permittee to make progress towards meeting them. Anticipated increases in BLM funding for implementation of the proposed LUPs will support additional conservation and restoration actions, as well as monitoring, to continue to ensure healthy public land grazing consistent with the conservation of GRSG habitat.

---

[9] Memorandum from Dan Ashe to Director, BLM and Chief, USFS, "Greater Sage Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important landscapes. October 27, 2014.

With regard to future leasing and development for oil and gas, the proposed LUPs recognize the value of encouraging future development in areas of low conflict with GRSG habitat. Analysis of existing and available data by the BLM indicates that a majority of the acres of land with high and medium potential for oil and gas development in the western U.S. are outside of identified GRSG habitat. To benefit GRSG conservation efforts and to assist developers in reducing the time and cost associated with oil and gas leasing and development in areas of likely conflict with other multiple-use values, the BLM will prioritize new leasing in areas outside of SFAs, PHMAs, and GHMAs.

Fire represents the greatest threat to GRSG survival in the Great Basin region. Recognizing the nature and extent of this threat, the ARMPAs/ARMPs provide specific guidance for improving efforts to reduce the risk of GRSG habitat loss to wildfire, including fire prevention and the restoration of habitats impacted by fire. However, to develop a more complete and comprehensive strategy for dealing with this threat, the Department of the Interior and the BLM convened a conference in November, 2014 of scientists, state and federal officials, leaders in the fire community, and an array of stakeholders to discuss ways to improve the efficiency and effectiveness of rangeland fire management. The conference led to Secretarial Order 3336 and recognition that,

> "Protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, greater sage-grouse habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department. Allocation of fire management resources and assets before, during, and after wildland fire incidents will reflect this priority, as will investmentsrelated to restoration activities.[10]

In accordance with that Order, a strategy for fire prevention, suppression, and post-fire restoration was developed and delivered to the Secretary in May 2015. The Order and subsequent report, *An Integrated Rangeland Fire Management Strategy: Final Report to the Secretary of the Interior*, directed substantial changes in policy and management direction affecting all aspects of the rangeland fire management program – from better coordination between resource managers and fire management officers; to the identification and prioritization of prevention, suppression, and restoration efforts in SFAs, PHMAs, and GHMAs; to the commitment of additional equipment and crews for rangeland firefighting; to additional funding and policy direction to improve post-fire restoration; to the completion of an initiative to collect, store, and better utilize native seed and sagebrush in post-fire restoration of sagebrush steppe ecosystems. This effort, and the initiative to fight the spread of non-native invasive species that contributes to higher rangeland fire risk (e.g. cheatgrass) discussed below, hold the potential to fundamentally change how rangeland fire is managed to benefit sagebrush ecosystems and GRSG habitat.

Comment [JRL78]: Add link

The COT report – and other more recent research and analysis – amplify concern for the contribution of cheat grass and other invasive species to the loss of GRSG habitat associated with increased fire frequency and intensity. Work initiated by the WAFWA and based on recent research by Chambers (Chambers et al, 2014b) led to the Fire and Invasives

---

[10] Secretarial Order 3336. Rangeland Fire Prevention, Management and Restoration. January 2015.

Assessment Tool[11] and a subsequent assessment that identified areas of resistance and resilience to fire. This information is leading to targeted and aggressive efforts to reduce the risk and impacts of rangeland fire that could impact hundreds of thousands of acres of GRSG habitat, as well as restore areas with high potential to be resilient to the impacts of climate change and subsequent rangeland fires. The BLM is also committed to and accelerating the registration and use of chemical and biological agents to stem the spread of cheatgrass and other invasive species. In addition, by using the FIAT assessments and overlaying maps of SFAs, PHMAs, and GHMAs, land managers from all levels of government can more efficiently allocate and use fire resources at initial attack, to stop fire early and prevent catastrophic habitat loss.

Even prior to completion of the FIAT assessment, BLM shifted funding for fuels management to protect landscapes of importance to the GRSG. Under the FY2014 Omnibus Appropriation, BLM prioritized the funding of treatments and activities within each state that benefit GRSG.

In 2014, treatment and activities which identified GRSG as a species of interest accounted for $28,328,658 in funding and treatments of 241,343 acres. Prior to FY2014, numerous other examples of positive impacts from the Fuels Management Program exist. The table below summarizes (by state) accomplishments and funding spent on fuels reduction projects that benefited GRSG from FY2003 to FY2013 (Table Z) .[12]

Table Z. FY2003 to FY2013 Fuels Funds Spent on GRSG by State

State	Acres	Funding
CA	28,719	$5,762,190
CO	18,534	$1,942,940
ID	529,972	$32,326,379
MT	15,496	$3,688,980
NV	161,353	$11,126,931
OR	196,180	$12,131,581
UT	277,014	$21,507,312
WY	78,956	$3,601,211
Grand Total	**1,306,224**	**$92,087,524**

Some areas that were not included as PACs may still have great potential for providing important habitat if active habitat management is implemented. For example, removal of early-stage juniper stands may render currently unsuitable habitat into effective habitat for GRSG (this is also true for degraded habitats within PACs). The COT report encourages state and federal agencies to actively pursue these opportunities.[13] As noted in this report, since 2010, the NRCS through its Sage Grouse Initiative (SGI) in collaboration with states and private landowners and BLM on public lands have worked to eliminate pinyon-juniper trees on over 400,000 acres of

---

[11] WAFWA FIAT report

[12] BLM Fuels Management Benefits Toward Sage Grouse Habitat. March 2014.

[13] COT Report. page 33.

private and over 400,000 acres of public lands, respectively, across western landscapes. In addition, using the FIAT the BLM has identified and prioritized areas for treatment of annual invasive grasses and conifer expansion on federal lands as a basis for improved targeting of federal resources[14] (See Figure Z. FY 2015 FIAT Priority Project Planning Areas). As illustrated, the areas designated as Priority 1and 2 project planning areas essentially coincide with the stronghold areas identified by the FWS and incorporated in the Great Basin ARMPAs as designated SFAs.

Comment [JRL79]: Should we include this here?

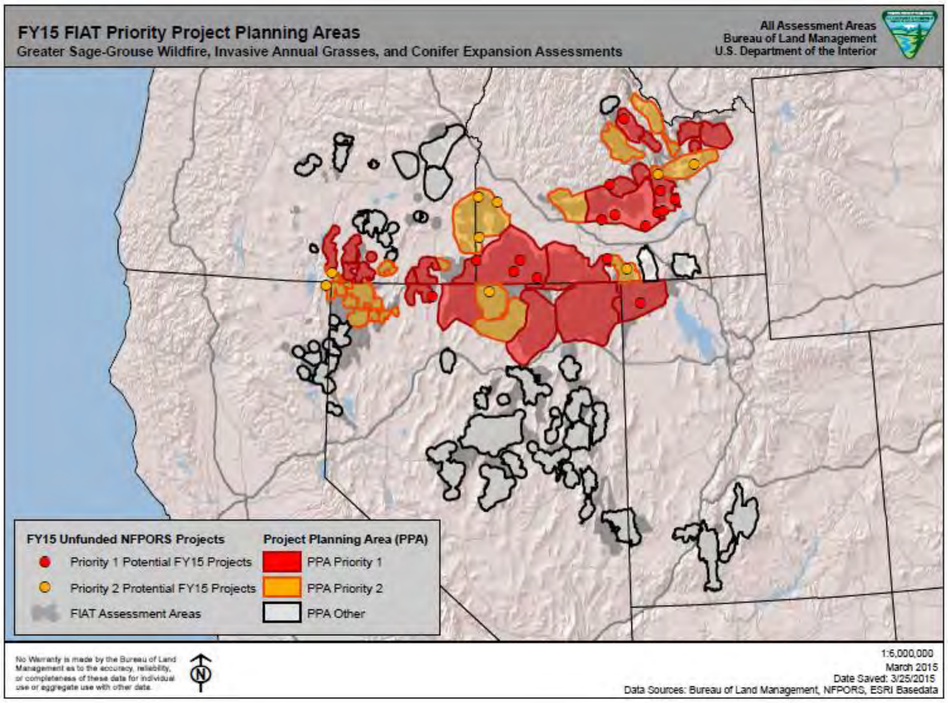

Figure Z. FY 2015 FIAT Priority Project Planning Areas with Focus on Invasive Annual Grasses and Conifer Expansion Assessments.

In addition, the Department has recently committed $7.5 million to projects in GRSG habitat to create more resilient landscapes and BLM has allocated $12 million to increase firefighting resources aimed at stopping fires while they are small in the Great Basin. The Department has identified required policy changes to increase the commitment, flexibility and timeframe for use of Emergency Stabilization and Burned Area Restoration (ES & BAR) funding on priority sagebrush-steppe habitats. Combined with commitments in the final rangeland fire report to Secretary Jewell to accelerate the registration and use of chemical and biological agents to stem the spread of cheatgrass and other invasives, these additional actions will lead to a more

---

[14] WAFWA. Greater Sage-Grouse Wildfire, Invasive Annual Grasses & Conifer Expansion Assessment. June 2014.

robust and effective rangeland fire management effort in 2015 and beyond. In 2016 and beyond, BLM is anticipating a funding increase to implement the GRSG proposed LUPs; these increases are included in both the House and Senate FY 2016 appropriations marks and will lead to more robust and effective management of GRSG habitat and the threats to it, including fire. BLM intends to continue to prioritize and request funding for GRSG management in 2017 and beyond.

The proposed LUPs also target additional conservation efforts to address other threats to the GRSG. Proposed LUP direction to incorporate GRSG habitat objectives into the establishment of allowable management levels (AMLs) for wild horses and burros (free-roaming equids) and to prioritize gathers and removal to reach AMLs in SFAs, PHMAs, and GHMAs (in that order) will better target these efforts to benefit the GRSG.. Anticipated funding increases for GRSG proposed LUP implementation in FY 2016 will allow the BLM to make substantial progress toward that goal, beginning with efforts to achieve AMLs in SFAs. At the same time, the BLM has made a considerable investment in concert with the National Academy of Sciences in new research of methods to reduce wild horse and burro reproduction rates. Through a combination of targeted gathers and the development of an effective agent for reducing future free-roaming equid reproductive rates, the BLM is optimistic that, over time, this threat to GRSG can be effectively mitigated.

Although future high voltage transmission lines will be avoided in PHMA, the planning, siting, and environmental review of a limited number of Presidential priority lines (Gateway West, Boardman to Hemingway, and Transwest Express, including those portions of Gateway South that are co-located) has been underway for a number of years. These lines are critical to expanding access to renewable sources of energy (especially wind) and to improving the reliability of the western grid. For these reasons, planning for these lines will proceed and potential impacts to GRSG will be fully mitigated (1) through micrositing to adjust the route to avoid important habitat and leks, (2) through transmission tower design to minimize the potential for adverse impacts to GRSG such as perching for predators, and (3) through compensatory mitigation measures, such as habitat restoration and pre-suppression activities to reduce the risk of habitat loss due to fire, to offset any unavoidable impacts to a conservation gain standard.

Mitigation for activities adversely impacting GRSG or GRSG habitat in PHMA or GHMA (PHMA only in Wyoming) will be designed to a net conservation gain standard consistent with the recommendation included in the September 2013 FWS report, *Greater Sage-Grouse Range-Wide Mitigation Framework*. According to the authors, the report was prepared

> "to communicate some of the factors the Service is likely to consider in evaluating the efficacy of mitigation practices and programs in reducing threats to GRSG. The recommendations provided here are consistent with the information and conservation objectives provided in the 2013 Conservation Objectives Team (COT) Report for sage-grouse"[15].

At the same time, BLM and Forest Service will partner with the states over the next 6 months

---

[15] USFWS. Greater Sage-Grouse Range-Wide Mitigation Framework. Version 1.0. September 3, 2014.

to develop regional mitigation strategies coinciding with WAFWA GRSG management zones, to guide mitigation efforts in each zone and monitor mitigation effectiveness. The collaborative effort to develop a mitigation strategy will ensure that mitigation is consistent with the principles and goals set out in Secretarial Order 3330, *Improving Mitigation Policies and Practices of the Department of the Interior* and accompanying report[16] and the new Departmental Manual guidance on landscape-level mitigation.

Additional conservation measures

In addition to land allocations and management actions included in the proposed LUPs to conserve the GRSG, measures were included to ensure that disturbance to leks could be reduced or minimized through the application of disturbance caps and required minimum buffer distances for a number of categories of disturbance, consistent with best available science.

Disturbance caps of 3% or 5% (for Wyoming and, likely in the future, Montana) were established in accordance with recommendations contained in the COT report. Disturbance will be calculated based on established Biologically-Significant Units (BSUs) developed by an interagency team and includes focus on protecting leks.

Formatted: Normal, Right: 0", Space After: 6 pt, Don't add space between paragraphs of the same style, No bullets or numbering, Widow/Orphan control, Tab stops: Not at 2.17"

The proposed ARMPAs also include an additional layer of protection for leks to be applied at project implementation. During NEPA development for a project, the appropriate buffer, based on the USGS report *Conservation Buffer Distance Estimates for GRSG – A Review* (Manier et al, 2014), will be used to site and mitigate projects, subject to applicable laws and regulations and valid existing rights. Because of the great variation in landscapes, local science, and local regulations, justifiable departures, both up and down, from these lek-buffer distances may be appropriate to fully address impacts to leks. In fact, the COT recommends that such conservation measures be based on best available science with consideration of local ecological conditions.

For BLM approved actions (not including Wyoming), the BLM and Forest Service will apply the lek buffer-distances identified above as required conservation measures to fully address the impacts to leks as identified in the NEPA analysis by preferentially locating the action outside of the buffer distance and, if that is not possible, approving the project only if certain criteria are met with the goal of ensuring no impacts to leks in PHMAs and no more than minor impacts in GHMAs.

This approach to minimizing impacts to leks reflects guidance from the COT report:

> "Conservation of sage-grouse habitats outside of the PACs should be closely coordinated with each state. For those states with sage-grouse management plans, or similar documents adequately addressing the conservation of sage-grouse that have been developed in coordination with FWS, decisions on management of those areas should defer to those plans. Conservation of habitats outside of PACs should include

---

[16] Clement, J.P. et al. 2014. A strategy for improving the mitigation policies and practices of the Department of the Interior. A report to the Secretary of the Interior from the Energy and Climate Change Task Force, Washington, D.C., 25 p.

> minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur".[17]

Consistent with recommendations contained in the 2006 WAFWA *Greater Sage-Grouse Range-wide Conservation Strategy,* the BLM and Forest Service conservation strategy places heavy reliance on monitoring and evaluation to assess the success of management decisions incorporated in the proposed LUPs and, ultimately, in the effectiveness of implementing these proposed LUPs. Monitoring plans will be interagency in nature and incorporate evaluation of GRSG population trends by the states and changes in habitat condition by the federal land management agencies. As the WAFWA report states,

> "Monitoring provides the "currency" necessary to evaluate management decisions and to assess progress or problems. Adequate monitoring should be considered an integral and inseparable component of all management actions, and there, not optional. Lack of proper monitoring will undoubtedly hinder this large-scale conservation effort."[18]

In addition, the conservation strategy incorporates an adaptive management framework that provides an "early warning system" of "soft triggers" to alert resource managers to the need to evaluate the effectiveness of their management strategies should changes in population levels or habitat conditions occur. If management responses to soft triggers do not adequately address the causes for population or habitat declines and "hard triggers" are reached, more significant changes in management actions and land allocations will occur to ensure that more protective measures to conserve the species are in place.

Guided by the COT report and NTT and WAFWA recommendations, the BLM and Forest Service conservation strategy directly addresses the threats identified in the COT report consistent with many of the specific recommendations provide by the COT, the NTT, and WAFWA. These changes in management direction from existing BLM (with the exception of the Lander LUP which was completed in 2014) and Forest Service LUPs are designed to avoid and minimize any additional surface disturbance in PHMAs and provide a high level of protection for FWS-identified stronghold areas. Recognizing the potential importance of areas in GHMA, the proposed LUPs include measures that protect and restore habitats in these areas while providing greater flexibility for development activities.

Formatted: Highlight

Comment [JRL80]:

The unprecedented collaboration with states in the development of these proposed LUPs, in conjunction with the close coordination between the BLM and Forest Service with input from the FWS, provides a strong foundation for conservation efforts to protect and restore habitats essential to the conservation of the GRSG. Informed by best available science, and in concert with additional actions, such as those to more efficiently and effectively address the threat of rangeland fire consistent with direction in S.O. 3336 and the investments made to improve sage-grouse habitat through voluntary actions on private lands through the NRCS' Sage Grouse Initiative (SGI), this strategy reflects a high level of commitment by state and federal partners to conserve the GRSG and its habitat. The landscape-level strategy consisting of reinforcing

---

[17] COT Report, page 36.
[18] WAFWA report, page xxiii.

conservation actions that will go into effect upon completion of the BLM and Forest Service ARMPAs as well as those actions being implemented currently to conserve the species, reflect a significant change in management direction and philosophy for both resource management agencies since 2010 and a long-term commitment to assure the conservation of the species consistent with the objectives set in the 2006 WAFWA conservation strategy and embraced by both the NTT and the COT.

2. DECISION

2.1 Summary of the Approved Management Decisions

The decision is hereby made to approve the Great Basin Region Greater Sage-Grouse ARMPAs for the Great Basin Region Greater Sage-Grouse Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah (attachments A, B, C, and D). This ROD serves as the final decision establishing the land use plan amendment decisions outlined in the ARMPAs and is effective on the date it is signed. No further administrative remedies are available for these land use plan decisions.

The decisions included in this ROD and attached ARMPAs amend the land use plans described in **Sections 1.1** of attachments A, B, C, and D. This ROD and ARMPAs become effective on the date this ROD is signed. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

The land use decisions provide conservation measures to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Land use plan decisions are expressed as goals and objectives (desired outcomes), and allocations, allowable uses, and management decisions anticipated to achieve desired outcomes. Although decisions identified in the ARMPAs are final and effective upon signing of this ROD, they generally require additional implementation decision steps before on-the-ground activities can begin. Subsequent NEPA analysis will be conducted, as necessary, for such implementation decisions.

2.2 What the Record of Decision and Approved Resource Management Plan Amendments Provide

The ARMPAs include GRSG and GRSG habitat land use plan level management decisions in the form of:

- Goals
- Objectives (Desired Future Conditions)
- Land Use Allocations and Allowable Uses

- Management Actions

Goals are the broad statements of desired outcomes, and are usually not quantifiable.

Objectives are specific desired conditions, usually quantifiable and measurable, and may have timeframes for achievement.

Land use allocations specify locations within the planning area that are available or not for certain uses and are also used prioritize conservation and restoration management actions. These include decisions such as what lands are available for livestock grazing, mineral material use, oil and gas leasing, and locatable mineral development, what lands may be available for disposal via exchange and/ or sale, and what lands are open, closed, or limited to motorized travel (please note that all acreages presented in the Approved Plan are estimations even when presented to the nearest acre).

Management actions include those provisions that help in meeting the established goals and objectives and include measures that will be applied to guide day-to-day activities on public lands..

The ARMPAs' management decisions were crafted to alleviate identified threats to GRSG and their habitats (see **Section 1.5**).

2.3 What the Record of Decision and Approved Resource Management Plan Amendments Do Not Provide

The attached ARMPAs do not contain decisions for public lands outside of GRSG habitat management areas, except for travel management decisions in the Idaho and Southwestern Montana ARMPA.

The ARMPAs do not affect valid existing rights.

The ARMPAs do not contain decisions for the mineral estates of lands located in the planning area for lands under the jurisdiction of other Federal agencies such as the Forest Service, or for private or State-owned lands and minerals that are not administered by the BLM. In addition, many decisions are not appropriate at this level of planning and are not included in the ROD. Examples of these types of decisions include:

- *Statutory requirements*. The decision will not change the BLM's responsibility to comply with applicable laws, rules, and regulations.
- *National policy*. The decision will not change BLM's obligation to conform to current or future National policy.
- *Funding levels and budget allocations*. These are determined annually at the National level and are beyond the control of the State/District of Field offices.

Implementation decisions (or activity-level decisions) are management actions tied to a specific location. Implementation decisions generally constitute the BLM's final approval allowing on-the-ground actions to proceed and require appropriate site-specific planning and NEPA analysis. Such decisions may be incorporated into implementation plans (activity or project plans) or may exist as stand-alone decisions. These ARMPAs do not contain implementation decisions. Future activity-level plans will address the implementation of the ARMPAs. Implementation decisions and management actions that require additional site-specific project planning, as funding becomes available, will require further environmental analysis.

2.4 Modifications and Clarifications

During preparation of the ARMPAs for all four sub-regions, minor changes were made to the Proposed RMP Amendments to correct errors and to clarify decisions. Clarifications and corrections made since the Proposed RMP Amendments were published on May 29, 2015 are hereby adopted by this ROD.

2.4.1 Modifications and Clarifications by Sub-region

Modifications and clarifications are summarized below for each of the sub-regional ARMPAs.

Idaho and Southwestern Montana

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Nevada and Northeastern California

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Oregon

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Utah

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

2.4.2 Protest Resolution

BLM's planning regulations at 43 CFR 1610.5-2 allow any person who participated in the planning process and has an interest that may be adversely affected by BLM's planning decisions to protest proposed planning decisions within 30 days from the date the Notice of Availability of the Proposed

RMPA/Final EIS was published in the Federal Register (May 29, 2015). Below are descriptions of the protest resolution process for each of the four sub-regional PRMPAs/FEISs.

These decisions are final for the Department of the Interior. With the exception of the granted protest issues, the Director concluded that the BLM followed the applicable laws, regulations, and policies and considered all relevant resource information and public input in developing the Proposed Land Use Plan Amendments/Final EISs. Each protesting party will be notified in writing of the Director's findings and the disposition of their protests. The BLM Director resolved the protests without making significant changes to the Proposed Land Use Plan Amendments/Final EISs, though minor clarifications were made and are summarized in Section 2.5.1.

Idaho and Southwestern Montana

For the Idaho and Southwestern Montana GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Idaho and Southwestern Montana GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Nevada and Northeastern California

For the Nevada and Northeaster California GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Nevada and Northeastern California Sub-Regional GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Oregon

For the Oregon GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Oregon GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Utah

For the Utah GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Utah GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

2.4.3 Governors Consistency Review

The BLM's planning regulations require that RMPs be "consistent with officially approved or adopted resource-related plans, and the policies and procedures contained therein, of other federal agencies, state and local governments, and Indian tribes, so long as the guidance and RMPs also are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands" (43 CFR 1610.3-2(a)). The general requirement in FLPMA/planning regulations is to coordinate the land use planning process with plans of other agencies, states, and local governments to the extent consistent with law (see FLPMA s. 202(c)(9) and 1610.3-1(a)); and the respective duties to be consistent with both officially approved or adopted plans (to the extent those plans are consistent with federal law, or to maximum extent practical) (see 1610.3-2(a)(b)). In accordance with FLPMA, the BLM was aware of and gave consideration to state, local, and tribal land use plans and provided meaningful public involvement of the Proposed RMP Amendments/Final EISs.

The BLM is aware that there are specific state laws and local plans relevant to aspects of public land management that are discrete from, and independent of, federal law. However, the BLM is bound by federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that BLM's land use plans be consistent with officially-approved state and local plans only if those plans are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands. Where officially-approved state and local plans or policies and programs conflict with the purposes, policies, and programs of federal law applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially-approved state and local policies and programs (as opposed to plans), this consistency provision only applies to the maximum extent practical. While county and federal planning processes, under FLPMA, are required to be as integrated and consistent as practical, the federal agency planning process is not bound by or subject to state or county plans, planning processes, policies, or planning stipulations.

In some instances, modifications to the Proposed RMP Amendments were addressed based on recommendations submitted to the BLM by the applicable states. These modifications to the ARMPAs are summarized below by sub-region and are now part of the attached ARMPAs.

Idaho and Southwestern Montana

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Nevada and Northeastern California

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Oregon

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Utah

Will need to populate the "X" areas towards the end of the GCR process (end of July).

3. ALTERNATIVES

3.1 Alternatives Considered

Each of the Great Basin sub-regional planning efforts analyzed in detail a set of alternatives in the draft and final sub-regional EISs. The alternatives were developed to provide direction for resource programs influencing land management for the protection and enhancement of GRSG and its habitat. All management under any of the alternatives complied with federal laws, rules, regulations, and policies.

Each alternative emphasized an altered combination of resource uses, allocations, and restoration measures to address issues and resolve conflicts among uses so that GRSG goals and objectives were met in varying degrees across the alternatives. The action alternatives offered a range of possible management approaches for responding to planning issues and concerns identified through public scoping, and to maintain or increase GRSG abundance and distribution in the planning area. While the land use plan goal was the same across alternatives for each sub-region, each alternative contained a discrete set of objectives and management actions constituting a separate RMP amendment. The goal was met in varying degrees, with the potential for different long-range outcomes and conditions.

The relative emphasis given to particular resources and resource uses differed as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs. When resources or resource uses are mandated by law there are typically few or no distinctions between alternatives.

3.1.1 Alternative A – No Action Alternative

Alternative A meets the CEQ requirement that a No Action Alternative be considered. This alternative continues current management direction derived from the existing field/district office RMPs, as amended. Goals and objectives for resources and resource uses are based on the most recent RMP decisions, along with associated amendments and other management decision documents. Laws, regulations, and BLM policies that supersede RMP decisions would apply.

Goals and objectives for BLM-administered lands and mineral estate would not change. Appropriate and allowable uses and restrictions pertaining to activities such as mineral leasing and development, recreation, construction of utility corridors, and livestock grazing would also remain the same. The BLM would not modify existing or establish additional criteria to guide the identification of site-specific use levels for implementation activities.

This alternative was not selected as the ARMPAs because it did not meet the purpose and need of this plan amendment. This alternative did not include changes that are needed to be made to the existing decisions based on the USFWS 2010 listing petition decision that identified inadequacy of regulatory mechanisms as a significant threat to GRSG and its habitat. This alternative did not incorporate the best available science pertaining to GRSG or its habitat.

3.1.2 Alternative B: National Technical Team Report Alternative

Alternative B was based on the conservation measures contained within the National Technical Team (NTT) Report. The GRSG National Technical Team (NTT), comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed *A Report on National Greater Sage-Grouse Conservation Measures* in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. The Report can be accessed at: http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

The BLM's Washington Office Instructional Memorandum (IM) Number 2012-044 directed the sub-regional planning efforts to analyze the conservation measures developed by the NTT, as appropriate, through the land use planning process and NEPA.

Alternative B would exclude ROW development in PHMA and avoid development in GHMA, would close PHMA to fluid mineral leasing, mineral material sales, and nonenergy leasable minerals, and would recommend withdrawal from locatable mineral entry in all PHMA. These management actions would reduce surface disturbance in PHMA and would minimize disturbance in GHMA, thereby maintaining GRSG habitat. Management actions for wildfire would focus on suppression in PHMA and GHMA, while limiting certain types of fuels treatments. Vegetation management would emphasize sagebrush restoration. Collectively, vegetation and wildfire management would conserve GRSG habitat. Grazing would continue with similar impacts under Alternative B as under Alternative A. The best management practices (BMPs) proposed in the NTT report would be included as required design features as part of Alternative B and are listed in Appendix X, Required Design Features (RDFs), of each of the attached ARMPAs.

This alternative was not selected in its entirety as the ARMPAs because the majority of the conservation measures in the NTT Report, as appropriate and applicable, were applied primarily to PHMA, and few conservation measures in the Report were provided for in GHMA. As a result, most management actions in GHMA reverted back to the No Action Alternative, which was found to not meet the purpose and need for the Amendments.

3.1.3 Alternative C: Citizen Groups' Recommended Alternative One

Alternative C was based on a citizen groups' recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and was applied to all occupied GRSG habitat (PHMA and GHMA. Alternative C limited commodity development in areas of occupied GRSG habitat, and closed or excluded large portions of the planning area to many land uses. This included all PHMA and GHMA as being closed to livestock grazing, recommended for withdrawal from locatable mineral entry, closed to fluid mineral leasing, closed to salable mineral and non-energy leasable mineral development, and exclusion areas for right-of-ways. The Utah LUPA/Draft EIS combined this alternative with Alternative F (discussed below).

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which, based on best available science, is not required to conserve GRSG and its habitats. Alternative C was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.4 Alternative D: Draft RMP Amendments' Preferred Alternative

Alternative D, which was identified as the Preferred Alternative in the Draft EISs, balanced opportunities to use and develop the planning area as well as conserving, maintaining, and enhancing GRSG and their habitat. Protective measures were applied to GRSG habitat, while still allowing for anthropogenic disturbances with stringent mitigation measures. This alternative represents the mix and variety of management actions based on BLM's analysis and judgment, which best resolve the resource issues and management concerns while meeting laws, regulations, and policies pertaining to BLM management. As a result of public scoping comments, internal review, and cooperating agency coordination on the Draft RMP Amendments/EISs, this alternative was modified to become the Proposed RMP Amendments and analyzed in the FEISs. The Preferred Alternatives, with slight variations, became the Proposed Plans in the FEISs.

In PHMA under Alternative D, there would be limitation on disturbance in GRSG habitat by excluding wind and solar energy development (except for certain counties in Southeastern Oregon where avoidance is applied), avoiding all other ROW development, applying no surface occupancy stipulations to fluid mineral development, and closing PHMA to nonenergy leasable mineral development and mineral material sales. These management actions would protect GRSG habitat, while allowing other activities, subject to conditions. In GHMA under Alternative D, allocations are less stringent, but still aim to protect GRSG habitat (for example, applying moderate constraints and stipulations to fluid minerals in GHMA).

Under Alternative D, the BLM management would support sagebrush/perennial grass ecosystem restoration, would increase fire suppression in PHMA and GHMA, and would manage livestock grazing to maintain or enhance sagebrush and perennial grass ecosystems.

3.1.5 Alternative E: State/Governor's Alternative

Alternative E is the alternative provided by the State or Governor's offices for inclusion and analysis in the EISs. It incorporates guidance from specific state conservation strategies, if developed or recommendations from the state on management of Federal lands and emphasizes management of GRSG seasonal habitats and maintaining habitat connectivity to support population objectives. This alternative was identified as a co-Preferred Alternative in the Idaho and Southwestern Montana Draft EIS. California did not provide the BLM with a state GRSG conservation plan and under this alternative, reverted back to Alternative A, the no-action alternative.

For Nevada, Alternative E would apply an avoid, minimize, and mitigate strategy to reduce direct and indirect impacts on GRSG from surface-disturbing activities on BLM-administered lands. Effects on GRSG habitat from certain resource programs, such as grazing, lands and realty, wildfire management, and minerals, would not be directly addressed because allocation decisions were not part of the state's plan.

For Oregon, Alternative E contains GRSG conservation guidelines from Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat. This document describes the Oregon Department of Fish and Wildlife's proposed management of GRSG on Federal lands. It also provides guidance for public land management agencies and land managers for GRSG conservation. GRSG conservation guidelines in the state plan are designed to maintain (at a minimum) or enhance the quality (the optimum) of current habitats. The guidelines would also assist resource managers in achieving the population and habitat objectives of the state plan.

For Idaho, Alternative E incorporates proposed GRSG protection measures recommended by the State of Idaho. Management in Montana would remain unchanged from the current RMPs (Alternative A). Alternative E addresses the following primary threats: fire, invasive weeds, and infrastructure development. It also includes guidance for several secondary GRSG threats such as recreation, improper livestock grazing, and West Nile virus for BLM and Forest Service programs that affect GRSG or its habitat.

For Utah, the planning area includes all occupied GRSG habitat in Utah. Alternative E1 is based on the State of Utah's Conservation Plan for Greater Sage-Grouse in Utah and would apply to all BLM-administered lands in Utah. Alternative E1 was designed to eliminate the threats facing the GRSG while balancing the economic and social needs of the residents of Utah. Conservation measures would be applied to 11 areas that the state identified, called Sage-Grouse Management Areas (SGMAs). Emphasis would be placed on expanding GRSG habitat by aggressively treating areas where there are encroaching conifers or invasive species. Alternative E1 includes a general limit on new permanent disturbance of 5 percent of habitat on state or federally managed lands within any particular SGMAs. Occupied habitat outside of the state-identified SGMAs would not receive new management protection. They would continue to be managed according to the GRSG actions in existing RMPs and conservation measures associated with existing activity-level plans.

This alternative was not selected, in whole, as the ARMPAs because some components of the state's plans were not consistent with the purposes, policies and programs of Federal laws and regulations applicable to public lands. However, many goals, objectives, and management actions in the ARMPA were carried forward.

3.1.6 – Alternative F: Citizen Groups' Recommended Alternative Two

Alternative F is also based on a citizen group recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and defines different restrictions for PHMA and GHMA. Alternative F would limit commodity development in areas of occupied GRSG habitat, and would close or designate portions of the planning area to some land uses. This alternative does not apply to the Utah sub-regional planning effort, as it was combined with Alternative C. Under Alternative F, wildfire suppression would be prioritized in PHMA. Concurrent vegetation management would emphasize sagebrush restoration and enhancement. Alternative F would reduce livestock and wild horse and burro management utilization by 25 percent within PHMA and GHMA.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. Alternative F was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.7 – Proposed Plan Amendment

As a result of public comments, best science, cooperating agency coordination, and internal review of the Draft RMP Amendments/EISs, the BLM has developed the Proposed Amendments/Final EISs for managing BLM-administered lands. The Proposed Amendments/Final EISs focus on addressing public comments, while continuing to meet the BLM's legal and regulatory mandates. The Proposed Amendments/Final EISs are a variation of the preferred alternatives (Alternative D) and are within the range of alternatives analyzed in the DEISs. The Proposed Plans, with slight variations (as outlined in Section 2.5 of this ROD), became ARMPAs.

3.1.8 Environmentally Preferable Alternative Considered in all Sub-Regions

Council on Environmental Quality (CEQ) regulations require that a ROD state which alternatives were considered to be "environmentally preferable" (40 CFR 1505.2(b)). Question 6A of CEQ's 40 most-asked questions regarding CEQ's NEPA regulations defines that term to ordinarily mean the alternative which best protects, preserves, and enhances historic, cultural, and natural resources.

Under that definition, Alternative C, as presented in each of the sub-regional Proposed RMP Amendments/Final EISs is the most environmentally preferable. However, NEPA expresses a continuing policy of the federal government to "use all practicable means and measures…to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans" (Section 101 of NEPA).

3.2 Alternatives Considered But Not Analyzed in Detail

The alternatives listed below by sub-region were considered but were not carried forward for detailed analysis because of one or more of the following reasons:

- They would not meet the requirements of FLPMA or other existing laws and regulations;
- They did not meet the purpose and need;
- The alternative was already captured within the range of alternative analyzed in the EIS;
- They were already part of an existing plan, policy, or administrative function; or
- They did not fall within the limits of the planning criteria.

For additional rationale as to why each of the alternatives listed below by sub-region were not carried forward for detailed analysis, refer to Section 2.11of each of the sub-regional Proposed Amendments/Final EISs.

Idaho and Southwestern Montana

- USFWS-Listing Alternative
- Elimination of Recreational Hunting Alternative
- Predation Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Consideration of Coal Mining Alternative

Nevada and Northeastern California

- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Elko County Sage-Grouse Plan Alternative
- Increase Grazing Alternative

Oregon

- USFWS-Listing Alternative
- Elimination of Livestock Grazing from all BLM Lands Alternative
- Increase Livestock Grazing Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative

Utah

- USFWS-Listing Alternative
- Increase Livestock Grazing Alternative
- Make GRSG Habitat Available for Oil Shale and Tar Sands Alternative
- Citizen Proposed Alternatives (in their entirety)
- Adoption of the State of Utah's Sage-Grouse Management Areas as PHMA for all Alternatives
- Use of Other Habitat Maps Alternatives
- County Sage-Grouse Management Plans Alternative
- Conservation Objectives Team (COT) Report Alternative
- BLM Policies and Regulations Alternative

4. MANAGEMENT CONSIDERATIONS

The BLM is tasked to provide multiple use management for public lands by the Federal Land Policy and Management Act (FLPMA) and numerous other laws and regulations that govern the management of public lands. Due to the diversity of community needs and stakeholders affected by management of BLM lands, there has been both support and opposition to certain components of the Proposed Plans. BLM's objective in choosing the Proposed Plan Amendments as the ARMPAs was to address diverse needs and concerns in a fair manner and provide a practical and workable framework for management of public lands in GRSG habitat. The BLM is ultimately responsible for preparing these ARMPAs consistent with its legal mandates that reflect collective professional judgment using the best available science. The ARMPAs provide a balance between those reasonable measures necessary to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat to meet the purpose and need of these plan amendments, and the ongoing public need for use of the public lands within the Great Basin Region planning area.

The ARMPAs were selected because they will reduce or eliminate threats to GRSG at a landscape scale, improve and sustain properly functioning resource conditions, and consider needs and demands for existing or potential resource commodities and values. In the end, GRSG habitat will be managed by integrating ecological, economic, and social principles in a manner that safeguards the long term sustainability, diversity and productivity of the land.

In 2012, the FWS convened a Conservation Objectives Team (COT) of state and federal representatives to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The final, peer-reviewed COT Report provided a brief overview of the threats to the greater sage-grouse's survival based upon the FWS 2010 listing decision and an assessment of the extent to which these threats affected remaining GRSG populations. A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG in the Great Basin Region– as articulated in the COT report – is summarized in **Table 1-2**. **Table 1-3** provides a crosswalk between the threats to GRSG and their habitat identified in the COT Report and the key management responses from the ARMPAs that aim to ameliorate these threats.

Comment [JRL81]: Addressed above.

~~5. MITIGATION MEASURES~~

~~In all GRSG habitat, in undertaking BLM management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the GRSG including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. Actions which result in habitat loss and degradation include those identified as threats which contribute to GRSG disturbance as identified by the FWS in its 2010 listing decision (75 FR 13910), COT report, and depicted in the ARMPAs' Monitoring Framework (which can be found in Appendix X of each of the attached ARMPAs). Mitigation will follow the regulations from the CEQ (40 CFR, Part 1508.20; e.g. avoid, minimize, and compensate). If impacts from BLM management actions and authorized third-party actions (which are consistent with the goals, objectives, and management actions in the attached ARMPAs) that result in habitat loss and degradation remain after applying avoidance and minimization measures (i.e., residual impacts), then compensatory mitigation projects would be used to provide a net conservation gain to the species. Any compensatory mitigation would be durable, timely, and in addition to what would have resulted without the compensatory mitigation (see the concepts of durability, timeliness, and additionality as described further in the Mitigation Strategy, which can be found in Appendix X of each of the attached ARMPAs).~~

~~All practical means to avoid or minimize environmental harm, specifically to GRSG and its habitat are encompassed in the attached ARMPAs and associated appendices. Mitigation measures, including the application of required design features have been identified.~~

~~The ARMPAs also identify the development of regional mitigation strategies, in partnership with the states, to guide and target mitigation to achieve the greatest benefit to GRSG and habitat conservation and restoration. Within 90 days of the issuance of the Record of Decisions, the BLM will establish a WAFWA Management Zone GRSG Conservation Team to develop a WAFWA Management Zone Regional Mitigation Strategy that will inform the NEPA decision making process including the application of the mitigation hierarchy for actions and third party authorizations that result in habitat loss and degradation. A robust and transparent Regional Mitigation Strategy will contribute to GRSG habitat conservation by reducing, eliminating, or minimizing threats and compensating for residual impacts to GRSG and its habitat. The mitigation strategy will be developed within one year of the issuance of the Record of Decisions.~~

~~6. PLAN MONITORING AND ADAPTIVE MANAGEMENT~~

Comment [MEM82]: Moved content from the original Section 1.5.3 to here. The CEQ regs do not state that "monitoring" needs to be a standalone, so I think we are ok here.

~~Plan Monitoring~~

~~Monitoring tied to the ARMPAs has two parts: (1) implementation monitoring (i.e., are decisions being implemented in a timely manner, are actions taken consistent with the plan decisions), and (2) effectiveness monitoring (i.e., are the decisions and implementation actions achieving the desired conservation goals). Through effectiveness monitoring, BLM can assess how decisions and actions impact GRSG habitat. Understanding the effectiveness and validating results of ARMPAs and management decisions is an important part of measuring performance under the Government Performance Results Act. For example, riparian condition is a primary measure for ARMPA effectiveness (see WO IM 2010-101). Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, size of patches, etc.). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by state wildlife agencies and other partners, will allow linking real or potential habitat changes (from both natural events and management actions) to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to ameliorate negative effects with appropriate conservation actions.~~

~~The BLM Assessment, Inventory, and Monitoring (AIM) Strategy (Toevs et al. 2011 and IB2012-080) describes a vision for integrated, cross-program assessment, inventory, and monitoring of resources at multiple scales of management. Following the AIM Strategy, the BLM is modernizing its resource monitoring approach to more efficiently and effectively meet local, regional, and national resource information needs. The AIM Strategy provides a process for the BLM to collect quantitative information on the condition, trend, amount, location, and spatial pattern of natural resources on the public lands. Each AIM-Monitoring survey, at any scale of inquiry (from the plot level to west-wide deployments), uses a set of core indicators, standardized field methods, remote sensing, and a statistically-valid study design to provide nationally-consistent and scientifically-defensible information to determine conditions (e.g., rangeland health) and trends on public lands.~~

Comment [KK83]: I think this can all be deleted and the first sentence can just flow into the next paragraph

~~The National-scale deployment of AIM, known as the Landscape Monitoring Framework (LMF), commenced in 2011 in coordination with NRCS, with the collection of 1,000 plots of field-collected monitoring data across the Western U.S. LMF aims to provide non-biased estimates of vegetation and soil condition and trend using a statistically balanced sample design across BLM lands. A group of GRSG habitat and sagebrush plant community subject matter experts from BLM, USFWS, WAFWA, NRCS, ARS, state wildlife agencies, and academia identified those vegetation indicators collected at LMF sampling points that inform GRSG habitat needs. The common indicators that were identified include: species composition, foliar cover, height of the tallest sagebrush and herbaceous plant, inter-canopy gap, percent of invasive species, sagebrush shape, and bare ground. To increase the precision of estimates of sagebrush conditions within the range of GRSG, additional plot locations in occupied GRSG habitat (Sage-grouse Intensification) were added in 2013. The common indicators are also collected on sampling locations in the NRCS Rangeland Monitoring Survey. The GRSG baseline data will be collected over a five year period and an annual report will be prepared describing the status of the indicators. Beginning in year six, the annual status report will be accompanied with a trend report which will be available on an annual basis thereafter contingent upon continuation of the current monitoring budget. This information, in combination with mapping information, mid-scale habitat suitability indicator measures, and sagebrush availability information will be used to assess the effectiveness of the planning strategy.~~

~~The BLM has made significant commitments in the ARMPAs to monitoring actions to conserve GRSG habitats at multiple scales. The results from the monitoring will inform the agencies of the effectiveness~~

~~of efforts to reduce disturbance and restore seasonal habitats in priority areas, and of the status of the triggers set in the proposed LUPs for adaptive management. The BLM will report annually on the results of the monitoring efforts.~~

~~The BLM's Monitoring Framework can be found in Appendix X of each of the attached ARMPAs.~~

~~Adaptive Management~~

~~The ARMPAs include an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are not specific to any particular project, but identify habitat and population thresholds. Triggers are based on the two key metrics that are being monitored – habitat loss and/or population declines. Adaptive Management with specific triggers provide additional certainty that the regulatory mechanisms included in the ARMPAs are robust and able to respond to a variety of conditions and circumstances quickly and effectively to conserve GRSG habitat.~~

~~Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the proposed LUPsARMPAs, the BLM's response is to apply more conservative or restrictive conservation measures to mitigate for the specific causal factor in the decline of populations and/or habitats, with consideration of local knowledge and conditions. In each ARMPA, a soft trigger begins a dialogue between the state, FWS, and the BLM to see if the causal factor can be determined and what implementation level activities can be used to reverse any trend. These adjustments will be made to preclude tripping a "hard" trigger (which signals more severe habitat loss or population declines).~~

~~Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the attached ARMPAs. In the event that new scientific information becomes available demonstrating that the hard trigger would be insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM ARMPAs, the BLM will immediately assess what further actions may be needed to protect GRSG and its habitat and ensure that conservation options are not foreclosed. This could include a formal directive such as an IM or a plan amendment, which, to the extent that it is supported scientifically, may be drawn from the range of alternatives analyzed in the development of the ARMPAs. ARMPA specific strategies can be found in Appendix X of each of the attached ARMPAs.~~

7. PUBLIC INVOLVEMENT, CONSULTATION AND COORDINATION

The BLM land use planning is conducted in accordance with NEPA requirements, CEQ regulations, and US Department of the Interior policies and procedures implementing NEPA, as well as specific BLM planning and NEPA policies. The NEPA and associated laws, regulations, and policies require the BLM to seek public involvement early in and throughout the planning process, to develop a range of reasonable alternatives to proposed actions, and to prepare environmental documents that disclose the potential impacts of proposed alternatives.

Public involvement and agency consultation and coordination have been at the heart of the planning process leading to these Great Basin Region ARMPAs. These efforts were achieved through Federal Register notices, public formal and informal meetings, individual contacts, media releases, planning

bulletins, and a series of GRSG planning-related Web sites. This section documents the outreach efforts that have occurred to date.

7.1 Public Involvement

The scoping period for the National GRSG Planning Strategy, including the four sub-regional planning areas in the Great Basin Region, began with the publication of the NOI in the Federal Register on December 9, 2011, and ended on March 23, 2012. Beginning in December and ending in February of 2012, the BLM hosted a series of public open house scoping meetings across Northeastern California, Idaho, Southwestern Montana, Nevada, Oregon and Utah. A final National GRSG Planning Strategy Scoping Report was released in May 2012.

A Notice of Availability (NOA) for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Draft RMP Amendments/EISs were published in the Federal Register on November 1, 2013. The Oregon Draft RMP Amendment/EIS was released to the public on November 26, 2013.

For the Great Basin Region GRSG Proposed RMP Amendments/FEIS, Idaho and Southwestern Montana conducted seven public meetings, Nevada and Northeastern California conducted seven public meetings, Oregon conducted seven public meetings, and Utah conducted eight public meetings between November 2013 and January 2014.

Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were considered and incorporated, as appropriate, into the Proposed Plans. The Great Basin Region received approximately 4,990 substantive comments, contained in 74,240 submissions during the four Draft EISs' comment periods. Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were carefully considered and incorporated as appropriate into the Proposed Plan Amendments. Public comments resulted in the addition of clarifying text, but did not significantly change Proposed RMP Amendments.

A Notice of Availability (NOA) for the Great Basin Region GRSG Proposed RMP Amendments and Final EISs for the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah Sub-Regions were released on May 29, 2015. The release of the EPA's NOA initiated a 30 day public protest period and a 60 day governors' consistency review. Refer to **Section 2.5** for a full description of the protest period and governors' consistency review outcomes.

7.2 Cooperating Agencies

A cooperating agency is any federal, state, or local government agency or Native American tribe that enters into a formal agreement with the lead federal agency to help develop an environmental analysis. Cooperating Agencies and tribes "work with the BLM, sharing knowledge and resources, to achieve desired outcomes for public lands and communities within statutory and regulatory frameworks" (BLM 2005). The benefits of enhanced collaboration among agencies in preparing NEPA analyses are:

- Disclosing relevant information early in the analytical process
- Applying available technical expertise and staff support
- Avoiding duplication with other federal, state, tribal, and local procedures
- Establishing a mechanism for addressing intergovernmental issues

The BLM entered into a formal Memorandum of Understanding (MOU) for the National GRSG Planning Strategy with the USFWS and the U.S. Forest Service. In addition, the Great Basin sub-regions' also invited local, state, other federal, and tribal representatives to participate as Cooperating Agencies for these RMP Amendments/EISs. In total, there were 13 MOUs signed with Federal agencies, 10 MOUs signed with state agencies, 55 MOUs signed with counties, and 5 MOUs signed with tribal entities. The MOUs outline the interests, expertise, and jurisdictional responsibilities of both the BLM and its cooperating agency partners and also outlines their respective roles and responsibilities in the planning and NEPA processes. For a full list of these cooperating agencies divided by sub-region, refer to the Cooperating Agencies List at the beginning of this ROD. Additional information can also be found in Chapter 6 of each of the Proposed Amendments/FEISs.

7.2 FWS Section 7 Consultation

Consultation with FWS is required under Section 7(c) of the ESA before the start of any BLM project that may affect any federally listed or endangered species or its habitat. These planning processes are considered a major project, and the four Great Basin sub-regional Final EISs defined potential impacts on threatened and endangered species as a result of management actions proposed in the alternatives analyzed in the FEISs. The FWS is a cooperating agency in this planning process. FWS staff participated in interdisciplinary team meetings and has been provided drafts of alternative decisions and analyses for discussion and input.

The BLM formally initiated Section 7 consultation with a letter to the USFWS prior to the release of the Draft RMP Amendments/EISs, and requested concurrence on which species would require consideration during consultation. Over the ensuing months, regular meetings were held to identify the species that would be analyzed in the biological assessment, to address which actions could affect those species, and to determine whether the implementation of the Proposed Plan Amendments "may affect" the species for which this consultation occurred.

Prior to the release of the Proposed Amendments/FEISs, the BLM formally submitted the biological assessments to the USFWS for review. The USFWS evaluated the biological assessments and concurred with the "no affect" determination via memorandum for Oregon, Nevada and Northeastern California, and Idaho and Southwestern Montana, which are appendices to each of these ARMPAs. For Utah, formal consultation was required with the FWS due to a "likely to adversely affect" determination associated with the threatened listed Utah Prairie Dog. The biological opinion from the FWS is attached to the Utah ARMPA (Appendix X of Attachment X).

[Verify that the above paragraph is applicable to UT once BLM UT hears back from their local FWS.]

7.3 Native American Consultation

In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation efforts related to preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent letters to 65 tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts

related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts.

The Draft RMP Amendments/EISs were provided to the Idaho, Montana, Nevada, California, Oregon, and Utah State Historic Preservation Offices (SHPO) concurrently with its release to the public. The Proposed Plan RMP Amendments/FEISs were also provided to the SHPOs.

[Verify that the above paragraph is applicable to UT.]

7. REFERENCES

Comment [MEM84]: Need to ask EMPSi if they can formulate.

8. APPROVAL

Land Use Plan Amendment Decisions

It is the decision of the Bureau of Land Management (BLM) to approve the Great Basin Region Approved Resource Management Plan (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub-regions, as described in this Record of Decision. The Proposed Plan Amendments and related Final Environmental Impact Statements (EIS) were published on May 29, 2015, in the Federal Register (80 FR 30711). I have resolved all protests and, in accordance with BLM regulations 43 CFR 1610.5-2, my decision on the protests is the final decision of the Department of Interior. The approval is effective on the date this Record of Decision is signed.

Approved by:

Neil Kornze Director Bureau of Land Management	Date

Secretarial Approval

I hereby approve the land use plan amendments decisions. My approval of the land use plan decisions constitutes the final decision of the Department of the Interior and, in accordance with regulations at 43 CFR 4.410(a)(3), is not subject to appeal under Department regulations at 43 CFR Part 4. Any challenge to these land use plan decisions must be brought in Federal district court.

Approved by:

Sally Jewell Secretary Department of the Interior	Date

(WO210)(1610)

Dear Reader:

Enclosed are the Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). The ROD approves the four Great Basin Region ARMPAs, which are part of seventeen other sub-regional RMP Amendments and RMP revisions associated with the National Greater Sage-Grouse Planning Strategy that was initiated on December 11, 2011.

The Bureau of Land Management (BLM) ARMPAs provide a ~~range wide~~ landscape-level, ~~comprehensive~~, science-based, collaborative strategy for addressing previously identified threats to the greater sage-grouse (GRSG) and its habitat. This strategy, while designed to address issues leading to the U.S. Fish and Wildlife Service's (FWS) 2010 "warranted but precluded" decision, was guided by over a decade of research, analysis and recommendations for GRSG conservation produced by the Conservation Objectives Team (COT) Report and the BLM National Technical Team and (NTT). Each of these reports was developed by a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research. Science-based decision-making and collaboration with the FWS, the U.S. Forest Service, and state and other partners were fundamental during the development of ~~the land use plan decisions within~~ these ARMPAs to address the identified threats to GRSG.

It is important to note that this ROD and these ARMPAs are specific only to BLM-administered lands. Throughout the GRSG planning process, the U.S. Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs included proposed GRSG management direction for National Forest System lands. The U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

The Federal Land Policy Management Act (FLPMA) requires the development and maintenance, and, as appropriate, the revision of land use plans for public lands. The National Environmental Policy Act (NEPA) requires Federal agencies to prepare an Environmental Impact Statement (EIS) for major Federal actions that could significantly affect the environment. In fulfillment of these requirements, the Draft

Comment [JRL2]: NEED TO CLARIFY WHAT THIS IS AND WHAT TRIGGERED THE "START" OF THE STRATEGY – not referenced in the ROD precisely as "start" of strategy.

Comment [JRL3]: NOT RANGEWIDE, SINCE BLM PLANS DON'T COVER THE ENTIRE RANGE. THEY ARE "LANDSCAPE-LEVEL".

Comment [JRL4]: NOT COMPREHENSIVE SINCE OTHER ACTIVITIES – E.G., IMPLEMENTATION OF THE RANGELAND FIRE STRATEGY IS ALSO A PART OF A "COMPREHENSIVE" STRATEGY – AND NOT PART OF THE DECISIONS COVERED IN THE ARMPAs.

Comment [GSD5]: FWS does not capitalize and neither does the Dept in our materials . . .

Comment [MEM6]: Caps is consistent with other BLM planning docs and our tech. guide. May need to discuss.

Comment [KK7]: Culminating in? – COT & NTT didn't really produce the decade of research, and analysis; or ". . . guided by over a decade of research for GRSG conservation and analysis and recommendations provided by the COT . . ."

Comment [JRL8]: Shouldn't this be "hyphenated" every time?
KK: contractor will take care of editorial items

RMP Amendments/Draft EISs incorporating analysis and input provided by the public; local, State, and other Federal agencies and organizations; Native American tribes; Cooperating Agencies, and BLM personnel were published in the fall of 2013. The 90-day public comment periods ensued, with more than 4,990 substantive comments from 1,348 letters that were submitted. These comments were reviewed, summarized and considered in preparing the Proposed RMP Amendments/Final EISs.

Comment [JRL9]: For all plans or just those in this subregion?
KK: just this subregion

The Proposed RMPAs/Final EISs were made available on May 29, 2015, for a 60-day governor's consistency review and 30-day protest period. The BLM received consistency review letters from X and has worked closely with these states to resolve these inconsistencies. X protest letters were received, of which X were valid protests in need of resolution. Protest issues are addressed and resolved in the Protest Summary Report, available on line at: http://www.blm.gov/nv/st/en/fo/wfo/blm_information/rmp.html.

After much consideration, the BLM now approves the attached ARMPAs as the land use planning documents that will guide greater sage-grouse habitat management and uses that may affect the GRSG and its habitat in the Great Basin Region for the life of the plan amendment for the benefit of GRSG and over 350 other species of wildlife as well as many other land uses, like grazing and recreation, that depend on ~~a~~ healthy sagebrush-steppe landscapes.

Comment [JRL10]: Actually, all land and resource management in the affected area – better to clarify?
KK: suggested edit

Copies of the ROD and ARMPAs can be obtained from the BLM's National Greater Sage-Grouse webpage at: http://www.blm.gov/wo/st/en/prog/more/sagegrouse.html.

The BLM extends special appreciation to the extensive public involvement and the involvement of groups, organizations, Cooperating Agencies; local, State, and other Federal agencies; and Native American tribal representatives who contributed to the completion of these ARMPAs. This participation informed and improved the planning process and the planning documents. Your continued involvement is encouraged as the ARMPAs are implemented and monitored for the conservation of Greater sage-grouse and their habitat.

Sincerely,
X

Enclosure:
1. Record of Decision and Approved Resource Management Plan Amendments

Summary

This Record of Decision (ROD) is the culmination of an unprecedented effort in public land management to meet the multiple-use and sustained-yield management objectives for public lands administered by the Bureau of Land Management (BLM) in accordance with the Federal Land Policy and Management Act of 1976 (FLPMA).

In response to a 2010 determination by the U.S. Fish and Wildlife Service (FWS) that the greater sage-grouse listing under the Endangered Species Act (ESA) is "warranted but precluded" by other priorities, the BLM, in coordination with the U.S. Department of Agriculture Forest Service (Forest Service), has developed a targeted, multi-tiered, landscape-level management approach, based on the best available science, that offers the highest level of protection for Greater Sage-Grouse (GRSG) in the most important habitat areas to address the specific threats identified in the 2010 U.S. Fish and Wildlife "warranted but precluded" decision and Conservation Objectives Team (COT) report.

This Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon; and Utah includes land use allocations in the ARMPAs that limit or eliminate new surface disturbance in Priority Habitat Management Areas (PHMA), while minimizing disturbance in General Habitat Management Areas (GHMA). In addition to establishing protective land use allocations, the ARMPAs implement a suite of management actions, such as the establishment of disturbance limits, GRSG habitat objectives, mitigation requirements, monitoring protocols, and adaptive management triggers and responses, as well as other conservation measures throughout the range. The cumulative effect of these conservation measures work in concert to protect, improve, and restore GRSG habitat across the remaining range of the species in the Great Basin and provide greater certainty that BLM land and resource management activities in GRSG habitat in the Great

Basin Region can lead to conservation of the GRSG and other sagebrush-steppe associated species in the region.

The targeted land use plan protections presented in this ROD and ARMPAs do not only protect the greater sage-grouse and their habitat, but also the over 350 wildlife species that call the sagebrush-steppe ecosystem home. Reversing the slow degradation of this valuable ecosystem will also benefit local rural economies and a variety of rangeland uses in addition to habitat protection, ~~ranging from~~ including recreation and ~~to~~ grazing ~~and energy development~~, in a manner that safeguards the long term sustainability, diversity and productivity of the land.

This conservation strategy, developed in collaboration with the 11 states in which the ARMPAs and ARMPs apply, in addition to other state and federal actions underway and in development, represents an unprecedented, collaborative effort among federal land management agencies and the states to manage an entire ecosystem and associated flora and fauna, in order to "conserve the sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future". [Dan Ashe. Transmittal letter to COT report. 2014]

Comment [GSD11]: We may want to add some language at the end here from the rollout materials about targeted protections that benefit GRSG, 350+ other species as well as economic activity that depends on a healthy range.

Comment [MEM12]: Added this last paragraph based on Sarah G's suggestion. Will this work or should we flesh out more?

1. INTRODUCTION

This Record of Decision (ROD) approves the Bureau of Land Management's (BLM) attached ARMPAs for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM--administered lands. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.), BLM planning regulations (43 Code of Federal Regulations [CFR] §1601 *et seq*.), and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA) and the Council on Environmental Quality's Regulations for implementing the procedural provisions of NEPA (40 CFR §1500.1 *et seq*.).

Comment [JRL13]: Hyphen?

Throughout the GRSG planning process, the ~~U.S.~~ Forest Service has been a Cooperating Agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft RMPAs/Draft EISs and Proposed RMPAs/Final EISs included proposed GRSG management direction for National Forest System lands. The ~~U.S.~~ Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Comment [JRL14]: Cited previously, so should reference consistently through here on out.

1.1 Great Basin Region Planning Area

The Great Basin Region is composed of four sub-regions, the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah sub-regions (see **Figure 1-1** – Great Basin Region Greater Sage-Grouse Sub-regions). Four separate National Environmental Policy Act (NEPA) documents were prepared for each of these sub-regions. Each sub-region conducted its own planning effort with input from local cooperators, stakeholders, and members of the public. The sub-regional boundaries were constructed to align with BLM administrative offices, state boundaries, as well as areas that shared common threats to the GRSG and their habitat. The boundaries for these sub-regions largely coincide with zones III, IV, and V identified by the WAFWA Greater Sage-Grouse Conservation Strategy to delineate management zones with ~~similarecological~~similar ecological and biological issues and similarities.

Comment [KK15]: We could add the WAFWA zones here as one additional element used to make the region/subregion boundaries??

[Insert **Figure 1-1** - Great Basin Region Greater Sage-Grouse Sub-regions]

The Great Basin Region planning area boundaries include all lands regardless of jurisdiction (see **Figure 1-2** - Great Basin Region Planning Area, Greater Sage-Grouse Habitat Management Areas). **Table 1-1** outlines the amount of surface acres that are administered by specific Federal agencies, states, local governments, and lands that are privately owned in the four sub regions that make up the Great Basin. The planning area includes other BLM-administered lands that are not allocated as habitat management areas for GRSG. The ARMPAs do not establish any additional management for these lands; these lands will continue to be managed according to the existing land use plan for the areas.

Source: BLM GIS 2015

The decision area for the Great Basin Region ARMPAs is BLM-administered lands in GRSG habitat management areas (see **Figure 1-3** - Great Basin Region Decision Area , Greater Sage-Grouse Habitat Management Areas), including surface and split-estate lands with BLM subsurface mineral rights. Any decisions in the Great Basin Region ARMPAs apply only to BLM-administered lands, including split-estate lands within GRSG habitat management areas (the decision area). These decisions are limited to providing land use planning direction specific to conserving GRSG and its habitat.

Formatted: Highlight

Formatted: Highlight

Comment [JRL16]: HOW DO THESE DECISIONS DIFFER FROM OTHER LAND USE DECISIONS?
KK: should this sentence be deleted? It just seems to open the door to a debate about whether every decision in the plan really is necessary for conservation. And obviously, since this amendment is for GRSG conservation, all decisions are pertinent to that.

[Insert **Figure 1-3** - Great Basin Region Decision Area, Greater Sage-Grouse Habitat Management Areas]

1.2 Threats to Greater Sage-Grouse

Currently, GRSG occupy an area that has been estimated to be a reduction of 44% from the historically occupied range. In addition, populations in most or all the range have been demonstrated to have declined from 1965- 2003, the period where data was collected most intensively.

The decline of the GRSG and its sagebrush-steppe habitat has been the focus of fish and wildlife agency and conservationists' concerns for decades. In 1994 the Western Association of Fish and Wildlife Agencies (WAFWA) formed a technical committee to monitor the distribution and abundance of GRSG. WAFWA formalized a program of interstate coordination and cooperation in 1995 to address the issues of GRSG population losses and degradation of sagebrush ecosystems in order to: 1) Maintain the present distribution of GRSG and 2) Maintain the present abundance of GRSG. In 1999 WAFWA amended the objectives to: 1) Maintain and increase where possible the present distribution of GRSG and 2) Maintain and increase where possible the present abundance of GRSG. The Bureau of Land Management, USFWS, and U.S. Forest Service formally joined with WAFWA in range-wide conservation efforts in 2000.

Between May 1999 and December 2003, eight petitions were filed with the U.S. Fish and Wildlife Service (USFWS) to have sage-grouse protected under provisions of the Endangered Species Act (ESA). In 2001 the USFWS determined that greater sage-grouse in the Columbia Basin of Washington state warranted protection under provisions of the ESA. On January 12, 2005, the FWS issued a decision that listing the GRSG for protection under the ESA was not warranted. However, in response to July 14, 2006 Western Watersheds Project filing alleging that the FWS 2005 finding was incorrect and arbitrary, the U.S. District Court of Idaho ruled that the 2005 finding was "arbitrary and capricious" and remanded it to the FWS for further consideration. Ultimately, as a result, in 2010 the FWS issued a finding that listing of the Greater sage-grouse was "warranted but precluded". Subsequent to that finding ~~and in accordance with a settlement agreement,~~[details?] the FWS committed to make a final determination regarding the need to list the GRSG by September 30, 2015. Two factors led to the FWS decision to list the species as "warranted but precluded": threats to habitat and the inadequacy of existing regulatory mechanisms.

Comment [JRL17]: Need to address.

Comment [KK18]: I suggest we just delete it – don't think this is necessary for the BLM ROD

Formatted: Highlight

The USFWS has identified a number of threats to GRSG in the Great Basin Region, focusing on the present and widespread threats of wildfire and the loss of native habitat to invasive species. Other threats, some of which are more localized by nature, include habitat fragmentation due to anthropogenic disturbances associated with energy development, mining, infrastructure, recreation, urbanization and sagebrush elimination, as well as disturbance associated with free-roaming equids and improper livestock grazing.

Additional information regarding potential threats to the GRSG is contained in the BLM National Technical Team (NTT) report and the Conservation Objectives Team (COT) reports. A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG in the Great Basin Region– as articulated in the COT report – is summarized in **Table 1-2**.

In addition, the FWS found that existing local, state and federal regulatory mechanisms were not sufficient to address threats to the habitat. For the BLM, which manages more than 40 percent of the remaining habitat range wide, regulatory mechanisms are the agency's Resource Management Plans (RMPs).

Comment [JRL19]: DO WE NEED TO FOOTNOTE SINCE WE USE "RANGE" AS THE BASE HERE AND A DIFFERENT CHARACTERIZATION/REFERENCE IN OTHER PARTS OF THE DOCUMENT?

The BLM initiated this planning effort with the U.S. Forest Service to provide the needed federal regulatory mechanisms to address the individual threats listed in Table 1-3. This ROD approves the BLM's attached ARMPAs for the Great Basin Region GRSG Sub-regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPAs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM- administered lands. ~~The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).~~

Comment [KK20]: I'm inclined to delete this as unneeded here

Comment [KK21]: Already in the 1st paragraph of the intro

1.3 Early GRSG Conservation

The BLM manages the majority of the GRSG habitat on Federal lands (i.e., the range of GRSG not including the Columbia Basin or Bi-State Distinct Population Segments). Efforts to conserve the habitat of this species by the BLM and other wildlife conservation agencies and organizations ~~did not begin with the 2011 BLM's National GRSG Planning Strategy, but rather,~~ have been ongoing for many years.

The Western Association of Fish and Wildlife Agencies (WAFWA) 2004 *Range-wide Conservation Assessment for Greater Sage-Grouse and Sagebrush Habitats* was the first range-wide assessment of GRSG using the vast amount of population data collected over the previous 60 years, habitat information spanning the previous 100 years, and literature dating back 200 years. The goal of the assessment, contributed to by the BLM, was to present an unbiased and scientific documentation of dominant issues and their effects on GRSG populations and sagebrush habitats. http://sagemap.wr.usgs.gov/docs/Greater_Sage-grouse_Conservation_Assessment_060404.pdf

In November 2004, the BLM released its *National Sage-Grouse Habitat Conservation Strategy*, which encouraged GRSG habitat conservation through consultation, cooperation, and communication with WAFWA, the U.S. Fish and Wildlife Service (FWS), the Forest Service, the U.S. Geological Survey (USGS), State wildlife agencies, local GRSG working groups, and various other public and private partners.

In 2006, WAFWA completed a *Greater Sage-Grouse Comprehensive Conservation Strategy*, with the assistance of the BLM, the Forest Service, and other contributors. The overall goal of the Strategy was to maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain those populations. The Strategy outlined the critical need to develop the associations among local, state, provincial, tribal, and federal agencies, non-governmental organizations, and individual citizens to design and implement cooperative actions to support robust populations of GRSG and the landscapes and habitats upon which they depend. The catalyst for this effort was widespread concern for declining populations and reduced distribution of GRSG. http://www.wafwa.org/documents/pdf/GreaterSage-grouseConservationStrategy2006.pdf

In 2008, the BLM created two national teams to investigate possible BLM management options for GRSG conservation as well as summarizing BLM's ongoing conservation efforts. A product of this effort was one of the first range-wide priority habitat maps for GRSG that were referred to as "key habitat". At the time, the primary purpose for the key habitat map was to inform and help prioritize fire suppression efforts in GRSG habitat on BLM lands. An additional outcome of this team was the signing of a Memorandum of Understanding by the WAFWA; the BLM, FWS, USGS in the Department of the Interior; and the US Department of Agriculture Forest Service and NRCS, to provide for cooperation among the participating state and federal land managers and wildlife management and science agencies in the conservation and management of GRSG sagebrush habitats and other sagebrush-dependent wildlife throughout the Western United States and Canada. http://www.blm.gov/style/medialib/blm/wo/Planning_and_Renewable_Resources/fish__wildlife_and/fwp.Par.95958.File.dat/SagegrouseMOU.pdf

In 2010, BLM commissioned an effort to map breeding densities of GRSG across the West. A conference was convened with the state wildlife agencies to get approval and to coordinate the lek survey data needed for this effort. This modelling project, through an agreement with the FWS, mapped known active leks across the West. This model served as a standard starting point for all states to identify priority habitat.

http://www.blm.gov/wo/st/en/prog/more/fish__wildlife_and/sage-grouse-conservation/bird_density.print.html

In March 2010, the US Fish and Wildlife Service (USFWS) published their 12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered (75 Federal Register 13910, March 23, 2010). In that finding, the USFWS concluded that GRSG was "warranted, but precluded" for listing as a threatened or endangered species. A warranted, but precluded determination is one of three results that may occur after a petition is filed by the public to list a species under the Endangered Species Act (ESA). This finding indicates that immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, the species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

The USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 Federal Register 13910, March 23, 2010). The USFWS identified the principal regulatory mechanisms for the BLM and Forest Service as conservation measures in land use plans.

1.4 National Greater Sage Grouse Planning Strategy

Based on the identified threats to the GRSG, especially inadequate regulatory mechanisms, and the FWS's timeline for making a listing decision on this species, the BLM recognized the need to incorporate explicit objectives and adequate conservation measures into RMPs by 2015 to conserve GRSG habitat and avoid the need to list the species under the Endangered Species Act. In August, 2011, the BLM chartered a planning strategy to evaluate the adequacy of BLM RMPs and address revisions and amendments throughout the range of the GRSG (with the exception of the bi-state population in California and Nevada, and the Washington state distinct population segment, which were addressed through other planning efforts). This Charter established the teams, team membership, and team operating procedures for the BLM's National GRSG Planning Strategy. The BLM's objective for chartering this planning strategy effort was to develop new or revised regulatory mechanisms through RMPs to conserve and restore the GRSG and its habitat on BLM-administered lands on a range-wide basis for the long-term (Figure C).
http://www.blm.gov/style/medialib/blm/wo/Communications_Directorate/public_affairs/sage-grouse_planning/documents.Par.2415.File.dat/Final%20Signed%20GSG%20Planning%20Strategy%20Charter.pdf

Two national teams and numerous other studies were used to help inform the planning efforts. The GRSG National Technical Team (NTT), comprised of BLM, FWS, USGS, NRCS, and State specialists, completed A Report on National Greater Sage-Grouse Conservation Measures in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats in the FWS listing action (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones (Figure 1-4). The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and

emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. ~~These WAFWA Management Zones are identified on **Figure 1-4** below.~~ http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

In 2012, FWS convened the Conservation Objectives Team (COT) of state and federal representatives to produce a peer-reviewed report which identified the principal threats to GRSG survival -- based upon the FWS 2010 listing decision -- and the degree to which these threats need to be reduced or ameliorated to conserve the GRSG so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future.[1] The COT report also identified Priority Areas for Conservation (PACs) and emphasized that "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". Finally, the COT report identified present and widespread, as well as localized threats by GRSG population across the West. These population specific threats, as specified from the COT report, are outlined in **Table 1-2**. **Figure 1-4** from the COT Report identifies the PACs, GRSG populations (and their names), and WAFWA Management Zones across the West.
http://www.fws.gov/greatersagegrouse/documents/COT-Report-with-Dear-Interested-Reader-Letter.pdf

[Insert **Figure 1-4** - GRSG Priority Areas for Conservation, Populations (and names), and WAFWA Management Zones.]

Additional science-based reviews by the US Geological Survey and related scientific literature provided further guidance on specific issues that arose in developing the ARMPAs.

To adequately address the reasons for the 2010 "warranted" determination by the FWS – and specific threats summarized in the COT report -- it was clear to the BLM that additional regulatory measures on federal public lands would be necessary to deal with present or threatened destruction, modification, or curtailment of habitat or range. These measures would need to be incorporated into land use plans that guide management actions on lands within the remaining range of the GRSG administered by the agencies to conserve GRSG such that listing under the ESA was no longer necessary.

In December 2011, the BLM published a Notice of Intent to prepare EISs and Supplemental EISs to incorporate GRSG Conservation Measures into Land Use Plans (LUPs) across the range of the species. A total of 15 sub-regional planning efforts (resulting in eight ARMPAs and nine ARMPs) would amend or revise 78 BLM RMPs ~~and 20 Forest LRMPs~~ across the range of the species.

The federal public land planning strategy reflected several key concepts:

- **Landscape-level**: The planning effort focused on the remaining habitat of the GRSG on public lands, covering 10 western states in the Great Basin and Rocky Mountain regions.
- **Best Available Science** – The ARMPAs/ARMPs are grounded in the best available science, drawn from published literature and input from recognized experts, state agencies, the US Geological Survey, the FWS and other sources. The COT report provided a "blueprint" for GRSG conservation by identifying specific threats to each remaining GRSG population and recommending measures to address each category of threat and the NTT report, prepared by the BLM, provided options for dealing with the most significant threats to the GRSG. A series of reports on how to improve efforts to reduce the threats of rangeland fire and invasive species prepared in collaboration with the Western Association of Fish and Wildlife Agencies also provided crucial guidance in formulating the conservation strategy.

Comment [KK22]: In this section we go back to talking about the whole planning area, not just the ARMPAs for Great Basin. Is this necessary? If it is, is it clear to the average reader that we have made that transition & what the difference is between ARMPA and ARMP?

---

[1] The Conservation Objectives Team (COT) report was prepared with the encouragement of the members of the Sage Grouse Task Force, chaired by former Secretary of the Interior Ken Salazar and Governor Meade of Wyoming and Governor Hickenlooper of Colorado.

- **Targeted, Multi-Tiered Approach** – The ARMPAs/ARMPs were designed to incorporate a layered management approach to avoid or minimize additional surface disturbance in the most valuable habitat, known as Priority Habitat Management Areas (PHMA), which are largely consistent with PACs identified in the COT Report. Within PHMA, the ARMPAs/ARMPs provide an added level of protection to limit or eliminate new surface disturbance through the delineation of Sagebrush Focal Areas (SFA), derived from areas identified by the FWS as "strongholds" essential for the species' survival. In General Habitat Management Areas (GHMA), the ARMPAs/ARMPs seek to minimize disturbance while providing greater flexibility for land use activities.
- **Coordinated**: The BLM ARMPAs/ARMPs were developed through a joint planning process led by the BLM with the Forest Service as partners. The USFWS provided guidance and input throughout the process to aid land managers in understanding the threats and the certainty and effectiveness of proposed land management actions in addressing those threats. The USGS and NRCS also provided key technical and scientific support.
- **Collaborative**: The ARMPAs/ARMPs reflected the input of states and local stakeholders from the outset and were developed with the benefit of input from the individual states and cooperators who signed formal agreements with the BLM to provide input into the planning process. The Western Governors Association Sage Grouse Task Force (SGTF), which is discussed below, was particularly useful in facilitating this kind of collaborative input. The ~~proposed LUPs~~ ARMPAs/ARMPs reflect state and stakeholder developed approaches and economic priorities where consistent with conservation objectives.

Most states across the range provided recommendations for the management of the BLM lands in their state to conserve GRSG. In all cases, this input was incorporated into the range of alternatives analyzed in the Final EISs. Components of these state recommendations were used to develop the ARMPAs/ARMPs where consistent with conservation objectives.

In addition, the ~~Western Governors Association Sage Grouse Task Force~~SGTF was established in 2011 to identify and recommend state and federal conservation actions necessary to preclude the need for the GRSG to be listed under the ESA. This group, which includes designees from the 11 western states where GRSG is found as well as representatives from USFWS, BLM, Natural Resources Conservation Service, US Forest Service, US Geological Survey, and the Department of the Interior, played an integral role throughout this land use planning process.

1.5 Addressing Threats to the Greater Sage-Grouse through the ARMPAs~~s~~

The 2006 WAFWA *Greater Sage Grouse Comprehensive Conservation Strategy* stated goal for management of the GRSG was to "maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain these populations".[2] The NTT report also endorsed this goal "as a guiding philosophy against which management actions and policies of BLM should be weighed"[3] And, in establishing the COT, with the backing of the SGTF, FWS Director Dan Ashe affirmed the commitment to the goal for GRSG conservation originally articulated in the 2006

---

[2] WAFWA 2006 Strategy. The 2006 objectives built on an initial framework and commitment made by the WAFWA directors, the BLM and the FWS in 2000 with the signing of an interagency sagebrush/sage-grouse conservation MOU.

[3] Sage-grouse National Technical Team. "A Report on National Greater Sage-Grouse Conservation Measures". December 21, 2011.

WAFWA report -- reversing negative population trends and achieving a neutral or positive population trend -- and emphasized the following,

> "The Service interprets this recommendation to mean that actions and measures should be put in place now that will eventually arrest what has been a continuing declining trend. Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels."7

Comment [JRL23]: Need to check footnotes – these do not run in order in present draft

Formatted: Highlight

The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT stated, "[m]aintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation". To achieve this, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT emphasized an "avoidance first strategy" and stressed that threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

The ARMPAs/ARMPs were developed to remove or reduce identified threats to the species and are an essential component of the effort to conserve GRSG and avoid a listing of the species under ESA. Across ten western States, the Great Basin and Rocky Mountain sub-regional ARMPs/ARMPAs contain updated land use plan direction on approximately 50 percent of the remaining habitat for the species. These ARMPAs/ARMPs are the product of extensive coordination between the BLM and the Forest Service and the active engagement of the USFWS in helping to inform land allocation and related management decisions by the BLM. The plans also benefit from strong collaboration with the states and reflect the unique landscapes, habitats, and circumstances in each.

Comment [KK24]: Why is SGTF 11 if this is 10 – Washington state is included?

Comment [JRL25]: I DON'T LIKE THIS NUMBER. WE HAVE BEEN SAYING WE MANAGED NEARLY 60% OF THE REMAINING HABITAT FOR SOME TIME. WE SHOULD NOT BE CHANGING THE NUMBERS NOW UNLESS OR ORIGINAL ANALYSIS WAS WRONG!

KK: we did change to 50% in the landscape report, so this is consistent with that. Did we use something like this in the FEISs?

~~Designation of~~ Habitat Management Areas

Comment [MEM26]: Let me know if you think I need to integrate this into this section better. I think it flows ok now.

Comment [JRL27]: THIS SECTION DEALS WITH MORE THAN "DESIGNATION" SO I SUGGEST THE MODIFICATION NOTED.

In order to protect the most important GRSG habitat areas, the conservation strategy began with mapping areas of important habitat across the remaining range of the GRSG and within each state. In collaboration with state fish and wildlife agencies, the BLM identified areas as preliminary priority habitat ~~(PPH)~~ and preliminary general habitat ~~(PGH)~~. Maps were revised and refined as further mapping was conducted and state fish and wildlife agencies – often in collaboration with GRSG experts and researchers – provided more detailed analysis of habitat characteristics and populations. The ARMPAs reflect this input and have generally aligned these habitats with Habitat Management Areas in the ARMPAs. GRSG habitat management areas on BLM-administered lands in the decision area consist of lands allocated as Priority Habitat Management Areas (PHMA) which largely coincide with Priority Areas for Conservation in the COT report, General Habitat Management Areas (GHMA), Other Habitat Management Areas (OHMA, applicable only to the Nevada and Northeastern California), and Important Habitat Management Areas (IHMA, applicable only to Idaho). **Table 1-4** identifies surface acres of PHMA, GHMA, OHMA, and IHMA in the decision area for the Great Basin Region.

PHMA, GHMA, OHMA, and IHMA are defined as follows:

- **PHMA**— BLM-administered lands identified as having the highest value for~~to~~ maintaining sustainable GRSG populations. The boundaries and management strategies for PHMA are derived from and generally follow the Preliminary Priority Habitat boundaries identified in the Draft LUPA/EIS. Areas of PHMA largely coincide with areas identified as Priority Areas for Conservation in the COT report.

- **GHMA**— BLM-administered lands where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMA are derived from and generally follow the Preliminary General Habitat boundaries identified in the Draft RMP/EIS.
- **OHMA** —BLM-administered lands ~~only~~ in Nevada, identified as unmapped habitat in the Proposed RMP/EIS that are within the planning area and contain seasonal or connectivity habitat areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse Habitat in Nevada and Northeastern California; Coates et al. 2014,) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.
- **IHMA** —BLM-administered lands in Idaho that provide a management buffer for PHMA and connect patches of PHMA. IHMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. ~~There are no IHMAs designated within southwestern Montana.~~ The IHMA boundaries and management strategies are derived from and generally follow the Preliminary Medial Management Area (PMMA) and Important Habitat Zone (IHZ) boundaries identified in Alternatives D and E, respectively, of the Draft LUPA/EIS, but may be modified based on the objectives of each alternative. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the ARMPA.

Table 1-4

Surface Acres of PHMA, GHMA, OHMA, and IHMA in the Decision Area for the Great Basin Region

BLM administered surface acres	PHMA	GHMA	OHMA	IHMA
Idaho and Southwestern MT	4,627,200	2,179,700	0	2,737,600
Utah	2,023,400	502,500	0	0
Oregon	4,547,000	5,660,150	0	0
Nevada and Northeastern CA	9,309,700	5,720,600	5,876,600	0
Total Acres	**20,507,300**	**14,062,950**	**5,876,600**	**2,737,600**

Source: BLM GIS 2015

The ARMPAs also identify Sagebrush Focal Areas (SFAs) on a portion of the landscape. SFAs are a subset of PHMAs (see **Figure 1-3** - Great Basin Region Decision Area - Greater Sage-Grouse Habitat Management Areas). Across the Great Basin Region, there are 9,076,948 acres of BLM administered SFAs. SFAs correspond to the areas identified by the FWS as GRSG "strongholds" as detailed in an October 27, 2014 memorandum from the FWS Director to BLM Director and Forest Service Chief in response to a request to "identify a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection". (http://www.fws.gov/greaterSageGrouse/documents/ESA%20Process/GRSG%20Strongholds%20memo%20to%20BLM%20and%20USFS%20102714.pdf)

This tiered habitat framework provides for a nested or layered conservation design with the goal of providing the greatest ~~protections~~ protections for habitat in PHMAs achieved through: ~~and~~ ~~(1)~~ the strongest limits ~~ed~~on- new surface disturbance – ~~achieved through~~such as (1) no surface occupancy with limited exceptions for fluid minerals development, (2) exclusions (with limited exception) for wind and solar development, (3) avoidance for new rights of way, (4) closures for saleable mineral, with limited exceptions, (5) -priority protection from rangeland fire~~, (6) priority for habitat~~

~~restoration~~, (7) accelerated efforts to reduce grazing impacts from free-ranging equids, and (7) priority review for compliance with cattle grazing standards for public land allotments, as well as priority for habitat restoration. ~~in SFAs,~~

These conservation prescriptions for the PHMAs provide a high degree of certainty that the integrity of PHMAs can be maintained through management decisions to avoid or minimize additional surface disturbance. In SFAs, maximize protection from new surface disturbance would be achieved by (1) requiring NSO without exceptions for fluid minerals, (2) additional limits on disturbance from mining and related activity by recommending- withdrawal from new hardrock mining claims~~,~~for areas of PHMA not already closed to hardrock mining, ~~and a commitment to reduce wild horse and burro populations to Appropriate Management Levels (AML) by 2020~~. Given the “existing high quality sage brush habitat for sage grouse … and highest breeding densities of sage grouse” in the SFAs, or strongholds, as identified by the FWS, the decision to recommend withdrawal of SFAs from future hard rock mining is consistent with the COT recommendation to “Avoid new mining activities and/or any associated facilities within occupied habitats, including seasonal habitats; and avoid leasing in sage-grouse habitats until other suitable habitats can be restored to habitats used by sage-grouse.”

~~p~~
Protection of remaining habitats in GHMAs would be managed consistent with the COT report recommendation -to recognize “that important habitats outside of PACs be conserved to the extent possible”. ~~,~~Thus, land allocations and management prescriptions for lands in GHMAs provide for ~~with~~ more flexibility for land use activities that would be designed to minimize impacts on existing GRSG leks. In all GRSG habitat management areas, anthropogenic surface disturbing activities would be mitigated, and degraded landscapes, due to fire or other causes, would be actively restored and protected. ~~with a priority on SFAs, then PHMAs, and then GHMAs~~. The combination of habitat classifications and land allocation decisions in the ARMPAs will provide the greatest protection for those areas identified as SFAs and meet the stated objective for these areas “where it is most important that the BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species.”

Major components of the attached ARMPAs ~~developed to~~that address the specific threats to the viability of the GRSG, as identified in the USFWS 2010 listing decision and COT r~~R~~eport (many of which were also identified by the BLM’s NTT Report) are listed in **Table 1-3** and summarized below. Throughout the ARMPAs, a particular focus is placed on an “avoidance first strategy” as emphasized in the COT report by limiting new disturbance and maintaining current intact GRSG habitat. This avoidance first strategy is accomplished through identification and allocation of important GRSG habitat and excluding or avoiding surface disturbing activities, appropriately managing grazing, and aggressively suppressing fire that could degrade or fragment remaining GRSG habitat. The plans also include decisions to restore degraded habitat, which although more difficult and requiring a longer time frame, is important to the long-term viability of GRSG. Restoration decisions include specific habitat objectives, and a priority on treating GRSG habitat for invasive species, particularly cheatgrass, and encroaching pinyon and juniper. These decisions are reinforced by Secretarial Order 3336 and the *Integrated Rangeland Fire Management Strategy* which provide a framework, specific actions, and Department-wide priority on managing Federal lands, particularly in the Great Basin, to protect and restore sagebrush-steppe habitat.

Comment [KK28]: Moved this down because the rest are surface disturbance, this is not.

Comment [KK29]: This new text is covered in the sections below about surface protection & habitat improvement – this section was supposed to be just about the designations, to provide context for the next sections. By moving it all up here, should we delete all following sections?

Comment [JRL30]: Correctly characterized?

Comment [KK31]: This is not an RMP thing so should not be included.

Comment [KK32]: I recommend moving all of this down to the surface disturbance section

Comment [KK33]: ?? is this correct

Comment [KK34]: Just to confirm, IHMA & OHMA are never part of this hierarchy?

Comment [KK35]: JL has deleted this, not sure why because it seems pertinent to explain the hierarchy.

Table 1-3
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
All threats	• Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met. • Require and ensure mitigation that provides a net conservation gain to GRSG and its habitat. • Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner. • Apply buffers necessary based on project type and location to address impacts on leks when authorizing actions in GRSG habitat. • Apply Required Design Features (RDFs) when authorizing actions that affect GRSG habitat. • Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.
All development threats, including mining, infrastructure, and energy development.	• PHMA: Implement an anthropogenic disturbance cap of 3% within the Biologically Significant Unit and proposed project analysis areas in PHMA (slight variations to this management component in the State of Nevada only) • PHMA: Apply a disturbance density cap of 1 facility per 640 acres (except in the State of Nevada)
Energy development—fluid minerals, including geothermal resources	• PHMA: Open to fluid mineral leasing subject to a No Surface Occupancy (NSO) stipulation without waiver or modification, and with limited exceptions. In SFAs, a NSO stipulation would be applied without waiver, modification, or exception. In Nevada only, in the portions of the PHMAs outside of SFAs, geothermal projects may be considered for authorization if certain criteria is met. • GHMA: Open to fluid mineral leasing subject to Controlled Surface Use (CSU) and Timing Limitation (TL) lease stipulations (except in the State of Utah where some portions of GHMA are open with standard lease stipulations)
Energy development—wind energy	• PHMA: Exclusion area (not available for wind energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Avoidance area (may be available for wind energy development with special stipulations) (except in the States of Utah and Idaho, where these areas would open to wind energy development)
Energy development—solar energy	• PHMA: Exclusion area (not available for solar energy development under any conditions) (except in southeastern counties in the State of Oregon where portions of PHMA are avoidance areas) • GHMA: Exclusion area (not available for solar energy development under any conditions) (except in the States of Oregon and Montana where these areas are avoidance areas for solar energy development and the State of Idaho, where these areas would open to solar energy

Table 1-3
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
	development)
Infrastructure—major ROWs	• PHMA: Avoidance area (may be available for major ROWs with special stipulations) • GHMA: Avoidance area (may be available for major ROWs with special stipulations) (except in the State of Utah where GHMA is open)
Infrastructure—minor ROWs	• PHMA: Avoidance area (may be available for minor ROWs with special stipulations)
Mining—locatable minerals	• SFA: Recommend withdrawal from the Mining Law of 1872
Mining—nonenergy leasable minerals	• PHMA: Closed area (not available for nonenergy leasable minerals)
Mining—salable minerals	• PHMA: Closed area (not available for salable minerals) with a limited exception (may remain open to free use permits and expansion of existing active pits if criteria are met)
Livestock grazing	• Prioritize the review and processing of grazing permits/leases in SFAs followed by PHMA. • The NEPA analysis for renewals and modifications of grazing permits/leases will include specific management thresholds, based on the GRSG Habitat Objectives Table, Land Health Standards and ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis. • Prioritize field checks in SFAs followed by PHMA to ensure compliance with the terms and conditions of grazing permits.
Free-roaming equid management	• Prioritize gathers in SFAs, followed by other PHMAs. • Manage Herd Management Areas (HMAs) in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives. • Prioritize rangeland health assessment, gathers and population growth suppression techniques, monitoring, and review and adjustment of AMLs and preparation of Herd Management Area Plans in GRSG habitat.
Range management structures	• Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats. • Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas subject to valid existing rights.
Recreation	• PHMA: Do not construct new recreation facilities unless required for health and safety purposes.

Table 1-3
Key Components of the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses of the Great Basin Region GRSG ARMPAs
	• Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain. • PHMA & GHMA: OHV use limited to existing routes (routes to be designated through future travel management planning)
Fire	• Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection. • Prioritize post-fire treatments in SFAs, other PHMAs and GHMAs.
Nonnative, invasive plant species	• Improve GRSG habitat by treating annual grasses. • Treat sites in PHMA and GHMA that contain invasive species infestations through an integrated pest management approach.
Sagebrush removal	• PHMA: Maintain a minimum of 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover. • All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and/or juniper expansion	• Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.
Agricultural conversion and exurban development	• GRSG habitat will be retained in federal management.

Comment [KK36]: Matt, I am pointing out that I added this to the table – it was in redline in the last version from me & Jim, but since I moved the table I think the whole table was redline so I just want to be sure you see it.

The ARMPAs were developed based on three range-wide objectives for conserving and protecting habitat: minimizing new and additional surface disturbances, improving habitat conditions, and reducing threats of rangeland fire to GRSG and sagebrush habitat. How the ARMPAs met these objectives is summarized below.

1.5.1 Avoid and Minimize Surface Disturbance

Allocations and Habitat Protection/Surface Disturbance Measures

Comment [KK37]: Are these subheaders needed or can we just let this section flow from paragraph to paragraph?

To avoid or minimize further surface disturbance in PHMAs the ARMPAs either close, exclude, or avoid major new surface disturbing activities. In SFAs, in addition to PHMA decisions described below and shown in **Table 1-3**, ARMPAs apply a no surface occupancy stipulation with no exceptions for oil and gas leasing and recommend these areas for withdrawal from future locatable mineral entry.

The four Great Basin ARMPAs provide land use allocations and management guidance for PHMAs to avoid new disturbance and minimize any disturbance associated with projects that might be developed in PHMA in the future. Allocations to avoid and minimize additional disturbance in PHMA include, fo~~i~~r example, the application of a no surface occupancy (NSO) stipulation associated with any future leasing and development of oil and gas in PHMAs. With the exception of a few areas in Utah and in eastern Nevada, there is low potential for fluid minerals in the Great Basin Region.

Similarly, mineral development is closed in PHMAs for non-energy leasable minerals and saleable minerals, ~~with the exception of~~but not for locatable minerals governed under the 1872 Mining Act. An exception is granted for free use permits and the expansion of existing active pits for ~~mineral~~ saleable minerals ~~material sales~~ and expansion of existing non-energy leasable development. Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses this threat. In Utah, at the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. PHMA is essential habitat for maintaining GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).

Comment [KK38]: I changed this so we used the same name as the previous sentence & Table 3.

Comment [GSD39]: What is the relevance of this statement, do we not have the coal language in the other plans?

Comment [MEM40]: Because energy development is a present and widespread threat to certain populations in UT, I thin k its important to state this. We can remove if needed.

In all PHMAs in the Great Basin Region, renewable energy development (solar and wind) is excluded, with the exception of three areas in southeastern Oregon where an avoidance allocation is applied; and new rights of way and development for transmission lines, pipelines, and related infrastructure is avoided through restrictions on land use authorizations. Where the allocation is avoidance, exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs, unless the development results in a net conservation gain to the GRSG or its habitat.

Comment [GSD41]: Do we need to explain why OR is different here or somewhere else?

Comment [KK42]: Is this three areas or three counties?

Comment [MEM43]: This should be addressed in section 1.6. May need assistance with this rationale.

While restrictions on future development in PHMA are intended to avoid or minimize additional surface disturbance, restrictions on development in GHMA are less stringent and can accommodate a limited amount of disturbance. Disturbance associated with oil and gas development, for example, is subject to a controlled surface use and timing limitation stipulation rather than an NSO stipulation see **Table 1-3** for more details on GHMA management decisions. However, any disturbance is subject to mitigation and should seek to first avoid and then minimize any impacts to GRSG or its habitat, while offsetting unavoidable impacts to a standard that produces a net conservation gain for the species. As noted in the COT report, "Conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur. …If development or vegetation manipulation activities outside of PACs are proposed, the project proponent should work with federal , state or local agencies and interested stakeholders to ensure consistency with sage-grouse habitat needs."

In addition to areas where uses are closed, excluded or avoided, the ARMPAs direct the BLM to proactively prioritize oil and gas leasing and development outside of identified SFAs, PHMAs, and GHMAs in order to encourage new development in areas that would not conflict with GRSG and thus maximize the potential to limit disturbance to remaining GRSG habitat. This approach will also assist developers in reducing the time and cost associated with oil and gas leasing development by avoiding sensitive areas and decreasing the need for compensatory mitigation.

Comment [JRL44]: SHOULD WE CITE FINDINGS IN THE WEST STUDY HERE TO HIGHLIGHT HIGH AND MEDIUM OIL AND GAS POTENTIAL OUTSIDE OF HABITAT?

In general, all forms of new development would be closed, excluded, avoided, or developed only if the resultant effect is a net conservation gain to the GRSG or its habitat, assuring that existing habitat would be protected and providing opportunities through compensatory mitigation to restore degraded habitats. This is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0*, published by the FWS in September 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse." In all instances, whether in PHMA or GHMA, any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation gain for the GRSG.

In addition to major surface disturbing activities such as energy and infrastructure development, the ARMPAs address other identified threats~~activities~~, including improper livestock grazing, wild horses and burros overuse ~~management~~, and recreation. Grazing is the most widespread use of the sagebrush steppe ecosystem in the Great Basin Region. The COT r~~R~~eport recommendation for grazing states, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage- grouse (e.g. shrub cover, nesting cover)." To ensure that grazing continues in a manner consistent with the objective of conserving the GRSG and its habitat, the four Great Basin ARMPAs require the incorporation of GRSG seasonal habitat objectives into grazing permits, consistent with the ecological site potential of the local areas, prioritize the review and monitoring of grazing permits, and take numerous actions to avoid and minimize the impacts of range management structures (see **Table 1-3**).

To address the localized threat due to negative influences of grazing by free-roaming equids (wild horses and burros (WHB)), the BLM will focus on meeting and maintaining WHB Herd Management Areas in GRSG habitat within established Appropriate Management Level (AML) ranges to achieve and maintain GRSG habitat objectives, including completing rangeland health assessments, prioritizing gathers and population growth suppression techniques, and developing or amending Herd Management Area plans to incorporate GRSG habitat objectives and management considerations. In SFAs and PHMA, the BLM will assess and adjust AMLs through the NEPA process within HMAs when WHBs are identified as a significant causal factor in not meeting land health standards, even if current AML is not being exceeded.

Comment [KK45]: Don't think we can just say maintaining since most are currently over AML

Comment [JRL46]: Should we make note of commitment to bring all SFAs to AML by 2020?

Comment [MEM47]: The 2020 deadline is not mentioned as a management action in the ARMPAs. The language as presented is within all 4 ARMPAs.

To ameliorate the threat from recreational activities, new facilities or expansion of existing facilities (e.g., roads, trails, campgrounds) will not be authorized in PHMA unless the development results in a net conservation gain to GRSG its habitat. In PHMA and GHMA travel would be limited to vehicle routes. Initially, vehicles would be limited to existing routes until implementation travel management planning could be completed to designate routes. Travel management plans, including route inventories, NEPA analysis, and route designation will be completed in a subsequent public planning process.

Disturbance Caps, Density Caps, and Lek Buffers

In addition to the management actions and allocations discussed in detail in the sections above, the ARMPAs limit the amount of anthropogenic disturbances in PHMAs through the use of disturbance caps, density caps and lek buffers. These elements further address threats related to surface disturbances by limiting the amount of habitat impacted and keeping resource uses an appropriate distance~~way~~ from leks. In general, disturbance caps of 3% were established in accordance with the recommendations contained in the COT report. ~~i~~If the 3% anthropogenic disturbance is exceeded on lands (regardless of land ownership) within PHMA in any given Biologically Significant Unit (BSU), no further discrete anthropogenic disturbances (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.) will be permitted within PHMAs in that Biologically Significant Unit. If the disturbance cap is exceeded on all lands (regardless of land ownership) within a proposed project analysis area in a PHMA, then no further anthropogenic disturbance will be permitted until disturbance in the proposed project analysis area has been reduced to be under the cap (subject to applicable laws and regulations, such as the Mining Law of 1872, as amended, valid existing rights, etc.). The ARMPAs have a few modifications to the disturbance cap: Oregon does not allow more than 1% new anthropogenic disturbance per decade, not to exceed 3% disturbance at any time. In Nevada, exceeding a 3% disturbance cap can occur at the BSU and/or the project level as long as the outcome results in a net conservation benefit as approved by the BLM in accordance with the process described in **Section 1.6**.

Comment [KK48]: Added a sentence to tie this section back to the threats it is addressing.

Comment [JRL49]: WHERE DO WE ADDRESS BSUs AND CALCULATION OF DISTURBANCE WITHIN BSUs? NEED TO DO SO WITH A PARAGRAPH OR REFERENCE TO A FOOTNOTE OR APPENDICE HERE.

~~Limiting Density of Disturbance~~

The ARMPAs incorporate a cap on the density of energy and mining facilities to encourage consolidation of structures and to reduce habitat fragmentation. The cap is set at an average of one facility per 640 acres in PHMA in a project authorization area, consistent with guidance contained in the NTT report. If the disturbance density in the PHMA in a proposed project area is on average less than 1 facility per 640 acres, the analysis will proceed through the NEPA process incorporating mitigation measures into an alternative. If the disturbance density is greater than an average of 1 facility per 640 acres, the proposed project will either be deferred until the density of energy and mining facilities is less than the cap or co-located into an existing disturbed area, subject to applicable laws and regulations, such as the 1872 Mining Law, valid existing rights, etc. The one facility per 640 density decision does not apply to Nevada, as described in **Section 1.6**.

~~Buffering Development Impacts~~

The ARMPAs require that impacts to leks be evaluated for actions requiring NEPA analysis. In addition to any other relevant information determined to be appropriate (e.g. State wildlife agency plans), the BLM will assess and address impacts from certain activities using the lek buffer-distances as identified in the USGS Report Conservation Buffer Distance Estimates for GRSG – A Review (Open File Report 2014-1239). The lek buffer distances required vary by type of disturbance (road, energy development, infrastructure, etc.) and are fully described in Appendix X of the ARMPAs.

The lek buffer distances will be applied as required conservation measures to fully address the impacts to leks as identified in the NEPA analysis. Impacts should be avoided by locating the action outside of the applicable lek buffer-distance(s) as defined in the ARMPAs. In PHMA, if the action cannot be located outside of the buffer-distance, the BLM may approve actions in PHMAs that are within the applicable lek buffer-distance only if a different buffer distance offers the same or greater level of protection to GRSG and its habitat. In GHMAs actions may be approved within the applicable lek buffer distance only if a different distance offers the same or a greater level of protection to GRSG and its habitat, including conservation of seasonal habitat outside of the analyzed buffer area; or impacts to GRSG and its habitat are minimized such that the project will cause minor or no new disturbance (ex. co-location with existing authorizations) and any residual impacts within the lek buffer-distances are addressed through compensatory mitigation measures sufficient to ensure a net conservation gain. This approach to determining relevant lek buffer distances is consistent with the COT recommendation that "conservation plans should be based on the best available science and use local data on threats and ecological conditions."[4]

Required Design Features

Required Design Features (RDFs) and Best Management Practices (BMPs) are required for certain activities in all GRSG habitat, including PHMA, GHMA, IHMA in Idaho and OHMA in Nevada. RDFs establish the minimum specifications for certain activities to help mitigate adverse impacts. However, the applicability and overall effectiveness of each RDF cannot be fully assessed until the project level when the project location and design are known. Because of site-specific circumstances, some RDFs may not apply to some projects (e.g., a resource is not present on a given site) and/or may require slight variations (e.g., a larger or smaller protective area). RDFs and BMPs have been developed for oil and gas

---

[4] COT report, p 34

development, infrastructure, range developments, and other surface disturbing activities and are fully described in Appendix X of the ARMPAs.

1.5.2 Habitat Mitigation and Restoration, Monitoring and Adaptive Management~~Improving Habitat Conditions~~

In addition to~~ improving~~ prescribing land allocations and~~-~~ managing~~ement of~~ resource uses ~~and~~ to minimize and avoid~~ing~~ further surface disturbance, the ARMPs/ARMPAs identify management actions to promote the ~~restoration and~~ mitigation and restoration ~~improvement~~ of GRSG habitat. ~~.~~ ~~The ARMPAs also describe a~~ M~~m~~itigation for habitat disturbing resource uses will ~~program, which~~ follow~~s~~ the avoid, minimize, and compensate mitigation hierarchy. ~~(See Section 5 for more information.)~~ Where compensatory mitigation is required to offset unavoidable impacts, habitat restoration activities will be developed ~~in coordination with the states,~~ to provide ~~for habitat restoration activities that produce~~ a net conservation gain for the GRSG.

During the implementation of the ARMPs/ARMPAs, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in GRSG habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation;~~ Wyoming will apply a net conservation gain standard to actions in PHMA only~~. This will be achieved by avoiding, minimizing, and compensating for unavoidable impacts by applying beneficial conservation actions to offset remaining impacts associated with the action. This standard is consistent with the recommendation included in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0* published by the FWS in September, 2014, which states that mitigation "be strategically designed to result in net overall positive outcomes for sage-grouse"[5]**.** Mitigation will follow the regulations from the White House Council on Environmental Quality (CEQ) (40 CFR 1508.20; e.g. avoid, minimize, and compensate) and be implemented on BLM-managed lands in a manner consistent with Departmental guidance for landscape mitigation pursuant to Secretarial Order 3330[6]. If impacts from BLM and Forest Service management actions and authorized third party actions result in habitat loss and degradation that remain after applying avoidance and minimization measures (i.e. residual impacts), then compensatory mitigation projects will be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation.

Within 90 days of the issuance of the Record of Decisions, BLM will establish WAFWA Management Zone GRSG Conservation Team, including members from the respective states, Forest Service, USFWS, NRCS, and other local governments. This team that will develop a WAFWA Management Zone Regional Mitigation Strategy to inform the NEPA decision making process including the application of the mitigation hierarchy for BLM and Forest Service actions and third party authorizations that result in habitat loss and degradation. These regional mitigation strategies will contribute to GRSG habitat conservation by reducing, eliminating, or

---

[6] Secretarial Order 3330. Improving Mitigation Policies and Practices of the Department of the Interior. October 2013.

Comment [MEM50]: Should we add a reference to adaptive management and monitoring?

Comment [KK51]: This section did not quite flow, so I reworked it a bit

Comment [KK52]: I think this reference should stay.

Comment [KK53]: Recommend moving down to mitigation section minimizing threats and compensating for residual impacts to GRSG and its habitat~~.~~, the BLM will establish a WAFWA Management Zone GRSG Conservation Team to help guide the conservation of GRSG. The zonal mitigation strategy will be developed within one year of the issuance of the Record of Decisions.

Comment [JRL54]: CONFUSING – ONE TEAM DEVELOPS OVERALL STRATEGY THEN TEAMS DEVELOP REGIONAL STRATEGIES? OR ONE TEAM DOES IT ALL? Why are the WAFWA zone teams as opposed to Sage Grouse Management zone teams?

KK: move to mitigation section

~~In addition to improving management of resource uses and avoiding further surface disturbance, the ARMPAs identify management actions to promote the restoration and improvement of GRSG habitat, Decisions related to improving and restoring habitat particularly addressing the threats of invasive species, pinyon and juniper expansion, as well as climate change. As with the management of uses, habitat management, restoration, and improvement action is prioritized first in SFAs, followed by PHMA, and then GHMA.~~

Comment [KK55]: Need to get the hierarchy of SFA, PHMA, GHMA into this section somewhere

~~The~~ARMPs/ ARMPAs ~~also~~ specify habitat objectives necessary for GRSG, used both to evaluate grazing and wild horse and burro management and for restoration purposes. These habitat objectives were developed for each of the GRSG's life history stages based on the ecology within each ARMPA's sub-region. These objectives will be used to meet the applicable land health standard in GRSG habitats. They also include maintaining a minimum of 70% of lands capable of producing sagebrush with 10-30% canopy cover, and address species richness and composition, as well as meeting land health standards considering the ecological potential for the site. ~~These habitat objectives are a core component of the adaptive management and monitoring strategy (see section 6 for more information). The ARMPA adaptive management and monitoring strategy provides for specific monitoring of GRSG and its habitat. The data collected is used to evaluate the effects of authorized uses, restoration, and other activities to determine if unexpected impacts to GRSG are occurring that require changes to management to meet the objectives.~~

Comment [JRL56]: DOESN'T WORK FOR ME!

Comment [KK57]: Tying adaptive management and monitoring to this section . . .

The ARMPAs also include specific decisions to improve habitat conditions and meet the habitat objectives related to treatment and removal of invasive annual grasses and the removal of encroaching pinyon juniper in SFA, PHMA, and GHMA, and restoration of degraded landscapes, including those impacted by fire events. ~~and post-fire restoration.~~

The COT identified wildfire and conversion of sagebrush habitat to invasive annual grass-dominated vegetative communities as two of the primary threats to the sustainability of GRSG in the Western portion of the species range (i.e., the Great Basin). The proposed LUPs contain a framework that provides a consistent approach to conduct assessments to identify priority habitat areas and management strategies to reduce the threats to GRSG resulting from impacts of invasive annual grasses, wildfires, and conifer expansion (FIAT 2014). To assist in addressing these threats, the Fire and Invasive Assessment Tool (FIAT) was developed to assess the major threats to the sagebrush-steppe in order to conserve the GRSG and its habitat. The purpose of the FIAT is to identify priority habitat areas and management strategies to reduce the threats to GRSG resulting from impacts of invasive annual grasses, wildfires, and conifer expansion. The FIAT is a process that uses the best available information from many disciplines including ecology, biology, soils, fire science as part of a strategic framework. The cornerstone of the FIAT protocol is recent scientific research on resistance and resilience of Great Basin ecosystems (Chambers, et al., 2014b). The final FIAT process report was completed in June 2014 by the Fire and Invasive Assessment Team. The BLM, the Forest Service, and FWS agreed to incorporate this approach into the final GRSG EISs. The FIAT is also a key element of the

Integrated Rangeland Fire Management Strategy, identifying focal areas for priority actions in fire and fuel management.

The FIAT process:

- Identifies important GRSG occupied habitats and baseline data layers to define and prioritize GRSG habitats.
- Assesses their resistance to invasive annual grasses and resilience after disturbance.
- Prioritizes focal habitats for conservation and restoration.
- Identifies geospatially-explicit management strategies to conserve GRSG habitats.

BLM ARMPs/ describe goals, objectives, and management actions ~~and Forest Service LRMPs describe desired conditions, objectives, standards, and guidelines~~ to conserve GRSG, but do not provide specificity related to project prioritization, extent, and location, which is information important to the 2015 FWS listing decision. As such, FIAT products, in conjunction with the Integrated Rangeland Fire Management Strategy, fulfill a key role by providing quantified descriptions of future conservation actions to inform the GRSG listing decision to increase the efficacy of fire management efforts.

Comment [KK58]: This should probably be largely moved to the fire section below. Although invasive species treatments & PJ removal are not limited to fire priority areas, so I think some of that discussion still belongs here.

~~Also important to responding to the threat of fire and invasive plant species is the FWS-sponsored project with WAFWA that assembled an interdisciplinary team to provide additional information on wildland fire and invasive plants and developed strategies for addressing these issues. (Mayer et al, 2013) The FWS-sponsored project is based, in part, on NRCS soil surveys that include geospatial information on soil temperature and moisture regimes associated with resistance and resiliency properties. While this assessment is applicable across the range of GRSG, the analysis is limited to WAFWA GRSG Management Zones III, IV, and V (roughly the Great Basin region) because of the significant issues associated with invasive annual grasses and the high level of wildfires in this region.~~

Comment [KK59]: Not pertinent to the BLM ROD??

With regard to the threat of climate change, the proposed ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the *Integrated Rangeland Fire Management Strategy* will further this effort. The Fire and Invasives Assessment Team (FIAT) assessments that inform that ARMPAs and supported the development of the *Integrated Rangeland Fire Management Strategy* are specifically designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). Additionally, by limiting or eliminating anthropogenic surface disturbance, especially in the SFAs, ensuring the integrity of the PHMAs, and restoring habitat through fuels management, post-fire restoration, and mitigation efforts, connectivity and availability of sagebrush habitat are expected to increase thus contributing to increased climate resilience.

The COT noted that "a monitoring program is necessary to track the success of conservation plans and proactive conservation activities. Without this information, the actual benefit of conservation activities cannot be measured and there is no capacity to adapt if current management actions are determined to be ineffective." The ARMPAs monitoring strategy has two parts: (1) implementation monitoring (i.e., are decisions being implemented in a timely manner, are actions taken consistent with the plan decisions), and (2) effectiveness monitoring (i.e., are the decisions and implementation actions achieving the desired conservation goals). Through effectiveness monitoring, BLM can answer questions about how decisions and actions impact GRSG habitat. Understanding the effectiveness and validating results of ARMPAs and management decisions is an important part of measuring performance under the Government Performance Results Act. For example, riparian condition is a primary measure for ARMPA effectiveness (see WO IM 2010-101). Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, size of patches, etc.). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by state wildlife agencies and other partners, will allow linking real or potential habitat changes (from both natural events and management actions) to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to ameliorate negative effects with appropriate conservation actions.

Each proposed LUP includes an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are not specific to any particular project, but identify habitat and population thresholds. Triggers are based on the two key metrics that are being monitored - habitat loss and/or population declines.

Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the proposed ~~LUPs~~ARMPAs, the BLM ~~and Forest Service~~ response is to apply more conservative or restrictive conservation measures to mitigate for the specific causal factor in the decline of populations and/or habitats, with consideration of local knowledge and conditions. In each proposed LUP, a soft trigger begins a dialogue between the state, FWS, and the BLM ~~or Forest Service~~ to see if the causal factor can be determined and what implementation-level activities can be used to reverse any trend. These adjustments will be made to preclude tripping a "hard" trigger (which signals more severe habitat loss or population declines). Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the BLM ~~and Forest Service proposed LUPs~~ARMPAs. In the event that new scientific information becomes available demonstrating that the hard trigger would be insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM ~~and Forest Service proposed LUPs~~ARMPAs, the BLM ~~and/or Forest Service~~ will immediately assess what further actions may be needed to protect GRSG and its habitat and ensure that conservation options are not foreclosed. This could include a formal directive such as an IM or a plan amendment, which, to the extent that it is supported scientifically, may be drawn from the range of alternatives analyzed in the development of the ~~proposed LUPs~~ARMPAs.

Comment [KK60]: This whole section needs to move to the monitoring & adaptive management section below – as I understand it from Matt, this needs to be its own section in the ROD.

~~With regard to the threat of climate change, the proposed ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the *Integrated Rangeland Fire Management Strategy* will further this effort. The Fire and Invasives Assessment Team (FIAT) assessments that inform that ARMPAs and supported the development of the *Integrated Rangeland Fire Management Strategy* are specifically designed to identify landscapes of high resistance and resilience based on research by Chambers (Chambers et al, 2014b). Additionally, by limiting or eliminating anthropogenic surface disturbance, especially in the SFAs, ensuring the integrity of the PHMAs, and restoring habitat through~~

~~fuels management, post-fire restoration, and mitigation efforts, connectivity and availability of sagebrush habitat are expected to increase thus contributing to increased climate resilience.~~

1.5.3 Reducing Threats of Rangeland Fire to GRSG and Sagebrush Habitat

The COT emphasized that " rangeland fire ~~o~~ (both lightning-caused and human-caused fire) in sagebrush ecosystems is one of the primary risks to the greater sage-grouse, especially as part of the positive feedback loop between exotic invasive annual grasses and fire frequency". For this reason, the ARMPAs ~~ameliorate the threat from fire, the ARMPs~~ seek to fight the spread of cheatgrass and other invasive species, position wildland fire management resources for more effective rangeland fire response, and accelerate the restoration of fire-impacted landscapes to native grasses and sagebrush. Prescribed fire will not be used unless necessary to facilitate site preparation for restoration of GRSG habitat. The BLM *Greater Sage Grouse Invasive Annual Grasses & Conifer Expansion Assessment* (FIAT 2014) modeled conifer expansion for PACs to provide an initial stratification to determine where conifer removal would benefit important sagebrush habitats. This information is being used to identify and design projects to change vegetation composition and/or structure to modify potential fire behavior for the purpose of improving fire suppression effectiveness and limiting fire spread and intensity due to invasive grasses and conifer encroachment. Consistent with this assessment, the BLM ARMPAs include management actions to remove invading conifers and other undesirable species, and prioritize vegetation treatments closest to occupied GRSG habitats and near occupied leks. Through guidance in the proposed ARMPAs supplemented by the *Integrated Rangeland Fire Management Strategy*, a commitment has been made to address the invasion and expansion of cheatgrass, medusa head, and other invasive grasses through expanded efforts to treat impacted acres and to accelerate and expand efforts to restore lands impacted by fire with native grasses and sagebrush seedlings. Efforts are underway to increase the acreages to be treated with chemical and biological agents to kill and stem the spread of invasive species and to accelerate the registration of other biologicals useful in addressing the threat of cheatgrass invasion.

In addition to and complementing the ARMPAs described in this ROD, Secretarial Order 3336 on Rangeland Fire made clear that "**protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, priority GRSG habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department".** (emphasis added) The strategy places a Departmental priority on activities to prevent, suppress, and restore fire-impacted landscapes in areas identified by the Fire and Invasives Assessment Tool (FIAT) in priority habitat, using recent information derived from a report prepared by WAFWA to assist in addressing the threat of rangeland fire. The FIAT process, applying recent science, identified highly resistant and resilient landscapes to target fire management activities to these most important lands. In addition, through the issuance of a Leaders' Intent letter, signed by the Secretaries of Agriculture and the Interior, rangeland fire was identified as an "additional priority" for the firefighting community in making strategic decisions with regard to the allocation of resources for firefighting in 2015. Additional resources have been allocated and will be targeted to fuel treatments (including invasive species control), suppression (through the prepositioning of fire-fighting resources and the training of additional Rural Fire Protection Associations, local volunteer firefighters, and veteran fire fighters), and habitat restoration in these areas. Firefighting assets (aircraft, firefighters and related equipment) will be located near areas of high priority for rangeland fire.

1.6 Unique Aspects of the Great Basin ARMPAs

Comment [MEM61]: Still need input from Sarah G here related to the rationale as to why these differences exists.

The ARMPAs and their associated environmental impact statements were developed through four ~~separate~~ planning efforts across the Great Basin Region (as described in **Section 1.1**). A landscape approach was used to create cohesive management across the range of GRSG, while also using the subregional plans to accommodate differences in resource conditions, degree of threats, and state management approaches. ~~BLM's land use planning process is a highly collaborative process, involving local cooperating agencies, stakeholders, and members of the public. As a result of conducting four separate planning efforts, each sub-region received unique comments and feedback from their differing cooperating agencies, stakeholders, and interested members of the public. These comments were used to develop the ARMPAs and as a result, the management direction presented in each of the attached ARMPAs addresses sub-regional conditions and management. In addition, a~~As a result of the varying subregional threats, ~~that were presented to local populations~~ (refer to Table 1-2), conditions, and management, each sub-region, in collaboration with their local cooperators and considering public comments, adapted the range-wide landscape-management strategy ~~approach~~ to address these differences while ~~crafting different approaches to~~ meeting the overall ~~purposed and need~~ objective to conserve, enhance, and restore GRSG and their habitats. Below is a brief description of the unique aspects of each of the Great Basin sub-regional ARMPAs.

Idaho and Southwestern Montana

The Idaho and Southwestern Montana ARMPA adopted specific aspects of the State of Idaho's Conservation Plan for GRSG. The most ~~important varying~~significant aspect adopted from the State's plan is a third tier of habitat management area, Important Habitat Management Areas (IHMA). IHMA are BLM-administered and National Forest System lands that provide a management buffer for PHMA and connect patches of PHMA. I-HMA encompasses areas of generally moderate to high conservation value habitat and/or populations, but that are not as important as PHMA. In a landscape that is most threatened by fire and invasive species, this three-tiered approach allows land managers to focus suppression and restoration resources on those areas of highest importance while providing an acceptable additional level of flexibility in IHMA and GHMA since development is not as great a threat to habitat in the state. The three tiers ~~This three-tiered approach~~ also serve~~s~~ as the foundation for an adaptive management approach that includes habitat and population hard and soft triggers ~~in areas most valuable to the GRSG~~that when hit require ~~and the~~ shifting ~~of~~ IHMA to PHMA ~~when triggers are hit~~to maintain sufficient PHMA to support populations. The Idaho ARMPA also includes a slightly different disturbance calculation, as described in Appendix X of the attached Idaho and Southwestern Montana ARMPA. The ARMPA ~~also~~ applies land use planning allocation decisions for certain distances from leks, which is a deviation from the other Great Basin ARMPAs.

Nevada and Northeastern California

The Nevada portion of the Nevada and Northeastern California ARMPA adopts key elements of the State of Nevada Greater Sage-Grouse Conservation Plan (State of Nevada 2014) and the State of Nevada Conservation Credit System (Nevada Natural Heritage Program and Sagebrush Ecosystem Technical Team 2014) by establishing conservation measures and focusing restoration efforts in the same key areas most valuable to the GRSG. ~~Ad~~The Nevada plan allows for an exception to geothermal NSO which is an energy development priority for the state and is projected to create very limited disturbance in predictable areas over the life of the plan. For those reasons, after conversation with the USFWS, the BLM determined that this exception is consistent with overall conservation objectives. The ARMPA also adopts a Disturbance Management Protocol (DMP) to provide for a 3% limitation on disturbance, except in situations where a biological analysis indicates a net conservation gain to the species, with concurrence from the BLM, State of Nevada, and FWS. The plan provides for this exception due to unique factors in Nevada including the lower threat posed by development versus fire and invasive species, the extremely

Comment [JRL62]: THESE NEED TO BE INCLUDED AS APPENDICES TO THE ROD TO MAKE IT EASIER TO READ THE ROD AS A COMPLETE DOCUMENT.

KK: they will be attached to the ROD as appendices to each RMP.

Comment [KK63]: I think we should be more explicit about this & state clearly how it differs; this sentence is a bit opaque

Comment [JRL64]: What does this mean?

Comment [KK65]: GSD: don't know how to explain different disturbance calculation & allocation buffers.

Comment [KK66]: GSD: BLM needs to explain why we made limited use of CCS

Comment [KK67]: The list from Stephanie also included :unique disturbance approach – is that different from the DMP? If it is, GSD: BLM needs to explain limited nature of certain habitat types (including wet meadows and riparian areas) located mostly on private land, and the development of strong mitigation tools in the state which may make disturbance on publicly-managed PHMA along with protection for higher value habitat in the conservation interest of the species under certain circumstances. Given those factors and the procedural protections in place, the BLM determined that this approach is consistent with conservation objectives.~~ditionally, other unique aspects of the Nevada and Northeastern California ARMPA includes an NSO exception to geothermal leasing and development and a separate Disturbance Management Protocol (DMP) that is intended to provide for a 3% limitation on disturbance, except in situations where a biological analysis indicates a net conservation gain to the species, with concurrence from the BLM, State of Nevada, and FWS~~. The Nevada and Northeastern California ARMPA also does not have density cap, which is present in the three other Great Basin Region ARMPAs.

Utah

The Utah ARMPA adopts the key elements of the GRSG conservation plans or directives developed by the State of Utah (Conservation Plan for Greater Sage-Grouse in Utah) and the State of Wyoming (Executive Orders 2011-05 and 2013-3), which establishes unique conservation measures for protecting GRSG and also focuses restoration within key areas deemed most valuable to GRSG. Additionally, within GHMA, the Utah ARMPA allows for wind energy and high voltage transmission ROW development (consistent with the mitigation framework for the ARMPA), as well as oil and gas development, which is open with standard constraints. The ARMPA provides additional flexibility for development in GHMA because 95% of the breeding GRSG in Utah are within PHMAs and understanding appropriate protections such as lek buffers and required design features will be analyzed and applied at the project-implementation stage. Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses this threat. In Utah, at the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. PHMA is essential habitat for maintaining GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).

Oregon

The Oregon ARMPA adopts key elements of the Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat (Hagen 2011) which establishes unique conservation measures for protecting GRSG and also focuses restoration within key areas most valuable to GRSG. In addition, the BLM plan adopts the unique disturbance cap approach developed by the state in which disturbance is capped at 1% per decade. The BLM Oregon plans provide additional flexibility for wind development in PHMA in the three counties that have SFAs by allowing for avoidance rather than exclusion in that part of PHMA that is outside of the SFAs. The BLM adopted this flexibility after coordination with the USFWS because of the priority the State of Oregon has placed on wind development in conjunction with the more rigorous disturbance cap approach and adaptive management triggers adopted by the Oregon plan. Avoidance for solar and wind in three SE counties in PHMA. Due to these factors, the BLM finds these limited areas of flexibility for wind development are consistent with overall conservation objectives.~~Also, three areas in southeastern Oregon within PHMA are not designated as exclusion areas to solar and wind energy development, but are instead avoidance areas to these types of development. This exception would not apply to areas designated as SFAs in this portion of southeastern Oregon.~~

Comment [JRL68]: NEED TO EXPLAIN AND JUSTIFY –OTHERWISE MIGHT SEEM "ARBITRARY AND CAPRICIOUS"

KK: see revised text from GSD

Comment [JRL69]: NEED TO EXPLAIN WHY; GSD: BLM needs to explain

Comment [KK70]: Stephanie's list included "updated map" GSD: BLM must explain

Comment [JRL71]: NEED TO CLARIFY – PERMITTED BY THE MITIGATION FRAMEWORK OR REQUIRING MITIGATION CONSISTENT WITH THE FRAMEWORK?

Comment [KK72]: Stephanie's list included: allocation/habitat exception language for GHMA – if that is different from what is here, GSD: BLM should explain

Comment [JRL73]: NEEDS CLARIFICATION

Comment [KK74]: JL: need to name the 3 counties

Comment [JRL75]: YES, NEED TO NAME

[SUGGEST INSERTION OF A SUMMARY TABLE HERE FROM THE LANDSCAPE REPORT THAT SHOWS DIFFERENCES BETWEEN OVERALL REGIONAL DIRECTION AND STATE-SPECIFIC MODIFICATIONS TO REGIONAL DIRECTION FOR THE 4 SUBREGIONAL PLANS!!!]

Formatted: Font: 14 pt, Bold

1.7 Summary of the BLM's National GRSG Planning and Conservation Strategy

Collectively, the BLM Great Basin subregional ARMPAs provide a landscape-level, science-based, comprehensive, coordinated, collaborative strategy for addressing previously identified threats to the GRSG and a means to remedy the need for "regulatory certainty" leading to the 2010 "warranted but precluded" finding by the FWS. ,

These plans reflect over a decade of research, analysis and recommendations for GRSG conservation produced by the WAFWA, the NTT, and the COT. Each of these reports was developed by a collaborative effort of state and federal biologists and scientists with extensive experience in GRSG management and research.

Comment [KK76]: I think the research was done by independent scientists/researchers, not the NTT, COT, WAFWA.

The COT report provided the primary blueprint for development of the GRSG conservation strategy embodied in the 15 sub-regional ARMPAs/ARMPs that will amend or revise 78 BLM and 20 Forest Service plans. Since the COT was chartered to provide guidance for the development of state and federal land management plans by the FWS with the backing of the Sage Grouse Task Force, this is appropriate.

Comment [JRL77]: ARE THESE NUMBERS CORRECT AND HOW MANY PLANS ARE WE NOW TALKING ABOUT?

In addition to these seminal documents, the Fire and Invasives Assessment Team (FIAT) report[7], the USGS compilation and summary of published scientific studies that evaluate the influence of anthropogenic activities and infrastructure on GRSG populations -- *Conservation Buffer Distance Estimates for Greater Sage-Grouse—A Review*, and the *Integrated Rangeland Fire Management Strategy: Final report to the Secretary* (Manier et al, 2014; DOI 2015b) provided important guidance in the development of critical aspects of the proposed ARMPAs/ARMPs and the overall GRSG landscape-level conservation strategy.

Comment [KK78]: Repeat of text in previous sections

In combination with the sage-grouse conservation actions taken by the individual states within the remaining range of the bird and separate but connected initiatives to address the threat of rangeland fire, ~~to curb the continuing spread of non-native invasive grasses,~~ and to promote conservation measures to benefit the Greater sage-grouse on private lands, the BLM ~~and Forest Service~~ proposed ARMPAs/ARMPs are an essential component of the effort to conserve GRSG and its habitat and obviate the need for a listing of the species under ESA. Combined, the 15 sub-

---

[7] Greater Sage-Grouse Wildfire. Invasive Annual Grasses, and Conifer Expansion Assessment. June 2013.

regional proposed ARMPAs/ARMPs would affect nearly half of the remaining habitat for the species.

Comment [JRL79]: Numbers? CHECK!

The BLM ARMPAs/ARMPs are the product of extensive coordination, including the active engagement of the FWS in helping to inform land allocation and related management decisions by the land management agencies. They also benefit from strong collaboration with the states and reflect the unique landscapes, approaches, and priorities in each. While this has added to the challenge of developing a complete, comprehensive, and coordinated conservation strategy, it has also strengthened the proposed ARMPAs/ARMPs and is likely to increase the commitment of all partners to implementation ~~upon completion~~of these plans.

Comment [KK80]: This seems to be a repeat of the last paragraph in this section – can we delete this and just keep the last paragraph?

Comment [KK81]: Since these are BLM plans, BLM can proceed with implementing; the benefit is that the partners can also implement on private & state lands . . . ???

In the introduction to the COT report, the state and federal partners who authored the report reiterated their charge,

> "… the development of range-wide conservation objectives for the sage-grouse to define the degree to which threats need to be reduced or ameliorated to conserve sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future."

And, in his transmittal letter accompanying the final report, FWS Director Dan Ashe reaffirmed this charge, "I asked the team to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. … Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels."[8]

The BLM ARMPAs/ARMPs were directly address the specific threats to the viability of the species identified in the COT report (many of which were also identified by the BLM NTT).

Comment [KK82]: Repeat of previous?

Land Allocations for Habitat Protection

Comment [KK83]: This section seems to be a repeat of 1.5.1

The COT emphasized the need to avoid or minimize additional disturbance in PACs (which largely coincide with PHMAs in the proposed LUPs). "Stop the bleeding" was the emphatic plea of the COT with regard to the need to protect the highly valued PACs. As previously noted, the COT stated, "Maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation." Specifically, the COT recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal". The COT recommended an "avoidance first strategy" and stressed that "threats in PACs must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy."

In response, the BLM ARMPAs/ARMPs include goals and objectives and land use allocations and management actions for BLM-administered surface and subsurface lands and

---

[8] COT report. Transmittal letter by Dan Ashe. February 2013.

resources in PHMAs to retain areas of existing habitats and to avoid new disturbance. Furthermore, the proposed plans avoid, minimize, and offset any unavoidable impacts associated with disturbance from projects that might be developed in PHMA in the future, subject to valid existing rights.

Comment [KK84]: This paragraph could go in the introductory part of 1.5

Land allocations to avoid and minimize additional disturbance in important habitat areas (identified as PHMAs in most ARMPAs/ARMPs) included some closures (primarily in portions of the Lander LUP) but rely primarily on the use of no surface occupancy (NSO) associated with any future development of oil, gas, and geothermal reserves in PHMAs for most proposed LUPs (with the exception of core areas in the Wyoming proposed LUPs and geothermal leasing in Nevada). Renewable energy development (solar and wind) is excluded in the PHMAs, in most proposed LUPs, with avoidance used in some proposed LUPs, particularly in Wyoming and Oregon.

Similarly, mineral development, with the exception of locatable minerals governed under the 1872 Mining Act, is closed in the large majority of PHMAs for non-energy leasable minerals and saleable minerals. An exception was granted for free use permits and the expansion of existing active pits for mineral material sales. The BLM will determine at the time of a new coal lease or lease modification whether the lease application area is "unsuitable" for all or certain coal mining methods recognizing that PHMAs are “essential habitat” for purposes of suitability determinations.

New rights of way for transmission lines, pipelines, and related infrastructure development in PHMAs will be avoided through restrictions on land use authorizations in the proposed LUPs. Exceptions would be limited and based on rationale that explicitly demonstrates that adverse impacts will be avoided or that residual impacts could be mitigated. Also, new recreation facilities would not be authorized in PHMAs unless there is a net conservation gain for GRSG.

In general, all forms of new development – from energy, to transmission lines, to recreation facilities and grazing structures would be excluded, avoided, or developed only if the resultant effect is neutral or beneficial to the GRSG in PHMA. In all instances, whether in PHMA or GHMA (except in Wyoming only in PHMA), any adverse impacts associated with development would have to be compensated for with habitat protection or restoration activities that produced a net conservation benefit for the GRSG.

While the COT report identified PACs as “crucial building blocks of a successful conservation strategy”, the COT also emphasized that “sage-grouse habitats outside of PACs may also be essential… [and therefore] conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities.” Consistent with this guidance, restrictions on development in GHMA are less stringent and can accommodate a limited amount of disturbance. Disturbance associated with oil and gas development, for example, is subject to seasonal and timing restrictions rather than NSO with limited exceptions and GHMA is generally an avoidance area for renewable energy rather than an exclusion area. However, any disturbance is subject to mitigation and should seek to first avoid, then minimize any adverse effects to habitat while offsetting unavoidable impacts to a standard that produces a net conservation gain for the species (except in Wyoming).

The proposed ARMPAs/ARMPs provide an added element of habitat protection for GRSG strongholds identified by the FWS in a memo to Director Kornze and Chief Tidwell in October, 2014[9]. The proposed LUPs designate a subset of PHMA as Sagebrush Focal Areas (SFAs) to be administered by the BLM and the Forest Service. SFAs consist of areas of largely intact priority habitat, primarily under federal management, with greater GRSG bird densities and high resistance and resilience to fire. As the FWS communicated to BLM and Forest Service leadership that "[s]trong, durable, and meaningful protection of federally administered lands in these areas will provide additional certainty and help obtain confidence for long term sage grouse persistence," land allocations for these areas were intended to avoid future surface disturbance to the maximum extent. Land allocations in the SFAs require NSO with no exceptions for oil, gas, and geothermal development. The proposed plans will also include a recommendation that these areas be withdrawn by the Secretary from mineral entry under the 1872 Mining Act (in the RODs of proposed Forest Service plans). SFAs will also be prioritized for restoration and conservation action. While the SFAs have minimal land surface disturbance and, based on existing, available data, limited mineral potential, valid existing rights – as in all habitat – will be recognized and be able to proceed in accordance with their legal rights.

Management Direction, Prioritization, and Mitigation

Comment [KK85]: Seems to be a repeat of 1.5.2 & 1.5.3, with a little 1.5.1

In addition to land allocations to protect SFAs, PHMAs, and GHMAs, the ARMPAs/ARMPs guide other uses of these landscapes to meet COT objectives consistent with existing, authorized uses of GRSG habitats and the sagebrush landscape.

Grazing is the most widespread use of the sagebrush steppe ecosystem. In order to ensure that grazing continues in a manner consistent with the objective of conserving the GRSG, the proposed LUPs will require the incorporation of GRSG habitat requirements into the vegetative management objectives for proposed actions, including authorizations for grazing allotments, consistent with the ecological potential of the landscape. The COT recommends, "Conduct grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for GRSG (e.g. shrub cover, nesting cover)."

The proposed LUPs place a priority on the review and update of grazing allotment management to incorporate standards, guidelines, and habitat objectives, and to ensure that they are being met consistent with ecological site potential. Priority will be given, first, to the review of allotments in SFAs, then PHMAs, followed by GHMA; focusing first on riparian and wet meadows, and, if the standards, guidelines, or habitat objectives are not being met due to improper grazing, to work with the permittee to make progress towards meeting them. Anticipated increases in BLM funding for implementation of the proposed LUPs will support additional conservation and restoration actions, as well as monitoring, to continue to ensure healthy public land grazing consistent with the conservation of GRSG habitat.

---

[9] Memorandum from Dan Ashe to Director, BLM and Chief, USFS, "Greater Sage Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important landscapes. October 27, 2014.

With regard to future leasing and development for oil and gas, the proposed LUPs recognize the value of encouraging future development in areas of low conflict with GRSG habitat. Analysis of existing and available data by the BLM indicates that a majority of the acres of land with high and medium potential for oil and gas development in the western U.S. are outside of identified GRSG habitat. To benefit GRSG conservation efforts and to assist developers in reducing the time and cost associated with oil and gas leasing and development in areas of likely conflict with other multiple-use values, the BLM will prioritize new leasing in areas outside of SFAs, PHMAs, and GHMAs.

Comment [KK86]: Could use some of this text to amplify smart from the start in 1.5.1 above

Fire represents the greatest threat to GRSG survival in the Great Basin region. Recognizing the nature and extent of this threat, the ARMPAs/ARMPs provide specific guidance for improving efforts to reduce the risk of GRSG habitat loss to wildfire, including fire prevention and the restoration of habitats impacted by fire. However, to develop a more complete and comprehensive strategy for dealing with this threat, the Department of the Interior and the BLM convened a conference in November, 2014 of scientists, state and federal officials, leaders in the fire community, and an array of stakeholders to discuss ways to improve the efficiency and effectiveness of rangeland fire management. The conference led to Secretarial Order 3336 and recognition that,

> "Protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, greater sage-grouse habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department. Allocation of fire management resources and assets before, during, and after wildland fire incidents will reflect this priority, as will investmentsrelated to restoration activities.[10]

In accordance with that Order, a strategy for fire prevention, suppression, and post-fire restoration was developed and delivered to the Secretary in May 2015. The Order and subsequent report, *An Integrated Rangeland Fire Management Strategy: Final Report to the Secretary of the Interior*, directed substantial changes in policy and management direction affecting all aspects of the rangeland fire management program – from better coordination between resource managers and fire management officers; to the identification and prioritization of prevention, suppression, and restoration efforts in SFAs, PHMAs, and GHMAs; to the commitment of additional equipment and crews for rangeland firefighting; to additional funding and policy direction to improve post-fire restoration; to the completion of an initiative to collect, store, and better utilize native seed and sagebrush in post-fire restoration of sagebrush steppe ecosystems. This effort, and the initiative to fight the spread of non-native invasive species that contributes to higher rangeland fire risk (e.g. cheatgrass) discussed below, hold the potential to fundamentally change how rangeland fire is managed to benefit sagebrush ecosystems and GRSG habitat.

Comment [JRL87]: Add link

Comment [KK88]: Compare this to 1.5.3 & adjust 1.5.3 if needed . . .

The COT report – and other more recent research and analysis – amplify concern for the contribution of cheat grass and other invasive species to the loss of GRSG habitat associated with increased fire frequency and intensity. Work initiated by the WAFWA and based on recent research by Chambers (Chambers et al, 2014b) led to the Fire and Invasives

---

[10] Secretarial Order 3336. Rangeland Fire Prevention, Management and Restoration. January 2015.

Assessment Tool[11] and a subsequent assessment that identified areas of resistance and resilience to fire. This information is leading to targeted and aggressive efforts to reduce the risk and impacts of rangeland fire that could impact hundreds of thousands of acres of GRSG habitat, as well as restore areas with high potential to be resilient to the impacts of climate change and subsequent rangeland fires. The BLM is also committed to and accelerating the registration and use of chemical and biological agents to stem the spread of cheatgrass and other invasive species. In addition, by using the FIAT assessments and overlaying maps of SFAs, PHMAs, and GHMAs, land managers from all levels of government can more efficiently allocate and use fire resources at initial attack, to stop fire early and prevent catastrophic habitat loss.

Comment [KK89]: Anything in here that should be in 1.5.2 or 1.5.3?

Even prior to completion of the FIAT assessment, BLM shifted funding for fuels management to protect landscapes of importance to the GRSG. Under the FY2014 Omnibus Appropriation, BLM prioritized the funding of treatments and activities within each state that benefit GRSG.

In 2014, treatment and activities which identified GRSG as a species of interest accounted for $28,328,658 in funding and treatments of 241,343 acres. Prior to FY2014, numerous other examples of positive impacts from the Fuels Management Program exist. The table below summarizes (by state) accomplishments and funding spent on fuels reduction projects that benefited GRSG from FY2003 to FY2013 (Table Z) .[12]

Comment [KK90]: Should this be included? Not ROD . . .

Table Z. FY2003 to FY2013 Fuels Funds Spent on GRSG by State

State	Acres	Funding
CA	28,719	$5,762,190
CO	18,534	$1,942,940
ID	529,972	$32,326,379
MT	15,496	$3,688,980
NV	161,353	$11,126,931
OR	196,180	$12,131,581
UT	277,014	$21,507,312
WY	78,956	$3,601,211
Grand Total	**1,306,224**	**$92,087,524**

Some areas that were not included as PACs may still have great potential for providing important habitat if active habitat management is implemented. For example, removal of early-stage juniper stands may render currently unsuitable habitat into effective habitat for GRSG (this is also true for degraded habitats within PACs). The COT report encourages state and federal agencies to actively pursue these opportunities.[13] As noted in this report, since 2010, the NRCS through its Sage Grouse Initiative (SGI) in collaboration with states and private landowners and BLM on public lands have worked to eliminate pinyon-juniper trees on over 400,000 acres of

---

[11] WAFWA FIAT report

[12] BLM Fuels Management Benefits Toward Sage Grouse Habitat. March 2014.

[13] COT Report. page 33.

private and over 400,000 acres of public lands, respectively, across western landscapes. In addition, using the FIAT the BLM has identified and prioritized areas for treatment of annual invasive grasses and conifer expansion on federal lands as a basis for improved targeting of federal resources[14] (See Figure Z. FY 2015 FIAT Priority Project Planning Areas). As illustrated, the areas designated as Priority 1and 2 project planning areas essentially coincide with the stronghold areas identified by the FWS and incorporated in the Great Basin ARMPAs as designated SFAs.

Comment [KK91]: Should this be included in the ROD?

Comment [JRL92]: Should we include this here?

Comment [KK93]: Is this true? – if it is true, it was not intentional, since FIAT was done without SFAs – I'd like to see the analysis that support this.

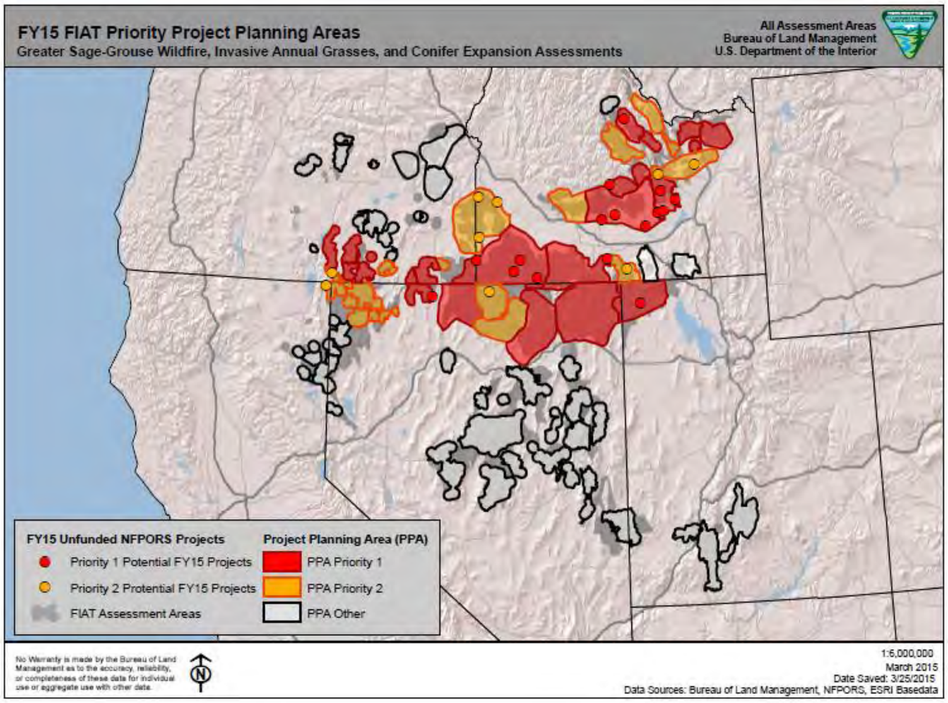

Figure Z. FY 2015 FIAT Priority Project Planning Areas with Focus on Invasive Annual Grasses and Conifer Expansion Assessments.

In addition, the Department has recently committed $7.5 million to projects in GRSG habitat to create more resilient landscapes and BLM has allocated $12 million to increase firefighting resources aimed at stopping fires while they are small in the Great Basin. The Department has identified required policy changes to increase the commitment, flexibility and timeframe for use of Emergency Stabilization and Burned Area Restoration (ES & BAR) funding on priority sagebrush-steppe habitats. Combined with commitments in the final rangeland fire report to Secretary Jewell to accelerate the registration and use of chemical and biological agents to stem the spread of cheatgrass and other invasives, these additional actions will lead to a more

---

[14] WAFWA. Greater Sage-Grouse Wildfire, Invasive Annual Grasses & Conifer Expansion Assessment. June 2014.

robust and effective rangeland fire management effort in 2015 and beyond. In 2016 and beyond, BLM is anticipating a funding increase to implement the GRSG proposed LUPs; these increases are included in both the House and Senate FY 2016 appropriations marks and will lead to more robust and effective management of GRSG habitat and the threats to it, including fire. BLM intends to continue to prioritize and request funding for GRSG management in 2017 and beyond.

Comment [KK94]: Is this Appropriate for a ROD?

The proposed LUPs also target additional conservation efforts to address other threats to the GRSG. Proposed LUP direction to incorporate GRSG habitat objectives into the establishment of allowable management levels (AMLs) for wild horses and burros (free-roaming equids) and to prioritize gathers and removal to reach AMLs in SFAs, PHMAs, and GHMAs (in that order) will better target these efforts to benefit the GRSG.. Anticipated funding increases for GRSG proposed LUP implementation in FY 2016 will allow the BLM to make substantial progress toward that goal, beginning with efforts to achieve AMLs in SFAs. At the same time, the BLM has made a considerable investment in concert with the National Academy of Sciences in new research of methods to reduce wild horse and burro reproduction rates. Through a combination of targeted gathers and the development of an effective agent for reducing future free-roaming equid reproductive rates, the BLM is optimistic that, over time, this threat to GRSG can be effectively mitigated.

Comment [KK95]: Supplement 1.5.1?

Although future high voltage transmission lines will be avoided in PHMA, the planning, siting, and environmental review of a limited number of Presidential priority lines (Gateway West, Boardman to Hemingway, and Transwest Express, including those portions of Gateway South that are co-located) has been underway for a number of years. These lines are critical to expanding access to renewable sources of energy (especially wind) and to improving the reliability of the western grid. For these reasons, planning for these lines will proceed and potential impacts to GRSG will be fully mitigated (1) through micrositing to adjust the route to avoid important habitat and leks, (2) through transmission tower design to minimize the potential for adverse impacts to GRSG such as perching for predators, and (3) through compensatory mitigation measures, such as habitat restoration and pre-suppression activities to reduce the risk of habitat loss due to fire, to offset any unavoidable impacts to a conservation gain standard.

Comment [KK96]: Is this detail needed in a ROD? Is this already somewhere else?

Mitigation for activities adversely impacting GRSG or GRSG habitat in PHMA or GHMA (PHMA only in Wyoming) will be designed to a net conservation gain standard consistent with the recommendation included in the September 2013 FWS report, *Greater Sage-Grouse Range-Wide Mitigation Framework*. According to the authors, the report was prepared

> "to communicate some of the factors the Service is likely to consider in evaluating the efficacy of mitigation practices and programs in reducing threats to GRSG. The recommendations provided here are consistent with the information and conservation objectives provided in the 2013 Conservation Objectives Team (COT) Report for sage-grouse"[15].

At the same time, BLM and Forest Service will partner with the states over the next 6 months

---

[15] USFWS. Greater Sage-Grouse Range-Wide Mitigation Framework. Version 1.0. September 3, 2014.

to develop regional mitigation strategies coinciding with WAFWA GRSG management zones, to guide mitigation efforts in each zone and monitor mitigation effectiveness. The collaborative effort to develop a mitigation strategy will ensure that mitigation is consistent with the principles and goals set out in Secretarial Order 3330, *Improving Mitigation Policies and Practices of the Department of the Interior* and accompanying report[16] and the new Departmental Manual guidance on landscape-level mitigation.

Comment [KK97]: Repeat of mitigation section

Additional conservation measures

In addition to land allocations and management actions included in the proposed LUPs to conserve the GRSG, measures were included to ensure that disturbance to leks could be reduced or minimized through the application of disturbance caps and required minimum buffer distances for a number of categories of disturbance, consistent with best available science.

Disturbance caps of 3% or 5% (for Wyoming and, likely in the future, Montana) were established in accordance with recommendations contained in the COT report. Disturbance will be calculated based on established Biologically-Significant Units (BSUs) developed by an interagency team and includes focus on protecting leks.

The proposed ARMPAs also include an additional layer of protection for leks to be applied at project implementation. During NEPA development for a project, the appropriate buffer, based on the USGS report *Conservation Buffer Distance Estimates for GRSG – A Review* (Manier et al, 2014), will be used to site and mitigate projects, subject to applicable laws and regulations and valid existing rights. Because of the great variation in landscapes, local science, and local regulations, justifiable departures, both up and down, from these lek-buffer distances may be appropriate to fully address impacts to leks. In fact, the COT recommends that such conservation measures be based on best available science with consideration of local ecological conditions.

For BLM approved actions (not including Wyoming), the BLM and Forest Service will apply the lek buffer-distances identified above as required conservation measures to fully address the impacts to leks as identified in the NEPA analysis by preferentially locating the action outside of the buffer distance and, if that is not possible, approving the project only if certain criteria are met with the goal of ensuring no impacts to leks in PHMAs and no more than minor impacts in GHMAs.

This approach to minimizing impacts to leks reflects guidance from the COT report:

> "Conservation of sage-grouse habitats outside of the PACs should be closely coordinated with each state. For those states with sage-grouse management plans, or similar documents adequately addressing the conservation of sage-grouse that have been developed in coordination with FWS, decisions on management of those areas should defer to those plans. Conservation of habitats outside of PACs should include

---

[16] Clement, J.P. et al. 2014. A strategy for improving the mitigation policies and practices of the Department of the Interior. A report to the Secretary of the Interior from the Energy and Climate Change Task Force, Washington, D.C., 25 p.

> minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur".[17]

Comment [KK98]: Repeat of 1.5.1 (except this section still has all the RM stuff in it)

Consistent with recommendations contained in the 2006 WAFWA *Greater Sage-Grouse Range-wide Conservation Strategy*, the BLM and Forest Service conservation strategy places heavy reliance on monitoring and evaluation to assess the success of management decisions incorporated in the proposed LUPs and, ultimately, in the effectiveness of implementing these proposed LUPs. Monitoring plans will be interagency in nature and incorporate evaluation of GRSG population trends by the states and changes in habitat condition by the federal land management agencies. As the WAFWA report states,

> "Monitoring provides the "currency" necessary to evaluate management decisions and to assess progress or problems. Adequate monitoring should be considered an integral and inseparable component of all management actions, and there, not optional. Lack of proper monitoring will undoubtedly hinder this large-scale conservation effort."[18]

In addition, the conservation strategy incorporates an adaptive management framework that provides an "early warning system" of "soft triggers" to alert resource managers to the need to evaluate the effectiveness of their management strategies should changes in population levels or habitat conditions occur. If management responses to soft triggers do not adequately address the causes for population or habitat declines and "hard triggers" are reached, more significant changes in management actions and land allocations will occur to ensure that more protective measures to conserve the species are in place.

Comment [KK99]: Duplicate of monitoring & adaptive management section

Guided by the COT report and NTT and WAFWA recommendations, the BLM ~~and Forest Service~~ conservation strategy directly addresses the threats identified in the COT report consistent with many of the specific recommendations provide by the COT, the NTT, and WAFWA. These changes in management direction from existing BLM RMPs ~~(with the exception of the Lander LUP which was completed in 2014) and Forest Service LUPs~~ are designed to avoid and minimize any additional surface disturbance in PHMAs and provide a high level of protection for FWS-identified stronghold areas. Recognizing the potential importance of areas in GHMA, the proposed LUPs include measures that protect and restore habitats in these areas while providing greater flexibility for development activities.

Comment [JRL100]:

The unprecedented collaboration with states in the development of these proposed LUPs, in conjunction with the close coordination between the BLM and Forest Service with input from the FWS, provides a strong foundation for conservation efforts to protect and restore habitats essential to the conservation of the GRSG. Informed by best available science, and in concert with additional actions, such as those to more efficiently and effectively address the threat of rangeland fire consistent with direction in S.O. 3336 and the investments made to improve sage-grouse habitat through voluntary actions on private lands through the NRCS' Sage Grouse Initiative (SGI), this strategy reflects a high level of commitment by state and federal partners to conserve the GRSG and its habitat. The landscape-level strategy consisting of reinforcing

---

[17] COT Report, page 36.

[18] WAFWA report, page xxiii.

conservation actions that will go into effect upon completion of the BLM ~~and Forest Service~~ ARMPAs as well as those actions being implemented currently to conserve the species, reflect a significant change in management direction and philosophy for both resource management agencies since 2010 and a long-term commitment to assure the conservation of the species consistent with the objectives set in the 2006 WAFWA conservation strategy and embraced by both the NTT and the COT.

Comment [KK101]: Seems like a good summary – but most of the rest seems to repeat what is already in the previous sections.

2. DECISION

2.1 Summary of the Approved Management Decisions

The decision is hereby made to approve the Great Basin Region Greater Sage-Grouse ARMPAs for the Great Basin Region Greater Sage-Grouse Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah (attachments A, B, C, and D). This ROD serves as the final decision establishing the land use plan amendment decisions outlined in the ARMPAs and is effective on the date it is signed. No further administrative remedies are available for these land use plan decisions.

The decisions included in this ROD and attached ARMPAs amend the land use plans described in **Sections 1.1** of attachments A, B, C, and D. This ROD and ARMPAs become effective on the date this ROD is signed. The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA) (43 United States Code [U.S.C.] 1701 et seq.) and other applicable laws. The BLM prepared EISs in compliance with the National Environmental Policy Act (42 U.S.C. 4321-4347) as amended (NEPA), and BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1601 et seq.).

The land use decisions provide conservation measures to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Land use plan decisions are expressed as goals and objectives (desired outcomes), and allocations, allowable uses, and management decisions anticipated to achieve desired outcomes. Although decisions identified in the ARMPAs are final and effective upon signing of this ROD, they generally require additional implementation decision steps before on-the-ground activities can begin. Subsequent NEPA analysis will be conducted, as necessary, for such implementation decisions.

2.2 What the Record of Decision and Approved Resource Management Plan Amendments Provide

The ARMPAs include GRSG and GRSG habitat land use plan level management decisions in the form of:

- Goals
- Objectives (Desired Future Conditions)
- Land Use Allocations and Allowable Uses

- Management Actions

Goals are the broad statements of desired outcomes, and are usually not quantifiable.

Objectives are specific desired conditions, usually quantifiable and measurable, and may have timeframes for achievement.

Land use allocations specify locations within the planning area that are available or not for certain uses and are also used prioritize conservation and restoration management actions. These include decisions such as what lands are available for livestock grazing, mineral material use, oil and gas leasing, and locatable mineral development, what lands may be available for disposal via exchange and/ or sale, and what lands are open, closed, or limited to motorized travel (please note that all acreages presented in the Approved Plan are estimations even when presented to the nearest acre).

Management actions include those provisions that help in meeting the established goals and objectives and include measures that will be applied to guide day-to-day activities on public lands..

The ARMPAs' management decisions were crafted to alleviate identified threats to GRSG and their habitats (see **Section 1.5**).

2.3 What the Record of Decision and Approved Resource Management Plan Amendments Do Not Provide

The attached ARMPAs do not contain decisions for public lands outside of GRSG habitat management areas, except for travel management decisions in the Idaho and Southwestern Montana ARMPA.

The ARMPAs do not affect valid existing rights.

The ARMPAs do not contain decisions for the mineral estates of lands located in the planning area for lands under the jurisdiction of other Federal agencies such as the Forest Service, or for private or State-owned lands and minerals that are not administered by the BLM. In addition, many decisions are not appropriate at this level of planning and are not included in the ROD. Examples of these types of decisions include:

- *Statutory requirements.* The decision will not change the BLM's responsibility to comply with applicable laws, rules, and regulations.
- *National policy.* The decision will not change BLM's obligation to conform to current or future National policy.
- *Funding levels and budget allocations.* These are determined annually at the National level and are beyond the control of the State/District of Field offices.

Implementation decisions (or activity-level decisions) are management actions tied to a specific location. Implementation decisions generally constitute the BLM's final approval allowing on-the-ground actions to proceed and require appropriate site-specific planning and NEPA analysis. Such decisions may be incorporated into implementation plans (activity or project plans) or may exist as stand-alone decisions. These ARMPAs do not contain implementation decisions. Future activity-level plans will address the implementation of the ARMPAs. Implementation decisions and management actions that require additional site-specific project planning, as funding becomes available, will require further environmental analysis.

2.4 Modifications and Clarifications

During preparation of the ARMPAs for all four sub-regions, minor changes were made to the Proposed RMP Amendments to correct errors and to clarify decisions. Clarifications and corrections made since the Proposed RMP Amendments were published on May 29, 2015 are hereby adopted by this ROD.

2.4.1 Modifications and Clarifications by Sub-region

Modifications and clarifications are summarized below for each of the sub-regional ARMPAs.

Idaho and Southwestern Montana

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Nevada and Northeastern California

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Oregon

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

Utah

All references to National Forest System lands in both text and on maps have been removed from the BLM ARMPA. This is because the U.S. Forest Service has completed a separate ROD and Land and Resource Management Plans under their planning authorities.

Need to populate once we have a clear idea as to what changes will need to be made. Will need to work with the planners.

2.4.2 Protest Resolution

BLM's planning regulations at 43 CFR 1610.5-2 allow any person who participated in the planning process and has an interest that may be adversely affected by BLM's planning decisions to protest proposed planning decisions within 30 days from the date the Notice of Availability of the Proposed

RMPA/Final EIS was published in the Federal Register (May 29, 2015). Below are descriptions of the protest resolution process for each of the four sub-regional PRMPAs/FEISs.

These decisions are final for the Department of the Interior. With the exception of the granted protest issues, the Director concluded that the BLM followed the applicable laws, regulations, and policies and considered all relevant resource information and public input in developing the Proposed Land Use Plan Amendments/Final EISs. Each protesting party will be notified in writing of the Director's findings and the disposition of their protests. The BLM Director resolved the protests without making significant changes to the Proposed Land Use Plan Amendments/Final EISs, though minor clarifications were made and are summarized in Section 2.5.1.

Idaho and Southwestern Montana

For the Idaho and Southwestern Montana GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Idaho and Southwestern Montana GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Nevada and Northeastern California

For the Nevada and Northeaster California GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Nevada and Northeastern California Sub-Regional GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Oregon

For the Oregon GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Oregon GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

Utah

For the Utah GRSG Proposed Land Use Plan Amendment/Final EIS, the BLM Director received X letters of protest within the protest period. Of these, X protesting parties had standing and included valid protest issues. Valid protest issues submitted included: X. Of those issues, the BLM granted in part X protest regarding X. The BLM Director's decisions on the protests are summarized in the "Director's Protest Resolution Report, Utah GRSG Proposed RMP Amendment/Final EIS," released on X and available on the following BLM website: http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

Will need to populate the "X" areas towards the end of the protest resolution process (end of July).

2.4.3 Governors Consistency Review

The BLM's planning regulations require that RMPs be "consistent with officially approved or adopted resource-related plans, and the policies and procedures contained therein, of other federal agencies, state and local governments, and Indian tribes, so long as the guidance and RMPs also are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands" (43 CFR 1610.3-2(a)). The general requirement in FLPMA/planning regulations is to coordinate the land use planning process with plans of other agencies, states, and local governments to the extent consistent with law (see FLPMA s. 202(c)(9) and 1610.3-1(a)); and the respective duties to be consistent with both officially approved or adopted plans (to the extent those plans are consistent with federal law, or to maximum extent practical) (see 1610.3-2(a)(b)). In accordance with FLPMA, the BLM was aware of and gave consideration to state, local, and tribal land use plans and provided meaningful public involvement of the Proposed RMP Amendments/Final EISs.

The BLM is aware that there are specific state laws and local plans relevant to aspects of public land management that are discrete from, and independent of, federal law. However, the BLM is bound by federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that BLM's land use plans be consistent with officially-approved state and local plans only if those plans are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands. Where officially-approved state and local plans or policies and programs conflict with the purposes, policies, and programs of federal law applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially-approved state and local policies and programs (as opposed to plans), this consistency provision only applies to the maximum extent practical. While county and federal planning processes, under FLPMA, are required to be as integrated and consistent as practical, the federal agency planning process is not bound by or subject to state or county plans, planning processes, policies, or planning stipulations.

In some instances, modifications to the Proposed RMP Amendments were addressed based on recommendations submitted to the BLM by the applicable states. These modifications to the ARMPAs are summarized below by sub-region and are now part of the attached ARMPAs.

Idaho and Southwestern Montana

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Nevada and Northeastern California

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Oregon

Will need to populate the "X" areas towards the end of the GCR process (end of July).

Utah

Will need to populate the "X" areas towards the end of the GCR process (end of July).

3. ALTERNATIVES

3.1 Alternatives Considered

Each of the Great Basin sub-regional planning efforts analyzed in detail a set of alternatives in the draft and final sub-regional EISs. The alternatives were developed to provide direction for resource programs influencing land management for the protection and enhancement of GRSG and its habitat. All management under any of the alternatives complied with federal laws, rules, regulations, and policies.

Each alternative emphasized an altered combination of resource uses, allocations, and restoration measures to address issues and resolve conflicts among uses so that GRSG goals and objectives were met in varying degrees across the alternatives. The action alternatives offered a range of possible management approaches for responding to planning issues and concerns identified through public scoping, and to maintain or increase GRSG abundance and distribution in the planning area. While the land use plan goal was the same across alternatives for each sub-region, each alternative contained a discrete set of objectives and management actions constituting a separate RMP amendment. The goal was met in varying degrees, with the potential for different long-range outcomes and conditions.

The relative emphasis given to particular resources and resource uses differed as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs. When resources or resource uses are mandated by law there are typically few or no distinctions between alternatives.

3.1.1 Alternative A – No Action Alternative

Alternative A meets the CEQ requirement that a No Action Alternative be considered. This alternative continues current management direction derived from the existing field/district office RMPs, as amended. Goals and objectives for resources and resource uses are based on the most recent RMP decisions, along with associated amendments and other management decision documents. Laws, regulations, and BLM policies that supersede RMP decisions would apply.

Goals and objectives for BLM-administered lands and mineral estate would not change. Appropriate and allowable uses and restrictions pertaining to activities such as mineral leasing and development, recreation, construction of utility corridors, and livestock grazing would also remain the same. The BLM would not modify existing or establish additional criteria to guide the identification of site-specific use levels for implementation activities.

This alternative was not selected as the ARMPAs because it did not meet the purpose and need of this plan amendment. This alternative did not include changes that are needed to be made to the existing decisions based on the USFWS 2010 listing petition decision that identified inadequacy of regulatory mechanisms as a significant threat to GRSG and its habitat. This alternative did not incorporate the best available science pertaining to GRSG or its habitat.

3.1.2 Alternative B: National Technical Team Report Alternative

Alternative B was based on the conservation measures contained within the National Technical Team (NTT) Report. The GRSG National Technical Team (NTT), comprised of BLM, Forest Service, FWS, USGS, NRCS, and State specialists, completed *A Report on National Greater Sage-Grouse Conservation Measures* in December, 2011. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) necessary to promote sustainable sage-grouse populations, and which focused on the threats (75 FR 13910) in each of the regional WAFWA Sage-Grouse Management Zones. The NTT Report proposed conservation measures based on habitat requirements and other life history aspects of sage-grouse and described the scientific basis for the conservation measures proposed within each program area. The Report also provided a discussion and emphasized the importance of standardizing monitoring efforts across the WAFWA Sage-Grouse Management Zones. The Report can be accessed at: http://www.blm.gov/style/medialib/blm/co/programs/wildlife.Par.73607.File.dat/GrSG%20Tech%20Team%20Report.pdf

The BLM's Washington Office Instructional Memorandum (IM) Number 2012-044 directed the sub-regional planning efforts to analyze the conservation measures developed by the NTT, as appropriate, through the land use planning process and NEPA.

Alternative B would exclude ROW development in PHMA and avoid development in GHMA, would close PHMA to fluid mineral leasing, mineral material sales, and nonenergy leasable minerals, and would recommend withdrawal from locatable mineral entry in all PHMA. These management actions would reduce surface disturbance in PHMA and would minimize disturbance in GHMA, thereby maintaining GRSG habitat. Management actions for wildfire would focus on suppression in PHMA and GHMA, while limiting certain types of fuels treatments. Vegetation management would emphasize sagebrush restoration. Collectively, vegetation and wildfire management would conserve GRSG habitat. Grazing would continue with similar impacts under Alternative B as under Alternative A. The best management practices (BMPs) proposed in the NTT report would be included as required design features as part of Alternative B and are listed in Appendix X, Required Design Features (RDFs), of each of the attached ARMPAs.

This alternative was not selected in its entirety as the ARMPAs because the majority of the conservation measures in the NTT Report, as appropriate and applicable, were applied primarily to PHMA, and few conservation measures in the Report were provided for in GHMA. As a result, most management actions in GHMA reverted back to the No Action Alternative, which was found to not meet the purpose and need for the Amendments.

3.1.3 Alternative C: Citizen Groups' Recommended Alternative One

Alternative C was based on a citizen groups' recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and was applied to all occupied GRSG habitat (PHMA and GHMA. Alternative C limited commodity development in areas of occupied GRSG habitat, and closed or excluded large portions of the planning area to many land uses. This included all PHMA and GHMA as being closed to livestock grazing, recommended for withdrawal from locatable mineral entry, closed to fluid mineral leasing, closed to salable mineral and non-energy leasable mineral development, and exclusion areas for right-of-ways. The Utah LUPA/Draft EIS combined this alternative with Alternative F (discussed below).

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. For example, this alternative closed all allotments to livestock grazing, which, based on best available science, is not required to conserve GRSG and its habitats. Alternative C was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.4 Alternative D: Draft RMP Amendments' Preferred Alternative

Alternative D, which was identified as the Preferred Alternative in the Draft EISs, balanced opportunities to use and develop the planning area as well as conserving, maintaining, and enhancing GRSG and their habitat. Protective measures were applied to GRSG habitat, while still allowing for anthropogenic disturbances with stringent mitigation measures. This alternative represents the mix and variety of management actions based on BLM's analysis and judgment, which best resolve the resource issues and management concerns while meeting laws, regulations, and policies pertaining to BLM management. As a result of public scoping comments, internal review, and cooperating agency coordination on the Draft RMP Amendments/EISs, this alternative was modified to become the Proposed RMP Amendments and analyzed in the FEISs. The Preferred Alternatives, with slight variations, became the Proposed Plans in the FEISs.

In PHMA under Alternative D, there would be limitation on disturbance in GRSG habitat by excluding wind and solar energy development (except for certain counties in Southeastern Oregon where avoidance is applied), avoiding all other ROW development, applying no surface occupancy stipulations to fluid mineral development, and closing PHMA to nonenergy leasable mineral development and mineral material sales. These management actions would protect GRSG habitat, while allowing other activities, subject to conditions. In GHMA under Alternative D, allocations are less stringent, but still aim to protect GRSG habitat (for example, applying moderate constraints and stipulations to fluid minerals in GHMA).

Under Alternative D, the BLM management would support sagebrush/perennial grass ecosystem restoration, would increase fire suppression in PHMA and GHMA, and would manage livestock grazing to maintain or enhance sagebrush and perennial grass ecosystems.

3.1.5 Alternative E: State/Governor's Alternative

Alternative E is the alternative provided by the State or Governor's offices for inclusion and analysis in the EISs. It incorporates guidance from specific state conservation strategies, if developed or recommendations from the state on management of Federal lands and emphasizes management of GRSG seasonal habitats and maintaining habitat connectivity to support population objectives. This alternative was identified as a co-Preferred Alternative in the Idaho and Southwestern Montana Draft EIS. California did not provide the BLM with a state GRSG conservation plan and under this alternative, reverted back to Alternative A, the no-action alternative.

For Nevada, Alternative E would apply an avoid, minimize, and mitigate strategy to reduce direct and indirect impacts on GRSG from surface-disturbing activities on BLM-administered lands. Effects on GRSG habitat from certain resource programs, such as grazing, lands and realty, wildfire management, and minerals, would not be directly addressed because allocation decisions were not part of the state's plan.

For Oregon, Alternative E contains GRSG conservation guidelines from Greater Sage-Grouse Conservation Assessment and Strategy for Oregon: A Plan to Maintain and Enhance Populations and Habitat. This document describes the Oregon Department of Fish and Wildlife's proposed management of GRSG on Federal lands. It also provides guidance for public land management agencies and land managers for GRSG conservation. GRSG conservation guidelines in the state plan are designed to maintain (at a minimum) or enhance the quality (the optimum) of current habitats. The guidelines would also assist resource managers in achieving the population and habitat objectives of the state plan.

For Idaho, Alternative E incorporates proposed GRSG protection measures recommended by the State of Idaho. Management in Montana would remain unchanged from the current RMPs (Alternative A). Alternative E addresses the following primary threats: fire, invasive weeds, and infrastructure development. It also includes guidance for several secondary GRSG threats such as recreation, improper livestock grazing, and West Nile virus for BLM and Forest Service programs that affect GRSG or its habitat.

For Utah, the planning area includes all occupied GRSG habitat in Utah. Alternative E1 is based on the State of Utah's Conservation Plan for Greater Sage-Grouse in Utah and would apply to all BLM-administered lands in Utah. Alternative E1 was designed to eliminate the threats facing the GRSG while balancing the economic and social needs of the residents of Utah. Conservation measures would be applied to 11 areas that the state identified, called Sage-Grouse Management Areas (SGMAs). Emphasis would be placed on expanding GRSG habitat by aggressively treating areas where there are encroaching conifers or invasive species. Alternative E1 includes a general limit on new permanent disturbance of 5 percent of habitat on state or federally managed lands within any particular SGMAs. Occupied habitat outside of the state-identified SGMAs would not receive new management protection. They would continue to be managed according to the GRSG actions in existing RMPs and conservation measures associated with existing activity-level plans.

This alternative was not selected, in whole, as the ARMPAs because some components of the state's plans were not consistent with the purposes, policies and programs of Federal laws and regulations applicable to public lands. However, many goals, objectives, and management actions in the ARMPA were carried forward.

3.1.6 – Alternative F: Citizen Groups' Recommended Alternative Two

Alternative F is also based on a citizen group recommended alternative. This alternative emphasizes improvement and protection of habitat for GRSG and defines different restrictions for PHMA and GHMA. Alternative F would limit commodity development in areas of occupied GRSG habitat, and would close or designate portions of the planning area to some land uses. This alternative does not apply to the Utah sub-regional planning effort, as it was combined with Alternative C. Under Alternative F, wildfire suppression would be prioritized in PHMA. Concurrent vegetation management would emphasize sagebrush restoration and enhancement. Alternative F would reduce livestock and wild horse and burro management utilization by 25 percent within PHMA and GHMA.

This alternative was not selected in its entirety as the ARMPAs because it limited the use of public land in PHMA and GHMA to such as extent that it did not give adequate accommodation to local needs, customs, and culture. Alternative F was also not selected in whole because it does not best achieve the mix of multiple uses necessary to fully implement the mandate of FLPMA.

3.1.7 – Proposed Plan Amendment

As a result of public comments, best science, cooperating agency coordination, and internal review of the Draft RMP Amendments/EISs, the BLM has developed the Proposed Amendments/Final EISs for managing BLM-administered lands. The Proposed Amendments/Final EISs focus on addressing public comments, while continuing to meet the BLM's legal and regulatory mandates. The Proposed Amendments/Final EISs are a variation of the preferred alternatives (Alternative D) and are within the range of alternatives analyzed in the DEISs. The Proposed Plans, with slight variations (as outlined in Section 2.5 of this ROD), became ARMPAs.

3.1.8 Environmentally Preferable Alternative Considered in all Sub-Regions

Council on Environmental Quality (CEQ) regulations require that a ROD state which alternatives were considered to be "environmentally preferable" (40 CFR 1505.2(b)). Question 6A of CEQ's 40 most-asked questions regarding CEQ's NEPA regulations defines that term to ordinarily mean the alternative which best protects, preserves, and enhances historic, cultural, and natural resources.

Under that definition, Alternative C, as presented in each of the sub-regional Proposed RMP Amendments/Final EISs is the most environmentally preferable. However, NEPA expresses a continuing policy of the federal government to "use all practicable means and measures…to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans" (Section 101 of NEPA).

3.2 Alternatives Considered But Not Analyzed in Detail

The alternatives listed below by sub-region were considered but were not carried forward for detailed analysis because of one or more of the following reasons:

- They would not meet the requirements of FLPMA or other existing laws and regulations;
- They did not meet the purpose and need;
- The alternative was already captured within the range of alternative analyzed in the EIS;
- They were already part of an existing plan, policy, or administrative function; or
- They did not fall within the limits of the planning criteria.

For additional rationale as to why each of the alternatives listed below by sub-region were not carried forward for detailed analysis, refer to Section 2.11of each of the sub-regional Proposed Amendments/Final EISs.

<u>Idaho and Southwestern Montana</u>

- USFWS-Listing Alternative
- Elimination of Recreational Hunting Alternative
- Predation Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Consideration of Coal Mining Alternative

Nevada and Northeastern California

- Close All or Portions of PHMA or GHMA to OHV Use Alternative
- Elko County Sage-Grouse Plan Alternative
- Increase Grazing Alternative

Oregon

- USFWS-Listing Alternative
- Elimination of Livestock Grazing from all BLM Lands Alternative
- Increase Livestock Grazing Alternative
- Close All or Portions of PHMA or GHMA to OHV Use Alternative

Utah

- USFWS-Listing Alternative
- Increase Livestock Grazing Alternative
- Make GRSG Habitat Available for Oil Shale and Tar Sands Alternative
- Citizen Proposed Alternatives (in their entirety)
- Adoption of the State of Utah's Sage-Grouse Management Areas as PHMA for all Alternatives
- Use of Other Habitat Maps Alternatives
- County Sage-Grouse Management Plans Alternative
- Conservation Objectives Team (COT) Report Alternative
- BLM Policies and Regulations Alternative

4. MANAGEMENT CONSIDERATIONS

The BLM is tasked to provide multiple use management for public lands by the Federal Land Policy and Management Act (FLPMA) and numerous other laws and regulations that govern the management of public lands. Due to the diversity of community needs and stakeholders affected by management of BLM lands, there has been both support and opposition to certain components of the Proposed Plans. BLM's objective in choosing the Proposed Plan Amendments as the ARMPAs was to address diverse needs and concerns in a fair manner and provide a practical and workable framework for management of public lands in GRSG habitat. The BLM is ultimately responsible for preparing these ARMPAs consistent with its legal mandates that reflect collective professional judgment using the best available science. The ARMPAs provide a balance between those reasonable measures necessary to conserve, enhance, and restore GRSG and their habitat by reducing, eliminating, or minimizing threats to GRSG habitat to meet the purpose and need of these plan amendments, and the ongoing public need for use of the public lands within the Great Basin Region planning area.

The ARMPAs were selected because they will reduce or eliminate threats to GRSG at a landscape scale, improve and sustain properly functioning resource conditions, and consider needs and demands for existing or potential resource commodities and values. In the end, GRSG habitat will be managed by integrating ecological, economic, and social principles in a manner that safeguards the long term sustainability, diversity and productivity of the land.

In 2012, the FWS convened a Conservation Objectives Team (COT) of state and federal representatives to produce a recommendation regarding the degree to which threats need to be reduced or ameliorated to conserve the greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The final, peer-reviewed COT Report provided a brief overview of the threats to the greater sage-grouse's survival based upon the FWS 2010 listing decision and an assessment of the extent to which these threats affected remaining GRSG populations. A summary of the nature and extent of threats identified by the COT for each remaining identified population of GRSG in the Great Basin Region– as articulated in the COT report – is summarized in **Table 1-2**. **Table 1-3** provides a crosswalk between the threats to GRSG and their habitat identified in the COT Report and the key management responses from the ARMPAs that aim to ameliorate these threats.

Comment [JRL102]: Addressed above.

~~5. MITIGATION MEASURES~~

~~In all GRSG habitat, in undertaking BLM management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the GRSG including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. Actions which result in habitat loss and degradation include those identified as threats which contribute to GRSG disturbance as identified by the FWS in its 2010 listing decision (75 FR 13910), COT report, and depicted in the ARMPAs' Monitoring Framework (which can be found in Appendix X of each of the attached ARMPAs). Mitigation will follow the regulations from the CEQ (40 CFR, Part 1508.20; e.g. avoid, minimize, and compensate). If impacts from BLM management actions and authorized third-party actions (which are consistent with the goals, objectives, and management actions in the attached ARMPAs) that result in habitat loss and degradation remain after applying avoidance and minimization measures (i.e., residual impacts), then compensatory mitigation projects would be used to provide a net conservation gain to the species. Any compensatory mitigation would be durable, timely, and in addition to what would have resulted without the compensatory mitigation (see the concepts of durability, timeliness, and additionality as described further in the Mitigation Strategy, which can be found in Appendix X of each of the attached ARMPAs).~~

~~All practical means to avoid or minimize environmental harm, specifically to GRSG and its habitat are encompassed in the attached ARMPAs and associated appendices. Mitigation measures, including the application of required design features have been identified.~~

~~The ARMPAs also identify the development of regional mitigation strategies, in partnership with the states, to guide and target mitigation to achieve the greatest benefit to GRSG and habitat conservation and restoration. Within 90 days of the issuance of the Record of Decisions, the BLM will establish a WAFWA Management Zone GRSG Conservation Team to develop a WAFWA Management Zone Regional Mitigation Strategy that will inform the NEPA decision making process including the application of the mitigation hierarchy for actions and third party authorizations that result in habitat loss and degradation. A robust and transparent Regional Mitigation Strategy will contribute to GRSG habitat conservation by reducing, eliminating, or minimizing threats and compensating for residual impacts to GRSG and its habitat. The mitigation strategy will be developed within one year of the issuance of the Record of Decisions.~~

~~6. PLAN MONITORING AND ADAPTIVE MANAGEMENT~~

Comment [MEM103]: Moved content from the original Section 1.5.3 to here. The CEQ regs do not state that “monitoring” needs to be a standalone, so I think we are ok here.

~~Plan Monitoring~~

~~Monitoring tied to the ARMPAs has two parts: (1) implementation monitoring (i.e., are decisions being implemented in a timely manner, are actions taken consistent with the plan decisions), and (2) effectiveness monitoring (i.e., are the decisions and implementation actions achieving the desired conservation goals). Through effectiveness monitoring, BLM can assess how decisions and actions impact GRSG habitat. Understanding the effectiveness and validating results of ARMPAs and management decisions is an important part of measuring performance under the Government Performance Results Act. For example, riparian condition is a primary measure for ARMPA effectiveness (see WO IM 2010-101). Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, size of patches, etc.). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by state wildlife agencies and other partners, will allow linking real or potential habitat changes (from both natural events and management actions) to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to ameliorate negative effects with appropriate conservation actions.~~

~~The BLM Assessment, Inventory, and Monitoring (AIM) Strategy (Toevs et al. 2011 and IB2012-080) describes a vision for integrated, cross-program assessment, inventory, and monitoring of resources at multiple scales of management. Following the AIM Strategy, the BLM is modernizing its resource monitoring approach to more efficiently and effectively meet local, regional, and national resource information needs. The AIM Strategy provides a process for the BLM to collect quantitative information on the condition, trend, amount, location, and spatial pattern of natural resources on the public lands. Each AIM-Monitoring survey, at any scale of inquiry (from the plot level to west-wide deployments), uses a set of core indicators, standardized field methods, remote sensing, and a statistically-valid study design to provide nationally-consistent and scientifically-defensible information to determine conditions (e.g., rangeland health) and trends on public lands.~~

Comment [KK104]: I think this can all be deleted and the first sentence can just flow into the next paragraph

~~The National-scale deployment of AIM, known as the Landscape Monitoring Framework (LMF), commenced in 2011 in coordination with NRCS, with the collection of 1,000 plots of field-collected monitoring data across the Western U.S. LMF aims to provide non-biased estimates of vegetation and soil condition and trend using a statistically balanced sample design across BLM lands. A group of GRSG habitat and sagebrush plant community subject matter experts from BLM, USFWS, WAFWA, NRCS, ARS, state wildlife agencies, and academia identified those vegetation indicators collected at LMF sampling points that inform GRSG habitat needs. The common indicators that were identified include: species composition, foliar cover, height of the tallest sagebrush and herbaceous plant, inter-canopy gap, percent of invasive species, sagebrush shape, and bare ground. To increase the precision of estimates of sagebrush conditions within the range of GRSG, additional plot locations in occupied GRSG habitat (Sage-grouse Intensification) were added in 2013. The common indicators are also collected on sampling locations in the NRCS Rangeland Monitoring Survey. The GRSG baseline data will be collected over a five year period and an annual report will be prepared describing the status of the indicators. Beginning in year six, the annual status report will be accompanied with a trend report which will be available on an annual basis thereafter contingent upon continuation of the current monitoring budget. This information, in combination with mapping information, mid-scale habitat suitability indicator measures, and sagebrush availability information will be used to assess the effectiveness of the planning strategy.~~

~~The BLM has made significant commitments in the ARMPAs to monitoring actions to conserve GRSG habitats at multiple scales. The results from the monitoring will inform the agencies of the effectiveness~~

~~of efforts to reduce disturbance and restore seasonal habitats in priority areas, and of the status of the triggers set in the proposed LUPs for adaptive management. The BLM will report annually on the results of the monitoring efforts.~~

~~The BLM's Monitoring Framework can be found in Appendix X of each of the attached ARMPAs.~~

~~Adaptive Management~~

~~The ARMPAs include an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are not specific to any particular project, but identify habitat and population thresholds. Triggers are based on the two key metrics that are being monitored – habitat loss and/or population declines. Adaptive Management with specific triggers provide additional certainty that the regulatory mechanisms included in the ARMPAs are robust and able to respond to a variety of conditions and circumstances quickly and effectively to conserve GRSG habitat.~~

~~Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the proposed LUPsARMPAs, the BLM's response is to apply more conservative or restrictive conservation measures to mitigate for the specific causal factor in the decline of populations and/or habitats, with consideration of local knowledge and conditions. In each ARMPA, a soft trigger begins a dialogue between the state, FWS, and the BLM to see if the causal factor can be determined and what implementation-level activities can be used to reverse any trend. These adjustments will be made to preclude tripping a "hard" trigger (which signals more severe habitat loss or population declines).~~

~~Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the attached ARMPAs. In the event that new scientific information becomes available demonstrating that the hard trigger would be insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM ARMPAs, the BLM will immediately assess what further actions may be needed to protect GRSG and its habitat and ensure that conservation options are not foreclosed. This could include a formal directive such as an IM or a plan amendment, which, to the extent that it is supported scientifically, may be drawn from the range of alternatives analyzed in the development of the ARMPAs. ARMPA specific strategies can be found in Appendix X of each of the attached ARMPAs.~~

7. PUBLIC INVOLVEMENT, CONSULTATION AND COORDINATION

The BLM land use planning is conducted in accordance with NEPA requirements, CEQ regulations, and US Department of the Interior policies and procedures implementing NEPA, as well as specific BLM planning and NEPA policies. The NEPA and associated laws, regulations, and policies require the BLM to seek public involvement early in and throughout the planning process, to develop a range of reasonable alternatives to proposed actions, and to prepare environmental documents that disclose the potential impacts of proposed alternatives.

Public involvement and agency consultation and coordination have been at the heart of the planning process leading to these Great Basin Region ARMPAs. These efforts were achieved through Federal Register notices, public formal and informal meetings, individual contacts, media releases, planning

bulletins, and a series of GRSG planning-related Web sites. This section documents the outreach efforts that have occurred to date.

7.1 Public Involvement

The scoping period for the National GRSG Planning Strategy, including the four sub-regional planning areas in the Great Basin Region, began with the publication of the NOI in the Federal Register on December 9, 2011, and ended on March 23, 2012. Beginning in December and ending in February of 2012, the BLM hosted a series of public open house scoping meetings across Northeastern California, Idaho, Southwestern Montana, Nevada, Oregon and Utah. A final National GRSG Planning Strategy Scoping Report was released in May 2012.

A Notice of Availability (NOA) for the Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah Draft RMP Amendments/EISs were published in the Federal Register on November 1, 2013. The Oregon Draft RMP Amendment/EIS was released to the public on November 26, 2013.

For the Great Basin Region GRSG Proposed RMP Amendments/FEIS, Idaho and Southwestern Montana conducted seven public meetings, Nevada and Northeastern California conducted seven public meetings, Oregon conducted seven public meetings, and Utah conducted eight public meetings between November 2013 and January 2014.

Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were considered and incorporated, as appropriate, into the Proposed Plans. The Great Basin Region received approximately 4,990 substantive comments, contained in 74,240 submissions during the four Draft EISs' comment periods. Comments on the Draft RMP Amendments/EISs received from the public and internal BLM review were carefully considered and incorporated as appropriate into the Proposed Plan Amendments. Public comments resulted in the addition of clarifying text, but did not significantly change Proposed RMP Amendments.

A Notice of Availability (NOA) for the Great Basin Region GRSG Proposed RMP Amendments and Final EISs for the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah Sub-Regions were released on May 29, 2015. The release of the EPA's NOA initiated a 30 day public protest period and a 60 day governors' consistency review. Refer to **Section 2.5** for a full description of the protest period and governors' consistency review outcomes.

7.2 Cooperating Agencies

A cooperating agency is any federal, state, or local government agency or Native American tribe that enters into a formal agreement with the lead federal agency to help develop an environmental analysis. Cooperating Agencies and tribes "work with the BLM, sharing knowledge and resources, to achieve desired outcomes for public lands and communities within statutory and regulatory frameworks" (BLM 2005). The benefits of enhanced collaboration among agencies in preparing NEPA analyses are:

- Disclosing relevant information early in the analytical process
- Applying available technical expertise and staff support
- Avoiding duplication with other federal, state, tribal, and local procedures
- Establishing a mechanism for addressing intergovernmental issues

The BLM entered into a formal Memorandum of Understanding (MOU) for the National GRSG Planning Strategy with the USFWS and the U.S. Forest Service. In addition, the Great Basin sub-regions' also invited local, state, other federal, and tribal representatives to participate as Cooperating Agencies for these RMP Amendments/EISs. In total, there were 13 MOUs signed with Federal agencies, 10 MOUs signed with state agencies, 55 MOUs signed with counties, and 5 MOUs signed with tribal entities. The MOUs outline the interests, expertise, and jurisdictional responsibilities of both the BLM and its cooperating agency partners and also outlines their respective roles and responsibilities in the planning and NEPA processes. For a full list of these cooperating agencies divided by sub-region, refer to the Cooperating Agencies List at the beginning of this ROD. Additional information can also be found in Chapter 6 of each of the Proposed Amendments/FEISs.

7.2 FWS Section 7 Consultation

Consultation with FWS is required under Section 7(c) of the ESA before the start of any BLM project that may affect any federally listed or endangered species or its habitat. These planning processes are considered a major project, and the four Great Basin sub-regional Final EISs defined potential impacts on threatened and endangered species as a result of management actions proposed in the alternatives analyzed in the FEISs. The FWS is a cooperating agency in this planning process. FWS staff participated in interdisciplinary team meetings and has been provided drafts of alternative decisions and analyses for discussion and input.

The BLM formally initiated Section 7 consultation with a letter to the USFWS prior to the release of the Draft RMP Amendments/EISs, and requested concurrence on which species would require consideration during consultation. Over the ensuing months, regular meetings were held to identify the species that would be analyzed in the biological assessment, to address which actions could affect those species, and to determine whether the implementation of the Proposed Plan Amendments "may affect" the species for which this consultation occurred.

Prior to the release of the Proposed Amendments/FEISs, the BLM formally submitted the biological assessments to the USFWS for review. The USFWS evaluated the biological assessments and concurred with the "no affect" determination via memorandum for Oregon, Nevada and Northeastern California, and Idaho and Southwestern Montana, which are appendices to each of these ARMPAs. For Utah, formal consultation was required with the FWS due to a "likely to adversely affect" determination associated with the threatened listed Utah Prairie Dog. The biological opinion from the FWS is attached to the Utah ARMPA (Appendix X of Attachment X).

[Verify that the above paragraph is applicable to UT once BLM UT hears back from their local FWS.]

7.3 Native American Consultation

In accordance with the National Historic Preservation Act and several other legal authorities (see BLM Manual 8120), and in recognition of the government-to-government relationship between individual tribes and the federal government, the BLM initiated Native American consultation efforts related to preparation of the four Great Basin sub-regional RMP Amendments/EISs. Coordination with Native American tribes occurred throughout the planning process. In December 2011, the BLM sent letters to 65 tribal governments providing initial notification of the RMP Amendments/EISs and background information on the project, an invitation to be a cooperating agency, and notification of subsequent consultation efforts

related to the planning process. Tribes have been participating in the RMP Amendments/EISs processes through numerous meetings and through personal BLM contacts.

The Draft RMP Amendments/EISs were provided to the Idaho, Montana, Nevada, California, Oregon, and Utah State Historic Preservation Offices (SHPO) concurrently with its release to the public. The Proposed Plan RMP Amendments/FEISs were also provided to the SHPOs.

8. APPROVAL

Land Use Plan Amendment Decisions

It is the decision of the Bureau of Land Management (BLM) to approve the Great Basin Region Approved Resource Management Plan (RMP) Amendments for the Nevada and Northeastern California, Oregon, Utah, and Idaho and Southwestern Montana sub-regions, as described in this Record of Decision. The Proposed Plan Amendments and related Final Environmental Impact Statements (EIS) were published on May 29, 2015, in the Federal Register (80 FR 30711). I have resolved all protests and, in accordance with BLM regulations 43 CFR 1610.5-2, my decision on the protests is the final decision of the Department of Interior. The approval is effective on the date this Record of Decision is signed.

Approved by:

Neil Kornze Director Bureau of Land Management	Date

Secretarial Approval

I hereby approve the land use plan amendments decisions. My approval of the land use plan decisions constitutes the final decision of the Department of the Interior and, in accordance with regulations at 43 CFR 4.410(a)(3), is not subject to appeal under Department regulations at 43 CFR Part 4. Any challenge to these land use plan decisions must be brought in Federal district court.

Approved by:

Sally Jewell Secretary Department of the Interior	Date

Summary

This Record of Decision (ROD) is the culmination of an unprecedented effort in public land management to meet the multiple-use and sustained-yield management objectives for public lands administered by the Bureau of Land Management (BLM) in accordance with the Federal Land Policy and Management Act of 1976 (FLPMA).

In response to a 2010 determination by the U.S. Fish and Wildlife Service (FWS) that the greater sage-grouse listing under the Endangered Species Act (ESA) is “warranted but precluded” by other priorities, the BLM, in coordination with the U.S. Department of Agriculture Forest Service (Forest Service) has developed a targeted, multi-tiered, landscape-level management approach, based on the best available science, that offers the highest level of protection for GRSG in the most important habitat areas to address the specific threats identified in the 2010 U.S. Fish and Wildlife “warranted but precluded” decision and Conservation Objectives Team (COT) report.

This Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon; and Utah includes land use allocations in the ARMPAs that would limit or eliminate new surface disturbance in Priority Habitat Management Areas (PHMA), while minimizing disturbance in General Habitat Management Areas (GHMA). In addition to establishing protective land use allocations, the ARMPAs would implement a suite of management actions, such as the establishment of disturbance limits, GRSG habitat objectives, ~~,~~ mitigation requirements, monitoring protocols, and adaptive management triggers and responses, as well as other conservation- measures throughout the range. The cumulative effect of these conservation measures would work in concert to protect, improve, and restore GRSG habitat -across the remaining range of the species in the Great Basin and provide- greater certainty that BLM land and resource management -activities in GRSG habitat in the Great Basin Region ~~can~~ will lead to conservation of the GRSG and other sage steppe associated species in the region.

Comment [JRL1]: The are not tools, but management actions to be implemented by the plans. DDCT is a tool, but establishing disturbance limits is a management action

Comment [JRL2]: This is the suite of actions facilitated by the plans

Comment [JRL3]: Certainty is better than “consistency” as that has become a “trigger” for negative response

Comment [JRL4]: Tie to ultimate goal and to benefit to other species and the ecosystem overall.

In conjunction with the management actions for GRSG included in the ROD and ARMPAs and ARMPRs for the Rocky Mountain GRSG subregion and the implementation actions identified in the Integrated Rangeland Fire Management Strategy to address the threat of fire and invasive species and the opportunity for improved restoration effectiveness, -this ROD and ARMPAs for the Great Basin subregion provides management direction to protect and restore habitat essential to the conservation of the GRSG across its remaining range. This conservation strategy, developed in collaboration with the 11 states in which the ARMPAs and ARMPRs apply, in addition to other state and federal actions underway and in development, represents an unprecedented, collaborative effort among federal land management agencies and the states to manage an entire ecosystem and associated flora and fauna, in order to "conserve the sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future". Spatially Explicit Modeling of Greater Sage-Grouse (*Centrocercus urophasianus*) Habitat in Nevada and Northeastern California—A Decision-Support Tool for Management

By Peter S. Coates[1], Michael L. Casazza[1], Brianne E. Brussee[1], Mark A. Ricca[1], K. Benjamin Gustafson[1], Cory T. Overton[1], Erika Sanchez-Chopitea[1], Travis Kroger[1], Kimberly Mauch[1], Lara Niell[2,3], Kristy Howe[1], Scott Gardner[4], Shawn Espinosa[3], and David J. Delehanty[5]

Abstract

Greater sage-grouse (*Centrocercus urophasianus*, hereafter referred to as “sage-grouse”) populations are declining throughout the sagebrush (*Artemisia* spp.) ecosystem, including millions of acres of potential habitat across the West. Habitat maps derived from empirical data are needed given impending listing decisions that will affect both sage-grouse population dynamics and human land-use restrictions. This report presents the process for developing spatially explicit maps describing relative habitat suitability for sage-grouse in Nevada and northeastern California. Maps depicting habitat suitability indices (HSI) values were generated based on model-averaged resource selection functions informed by more than 31,000 independent telemetry locations from more than 1,500 radio-marked sage-grouse across 12 project areas in Nevada and northeastern California collected during a 15-year period (1998–2013). Modeled habitat covariates included land cover composition, water resources, habitat configuration, elevation, and topography, each at multiple spatial scales that were relevant to empirically observed sage-grouse movement patterns. We then present an example of how the HSI can be delineated into categories. Specifically, we demonstrate that the deviation from the mean can be used to classify habitat suitability into three categories of habitat quality (high, moderate, and low) and one non-habitat category. The classification resulted in an agreement of 93–97 percent for habitat versus non-habitat across a suite of independent validation datasets. Lastly, we provide an example of how space use models can be integrated with habitat models to help inform conservation planning. In this example, we combined probabilistic breeding density with a non-linear probability of occurrence relative to distance to nearest lek (traditional breeding ground) using count data to calculate a composite space use index (SUI). The SUI was then classified into two categories of use (high and low-to-no) and intersected with the HSI categories to create potential management prioritization scenarios based on

information about sage-grouse occupancy coupled with habitat suitability. This provided an example of a conservation planning application that uses the intersection of the spatially-explicit HSI and empirically-based SUI to identify potential spatially explicit strategies for sage-grouse management. Importantly, the reported categories for the HSI and SUI can be reclassified relatively easily to employ alternative conservation thresholds that may be identified through decision-making processes with stake-holders, managers, and biologists. Moreover, the HSI/SUI interface map can be updated readily as new data become available.

Introduction

Greater sage-grouse (*Centrocercus urophasianus*, hereafter referred to as "sage-grouse") are considered an umbrella (Rich and Altman, 2001; Rich and others, 2005; Rowland and others, 2006) or indicator species for the ecological integrity of sagebrush (*Artemisia* spp.) ecosystems due to the dependence of sage-grouse on sagebrush habitat, as well as their propensity to occupy sagebrush habitat across large spatial scales during the course of seasonal self-maintenance needs and reproduction (Knick and Connelly, 2011). Sage-grouse populations have declined concomitantly with the loss, degradation, and fragmentation of sagebrush ecosystems (Knick and Connelly, 2011), and currently (circa 2014) occupy slightly more than one-half of their former range across Western North America (Schroeder and others, 2004; Miller and others, 2011). Accordingly, sage-grouse have been identified as a candidate species for listing under the Endangered Species Act (U.S. Fish and Wildlife Service, 2010).

Sage-grouse in Nevada and northeastern California represent more than 25 percent of the present range-wide distribution of the species. Hence, empirically-based analytical tools that inform management decisions within Nevada and California are needed, especially where state and local resource managers have site-specific information that could be incorporated into a data-driven analytical tool for managers. One approach to aid sage-grouse management would be to develop an analytical tool that uses data replicated across broad geographical ranges to inform landscape level decisions, but that also can then be downscaled to inform local management decisions.

Currently available computational tools now allow for greater quantification of probabilistic habitat use at multiple spatial scales. In particular, habitat suitability indices (HSIs) generated from resource selection functions (RSFs) are powerful empirical quantifications that simultaneously consider habitat characteristics with animal distribution. Furthermore, these values can be measured at multiple local sites and then be used to project the relative probability of species occurrence across broader and un-sampled areas as a function of habitat characteristics (Boyce and McDonald, 1999; Manly and others, 2002).

The utility of Geographic Information System (GIS)-derived HSIs for understanding sage-grouse ecology has been facilitated by the increased availability of remotely sensed imagery used to accurately classify vegetation types across large geographic areas in conjunction with the availability of large datasets of sage-grouse locations generated from monitoring radio-marked sage-grouse (Aldridge and others, 2012). Moreover, coupling HSI values with predictions of sage-grouse occurrence based on space use models and indices (for example, Doherty and others, 2010a; Coates and others, 2013) will assist managers in recognizing the relative importance of particular areas to sage-grouse. For example, an understanding of the distribution and density of breeding sage-grouse at lek sites (that is, traditional breeding grounds) can aid in region-wide management of sage-grouse by targeting actions in areas with high quality habitat coupled with information on how sage-grouse use the habitat spatially and seasonally.

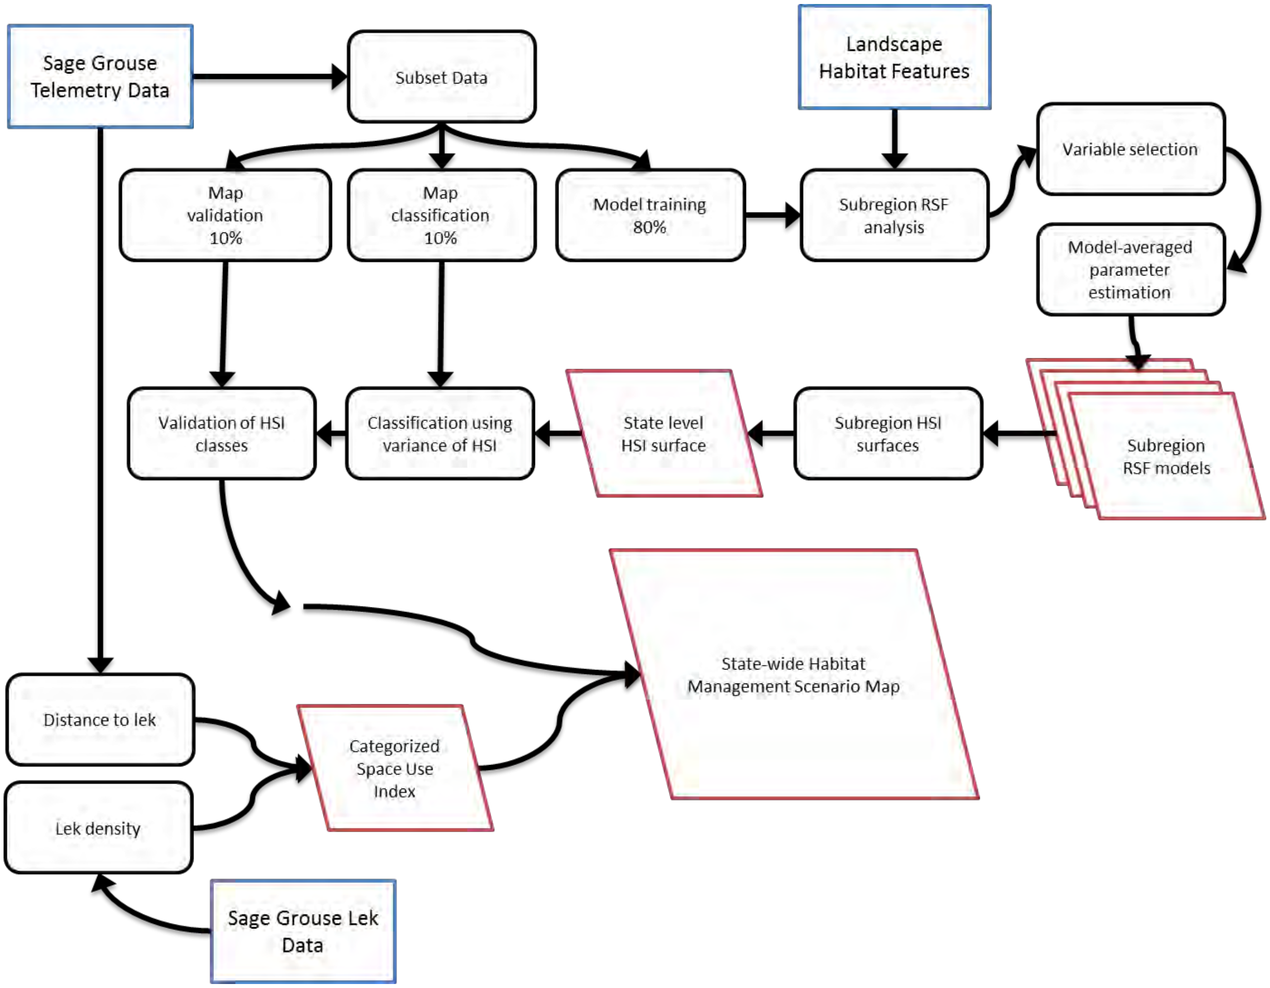
This report describes the process used to develop a region-wide habitat suitability map for sage-grouse within the southwestern portion of sage-grouse range (that is, Nevada and northeastern California). Because, variation in habitat composition across the sage-grouse range influences sage-grouse populations, this map was generated using averaged parameter estimates from RSFs informed by telemetry location data across 12 project areas with data that range 15 years. We then describe a method for applying a quantitative approach to conservation planning based on the simultaneous consideration of objectively categorized HSI values and space use indices (SUIs) derived from lek location data. The goal was to employ empirical information to evaluate different management scenarios for areas where sage-grouse conservation is a management goal. These scenarios can take many forms. For example, quantification could help to identify core areas to conserve sagebrush habitat with an emphasis on areas occupied frequently by sage-grouse, or help to identify conservation priorities and management actions for less suitable habitat, or suitable yet unoccupied habitat. Importantly, the indices created through the analytical processes described can be reclassified easily to incorporate alternative thresholds for conservation such as those that arise through decision-making processes with stake-holders, managers, and biologists. This work was completed in partnership with the State of Nevada Sagebrush Ecosystem Technical Team, the Nevada Department of Wildlife (NDOW), the Bureau of Land Management, and the California Department of Fish and Wildlife (CDFW).

Methods and Results

Overview and Conceptual Models

The quantitative approach to develop a spatially explicit support tool for conservation planning consisted of multiple steps that we describe in detail below and outline in a conceptual model (fig. 1). The overall modeling framework comprised input data sets (blue rectangular boxes) that were subjected to a series of processing steps (black rounded boxes) to produce interim and final spatially explicit maps (red parallelograms) (fig. 1).

First, we compiled sage-grouse telemetry location data from multiple areas across Nevada and northeastern California, and divided these data into three independent sets for the purposes of model training (80 percent of locations), mapping classification (10 percent), and map validation (10 percent) (*see: ‘Habitat Suitability Model Development’*). The training data set was linked spatially with corresponding environmental covariates to enable calculation of population-level RSFs (Manly and others, 2002) within 12 subregions with adequate data. To achieve this, we first identified the relevant spatial scale and linear relationships of environmental characteristics. Next, model-averaged parameter estimates for influential covariates among all candidate models were calculated to account for model selection uncertainty (Burnham and Anderson, 2002) (*see ‘RSF Analyses’*). We then used those estimates to develop spatially explicit models reflecting the relative probability of selection at each subregion. For each of the 12 subregional RSF models, we: (1) transformed the model into an HSI; (2) extrapolated the HSI across the extent of the region; and (3) averaged the HSI predictions generated from each subregion to provide an unbiased region-wide HSI map. The independent classification telemetry data set was then used to extract the region-wide HSI predictions and categorize the continuous HSI value based on the mean and variance of the extracted data that resulted in a region-wide categorical habitat map grouped into four hierarchical classes of descending probability of selection. The third independent data set was used to validate the region-wide map by calculating the proportion of locations within each category. We calculated these proportions for telemetry data within each of the training subregions and telemetry data from multiple independent subregions (that is, non-RSF subregions). Data from independent subregions were used for the purpose of assessing the map in interpolated areas. Locations of active leks were used as an additional dataset for map validation (*see*: '*Region-wide Habitat Suitability Index and implementation for Conservation Planning*').



,

Figure 1. Diagram showing conceptual model for a statewide greater sage-grouse (*Centrocercus urophasianus*) habitat suitability model and habitat management scenario map, Nevada and northeastern California. Input datasets (blue rectangular boxes) were subjected to a series of processing steps (black rounded boxes) to produce interim and final spatially explicit maps (red parallelograms). HSI, habitat suitability index; RSF, resource selection function; %, percent.

From the RSFs, information about the probability of selection was produced solely on predicted associations of sage-grouse with environmental covariates. However, the model does not incorporate knowledge of sage-grouse abundance and density that represents space occupied currently by sage-grouse. Therefore, a SUI was created based on lek count data and existing information regarding how sage-grouse use space in relation to leks. Specifically, the SUI integrated information on lek density, lek size (that is, average number of males attending leks), and the non-linear relation between probability of space use and distance to lek, which was then used to create categories of high use or low-to-no use across the region. To provide a modeling tool that can aid conservation planning, the region-wide HSI (categorized into high, moderate, low, and non-habitat based on the variance distribution of HSI values) and high and low-to-no use SUI categories were combined into a single region-wide map. This map simultaneously reflects both the presence of sage-grouse and the presence of habitat features associated with sage-grouse occupancy, and can then be used to prioritize areas for different management scenarios. The strength of this map is to account for characteristics that describe the quality of the environment for sage-grouse as well as an index of population abundance. This technique can be used to aid decision-making processes across the landscape (*see 'Implementation of the Region-wide HSI map for Conservation Planning: An Example'*).

Habitat Suitability Model Development

Delineating the Region-Wide Scale.

The region-wide extent of the project area was defined by using the outer perimeter of all combined sage-grouse Population Management Units (PMU; Nevada Department of Wildlife, 2014) in Nevada and northeastern California plus a 10-km buffer (fig. 2). This approached yielded an area of 21.5 million hectares that approximated the total potential sage-grouse range in Nevada and California (excluding the Bi-State Distinct Population Segment on the eastern side of the central Sierra Nevada Mountains). The purpose of the buffers was to ensure adequate representation of available habitats to sage-grouse at and near the PMU boundaries. Floristically, the region was typical of the Great Basin with Wyoming big sagebrush (*Artemesia tridentata* ssp. *wyomingensis*) and black (*Artemesia nova*) and low (*Artemesia arbuscula*) sagebrush occurring at elevations below 2100 m, and with mountain big sagebrush (*Artemesia tridentata* ssp. *Vaseyana*) occurring more frequently at higher elevations. Common non-sagebrush shrubs included rabbitbrush (*Chrysothamnus* ssp.), Mormon tea (*Ephedra viridis*), snowberry (*Symphoricarpos* ssp.), western serviceberry (*Amelanchier alnifolia*), and antelope bitterbrush (*Purshia tridentata*). Conifer forests were most frequently comprised of single-leaf pinyon pine (*Pinus monophylla*) and Utah juniper (*Juniperus osteosperma*) (hereafter, "pinyon-juniper"). Non-native and highly invasive annual grasses included cheatgrass (*Bromus tectorum*) and medusahead rye (*Taeniatherum caput-medusae*). Native perennial grasses included needle and thread (*Hesperostipa comata*), Indian ricegrass (*Achnatherum hymenoides*), and squirreltail (*Elymus elymoides*).

Sage-Grouse Telemetry Data.

Data used in the study were generated from several sage-grouse telemetry studies across Nevada and northeastern California conducted from 1998 through 2013 by USGS, NDOW, CDFW, Idaho State University, University of Idaho, and University of Nevada-Reno. Field data collection protocols for tracking and locating sage-grouse were generally consistent across sites and years. Data were excluded from the analyses in situations where data collection procedures or supporting information differed substantially from norms. For example, telemetry data were removed from the analyses when a unique bird identifier or location date was absent or birds had less than two locations total.

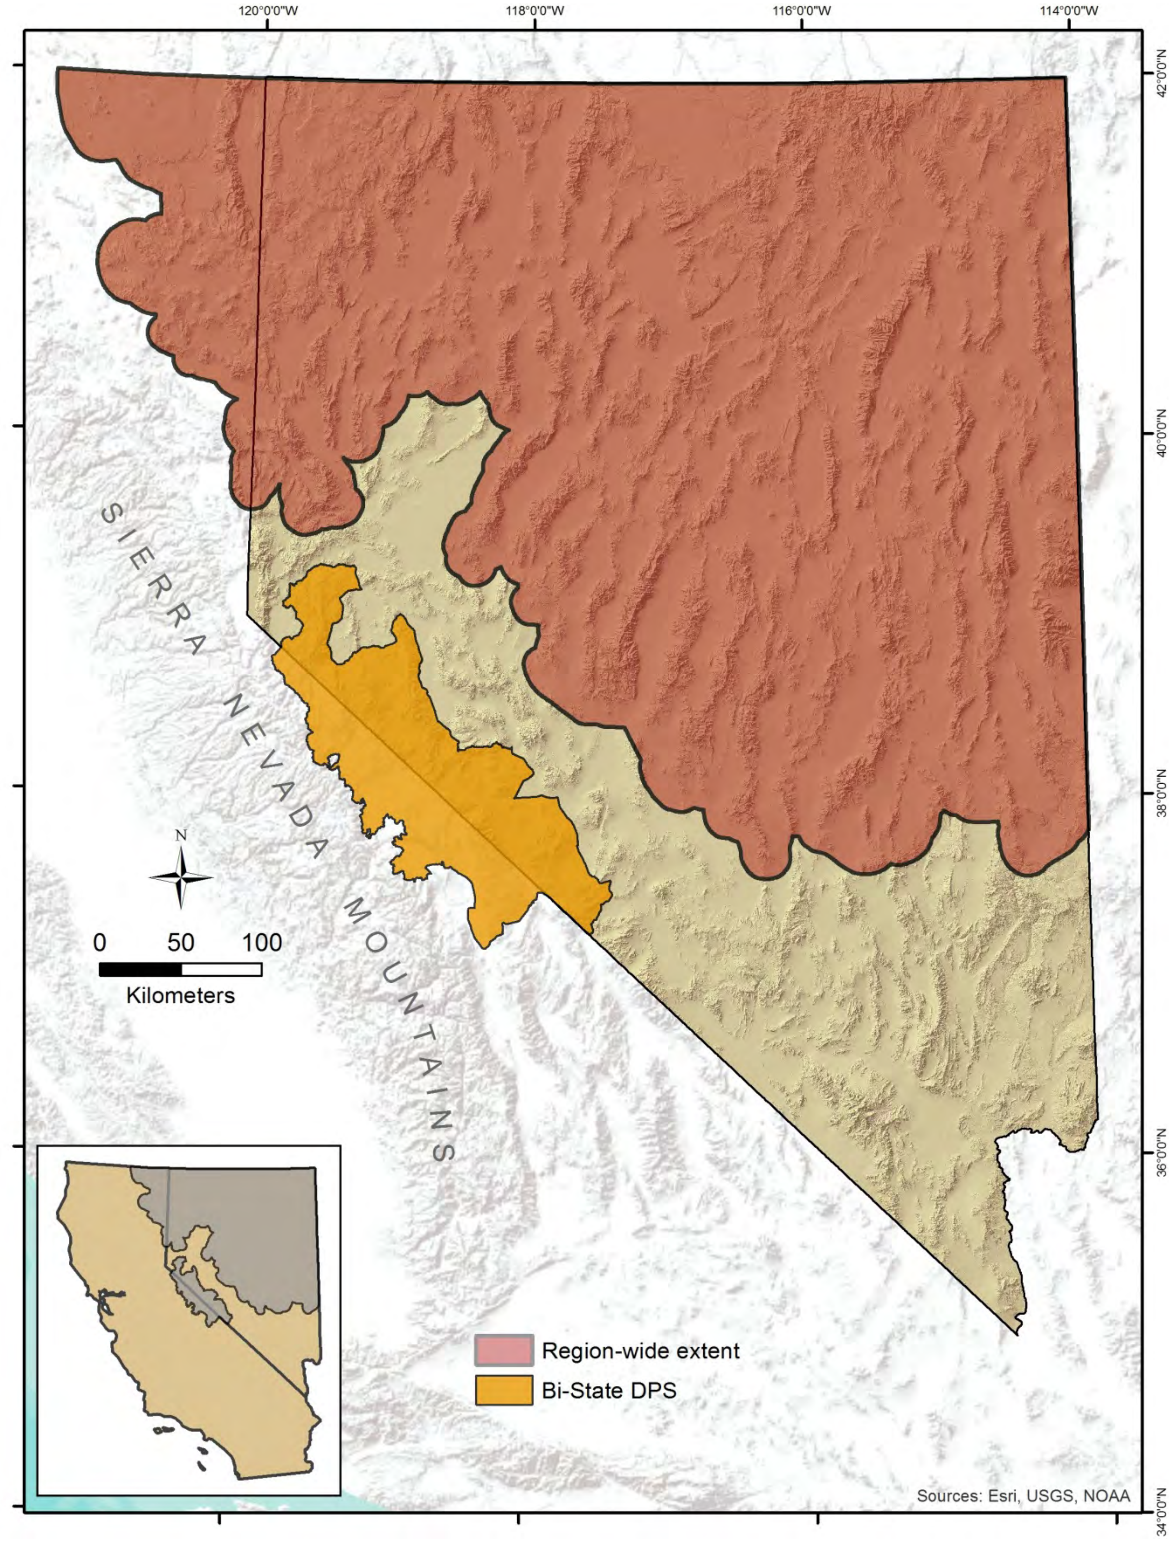


Figure 2. Map showing project area, which included the segment of greater sage-grouse (*Centrocercus urophasianus*) range in Nevada and northeastern California, excluding the Bi-State Distinct Population Segment (Bi-State DPS).

Generally, sage-grouse were captured in close proximity to leks in spring (March–April) and at various areas where sage-grouse congregate in autumn (October–December) using spotlighting techniques at night (Giesen and others, 1982; Wakkinen and others, 1992). Captured sage-grouse were outfitted with necklace-style VHF radio-transmitters (Kolada and others, 2009). Over the 15-year period (1998–2013), personnel across agencies and organizations conducted on-the-ground monitoring of sage-grouse. In lieu of VHF only radio-transmitters, a subsample of sage-grouse at some sites during 2012 and 2013 were outfitted with a combined Global Positioning Systems (GPS) - Platform Transmitter Terminals (PTTs; North Star Science and Technology, LLC, King George, Virginia) and VHF transmitter system. This system had a combined weight or less than 3 percent of sage-grouse body mass. The purpose of the GPS transmitter was to collect locations remotely, and the PTT transmitted stored location data via satellite communication to a central database. The VHF marked sage-grouse were relocated using hand-held radio receivers and antennas, whereby ground observers circled sage-grouse at a radius of 30–50 m and used the loudest signal method to minimize location error. Location coordinates for VHF-marked sage-grouse were obtained using a hand-held GPS (Universal Transverse Mercator, UTM).

Both VHF and GPS - PTT telemetry data were used in our analyses, and were screened for completeness and comparability prior to inclusion in models. GPS - PTT transmitters were programmed to collect 9–12 locations per day. To prevent autocorrelation among GPS - PTT location data, only a single random location per day (during daylight hours) was used in our analyses, and the remaining daily locations were removed. In total, 35,883 telemetry locations from 1,612 sage-grouse were compiled into a region-wide database for all analyses. The majority of locations from marked sage-grouse were obtained within a single year (that is, few unique grouse were marked across multiple years). All locations were generated from adult sage-grouse (that is, older than 1 year of age) of each sex across all seasonal life stages.

Sage-grouse telemetry locations were divided into three independent data subsets for use in different steps of model processing and validation. These data sets were considered independent in that no telemetry locations across sets were shared by the same individual. Thus, different sage-grouse were used for each data set. These data sets consisted of: (1) an RSF model training subset employing 80 percent of location data; (2) a classification subset employing 10 percent of location data to delineate areas of differing habitat quality; and (3) a validation subset employing 10 percent of location data from RSF subregions to assess predictiveness and consistency of habitat quality areas. Individual sage-grouse were randomly assigned to these three categories at the given proportions.

Delineating Subregions.

Spatial associations between marked sage-grouse and existing PMU boundaries (Nevada Department of Wildlife, 2014) were used as an initial starting point for delineating subregions for habitat selection analyses and naming conventions across Nevada and northeastern California (fig. 3). Ultimately, the data were partitioned into 19 subregions based on movement patterns of individual radio-marked sage-grouse for habitat analyses, with each grouse occupying one subregion only. Some subregions contained too few marked sage-grouse for sufficient training data to develop a habitat model, which resulted in the exclusion of seven subregions with fewer than 20 marked sage-grouse or less than 100 telemetry locations. However, data from these excluded ‘non-RSF’ subregions were sufficient to provide further validation of the region-wide model in areas that were not used to train the model (*see*

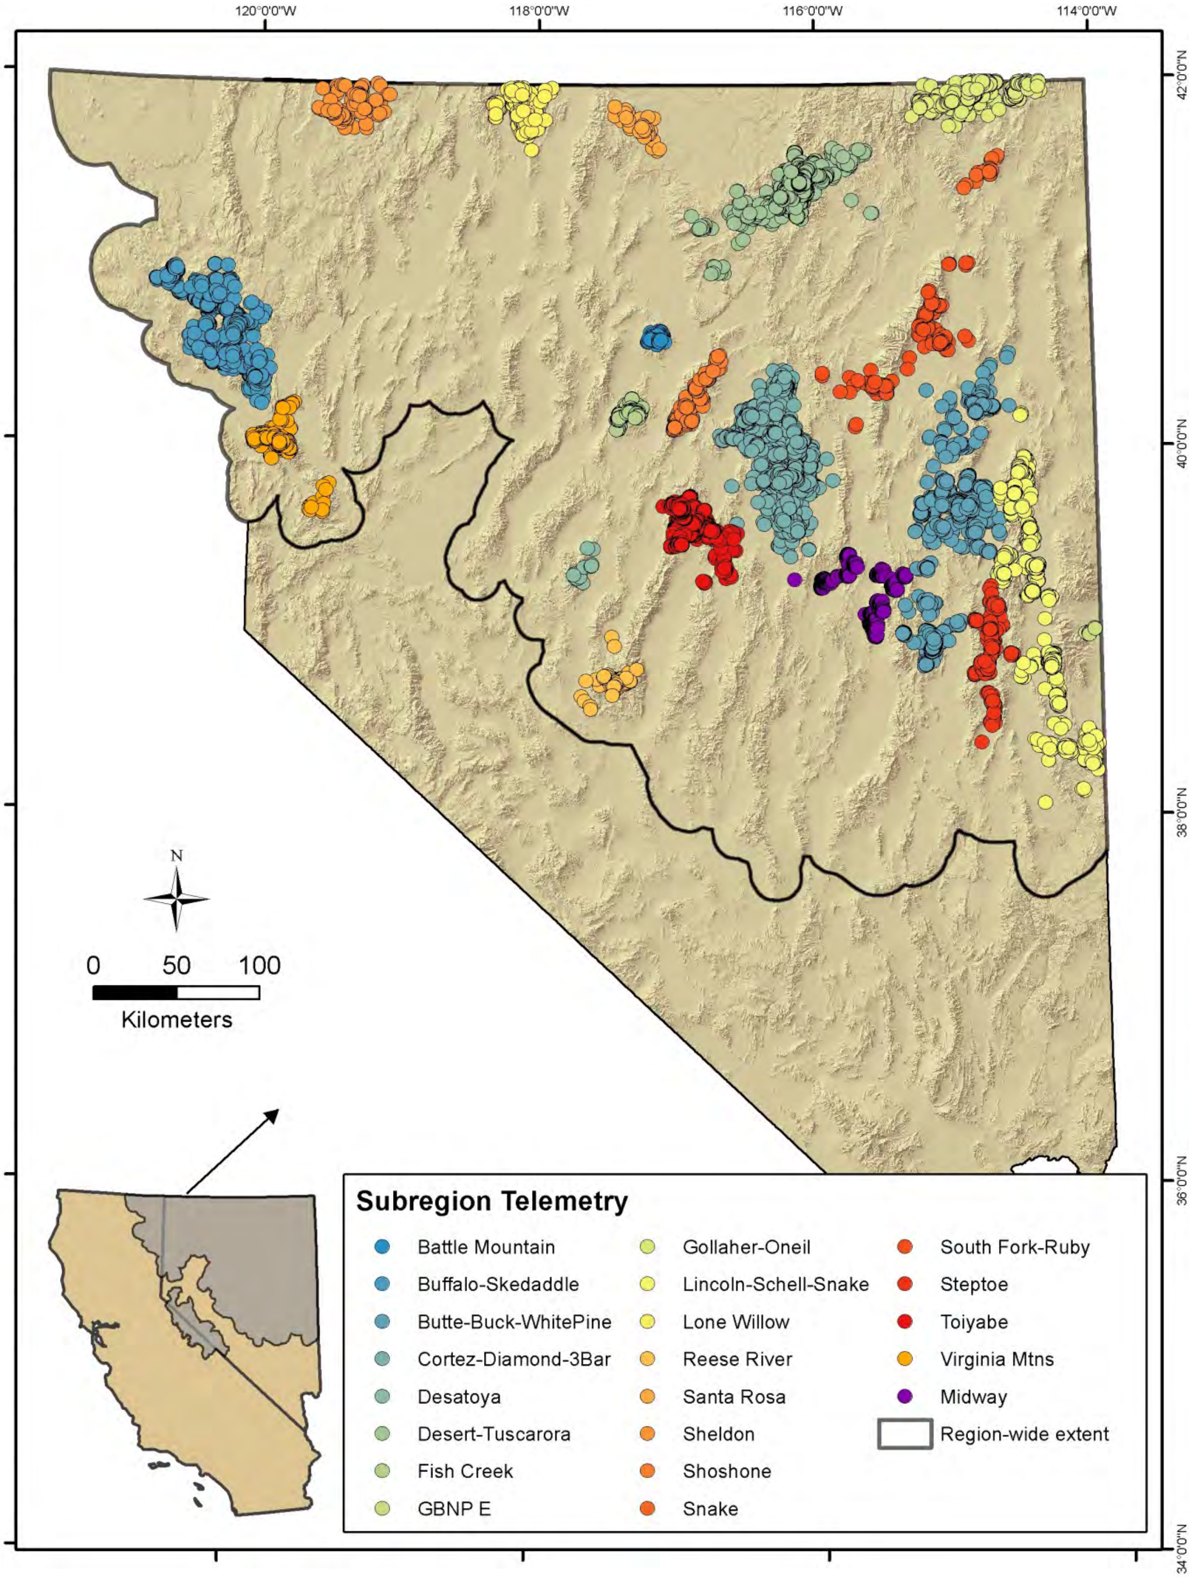

Figure 3. Map showing telemetry points (colored dots) comprising greater sage grouse (*Centrocercus urophasianus*) locations available for use in resource selection function modeling, Nevada and northeastern California. Names refer to locations associated with NDOW Population Management Units.

'HSI Classification and Validation'). After data-screening, we included telemetry data from 12 subregions in the habitat training models: Buffalo-Skedaddle, Butte-Buck-White Pine, Cortez, Desert-Tuscarora, Gollaher-O'Neil, Lincoln-Schell-Snake, Lone Willow, Midway, Sheldon, South Fork-Ruby Valley, Toiyabe, and Virginia Mountains (fig. 4). The spatial extent of habitat availability for use in habitat modeling was defined by first calculating a minimum convex polygon (MCP) that encompassed all telemetry locations within each subregion, and then buffering each MCP by the maximum average daily sage-grouse movement (1,451 m). Using the MCP to identify the study extent is a common and useful approach for habitat studies (Aebischer and others, 1993), and buffering by the maximum average daily movement helps ameliorate underestimation of habitat availability.

Classification of Landscape Habitat Features.

A broad suite of biotic and abiotic variables potentially associated with sage-grouse occurrence was quantified to provide inputs to estimated HSIs as spatially explicit environmental covariates. Land-cover types representing the dominant vegetation within 30 x 30 m pixels were classified into binary raster layers using existing mapping products. For Nevada, detailed land cover classes were derived from the Nevada SynthMap (Peterson, 2008). Land cover classes were then reclassified into broad habitat categories that were guided by classification levels from NatureServe (NatureServe, 2013), Landscape Fire and Resource Management Planning Tools (LANDFIRE) (2010), and The Nature Conservancy. Land cover classes for the northeastern California portion of the project area were derived from LANDFIRE, SageStitch (Comer and others, 2002), and California Department of Forestry and Fire Protection (2006) data sets. To facilitate region-wide compatibility across land cover classes, each data set was reclassified into the broadest categories used to reclassify the Nevada SynthMap, and then compared across pixels. Pixel values that matched for at least two of the data sets were chosen, whereas the reclassified LANDFIRE value was used when no agreement occurred. The final Nevada and northeastern California layers were then merged. The final set of non-sagebrush land cover classes used in the analysis comprised annual grass, perennial grass, lowland non-sagebrush shrub, upland non-sagebrush shrub, wet meadow, riparian, pinyon-juniper conifer, non-pinyon-juniper conifer (forest), agricultural cropland, and bare ground. All sagebrush species (for example, Wyoming big, mountain big, low, and three-tip [*Artemisia tripartita*]) were ultimately condensed into a single "sagebrush" land cover class for analysis (table 1).

Because variation in sage-grouse habitat selection can be strongly scale-dependent (Aldridge and Boyce, 2007; Doherty and others, 2008; Casazza and others, 2011; Aldridge and others, 2012), the analysis was performed on each land cover raster at three different spatial scales relevant to sage-grouse movement patterns. Specifically, the scale-dependent analysis used a circular moving window (neighborhood analysis tool, ArcGIS™ Spatial Analyst) with a radius of 167.9 m (8.7 ha), 439.5 m (61.5 ha), or 1,451.7 m (661.4 ha) that represented averages across sage-grouse of the minimum, mean, and maximum daily distance traveled by sage-grouse in this study, respectively, to calculate the proportion of a particular habitat within a respective spatial scale. Other land cover related variables measured at the three spatial scales included variety of land cover types (that is, the number of unique land cover types), variety of edge types (that is, the number of unique combinations of adjacent land cover types), and the amount of edge, quantified as the total number of pixels that represented interface of two adjacent cover types (hereafter, "edge effect") (table 1).

Topographic position index	510 m	2,010 m	

Distance Metrics, and Topographic Indices.

Distances to landscape features that may affect the probability of sage-grouse use were calculated from the GIS (table 1). These landscape features included various water features, agricultural development, and habitat edge (table 1). The influence of distance to water was measured using multiple landscape features from the National Hydrography Dataset (U.S. Geological Survey, 2014) that included perennial streams, intermittent streams, springs, and open water bodies. Distance to wet meadows was also measured, as identified by the land cover maps. For all landscape features, linear distance was calculated as a simple Euclidean distance from a used or available point using the Distance tool in Spatial Analyst (ArcGIS™ 10.1). Non-linear relationships were assessed with an exponential decay function, $e^{-d/\alpha}$, where d was the Euclidean distance from a used or available point to a landscape feature, and α was the mean linear distance from that feature. This decay function allowed estimation of the degree to which the effect of a habitat feature strengthened or weakened with increasing distance from that feature. A metric estimating the distance to road was also calculated but not included in the set of variables because the sage-grouse locations obtained by hand-held VHF were closer to roads than those obtained by GPS-PTT and could result in biased results across data sources (P.S. Coates, U.S. Geological Survey, unpub. data, 2014).

Topographic characteristics were calculated to assess the probability of sage-grouse use with several indices. Elevation and topographic roughness (within 30 x 30 m pixels) were determined from the National Elevation Dataset (U.S. Geological Survey, 2009). Topographic roughness, which measures variance in elevation change (Riley and others, 1999), was calculated using the Geomorphometry and Gradient Metrics Toolbox (Evans and Oakleaf, 2012) and normalized by dividing each pixel value by the maximum value. Topographic position indices (TPI; Jenness, 2006) were calculated as the difference between elevation at a central point and the surrounding average elevation within radii of 510 and 2,010 m. Positive and negative TPI values indicated central point elevations that were higher and lower than the surrounding area, respectively, and depressions or valleys can represent areas of increased moisture (De Reu and others, 2013).

Values of all landscape habitat features, distance metrics, and topographic indices were extracted from the GIS for input into the habitat selection analyses (*see 'Subregional RSF Modeling'*) at used locations (telemetry data) and random locations. The purpose of generating random locations was to characterize the environment available to sage-grouse populations. Five random locations within the buffered MCP were generated for every used location to account for heterogeneity of available land cover types (Aldridge and others, 2012).

RSF Analyses

Subregional RSF Modeling.

Resource selection functions (RSFs) are calculated frequently using data from wildlife telemetry studies. Typically, selection and avoidance for particular landscape features are estimated by contrasting measurements at used locations (telemetry data) with measurements at random locations that represent areas available to all individuals within a population (Boyce and McDonald, 1999; Manly and others, 2002; Johnson and others, 2006). We estimated population-level RSFs using generalized linear models with a binomial error distribution and specified logit-link function (that is, logistic regression) in a mixed effects model framework, where environmental variables (described above) were modeled as explanatory covariates (predictors). The number of sample locations was not equal across individual sage-grouse. Therefore, the individual sage-grouse was treated as a random effect (that is, random intercept) to account for potential autocorrelation among locations associated with each individual (Gillies and others, 2006). Year was also included as a random effect for those subregions with more than 1 year of telemetry data to account for temporal intraclass correlation. A weight of 0.2 was specified in the model structure for each random location that was used to characterize available habitat. This value allowed equal influence by used (weight = 1) and random points because 5 random points were generated per actual grouse location. To avoid seasonal sampling bias, we also added an additional weight to each location based on the proportion of use occurring during spring/summer (March–August), fall (September–November), and winter (December–February). The seasonal weight allowed all seasons to be represented equally. We fit all models using the lme4 package (Bates and others, 2012) in Program R (R-Core-Team, 2012).

A two-part selection procedure was employed to reduce the number of covariates. This procedure relied on bias-corrected Akaike's information criterion (AIC_c) (Burnham and Anderson, 2002) to identify the most parsimonious RSF model for each subregion. In the first part, proposal covariates (table 1; appendixes A– L) were used to determine the spatial scale, distance function, or topographic index that best approximated the probability of selection for each corresponding covariate relative to a null model (that is, random effect only) in an information-theoretic framework. The most appropriate fit for percent cover estimated at the three spatial scales (8.7 ha, 61.5 ha, or 661.4 ha) was evaluated for each land cover type. The most relevant distance function (linear or exponential decay) was evaluated for water features, edge habitat, and agriculture. All topographic measures were evaluated relative to a null model. Candidate covariates from models that represented the best performing scale/distance function were then carried forward providing that the model also outperformed the null model by greater than 2.0 ΔAIC_c units (Burnham and Anderson, 2002).

The second part of model development comprised a series of additive models containing all possible 2-covariate combinations of our "candidate" covariates carried over from the first stage. Models in this set estimated the effect (slope) of a covariate on probability of selection while accounting for the presence of all other covariates. We sought to reduce multicollinearity by constructing correlation matrices and removing models with evidence of correlated effects ($r \geq | 0.65 |$). We then calculated model-averaged parameter estimates (βs; appendixes A–L) for each covariate across the set of additive models to account for model selection uncertainty (Burnham and Anderson, 2002). The purpose of this stage was not to develop the most parsimonious additive model with multiple covariates, but instead estimate the effect of each covariate and use the model-averaged parameter estimates to calculate an RSF. Covariates were excluded when their model-averaged 95 percent confidence intervals overlapped zero. The RSF took the form:

$$\mathrm{w}(x) = exp(\beta_1 \mathrm{X}_1 + \beta_2 \mathrm{X}_2 +, \ldots, +\beta_{\mathrm{k}} \mathrm{X}_k) \quad (1)$$

where

$w(x)$ is the resource selection function (RSF), and

β is the averaged parameter estimate for each covariate ($\mathrm{X}_1, \ldots, \mathrm{X}_\mathrm{k}$) (Manly and others, 2002).

Although the RSF cannot be considered an absolute probability because unused areas were not known, the RSF is useful as a representation for the probability of selection (Manly and others, 2002).

Summary of Subregional RSF Results.

A total of 25 covariates were modelled in 12 subregional RSF analyses (table 2; appendixes A–L). Sixteen of these covariates were present in a majority of the subregional RSF models consisting of: (1) seven covariates characterizing land cover – sagebrush, lowland shrub, upland shrub, riparian, forest, pinyon-juniper, and perennial grass relative cover; (2) four covariates characterizing distance to water sources – nearest water body of any type, nearest spring, nearest wet meadow, and nearest perennial stream; and (3) six covariates characterizing land cover interfaces or abiotic features – amount of edge habitat, number of adjacent habitat types, topographic roughness, topographic position, and elevation.

While coefficient direction and magnitude for several covariates varied across subregions, some consistent patterns were evident in covariate coefficients that indicated use or avoidance of a covariate by sage-grouse (table 2; appendixes A–L). On average, 6.5 land cover covariates were present in final models for each subregion. The Sheldon subregion was the only notable exception, where just one cover type was retained in the final model. Sagebrush was selected by sage-grouse in all eleven subregions containing the sagebrush covariate, and pinyon-juniper and forest were avoided by sage-grouse in the subregions that contained those covariates (9 and 7 subregions, respectively). Strong correlations between pinyon-juniper and sagebrush did not occur among any subregions ($r < |0.65|$). Final RSF models in every subregion indicated selection for at least one type of water source. Some inconsistencies occurred among coefficients that represented relationships with agriculture across subregions, whereby use of agriculture ranged from selection, proportional use to availability, and avoidance. Effects related to either the amount of or distance to edge habitat were evident in RSFs for every subregion, but the magnitude of these effects varied among subregions. Edge types or land cover types were present in RSFs for all subregions except for the South Fork/Ruby Valley, and the direction of these effects were similar among subregions. A covariate that represented distance to some source of water was influential and, thus, included in every subregional RSF.

Table 2. Magnitude of significant model-averaged effects among 12 subregional resource selection function models for all proposed variables included in modeling of greater sage-grouse (*Centrocercus urophasianus*) habitat, Nevada and northeastern California.

Region-Wide Habitat Suitability Index and Implementation for Conservation Planning

Region-Wide Average Habitat Suitability Surface Map.

The final RSF equation was applied for each subregion across all pixels in the region-wide extent using the Raster Calculator in Spatial Analyst. Because the subregional RSF consisted of extreme values, a monotonic transformation of the RSF was conducted, expressed as:

$$\mathrm{HSI} = \frac{w(x)}{1+w(x)}, \tag{2}$$

that resulted in subregional HSI surfaces. These HSI surfaces provided a relative metric of habitat quality for any given pixel where habitat quality reflects range-wide mean propensity to be used by sage-grouse given the attributes of the pixel. The HSI equation is equivalent to a logistic transformation on the $\beta_k X_k$, for each covariate X_k. However, the function was used only to express relative influence among different RSF values by expressing influence as a value between 0 and 1. Although we did not assume that HSI values represent absolute probabilities, an increase in HSI corresponds to an increase in the probability of selection. The subregional HSIs were averaged across each pixel to calculate a single continuous surface for the region. This was an appropriate technique for developing a region-wide HSI because it reduces the potential for non-typical selection patterns at a local site to influence HSI values elsewhere within the region. Further refinement by averaging across subregions at smaller scales is possible; however, we suspect that representation from 12 subregions is not broad enough to warrant further delineation. Our end result was a region-wide HSI surface that accounts for variability in predicted HSI values from each of the subregional areas (fig. 5).

Implementation of the Region-Wide HSI Map for Conservation Planning—An Example

Effective conservation planning is an inherent stakeholder-driven process, and stakeholders may use quantitative tools to aid decision making. Here, an example is provided for how a HSI continuous surface map can be used as a tool to aid conservation planning and the decision-making process. In this example, two categorized sources of information are employed to identify spatially explicit management areas: (1) suitability of landscape characteristics; and (2) likelihood of sage-grouse occurrence.

HSI Classification and Validation—An Example

The relative suitability of habitat occurring in an area may be obtained directly from the region-wide HSI map. However, the continuous index at each 30 x 30 m pixel provided by the map is an unwieldy mechanism for decision-making related to distinct areas, especially at relatively large scales. Therefore, it can be valuable to categorize the region-wide HSI surface into classes that represent habitat quality at larger spatial scales. To do this, pixels that represented large bodies of water (for example, lakes and reservoirs) identified from Landsat land cover classifications (that is, SynthMap) were first masked from the region-wide HSI. The region-wide HSI was then objectively binned into four discrete categories in multiple steps. First, HSI values were extracted using the 10 percent of independent telemetry locations that were intentionally withheld from the data set used to develop subregion RSFs. This data set comprised the 'map classification data set', as it represented data that were statistically independent of RSF outcomes. Second, four suitability categories were developed using cutoff values based on the standard deviation (SD) from the mean HSI ($\bar{x}$) derived from the map classification data set. For these purposes, we assumed the data arose from a normal distribution. High suitability habitat was comprised of all HSI values greater than 0.5 SD below $\bar{x}$. This constituted a percentile rank range of 30.9–100.0 percent of HSI values (fig. 6). Moderate suitability habitat was comprised of HSI values between 1.0 and 0.5 SD below $\bar{x}$, constituting a percentile rank range of 15.0–30.9 percent (fig. 7). Low suitability habitat was comprised of HSI values between 1.5 and 1.0 SD below $\bar{x}$, constituting a percentile rank range of 6.7–15.0 percent (fig. 8). Non-suitable habitat was comprised of HSI values 1.5 SD below $\bar{x}$ (less than 6.7 percent; fig. 9). The cutpoint of 1.5 SD was identified as the most appropriate value to determine the lowest threshold (non-habitat vs. habitat) using an ancillary analysis. Specifically, habitat areas were generated using cutpoints from SD of 0.5, 1.0, 1.5, and 2.0 below $\bar{x}$. For each successive SD cutpoint, we then calculated the ratio of percent potential habitat area gained to the percent of RSF telemetry points added. A curvilinear line between this ratio (y-axis) and SD cutpoint (x-axis) was fitted, and the point where the line intercepted 1.0 on the y-axis was closest to the 1.5 SD. This analysis indicated that cutpoints beyond 1.5 SD incorporated disproportionately fewer telemetry points per unit area (fig. 10). As further rationale for 1.5 SD, this value represents the 6.7 percentile of the HSI distribution. Assuming that sage grouse locations are normally distributed in relation to habitat quality and sampling was random, this value roughly corresponds to the 5-10 percent of time that sage-grouse may spend moving between seasonal habitats.

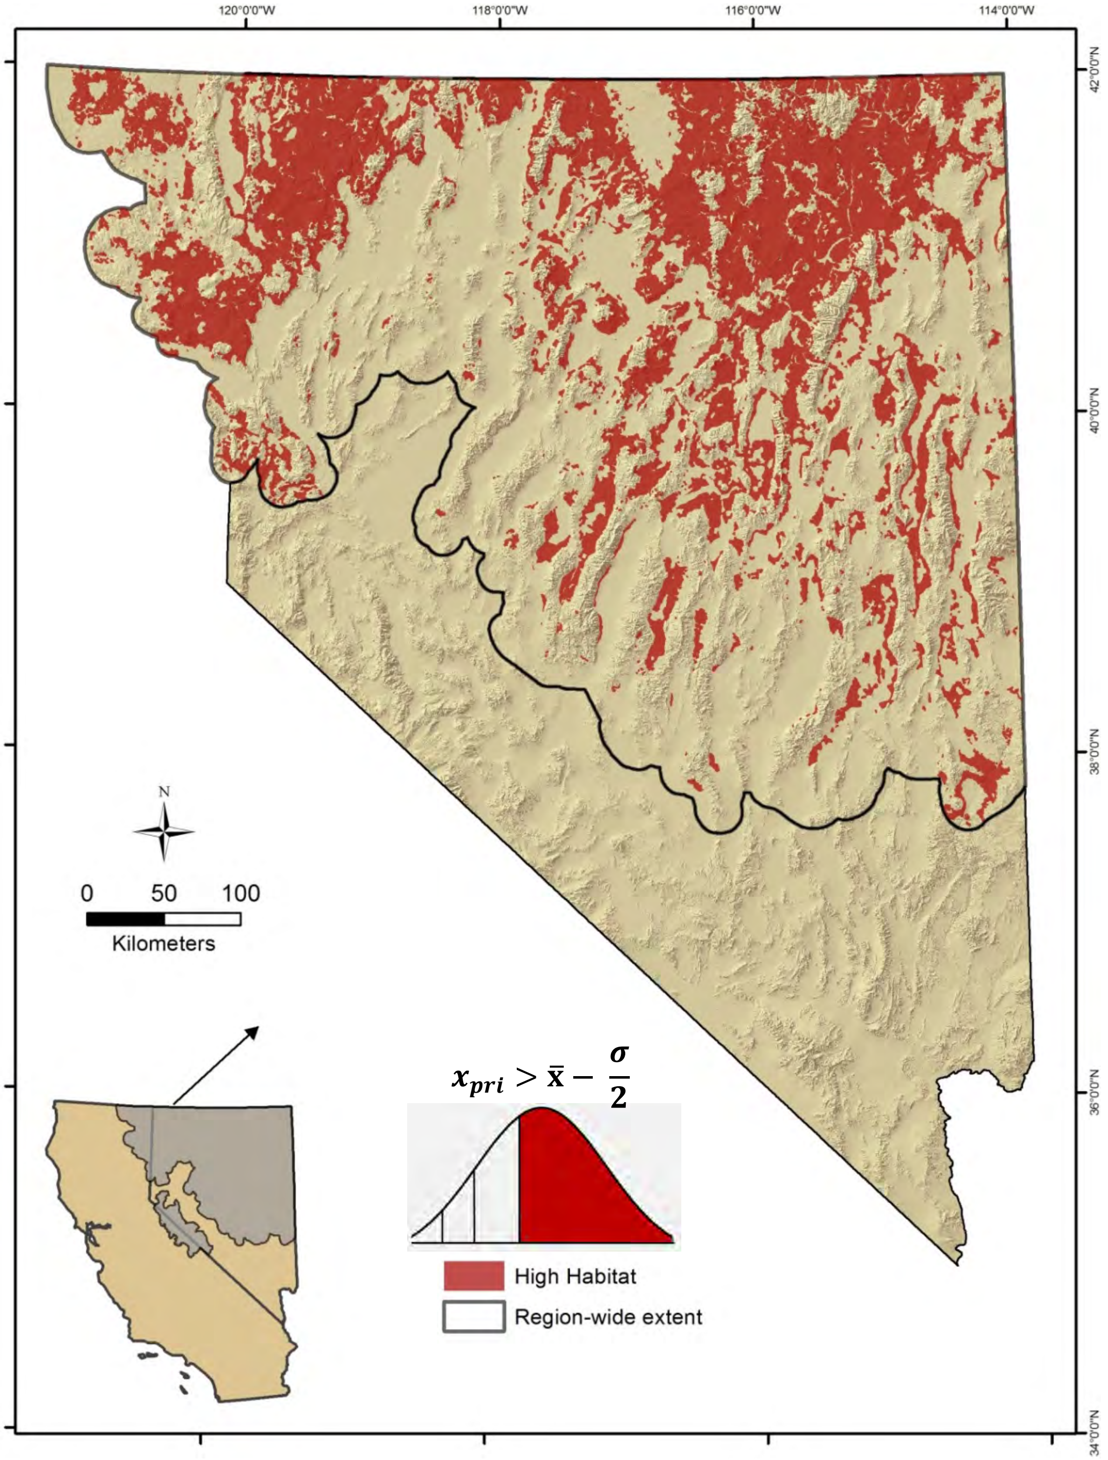

Figure 6. Map and graph (resource selection function [RSF] and probability distribution) showing example region-wide distribution of categorized high suitability habitat for greater sage grouse (*Centrocercus urophasianus*), Nevada and northeastern California. x_{pri} = classification as priority habitat; $\bar{x}$ = mean of the suitability values derived from classification data set; σ = standard deviation of suitability values derived from classification data set.

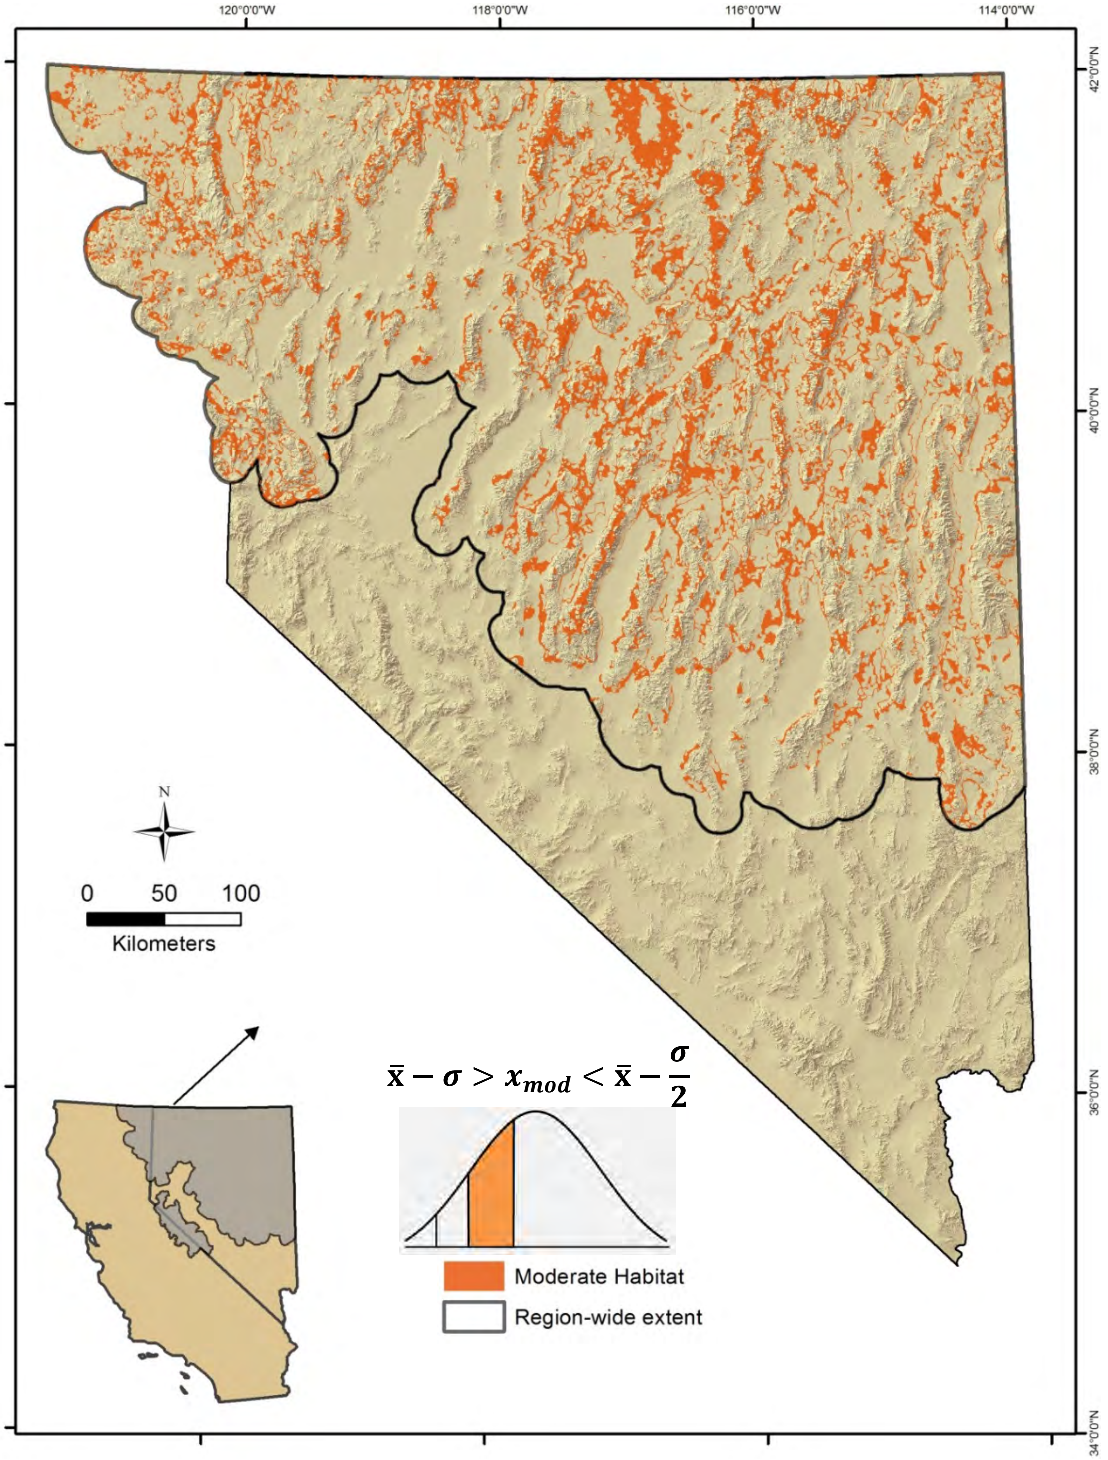

Figure 7. Map and graph (resource selection function [RSF] and probability distribution) showing example region-wide distribution of categorized moderate suitability habitat for greater sage grouse (*Centrocercus urophasianus*), Nevada and northeastern California. x_{mod} = classification as moderate habitat; $\bar{x}$ = mean of the suitability values derived from classification data set; σ = standard deviation of suitability values derived from classification data set.

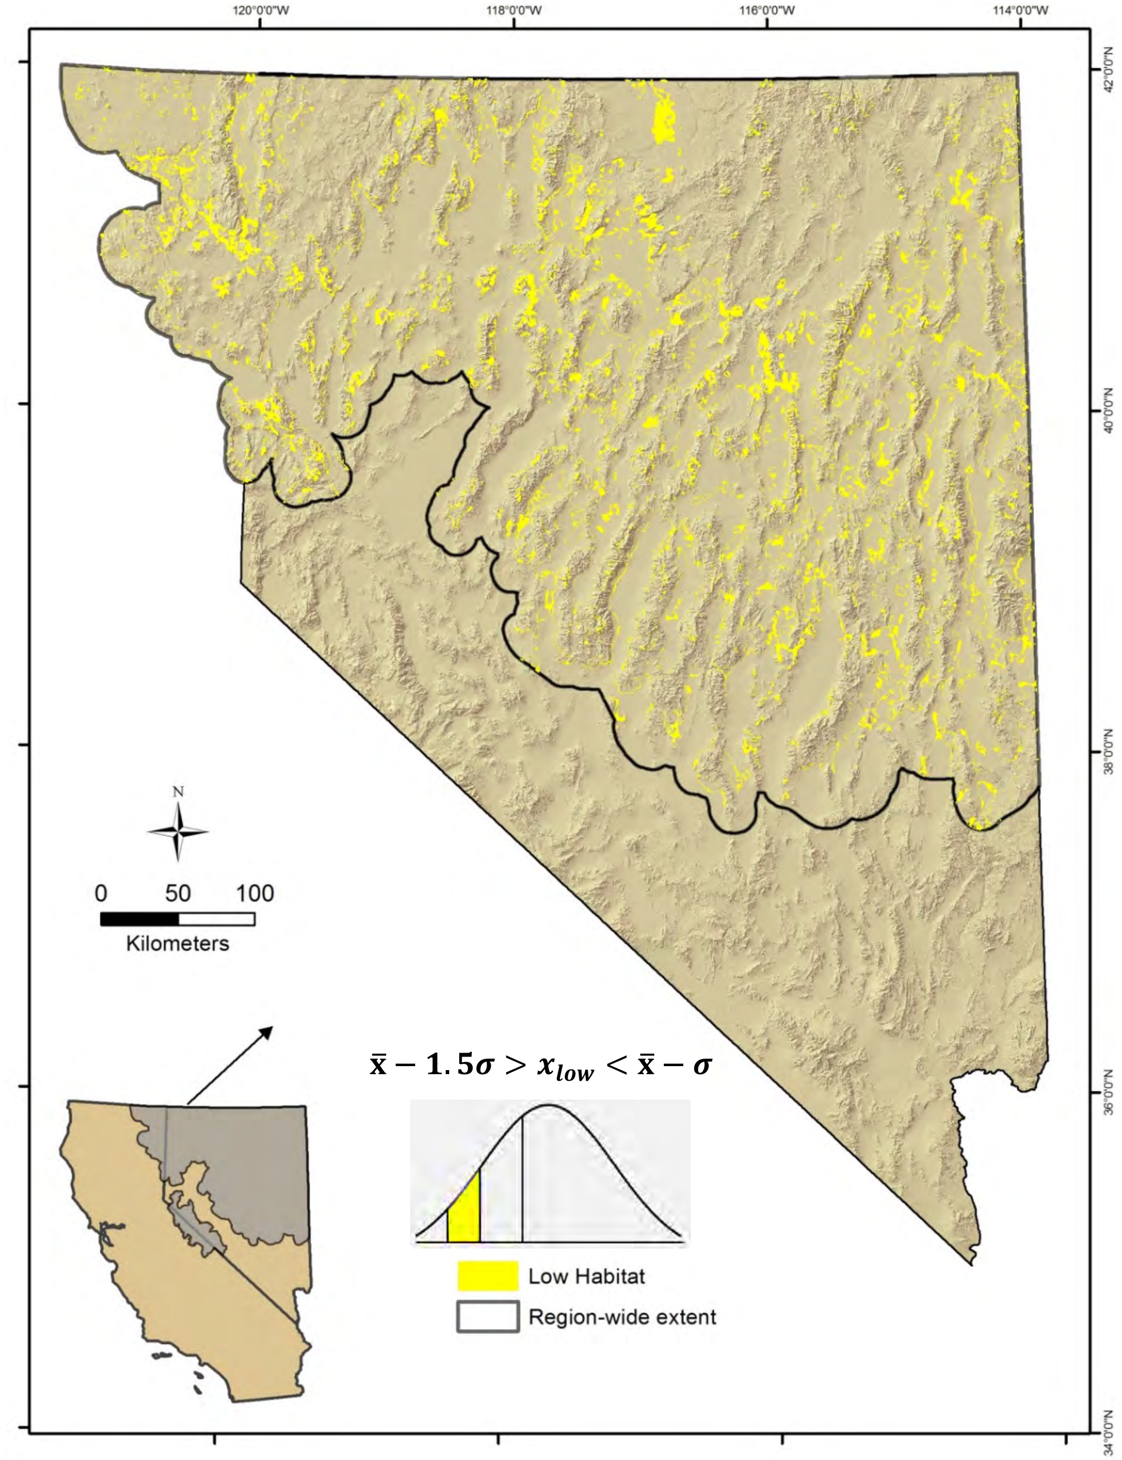

Figure 8. Map and graph (resource selection function [RSF] and probability distribution) showing example region-wide distribution of categorized low suitability habitat for greater sage grouse (*Centrocercus urophasianus*), Nevada and northeastern California. x_{low} = classification as low habitat; $\bar{x}$ = mean of the suitability values derived from classification data set; σ = standard deviation of suitability values derived from classification data set.

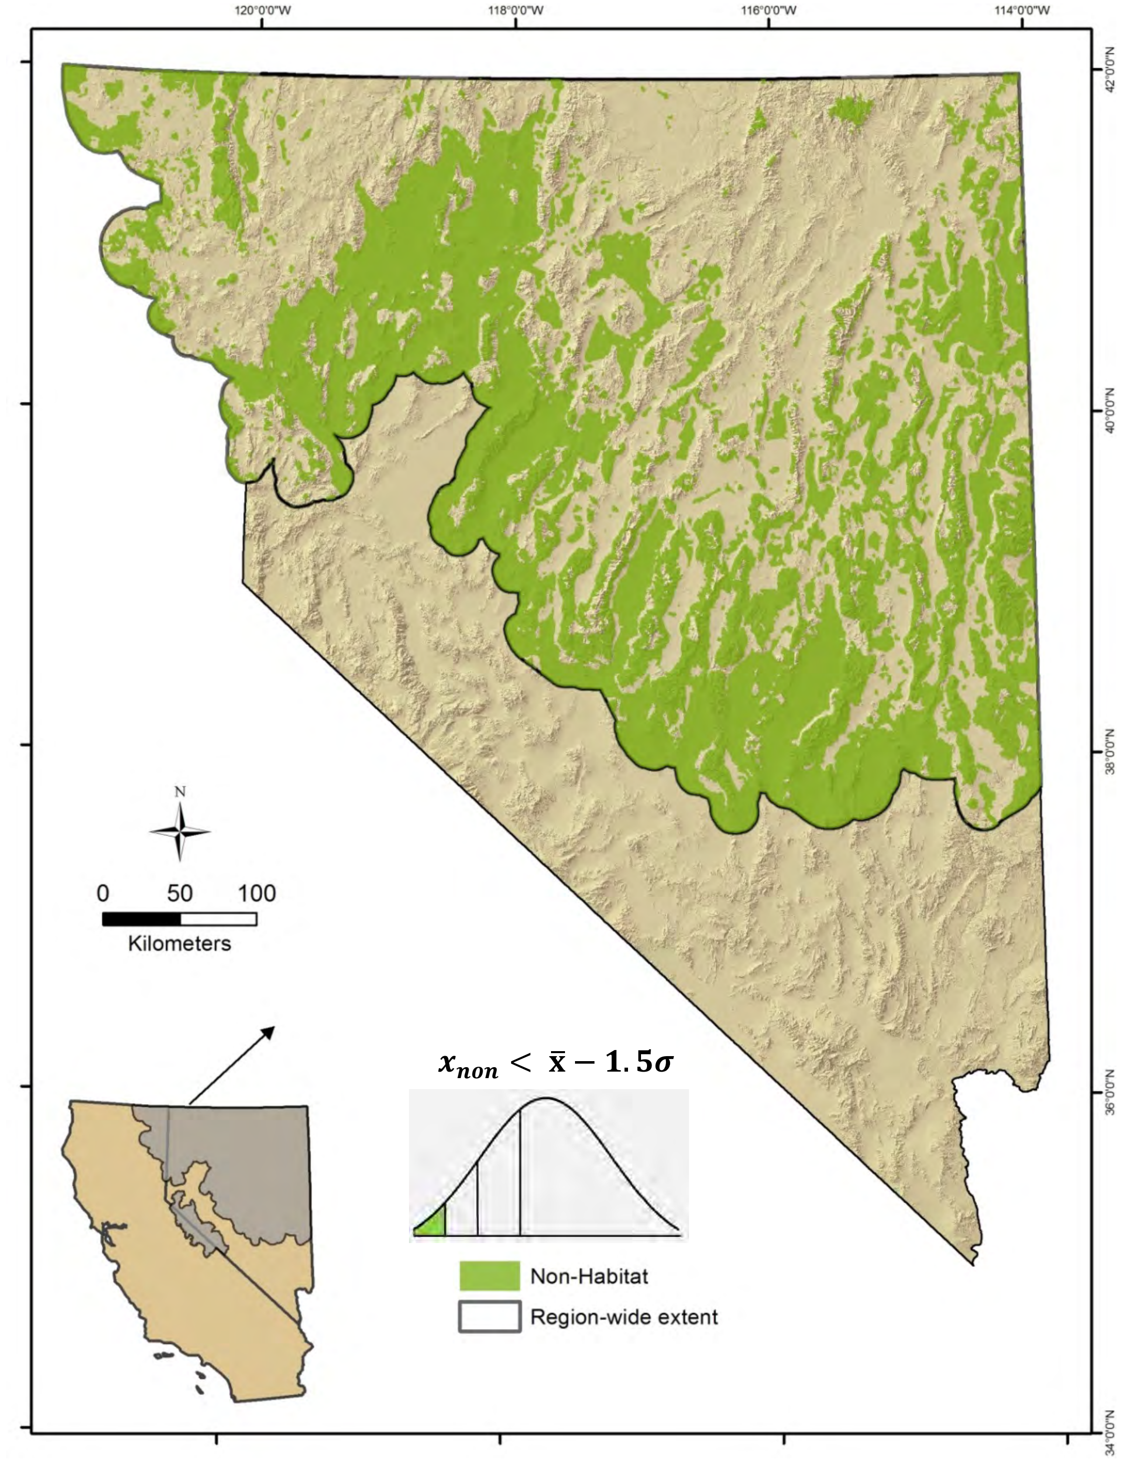

Figure 9. Map showing example region-wide distribution of categorized non-suitable habitat for greater sage grouse (*Centrocercus urophasianus*), Nevada and northeastern California. x_{non} = classification as non-habitat; $\bar{x}$ = mean of the suitability values derived from classification data set; σ = standard deviation of suitability values derived from classification data set.

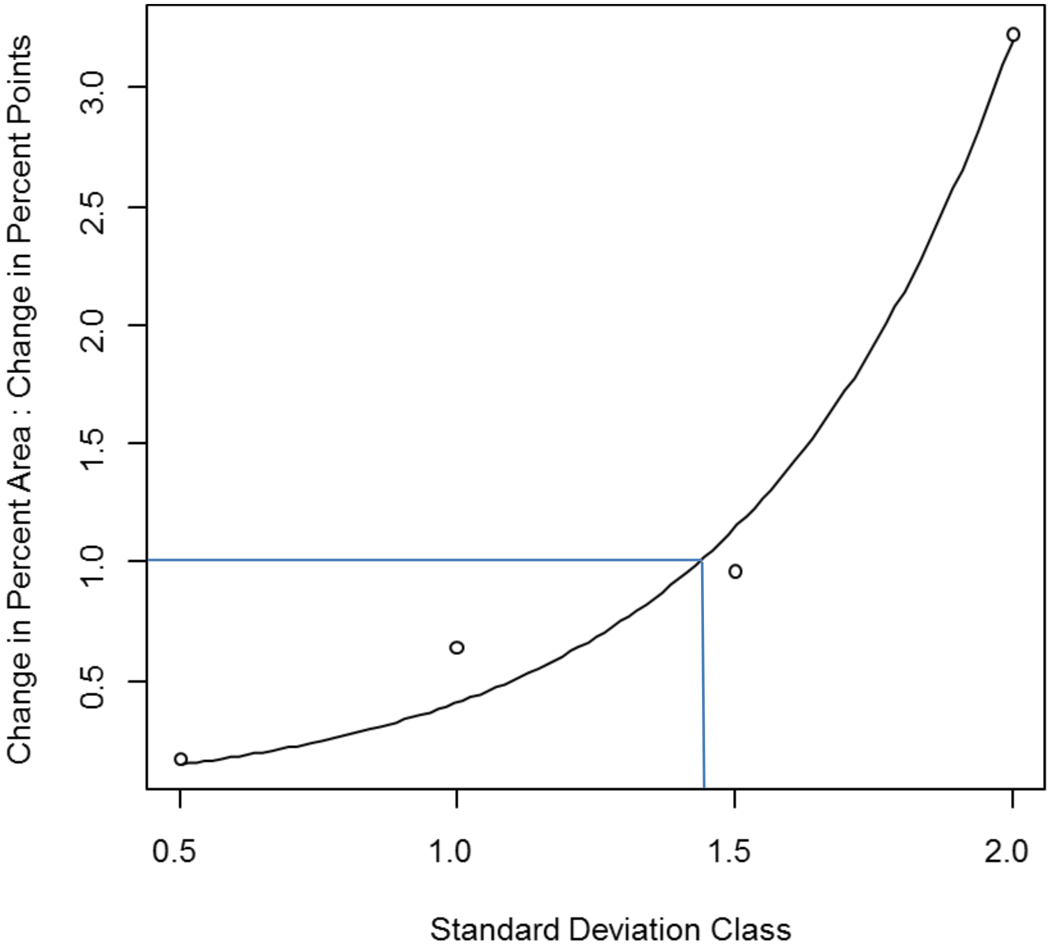

Figure 10. Relation between ratio of added potential habitat to added telemetry points validated and SD cutoff. SD, standard deviation

We used three data sets to assess the accuracy of the habitat suitability categories. The first set was comprised of locations from the 10 percent validation set within RSF regions (n = 3,124). The second set was comprised of all locations from non-RSF subregions with insufficient sample size for inclusion in the original RSF analyses (n = 609, subregions = 7). The third set was comprised of locations for active leks (see *Spatial Use Index* for data source). Locations from all validation sets were overlaid onto the categorized HSI map, and then evaluated for agreement between percentages of locations falling within each habitat category and SD percentile classes used for the habitat classification (fig. 11). In addition, Cohen's Kappa coefficient (κ) was used to assess agreement between the frequencies of observed (actual) validated HSI values versus expected values based on SD percentile bins. Cohen's Kappa is a more robust measure than a simple percentage of agreement because κ takes into account the agreement that can occur by chance alone. Values of κ greater than 0.75 constitute excellent agreement, 0.40–0.75 are acceptable, and less than 0.40 are poor (Fleiss, 1981). Relatively good agreement occurred among the validation data and habitat categories based on both percentages and κ (table 3). Agreement across all categories was exceptionally strong within the RSF subregion validation set, and acceptable for the non-RSF subregional set. On a cumulative basis, 79 percent, 94 percent, and 97 percent of leks occurred within the categories: (1) high only; (2) moderate and high; and 3) high, moderate, and low habitat, respectively. Acceptable agreement occurred for the lek validation set, but more leks occurred in high and moderate habitat than expected, and fewer leks occurred in low and non-habitat than expected.

Space Use Index

Habitat suitability categories provide a crucial piece of information to support decision-making. The second source of information that we used incorporated data regarding lek sites to estimate use of areas by sage-grouse across the landscape. We developed a composite SUI that combined the density of lek sites (breeding density) with the non-linear probability of space use relative to distance to lek (distance). Lek locations were the basis for both indices for multiple reasons. Leks are ideal locations to conduct space use analyses because they are considered hubs for nesting (Autenrich, 1985; Connelly and others, 2004) and generally are centered within seasonal use areas, meaning lek location provides an appropriate focal point for areas critical to all life phases of sage-grouse (Doherty and others, 2010a; Coates and others, 2013). Leks also are detectable using standard survey procedures and established protocols exist for counting male sage-grouse at these sites (Connelly and others, 2004), whereby males at leks were typically counted 3–4 times per season and the maximum count was recorded. Spatial coordinates for leks and associated data on sage-grouse abundance and activity were obtained from databases compiled by the NDOW and CDFW. Although 3–4 counts were typically conducted for counted leks, not all leks were counted every year across the project area. For our analyses, all included leks were classified by agency personnel as "active" (that is, leks with known male attendance) within the last 5–6 years (2009–2013) and "pending" (that is, leks with no males observed or leks that had not been surveyed adequately). Pending leks were included to allow for a more robust likelihood of sage-grouse occupancy across the landscape given the uncertainty associated with whether or not a pending lek had actually become inactive.

Table 3. Summary of habitat suitability model validation tests used to evaluate habit suitability classes for greater sage-grouse (*Centrocercus urophasianus*), Nevada and northeastern California.

[Three independent sets used for validation included: (1) radio telemetry data selected from within the subregions where RSFs (RSF subregions); (2) telemetry data outside the subregions (Non-RSF subregions); and (3) Active leks. Percent, %; Values for Cohen's kappa coefficient (κ) are in parentheses]

Habitat Suitability Classification	Expected %	Validation Sets		
		RSF subregions % (κ)	Non - RSF subregions % (κ)	Active leks % (κ)
High	69	68 (0.97)	56 (0.50)	79 (0.73)
Moderate	15	20 (0.83)	34 (0.37)	15 (0.98)
Low	9	7 (0.89)	3 (0.61)	3 (0.50)
Non-Habitat	7	5 (0.81)	7 (0.85)	3 (0.57)

To estimate density of lek sites (breeding density), we used a kernel density analysis (Silverman, 1986) and estimated the smoothing parameter (that is, bandwidth) using likelihood based cross-validation (Horne and Garton, 2006). Because substantial variation in lek size (number of attending males) existed among lek sites, individual leks were weighted by the most recent 5-year average for maximum male attendance per year. Therefore, breeding density was a function of lek distribution on the landscape (that is, proximity to each other) and lek size. Parameter estimation was conducted using Geospatial Modeling Environment (Beyer and others, 2010) and in Program R (R-Core-Team, 2012) with the 'ks' package (Duong, 2012).

The other component of the SUI consisted of adjusting for the use of space around lek sites (lek distance index), largely because leks are considered points on the landscape whereas sage-grouse use areas in relation to lek sites. Because the probability of occurrence is not likely to be a linear relationship with the Euclidean distance from a lek, we used a non-linear effect based on an average space use response curve derived by Coates and others (2013) from nearby populations of sage-grouse within the Bi-State Distinct Population Segment. Specifically, the curve was derived from quantification of the volume of population level utilization distribution (vUD) within a range of areas that varied in size and were centered on leks, up to a distance of 30 km. Utilization distributions were represented by an individual probability density function for each of 193 sage-grouse totaling nearly 11,878 sage-grouse locations. To obtain the distance index for our purposes, we simply subtracted the derived vUD value from one for every 30 m distance away from leks up to 30 km. Therefore, the lek point received a value of one, and as distance increased the value declined exponentially until it flattened at distances of 5–8 km. This calculated value provided a relative likelihood of occurrence based on previously published probability density functions from radio-telemetry data for sage-grouse. The curve developed for the Bi-State was appropriate to adopt for this analysis for multiple reasons because the curve: (1) accounted for seasonal patterns; (2) represented multiple isolated populations; (3) represented a relatively large spatial extent; and (4) likely represents other areas of the Great Basin because it consisted of substantial variation among populations as described in Coates and others (2013).

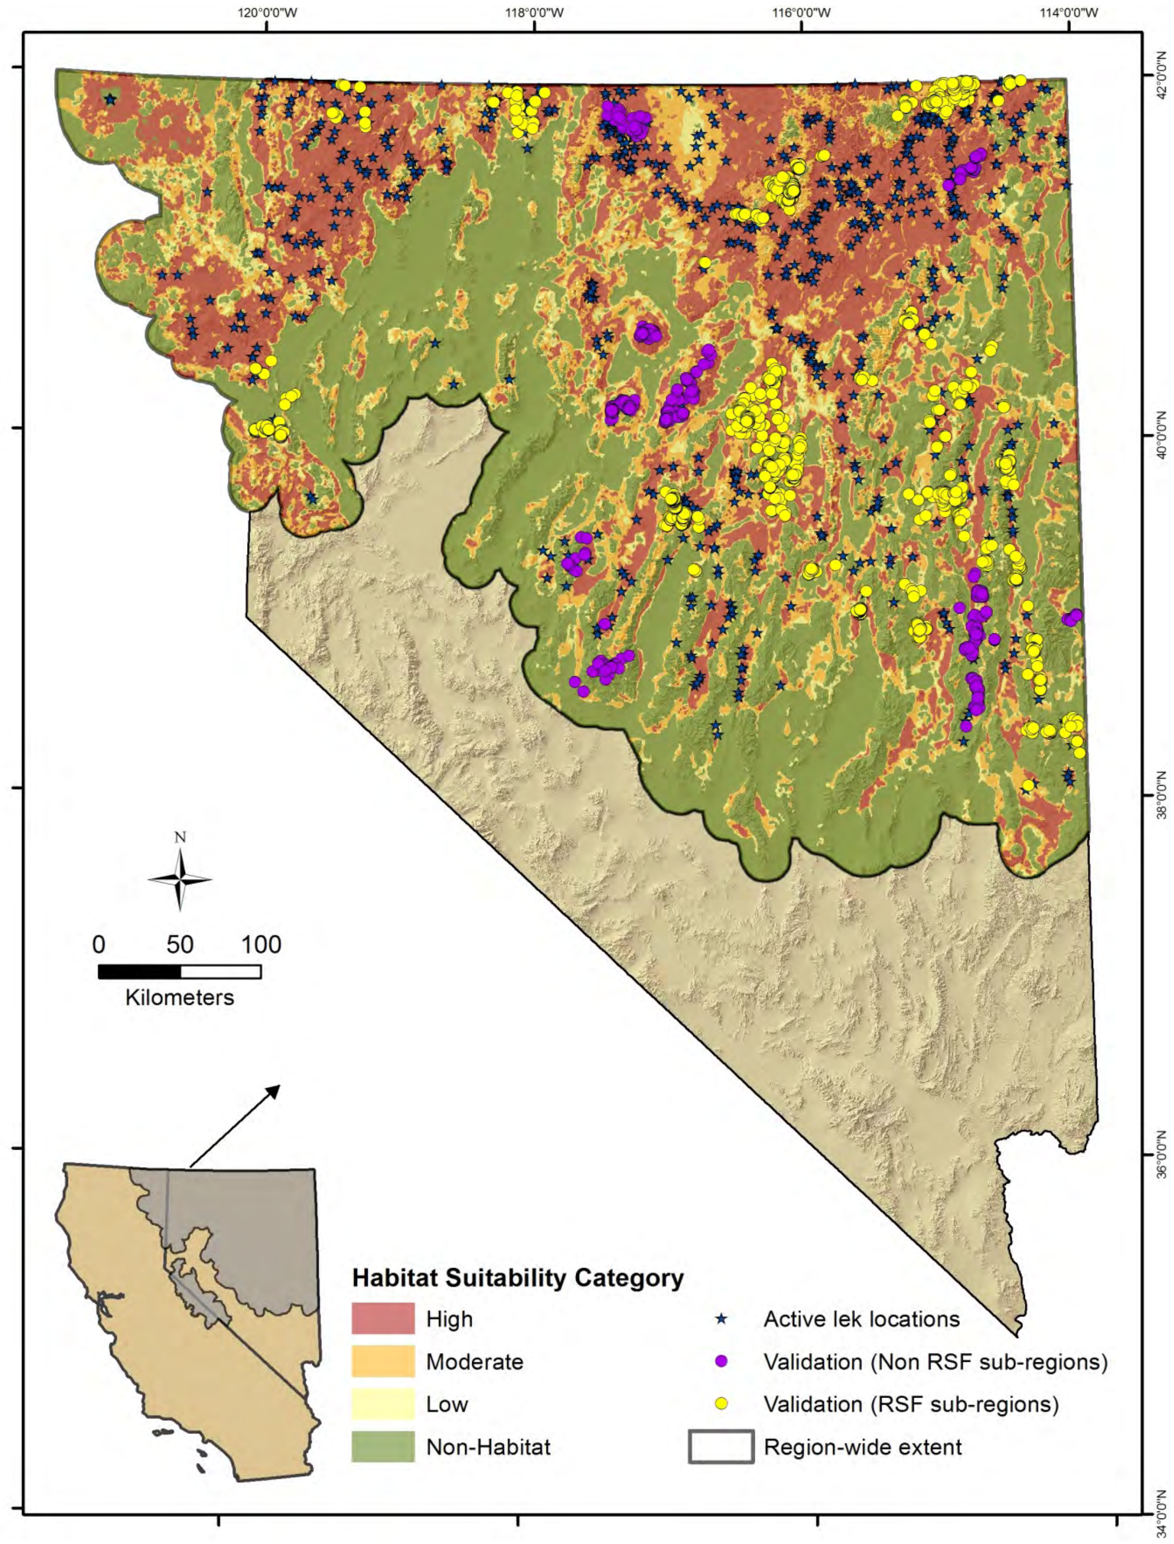

Figure 11. Map showing overlay of radio-telemetry data and lek locations used to validate habitat suitability classes for greater sage grouse (*Centrocercus urophasianus*), Nevada and northeastern California. RSF, resource selection function.

To create the SUI, grid-cell (30 x 30 m) values for lek density index and lek distance index were first normalized by dividing by the maximum of their respective index, and then averaged across all grid cells. The SUI, therefore, is a continuous, spatially explicit relative measure of sage-grouse occurrence weighted by local population size. For development of the example decision support tool, the SUI was categorized into two categories: “high use” and “low-to-no use” areas. High use areas consisted of areas that included up to 85 percent of the highest SUI density (cumulative density values). Low-to-no use areas of the landscape consisted of areas with less than 15 percent of the cumulative SUI density (fig. 12). The identification of high use regions allowed for spatial connectivity among areas of likely sage-grouse use and is consistent with previously used standards for sage-grouse breeding density (for example, Doherty and others, 2010b).

Developing a Decision-Support Tool—Combining RSF Categories with Space Use

To promote clear and effective policy decisions, it is often desirable to simplify a suite of important considerations regarding habitats or populations into a few non-overlapping classes, each of which are subject to specific rules, valuations, or interpretation for aiding in the decision-making process. The following is an example of how the intersection between habitat quality (a function of environmental attributes) and sage-grouse space use (a function of sage-grouse occurrence) can provide spatially explicit information to policymakers. Four habitat management classes were developed from the intersection of HSI and SUI categories (table 4). The rubric used to develop management classes and rationale is as follows:

1. Core Areas (fig. 13): Defined as the intersection between all suitable habitats (high, moderate, and low categories) and the high use SUI category. This habitat management class is intended to incorporate all suitable habitats that have relatively high certainty of current sage-grouse occupancy.

2. Priority Areas (fig. 13): Defined as both high suitability habitat that is present within the low-to-no use SUI category or non-suitable habitat occurring within the high use SUI category. This habitat management class encompasses: (1) high-quality habitats based on environmental covariates with a lower potential for occupancy given the current distribution of sage-grouse; and (2) sage-grouse incursion into areas of low quality habitat that is potentially important for local populations (for example, corridors of non-habitat connecting higher quality habitat).

3. General Areas (fig. 13): Defined as moderate and low habitat suitability that is present within the low-to-no use SUI category. This habitat management class represents areas with appropriate environmental conditions for sage-grouse, but are less frequently used by sage-grouse.

4. Non-habitat Areas (fig. 13): Defined as non-suitable habitat that is present within the low-to-no use SUI. This scenario represents habitat of marginal value to sage-grouse populations.

Table 4. Rubric for determining habitat management classes from habitat suitability and space use categories.

	Space Use Index Category	
Region-wide RSF Category	High Use Area	Low-to-No Use Areas
High Habitat Suitability	*Core Area*	*Priority Area*
Moderate Habitat Suitability	*Core Area*	*General Area*
Low Habitat Suitability	*Core Area*	*General Area*
Non-suitable Habitat	*Priority Area*	*Non Habitat Area*

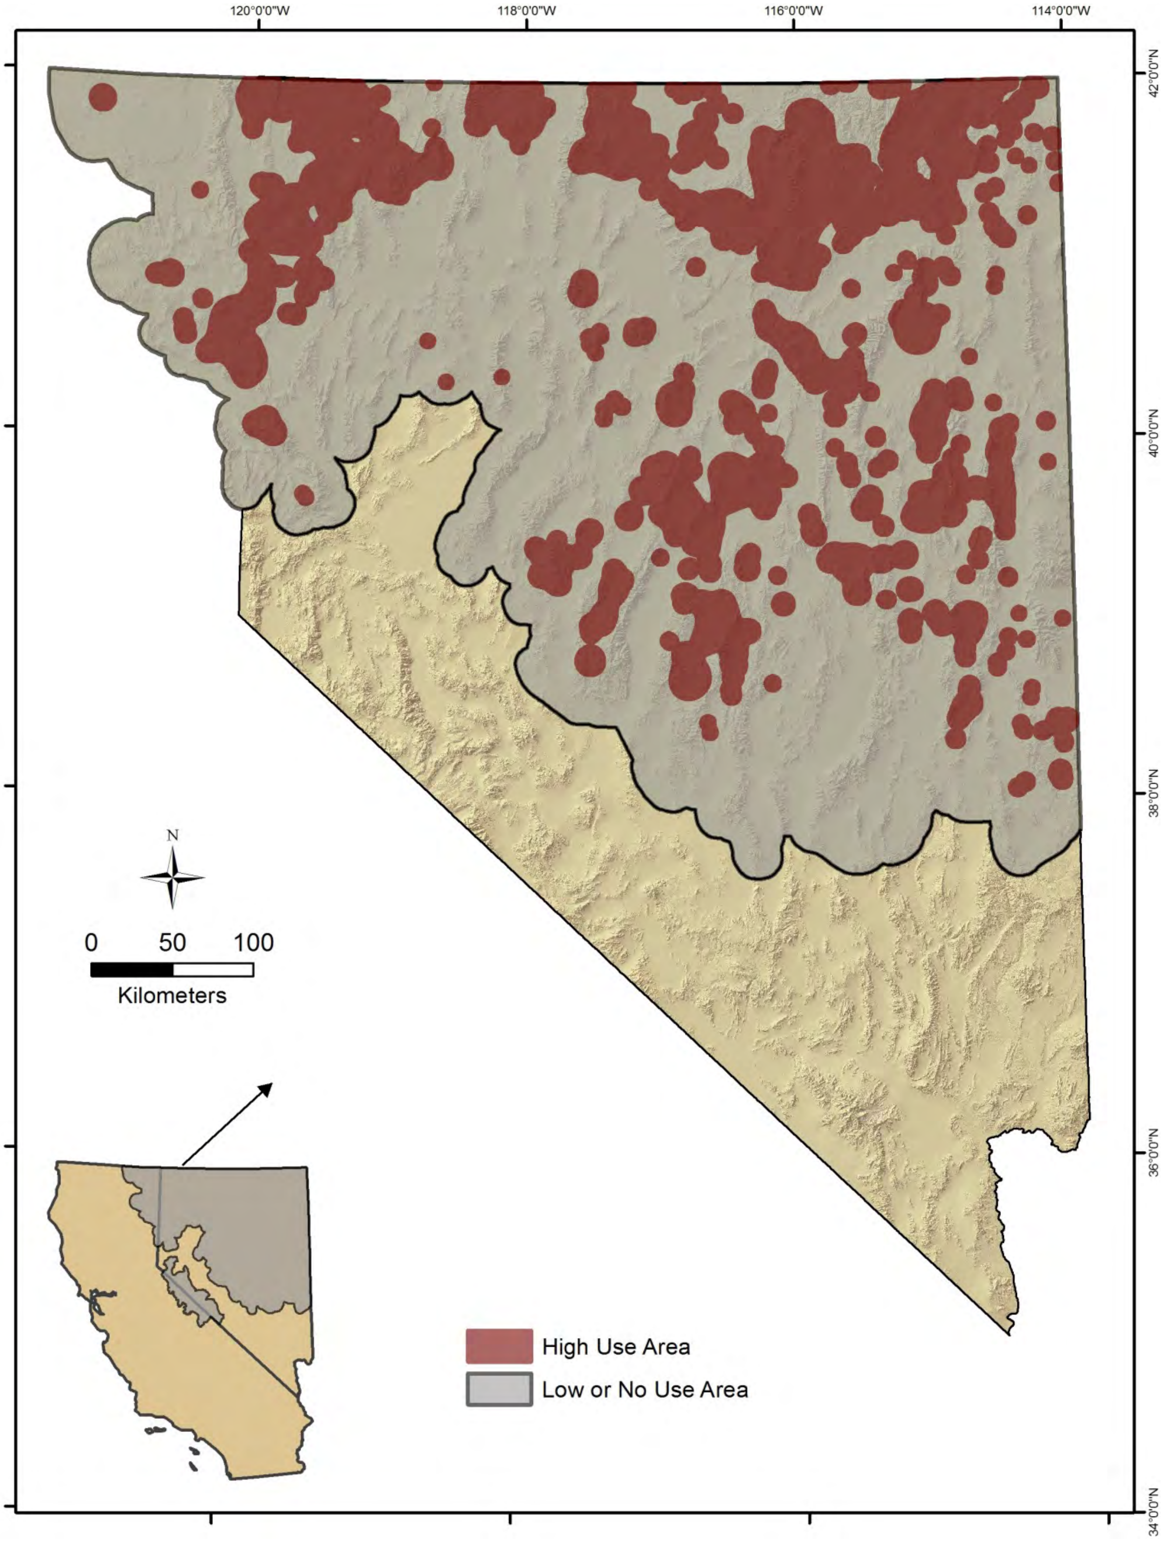

Figure 12. Map showing a space use index (SUI) that was developed compiling data on greater sage-grouse (*Centrocercus urophasianus*) use and distribution of leks, Nevada and northwestern California. Areas that contained 85 percent (%) of the total SUI density were identified as “high use” areas (reddish-brown).

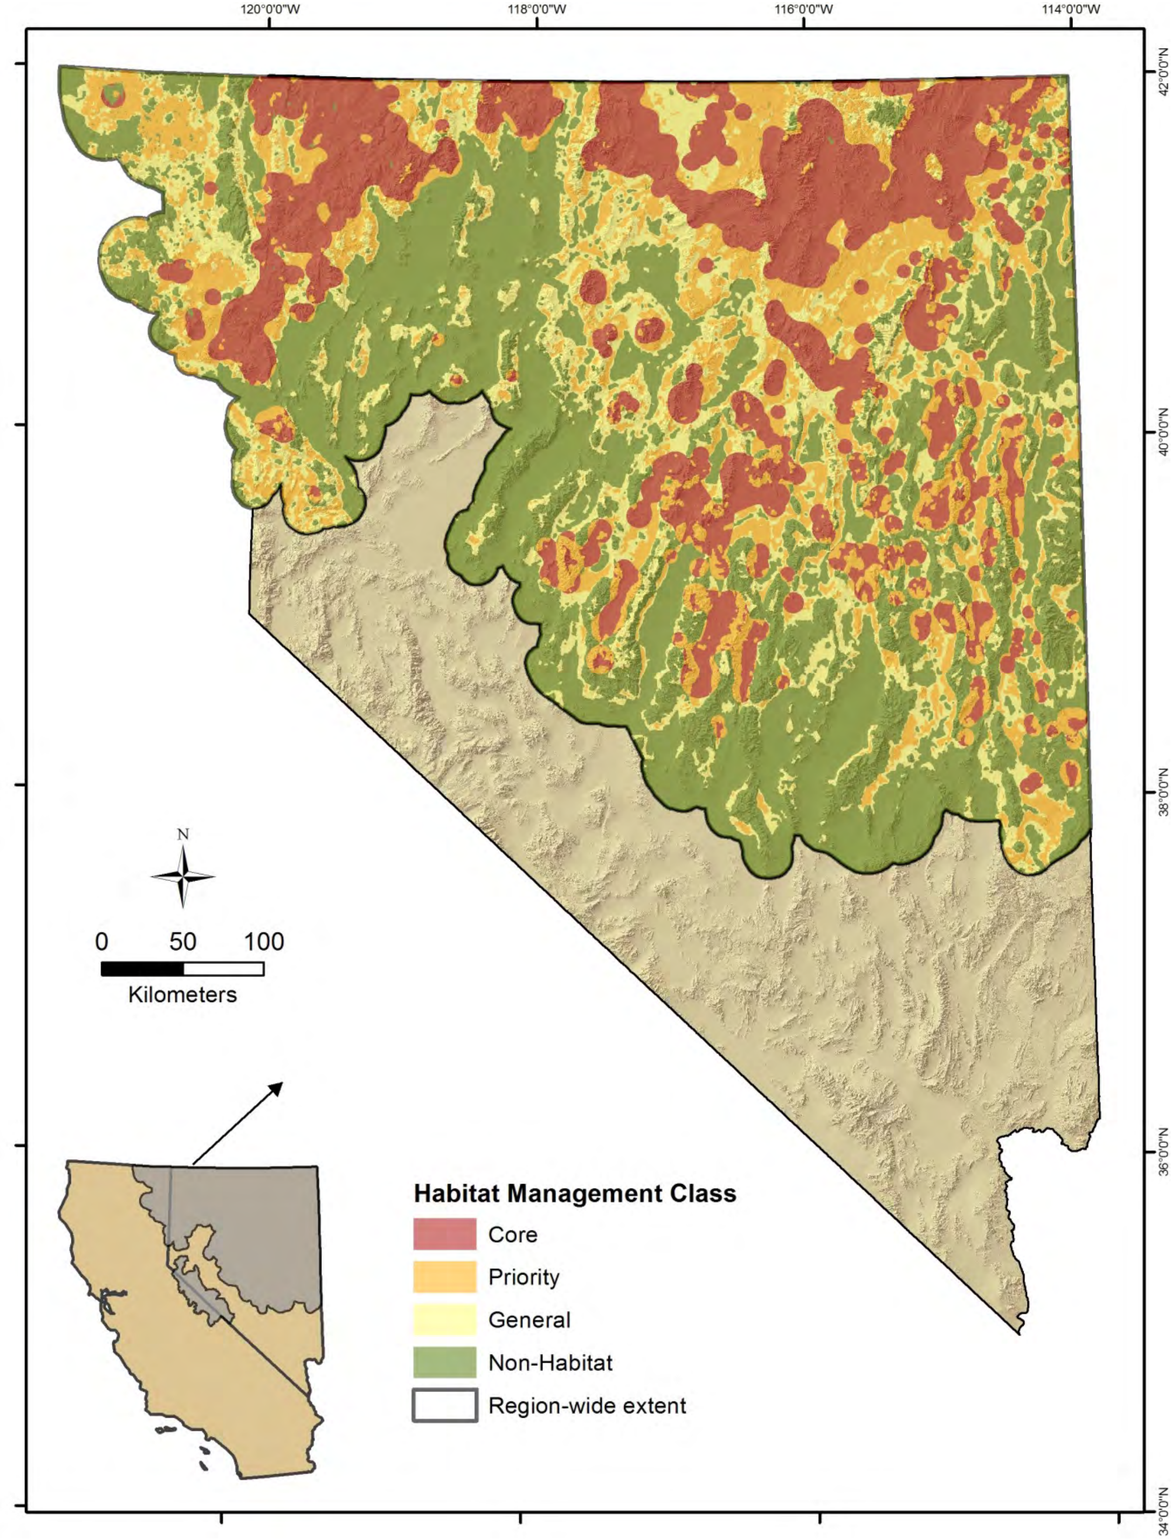

Figure 13. Map showing habitat management classes that can be determined based on the intersection of habitat suitability classes and space use index categories for greater sage grouse (*Centrocercus urophasianus*), Nevada and northeastern California.

Conclusion

This report presents a ‘first of its kind’ spatially explicit map of greater sage-grouse (*Centrocercus urophasianus*) habitat suitability across Nevada and northeastern California. Importantly, the map was informed by resource selection functions derived from data across multiple site-specific studies of sage-grouse and scaled up to a region-wide level as a habitat suitability index. The power of this approach rests within the map output that can be downscaled back to the local level that may help inform specific, “on the ground”, habitat-management decisions. However, it is important to recognize that field data and other sources of information should be used in conjunction with inferences from this model.

The example of incorporating information about space use further improves the utility of the model for conservation planning. Merging sage-grouse space use with habitat characteristics helps to identify areas with the highest likelihood of occurrence coupled with suitable habitat so that biologically significant areas can receive conservation priority. However, it must be stressed that the habitat categories and management scenarios presented serve only as examples for the types of output that can be created with this conservation planning method. Levels of habitat suitability and frequency of space use can be reclassified readily, or other space use models could be employed (that is, other home range estimators) as might be deemed appropriate through a structured decision making process among various stakeholders in sage-grouse management. In addition, either the provided or newly generated map can be updated readily as new data become available. Further estimation of variance in habitat selection associated with life history specific habitat requirements (for example, nesting, brood rearing, overwinter) and anthropogenic disturbances (for example, power lines, energy development) would be beneficial and could also be incorporated into this model framework.

Acknowledgments

We thank the countless biologists and technicians who captured and tracked radio-marked sage-grouse and whose data that made this modeling effort possible. A special “thanks” to M. Atamian, E. Blomberg, and D. Gibson from the University of Nevada Reno (UNR); D. Davis and K. Reese from the University of Idaho; Z. Lockyer, J. Dudko, and S. Matthews from Idaho State University; B. Prochazka and J. Hull from the University of California Davis; and K. Andrle, T. Tam, T. Allen, and J. Ragni from the U.S. Geological Survey, Western Ecological Research Center.

We thank Cory Hunt from the Nevada State Governors Office for his support. We also thank T. Rubald, J. Copeland, M. Faigeles, and K. McGowan from the Nevada State Sagebrush Ecosystem Technical Team and all members of the Sagebrush Ecosystem Council. We thank J. Tull (NDOW), B. Halstead (USGS), and J. Yee (USGS) for important statistical consultation and constructive comments on previous draft reports. We are also thankful for the help of S. Abele (U.S. Fish and Wildlife Service), R. Mazur (U.S. Department of Agriculture, Forest Service), S. Brewer and P. Zieglar (Bureau of Land Management), and J. Sedinger (UNR) as part of an expert review team that periodically provided feedback on this project. This work was a collaborative effort between the Nevada Department of Wildlife, California Department of Fish and Wildlife, and Bureau of Land Management, and was funded by the Nevada State Sagebrush Ecosystem Program.

Greater Sage-Grouse

Range-Wide Mitigation Framework

DOCUMENT STRUCTURE

PART I	provides general goals and regulatory considerations for any mitigation program within the context of the mitigation hierarchy
PART II	provides overarching mitigation principles, standards, and recommendations for the development of mitigation processes and programs
APPENDIX I	glossary of important terms, *italicized* on first use in this document
APPENDIX II	detailed questions to consider when developing or assessing a mitigation program

Document Purpose

In 2010, the U. S. Fish and Wildlife Service (Service) determined that the greater sage-grouse (Centrocercus urophasianus; hereafter sage-grouse) warranted protections under the Endangered Species Act (ESA). This finding was based on two primary factors: 1) the present or threatened destruction, modification, or curtailment of habitat or range, and 2) the inadequacy of existing regulatory mechanisms.

The purpose of this document (Framework) is to communicate some of the factors the Service is likely to consider in evaluating the efficacy of mitigation practices and programs in reducing threats to sage-grouse. The recommendations provided here are consistent with the information and conservation objectives provided in the 2013 Conservation Objectives Team (COT) Report[1] for sage-grouse.

The Service recommends an avoidance first strategy be employed for all identified sage-grouse habitat, especially *Priority Areas for Conservation* (PACs) and other areas of habitat identified as important to sage-grouse populations. Unavoidable impacts occurring in any sage-grouse habitat should be fully compensated.

This document is guidance only and subject to modification as new information on sage-grouse science or mitigation policies emerge. As subject-specific mitigation guidance related to sage-grouse is developed, it may to be appended to this document.

continued on pg 2

mitigation

As used in this document, the term **mitigation** encompasses the full suite of activities to avoid, minimize, and compensate for adverse impacts to sage-grouse and sage-grouse habitat.

Our goals in providing this Framework are twofold:

- Help states, the Bureau of Land Management (BLM), and other partners develop and implement coordinated and robust mitigation processes across the range to reduce threats and the potential need to list the species under the ESA; and
- If the sage-grouse should be listed, application of these recommendations will improve permitting processes, Section 7 consultations, mitigation outcomes, and contribute to sage-grouse recovery.

---

Document Purpose *(continued)*

The Service recognizes that state wildlife agencies have management expertise, authority, and responsibility for sage-grouse conservation in their respective jurisdictions and that private and public land managers have management expertise and authority for sage-grouse habitat conservation. Coordination among federal, state and local agencies, tribes, and stakeholders in forming landscape-scale strategies that include mitigation processes is vital. Using this Framework as a guide can promote consistency in mitigation programs across the species' range and across agencies while providing for some degree of local flexibility.

- Consistency will better enable stakeholders to implement established mitigation actions that positively affect sage-grouse conservation. Consistency will enable the Service to better assess the intended biological effects of these mitigation efforts at the range-wide scale. It is important that locally-adopted processes support national and regional sage-grouse management goals and result in a reporting process that is sufficiently standardized so that data, threats, and accomplishments can be adequately conveyed.
- The Service believes it is important to maintain flexibility in this Framework to accommodate the many differences in the regulatory, socio-economic, and ecological environments between and within states that influence the efficacy of any tool. Flexibility will also allow for and encourage local innovation as programs are developed and tested.
- Generally, while mitigation programs can be flexible to accommodate social and economic considerations, it is important that program elements are based on sound science and are linked to conservation objectives in a transparent manner. Ultimately, we all must be able to demonstrate that impacts are truly unavoidable, compensatory actions appropriately mitigate residual impacts, and the net effect is a conservation gain to the species.

There is no one right or correct design for a mitigation program. Rather, our hope in providing this guidance is that it will encourage consistency across the range and help our many partners develop mitigation processes that simultaneously conserve sage-grouse while maintaining or enhancing economic opportunities throughout the sage-grouse range. Mitigation processes should be fair, implementable, fully compensatory, and effective for sage-grouse.

RELATIONSHIP TO MITIGATION AND RELATED POLICIES AND GUIDANCE

This Framework draws from a variety of mitigation and related policies and guidance, including the Secretary of the Interior's Order 3330[2] entitled "Improving Mitigation Policies and Practices of the Department of the Interior" (October 31, 2013) and the Department of Interior's mitigation report (April 2014).[3] This Framework is consistent with these recent Departmental statements regarding mitigation.

As appropriate, this Framework also draws from the Service's 1981 Mitigation Policy and 2003 conservation banking guidance. However, these Service policies do not specifically cover mitigation for non-listed species, such as the greater sage-grouse. In addition, the scope and terminology of mitigation approaches has grown since these policies were adopted. As a result, the Service is currently in the process of revising its 1981 Mitigation Policy and establishing a new ESA Compensatory Mitigation Policy that will replace the 2003 conservation banking guidance and provide operational detail lacking in current guidance.

These efforts align agency mitigation policies with the Department's recent statements regarding mitigation and current mitigation principles. This Framework reflects accepted principles and standards in the current mitigation realm and principles of the DOI Report, which will in turn form the basis for near future Service-wide mitigation policies. As new Service policy or guidance relevant to this Framework is released, the Service will consider amending this Framework.

[3] http://www.doi.gov/news/upload/Mitigation-Report-to-the-Secretary_FINAL_04_08_14.pdf

VERSION 1.0 NOTE

In July 2014, the Service released a draft policy for Voluntary Prelisting Conservation Efforts. There are similarities and differences between the proposed policy and this Framework. Central to both efforts is incentivizing landowners, states, and federal partners to conserve at-risk species by recognizing that actions taken prior to listing can be counted as potential mitigation for future impacts, should a species be listed. The draft policy proposes the program be state-administered and only cover actions that are truly voluntary and not required by a federal, state, or local regulatory mechanism.

The principles and standards in this Framework are applicable to both voluntary and regulatory programs. However, through the Framework the Service encourages any stakeholder, including our federal partners, to develop robust mitigation programs under their applicable regulatory mechanisms and authorities.

Specific to Candidate Conservation Agreement with Assurances (CCAAs), both the Framework and the proposed policy accept that conservation actions above those commitments agreed to in a CCAA may be applied as mitigation. This Framework provides additional sideboards regarding how mitigation actions may be implemented on land enrolled in a CCAA.

The Service encourages our partners to provide feedback on the proposed policy during the public review period.

PART I

Mitigation Program Goals & General Considerations

Mitigation Program Goals

As described above, the Service expects mitigation approaches across the range to be flexible and innovative in how unavoidable impacts from development are mitigated. However, we recommend that all mitigation programs strive for the following goals and incorporate the principles and standards outlined in this document to increase likelihood of contributing to successful sage-grouse conservation.

1. **Achieve net positive conservation.** Mitigation programs should be strategically designed to result in net overall positive outcomes for sage-grouse. This is accomplished by employing avoidance, minimization, and *compensatory mitigation* actions that are based on accepted mitigation principles and standards, use best available science for sage-grouse conservation, and address population-level threats within landscape-level plans. Programs that are structured with a goal of only *no net loss* will be evaluated more conservatively by the Service because they are unlikely to positively influence the conservation status of the species.

2. **Don't reinvent the wheel, integrate existing processes.** To the extent practical and where national management and reporting goals are supported, the program should integrate existing regional, state, and local-level processes as the authorizing, implementing, and enforcement tools for a mitigation program. Partnerships should result in mitigation implementation strategies that prevent fragmented landscapes, restore core areas, and provide connectivity necessary to sustain sage-grouse populations regardless of land ownership or jurisdictional borders.

3. **Make sage-grouse an asset, not a liability.** The mitigation program should provide economic incentives for private landowners and industry to conserve and restore sage-grouse and its habitat. The program should allow for well-sited, well-designed, and appropriately mitigated actions to move forward smoothly and quickly.

4. **Be consistent and fair.** Structure mitigation programs to apply the mitigation hierarchy (avoidance, then minimization, followed by compensatory mitigation) consistently across anthropogenic activities that impact sagegrouse including energy, infrastructure development, land conversion, ex-urban development, mining, and others as appropriate.

Generally, a mitigation program for sage-grouse should address how impacts will be avoided and how a *net conservation gain* will be achieved by compensatory mitigation for unavoidable impacts to sage-grouse across all habitats. Before developing a mitigation program, the Service recommends first considering the types of development activities that will be covered, how avoidance will be assessed, the regulatory mechanisms that relate to those activities, and if regulatory predictability within the context of the ESA is desired. Each of these topics will be covered in this section. See Appendix 2 for specific questions to consider.

Covered Activities

A robust mitigation program will clearly identify the development activities and the associated direct and indirect impacts that may negatively affect sage-grouse; the avoidance, minimization, and compensatory mitigation standards for addressing those impacts; and the consequences of mitigation failure.

While generally some impacts will be universal to each development activity, the actual impacts from such activities will be determined by site-specific parameters (e.g. landscape level values, habitat type impacted, and proximity to leks). Mitigation processes should provide proponents the ability to incorporate mitigation objectives into the design of projects.

At a minimum, mitigation programs should cover anthropogenic development actions that:

- Negatively impact sage-grouse habitat, especially those identified as threats in the COT Report;
- Create spatially discreet, measurable impacts; and
- Are implemented, funded, or permitted by federal, state, or local agencies.

The mitigation program should describe the impact assessment methodology that will be used to measure a development activity's remaining and unavoidable direct and indirect effects to sage-grouse over the life of a development and its impacts, and quantify the potential direct and indirect impacts that likely accrue from each of the specific development types.

The COT Report describes the types of developments that cause the greatest direct and indirect impacts to sage-grouse and provides initial guidance on impact avoidance, minimization, and to a lesser extent compensatory mitigation for these development activities. It can be used as a starting point to further refine and identify local impacts to be considered in a mitigation program.

Activities such as irregular off-road recreational vehicle use or over-grazing may be difficult to both measure and address in mitigation programs due to the diffuse nature of these impacts.

©Alan Krakauer

Avoidance & Minimization

The Service strongly recommends avoidance of direct and indirect impacts to sage grouse habitat, especially in PACs and other habitats identified as important (*see* COT Report). Compensatory mitigation should only be considered if efforts to avoid and minimize the direct effects, indirect effects, and cumulative impacts (each as defined in 40 CFR §§1500-1508) of a development project have been exhausted or are not possible.

Direct effects are caused by an action and occur at the same time and place. Indirect effects are those that are caused by or will result from an action and are later in time or farther removed in distance, but are still reasonably foreseeable. The result is an affect to some aspect of the species' ecology which diminishes the species' ability to shelter, feed, or breed. For example, tall anthropogenic structures can cause avoidance behavior of sage-grouse to leks and brood rearing areas well beyond their direct development footprints.

Cumulative impacts result from the incremental or synergistic impact of an action when added to other past, present, and reasonable foreseeable future actions. For example, outside of its direct footprint a development may, over time, result in a loss of suitability of surrounding habitat through isolation, increased noise levels, acceleration of invasive species colonization, degraded water quality inputs, or other factors.

Avoidance mechanisms can include moving a project, the use of exclusion areas, and caps on habitat disturbance to prevent negative impacts. True avoidance is only achieved when sage-grouse and/or their habitat have no exposure to the activities associated with the action or the activities will have no effect on sage-grouse behavior or habitat use over time.

Minimization mechanisms can include, for example, timing stipulations for noise or other activities which may disturb sage-grouse, removing water sources to reduce exposure to West Nile virus, limiting activities or practices that may result in wildfires, best management practices for construction projects to prevent invasive plant issues, predator attractant management, co-location or burying of necessary support utilities, and/or marking fences to minimize direct mortality of birds. Most minimization actions will still have temporary (e.g. construction-related) or residual effects (e.g. reducing noise may not eliminate all effects) that should be accounted for, avoided, and if unavoidable then offset through compensatory actions.

By fully avoiding impacts up front, there is no need to take additional mitigation hierarchy steps. Compensatory mitigation should only occur when disturbances are proven unavoidable, minimization does not provide for complete direct or indirect impact avoidance, or avoidance and minimization cannot achieve the best possible conservation outcome for the species. For the purposes of this document, we borrow from general mitigation banking terminology and refer to any impact as a *debit* and any compensatory mitigation action as a *credit*.

©Loren Kerns

Regulatory Mechanism

The combination of increased development and the inadequacy of regulatory mechanisms in requiring proposed development to avoid impacts is a pressing issue for sage-grouse conservation. Even in areas where the primary threat is not development, providing adequate regulatory mechanisms to address anthropogenic impacts and other threats is necessary to ensure long-term protection of the species.

States hold the primary responsibilities for the management of sage-grouse, while federal agencies manage almost two-thirds of the species' habitat. The Service recommends clearly identifying the federal, state, local and tribal regulatory mechanisms for siting and permitting each major development type that impacts sage-grouse. It is important to note if environmental review is triggered for each development type and how that review may result in avoidance, minimization, and offset requirements. A lack of clear regulatory incentives to follow the mitigation hierarchy will decrease the Service's ability to assess the long-term likelihood of successful implementation.

Regulatory Predictability and ESA

While mitigation programs should be designed first with an eye towards conserving sage-grouse, and thus be able to function outside the ESA, users and suppliers of compensatory mitigation may still wish to know from the Service that any mitigation actions produced in advance of a potential listing will count in a post-listing scenario.

A program that utilizes *prelisting mitigation* credits could provide a major incentive to get conservation on the ground now and may also be a market driver for mitigation programs. In this guidance, prelisting mitigation refers to explicit recognition from the Service that actions or credits developed or acquired both in advance of impacts, and in advance of a listing decision, will be considered as a conservation action in a status review. These credits may be used as compensatory mitigation through ESA consultations should the species be listed, in which case the status review will evaluate the net effect of the actions or credits produced. Additionally, suppliers of compensatory mitigation may be able to attain regulatory predictability that, should the species become federally listed, the management to which they agreed will not change and/or incidental take coverage will be provided for these management actions.

Programs with prelisting mitigation options that wish to have these credits treated as measures to minimize and mitigate the impact of incidental take, should sage-grouse be listed, will need to enter into a prelisting mitigation agreement with the Service.

Securing mitigation prior to project development should not act as a substitute for avoiding and minimizing impacts. Developers should design their projects to avoid and minimize direct, indirect, and cumulative biological impacts regardless of whether compensatory mitigation credits have already been acquired.

If sage-grouse is listed, robust mitigation programs endorsed by the Service and implemented prior to the listing decision can provide benefits to participants and sage-grouse alike. Most importantly, such programs will more likely be designed to contribute to recovery. In addition, if the species is listed as threatened, the Service may propose a special rule under section 4(d) of the ESA to allow for take incidental to activities conducted pursuant to an adequate local mitigation program. The Service will work closely with interested states or other stakeholders to provide greater regulatory predictability, to the extent possible, for these advanced implemented mitigation actions.

PART II
Principles, Standards & Mitigation Program Elements

Principles of Mitigation

Any mitigation program for sage-grouse which includes compensatory mitigation is best developed consistent with the goals outlined in the beginning of this document and with the following principles, which are meant to provide clarity and guidance in cases where the Framework is silent or unclear:

- **Observe an appropriate mitigation sequence:** Compensatory mitigation is only considered after all avoidance and minimization measures have been explored. Avoidance is the most desirable approach to preventing impacts to sage-grouse from development.

- **Attain net conservation gain:** Overall outcomes must result in no net loss to the species at the population or landscape-scale. To achieve this and improve overall conservation status, programs should be structured to attain a net conservation gain.

- **Use a landscape-scale approach to inform mitigation:** Develop mitigation programs in conjunction with, or guided by, a landscape-level conservation plan. Cross-jurisdictional partnerships are better positioned to design mitigation strategies that will prevent fragmented landscapes and restore core areas and connectivity necessary to sustain the sage-grouse.

- **Ensure transparency, consistency, and participation:** Use timely and transparent processes that provide predictability and uniformity through the consistent application of standards, protocols, and metrics developed to achieve effective mitigation. Appropriate and effective stakeholder participation in mitigation recommendations and decisions should be facilitated.

- **Base mitigation decisions in science:** Use the best available science in formulating mitigation recommendations and decisions, consistent with all applicable policy.

Standards of Mitigation

Approaches to compensatory mitigation that follow these principles and adhere to the standards below are expected to achieve the best outcomes for conservation through effective management of the risks associated with compensatory mitigation. Application of equivalent standards across all compensatory mitigation sources will better ensure conservation goals are met.

- **Siting:** The mitigation sequencing hierarchy should be applied in the context of conservation objectives derived by a landscape-scale approach. Compensatory mitigation actions should be sited in locations that have been identified in conservation plans to most likely successfully and fully compensate losses to sage-grouse.

- **Duration:** Compensatory mitigation actions should achieve targeted biological conditions in a timeframe commensurate and proportional with the biological impacts to be offset.

- **Additionality:** Actions proposed as compensatory mitigation should provide benefits beyond those that would be achieved if the mitigation actions had not taken place and should exceed what is otherwise required by federal, state, and local regulations.

- **Effectiveness:** Compensatory mitigation actions should be proven to be reasonably likely to deliver expected conservation benefits, target those actions that will provide the greatest benefit to sage-grouse, and be measurable.

- **Durability:** Actions or plans proposed as compensatory mitigation must be accompanied by management, legal, and financial assurances that ensure the action or plan will be in place and effective for the intended duration. Assurances should address the unintentional loss as well as the intentional loss of a compensatory mitigation action.

- **Metrics:** Determinations of the expected impacts of actions and the measures necessary to avoid, minimize, or compensate for those impacts should be based on biological conditions and upon reliable, repeatable, and quantitative science-based methods.

Mitigation Program Elements

With these principles and standards in mind, the following discussion provides specific information to consider when developing a compensatory mitigation program.

With sage-grouse it is important that the program's rules governing *additionality*, *effectiveness*, and *durability* are designed in a way that is equitable between public and private lands and can address potential issues with properties of *split estate* ownership.

The information provided below, plus the list of detailed questions in Appendix 2, are designed to help entities develop thoughtful and robust mitigation programs and processes in the context of the full mitigation hierarchy.

1. PROGRAM GOVERNANCE

The Service encourages our state and federal partners to integrate mitigation planning into a broader ecological landscape context, which means moving toward a programmatic approach. Whether mitigation requirements occur through a local (e.g. county) permit process or a larger state- or regionally-administered program covering many permitting agencies, a mitigation program requires a broad array of elements and functions to operate.

Program goals, covered activities, requirements, and administrative roles should be clearly defined. The program should address how the mitigation hierarchy will be implemented, account for avoidance, and clearly establish when and why impacts are deemed unavoidable. To improve operational certainty in compensatory mitigation, programs should clarify up front the manner in which mitigation obligations will be quantified, the types of actions that will qualify as mitigation, and the consequences of mitigation failure. Because sage-grouse is a landscape-scale species, a process for coordinating mitigation programs both intra- and inter-state should be outlined within programs.

1a. Mitigation Program Types

Traditional compensatory mitigation mechanisms include *permittee responsible mitigation*, *conservation banks*, *in-lieu fee*, and other third party mitigation programs (e.g. *habitat credit trading systems* or *habitat credit exchanges*). The mitigation mechanisms differ by who is ultimately responsible for the success of the mitigation site (the permittee or a third party) and when mitigation actions occur relative to impacts.

The Service prefers mitigation programs that promote compensatory mitigation achieved prior to impacts, aggregate mitigation as part of a larger landscape approach, and provide long term protection and management of mitigation sites. Regardless of the type of mitigation mechanism utilized, mitigation actions or types should be held to equivalent standards for siting, duration, additionality, effectiveness, and durability and utilize consistent metrics.

CONSERVATION BANKING

The Service has a proven track record with conservation banking agreements and such agreements represent a familiar and durable type of mitigation program. While some deviations may be needed to develop a commercially viable and biologically relevant sage-grouse compensatory mitigation program, the closer the requirements of a compensatory mitigation program track those of conservation banking, the more likely the program is to provide certainty of implementation and effectiveness in improving the status of the species.

1. PROGRAM GOVERNANCE *(continued)*

1b. Program Administration

The *program administrator* will be the entity with enforcing authority for the establishment, operation, and management of a mitigation program. The administrator or their designee(s) must have the ability to enforce management actions, reconcile funding issues, incorporate adaptive management, track debits and credits, report results, etc.

The degree of authority granted to the administrator ensures that conservation benefits from compensatory mitigation will persist.

Since successful habitat conservation will require coordination across federal, state, tribal, and private interests, the program administrator should be recognized through a formal agreement developed with major stakeholders including federal, state, and tribal partners. The agreement should clearly articulate the selection process for any third party responsible for administration of various elements of the program.

The entity handling monetary funds must have the ability to separately manage, collect, and distribute funds.

Prior to collection of any funds, plans should be in place that explain the maximum time funds can be held before spent, how funds will be invested (including inflation protection), tracking and accounting for benefits generated by funds, guidelines for avoiding potential conflicts of interest between collecting and spending funds, and responsibility for performance of mitigation projects.

1c. Compliance and Enforcement

Compliance can be monitored several ways, including through a credit verification process, tracking system, and review of periodic monitoring reports. Processes to verify that mitigation actions meet program standards and are releasable for offsetting impacts provide assurance that compensatory mitigation sites are delivering benefits. A system to track both debits and credits is essential in ensuring compliance, increasing transparency, and allowing the administrator to determine the success of mitigation efforts in achieving conservation.

Monitoring reports at both the program and site level should be required at least annually. Monitoring should be structured to provide feedback on which compensation projects and actions successfully yield intended results and which have a higher likelihood of failure. Site-level reports should document site conditions, attainment of administrative and ecological *performance standards* (measurable attributes used to determine if the management plan meets the agreed upon goals and objectives), and management actions taken and expected to be taken in the future.

Enforcement structure and procedures should be developed at the program level. At the site level, agreements should include clear enforcement provisions that dictate the consequences of non-compliance, including a requirement that if the compensation fails to meet performance standards, the mitigation provider should provide equal compensation through other means. If the agreement holder does not satisfy the mitigation requirements, the regulating entity should have the ability to suspend or terminate credit releases, credit sales, or the agreement itself and pursue penalties for violations as appropriate.

1d. Role of the Service

The exact nature of the Service's involvement in any given mitigation program will vary and may include the following roles:

- Provide ongoing expertise and advice to state mitigation programs and state wildlife agencies as requested;
- Participate as a member of the BLM "WAFWA (Western Association of Fish and Wildlife Agencies) Management Zone Greater Sage-Grouse Conservation Team" or similar regional teams;
- Provide, as necessary, any conferencing or consultations which may result from mitigation projects or programs on federal lands;
- Accept and evaluate annual reports from mitigation programs, including evaluation of the effectiveness of any mitigation performed in relation to both sage-grouse and mitigation program functionality monitoring;
- Review and consider for approval or endorsement programs that seek to provide prelisting mitigation credits.

1e. Confidentiality

The Service recognizes that some participants in mitigation programs, especially private land compensatory mitigation providers, may be concerned about the potential for public disclosure of information through local, state, or federal rules. We recommend that any mitigation program provide for a transparent process by which the actions and effectiveness of the entire mitigation program can be evaluated, and that individual agreement holders be made aware of any potential for information to be publicly disclosed by participation in these programs.

2. DEVELOPING SERVICE AREAS

Identifying geographic areas where compensatory mitigation can best be located and successfully implemented is critical to ensuring that unavoidable impacts are adequately offset. In traditional mitigation terms this is known as a *service area*, the geographic area within which credits may be applied to offset debits associated with development activities. Service areas are mapped geographies with unique ecological and sometimes political significance. In general, larger service areas provide greater flexibility to exchange credits and debits. Landscape, economic, and regulatory realities inform and constrain decisions on service areas.

The geographic extent of a service area should be guided by the conservation needs of sage-grouse. Populations are identified in the COT Report. This is a recommended starting point. The location of the COT PACs, other key habitats defined in local plans, and the current and potential for future threats to a population should factor strongly into the designation and size of service areas. For larger populations, PACs may be a more appropriate scale for service areas so that PACs are kept as strongholds. For small populations, offsets may be most appropriately kept within that population. For small or large populations with positive population trends, offsets may be best directed at connecting habitat. If a particular area is under heavy development pressure, it may be best to focus offsets on an area removed from possible cumulative effects of those impacts. Service areas should reflect these more local population-based conservation needs.

To meet conservation goals and provide flexibility in mitigation programs, secondary service areas may be devised. A secondary service area is a larger area within which mitigation would be acceptable if more preferable options in the primary service area do not exist. Typically, a proximity factor (i.e. additional mitigation in the form of a multiplier or increased *mitigation ratio*) is added to mitigation going outside the primary service area. These tools can provide for flexibility of trades between service areas while encouraging offsets to stay within certain areas.

Jurisdictional issues should also be considered when developing service areas. Many large-scale development projects cross state and county boundaries. Service areas that span such political boundaries, though they have little to no biological or ecological significance, can provide efficiencies and greater conservation benefits for sage-grouse.

Service areas should be defined early in the development of a compensatory mitigation program in collaboration with all land ownerships and management agencies. The service area is an important component for third-party mitigation providers, who need to evaluate the marketability of their credits. An appropriate mix of public and private lands for compensatory mitigation is essential to implement a landscape approach to mitigation of habitat that is so widely distributed and intermixed. If Service areas are delineated primarily on the basis of jurisdictional or policy considerations, they should be well-justified in terms of their benefits to sage-grouse.

3. SITE SELECTION, CONSERVATION ACTIONS AND MANAGEMENT

Compensatory mitigation may be established on private, public, or tribal lands with the first criteria that specific areas provide the greatest benefit and reduce the greatest threats to sage-grouse. Priority areas in which to place mitigation actions should be biologically based and will be integrated among private and public land ownerships. However, maintaining the same classification of land ownership between the impact and mitigation site (e.g. mitigating impacts to private land on other private land) may be important in preventing a long-term net loss in conservation to sage-grouse.

A mitigation program should require that all lands being used for compensatory mitigation comply with program goals and objectives for managing habitat for the continued use of sage-grouse for at least the life of the impacts that the mitigation actions intended to offset.

Minimum requirements for establishment and operation of mitigation areas include:

- A site-level mitigation agreement which defines the roles and responsibilities of the mitigation provider, the agencies, and any other parties, and provides an operational framework for development, implementation, monitoring, and compliance of the project;
- Real estate assurances that will protect the mitigation area for the designated duration, including restriction of incompatible uses;
- Financial assurances to fund establishment and management of the mitigation area for the designated duration; and
- A management plan that will provide for the habitat management, monitoring, and continued adaptive management of the mitigation area.

3. SITE SELECTION, CONSERVATION ACTIONS AND MANAGEMENT *(continued)*

Site-level agreements should include a description of the amount of mitigation (or credits) to be provided, including a brief explanation of the metric used for this determination, and a process for adaptive management that will address uncertainties, including new information and unforeseen or unregulated situations (e.g. weather, fire). Each agreement should identify discrete ecological and administrative performance standards to be met and possible contingencies and consequences for not meeting standards. Monitoring should be designed to validate the effectiveness of the mitigation, answer program questions, contribute to knowledge gaps, and provide data to inform adaptive management decisions.

Compensatory mitigation should target projects in areas providing the greatest benefit and reducing the greatest threats to sage-grouse given jurisdictional and other constraints. States and federal land management agencies have already undertaken considerable efforts to identify and map key habitats necessary to maintain redundant, representative, and resilient populations in the development of their state and federal management plans (i.e. PACs). Additional finer-scale planning efforts by states or federal land management agencies may be necessary to determine if other essential habitats exist, particularly for connectivity, range or population expansion, and flexibility in managing habitat changes that may result from climate change.

Site selection criteria should outline the types of sites that are ecologically suitable for providing the desired habitat conditions and functions. In determining the ecological suitability of the project site, the following factors should be considered, to the extent practicable:

- Physical characteristics of the site;
- Landscape-scale features such as habitat diversity, function, and connectivity;
- Juxtaposition of the compensatory mitigation site relative to other areas of suitable habitat and ecological features;
- Ecological and legal compatibility with adjacent land uses;
- Compatibility with existing conservation plans and assessments;
- Development trends;
- Anticipated land use changes;
- Habitat status and trends;
- The relative locations of the impact and compensation sites; and
- Local or regional goals for the protection or restoration of particular habitat types or functions.

It is essential that efforts to offset unavoidable impacts through compensatory mitigation target the highest priority conservation actions for a population (or at the PAC scale for larger populations) to be effective. The Service recommends following the broadly-identified project types and conservation measures identified in the COT Report, based on local conditions and threats. Measurement of outcomes should be achieved using standard methods that link to sage-grouse population size to improve consistency and efficiencies and demonstrate that actions provide the necessary level of conservation benefit.

At a site-level scale, the mitigation actions taken on a given site should measurably offset impacts (from another site) and programmatically provide a net benefit to sage-grouse at the population or PAC (for larger populations) scale. For example, marking fence line and removing invasive juniper may not adequately offset permanent, limiting-factor, habitat impacts. However, these actions, in combination with other actions, such as permanent protection and active management, may collectively provide a net benefit. Research and education, although very important to the conservation of sage-grouse, should not be considered for compensatory mitigation as they are not actions that replace actual impacts to the species.

4. ADDRESSING ADDITIONALITY

Actions proposed as compensatory mitigation, regardless of land ownership, should provide benefits additional to those that would be achieved if the mitigation actions had not taken place. The additional value may result from conservation benefits to sage-grouse associated with *restoration* or *enhancement* of habitat; management actions that protect, maintain or create habitat (e.g., fire protection measures, legal and financial site protections); other activities (e.g., reduction of threats from disease or predation); and most likely a combination of all three categories.

4a. Program and Regulatory Considerations

To achieve additionality, compensatory actions must comply with all applicable federal, state, and local laws and exceed all existing regulatory or policy obligations associated with the project site. Lands already designated for conservation purposes cannot be used as compensatory mitigation unless the proposed compensatory mitigation project would add additional conservation benefit above and beyond that attainable under the existing land designation. This includes public lands dedicated for conservation purposes; private lands enrolled in government programs that compensate landowners who permanently protect, restore, or create habitat for sage-grouse; or lands protected by a habitat management agreement with the Service or similar programs.

For example, because the Service is mission-committed to species conservation, compensatory mitigation on National Wildlife Refuges is unlikely to be considered additional. However, additionality may be possible on a BLM Area of Critical Environmental Concern (ACEC) if, for example, existing mineral rights are resolved in some manner, thus providing additionality by avoidance of future loss of sage-grouse habitat from the rights being executed. Private lands enrolled in short term sage-grouse related conservation agreements with public entities, such as the Service's Partners for Fish and Wildlife Program or USDA Natural Resources Conservation Service Sage Grouse Initiative (SGI), may be eligible as mitigation lands if additional conservation benefits are provided above and beyond the terms and conditions of the agreement.

4b. Public Funds

Except for projects where federal funding is specifically authorized to provide compensatory mitigation, federally-funded conservation projects undertaken for purposes other than mitigation will not be considered additional. However, compensatory mitigation credits may be generated by activities undertaken in conjunction with, but supplemental to, such programs in order to maximize the overall ecological benefits of the restoration or conservation project (e.g. SGI). Where federal funds have been used in the establishment of a mitigation area, the allocation of credits should be proportionate to the non-federal contribution. If SGI funds are used to fund sagebrush restoration for sage-grouse, a landowner may participate in a compensatory mitigation program once the financial term of the SGI conservation plan contract expires. However, as specified by the agency administering the program or the Service, these properties may not qualify for full mitigation credit compared to a property that was not enrolled in such a program.

4c. Ecological Considerations

Credit *stacking* occurs when there is more than one resource or credit type on spatially overlapping areas. Stacking of mitigation credits within a mitigation site is possible, but the stacked credits should not be used to provide mitigation for more than one environmental impact action. However, compensatory mitigation projects may be designed to holistically address requirements under multiple programs and authorities for the same action and may use stacked credits to accomplish this goal. For example, a single credit may satisfy compensatory mitigation needs of an impact site where habitat for mule deer and sage-grouse overlap. The processes for use and accounting of stacked credits should be transparent across the entities that regulate the credits.

To ensure ecological benefits are measurably additional, programs should identify when or if it is appropriate to trade impacts to one form of sage-grouse habitat for offsets to another form. For sage-grouse, while *in kind* mitigation for habitat types (e.g. an impact to nesting habitat offset with restoration of nesting habitat functions and values) is preferred, *out of kind* compensatory mitigation for sage-grouse habitat may be appropriate where priority recovery needs can be addressed (e.g. loss of wintering habitat may be offset with brood rearing habitat in areas where the latter is a limiting factor).

4. ADDRESSING ADDITIONALITY *(continued)*

4d. Baselines

In order to determine ecological uplift (for mitigation sites) and potential impacts (for development sites), pre-project *baselines* must be assessed. Pre-project baseline refers to the habitat and/or species population conditions at any given point in time against which conservation actions are measured to determine ecological gain or loss. Baseline conditions should be assessed and measured using the same methodology employed to predict future conditions during project planning stages and ultimately to verify project conditions and associated credits during periodic and final monitoring of mitigation sites. The Service strongly recommends that a consistent methodology also be applied to predict impacts to sage-grouse and sage-grouse habitat (*see* Determining Metrics). For mitigation sites, baseline measures should explicitly acknowledge the potential threat of anthropogenic and natural disturbance, as well as the overall landscape resiliency of the site. Baseline methods should be consistently employed across the area covered by the mitigation program, unless variation of conditions and available data justify differences.

The Service has not developed or endorsed any one specific methodology for determining baseline conditions. States and other management entities may find it useful to cooperatively develop, adapt, adopt, or align methods that can be consistently applied across larger landscapes. The methods that will be used for measuring these types of baselines should be determined as part of early mitigation program development. Consider including information about scale (e.g. plan-level, state level), vegetation base layers, existing disturbance layers, lek data, sage-grouse occupied habitat, etc.

4e. Candidate Conservation Agreements

Landowners enrolled in *Candidate Conservation Agreements* (CCAs) or *Candidate Conservation Agreement with Assurances* (CCAAs) can provide compensatory mitigation if the actions related to mitigation are additional to the minimum conservation measures required by the CCA/CCAA. In order to track conservation actions and ensure additionality, conservation measures and mitigation-related conservation actions should be independently accounted for and reported to each respective program. Actions managed in perpetuity through mitigation agreements would provide both additionality and durability to the conservation measures provided under often shorter term candidate agreements. The ability to fund additional conservation on individual CCA/CCAA properties through mitigation dollars could further guarantee implementation of positive conservation actions. By keeping open the ability for those in CCA/CCAAs to market their additional conservation uplift to others needing to offset unavoidable impacts, more landowners will be encouraged to enroll in candidate agreements now.

Providing a menu of conservation options for landowners and reducing risk and uncertainty in conservation actions by securing them under mitigation agreements may contribute to an overall positive conservation goal for a species that operates on a landscape scale and for which protection and management of existing habitat is key to its survival.

©Tatiana Gettelman

5. DEMONSTRATING EFFECTIVENESS & DURABILITY

Effectiveness may be compromised when the benefits of compensatory mitigation either do not come to fruition or do not persist for the full duration that is required based on the impact that is intended to be offset. Effective actions or plans proposed as compensatory mitigation will demonstrate timeliness (i.e. achieve targeted biological conditions in a timeframe that benefits sage-grouse), biological effectiveness (i.e. ecological durability), and will be accompanied by durable site protections and financial assurances that secure and protect the conservation status of the mitigation site and credits for at least as long as associated impacts persist. In order to ensure that obligations for compensatory mitigation are durable, when a project requires compensatory mitigation, the regulating entity should include the compensatory mitigation requirement as one of the conditions in the project's permit or other required authorization.

5a. Duration

The length of time compensatory mitigation actions persist on and influence the landscape should meet or exceed the length of time that projected impacts will negatively affect sage-grouse. Duration includes the time extent of the direct, indirect, and cumulative effects of an impact as well as the time period for an impact site to be fully restored.

Because most impacts typically begin to occur in the early stages of projects (i.e., construction and initial operations), benefits of proposed mitigation actions should accrue before or as early in the life of the project as possible. When the success of compensatory mitigation is demonstrated prior to impacts occurring, ecological risk (due to uncertainty of implementation and time lag) is reduced. These benefits should be verified via standardized monitoring.

On the impact side, the effect to a species may vary widely based on the size, location, quality of habitat affected, temporal nature of the impact, and other factors. Impacts to the species may be generally separated into short term and permanent impacts. Short term impacts have a known conclusion date whereby the adverse effects to the species are removed and the result of the impact to the species has been completely remediated through natural or active restorative processes. Short term impacts should be predictable, justified by the current knowledge of the species and its habitat, and be concluded by documentation of the habitat functioning for the species at the same or greater level than before the impact.

Short term impacts are often mitigated through permanent compensation actions, either at the same or a reduced amount of permanent impacts (e.g. a short term impact may require 1 permanent credit as offset where the same impact that is permanent may require 5 credits to fully compensate). This is preferable to limited-term credits given the economies of scale gained from the longer term management and protections of permanent mitigation sites. Potential scenarios where limited-term credits may effectively be used as an offset include: 1) applying higher ratios for limited-term credits; 2) limiting use of limited-term credits within a service area or program to a small percentage of total credits available; 3) use of limited-term credits on restored habitats instead of preserved areas to reduce risk of net loss of intact existing habitat; 4) setting the duration of the offset to include the restoration period of the impacted site plus additional time to recover lost productivity; and 5) using only a portion of limited-term credits in a given area and permanently retiring the rest to address risk and uncertainty. In any situation, the rationale for development of temporary compensation should be biologically justified.

5b. Biological Effectiveness

Compensatory mitigation actions must have a high likelihood of success based on the biophysical setting. Actions should be supported by sound science. Actions that are unproven, especially those where time lags in providing conservation benefits are not adequately addressed, should not be prioritized for compensatory mitigation. However, such unproven actions can be encouraged without causing significant environmental risk by allowing a portion of credit to be released for implementation of actions, and holding back the majority of credit until defined and observable performance criteria related to habitat quality are achieved (*see* Credit Release).

Conservation actions are also more likely to be meaningful if they are aggregated. Compensatory mitigation areas are most effective if they are large enough so that they will, either in themselves or in conjunction with adjacent landscape conditions, provide the targeted biological benefits long term. Compensatory mitigation is not effective if it occurs in areas impacted by a development project (i.e. on-site), where future development is likely to occur, or in areas where benefits are likely to be reduced over time by incompatible land-uses and surrounding landscape edge effects. Applying credits from one area to multiple debit sources may provide more concentrated landscape level conservation benefits.

continued on pg 16

5. DEMONSTRATING EFFECTIVENESS & DURABILITY *(continued)*

5b. Biological Effectiveness *(continued)*

Potential credit associated with proposed restoration and enhancement activities should be evaluated on a given site in comparison with both pre-project baseline and projected future condition that would be expected in the absence of the proposed mitigation activity. *Preservation* projects should be evaluated, and credits proportionately assigned, according to the magnitude and likelihood of existing and future threats to the habitat and/or the value of that site to conservation of the species. Crediting for such avoided loss may be acceptable if it reduces primary threats, is discounted according to the likelihood of loss, and includes actions above and beyond closure to development (e.g. permanent conservation easement).

Preservation projects can help maintain the integrity of PACs, a key conservation objective in the COT Report.

5c. Durability — Site Protection

An ecologically sound compensatory mitigation plan offers limited value if the area may be affected by future disturbance. Durability can be reached with site protections (e.g., real estate-related designations and management plans) and financial protections (e.g., bonding for construction, endowment for management). The Service recognizes that durability is a relative concept and that certain land protection designations are more subject to modifications over time than others, therefore it is important that compensatory mitigation programs clearly define how durability will be addressed across various land ownership types.

A site protection (or real estate) instrument or agreement is a written description of the legal arrangements including ownership, management, and enforcement of any restrictions that will be used to ensure the protection of a compensatory mitigation site, whether the mitigation is placed on federal or nonfederal lands. Instruments most commonly used for this purpose include conservation easements, deed restrictions, transfer of title, multiparty agreements, contractual documents such as conservation land use agreements, and regulatory mechanisms governing management of federal lands such as federal land management plans. Where possible, a site protection instrument should designate an appropriate third party the right and resources to enforce site protections.

Lands with split estate ownership and laws and policies governing existing rights (e.g. mining laws) may prevent a particular site from meeting the durability test when durable land protection instruments (e.g. permanent conservation easements) cannot be applied. The Service recommends that the risk of using split estate properties be carefully considered in siting compensatory mitigation. Layering several site protection tools or using risk management tools such as pooled *reserve accounts* and *retired credits* can be used to bolster durability (*see* Reversals).

Written into any instrument or agreement and identified in the administrative and regulatory documents (e.g. Records of Decision) that enable the original mitigation should be provisions for alternative adequate mitigation if subsequent changes in management direction result in incompatible uses on the land. Site protection instruments should also have written agreement that provides for alternative and adequate mitigation should the site fail.

For any site protection instrument, the following information should be included:

1. Express reference to the mitigation program and its purpose to protect a compensatory mitigation site under federal, state, and/or local law;
2. Survey/legal description and identification of other property rights or interests;
3. Baseline description of conservation resources on the site, including any state or federally listed or imperiled species;
4. Third-party right of enforcement by the regulating agency (preferable);
5. Amendment and transfer notification requirements;
6. Any prohibited and acceptable uses;
7. Subordination clause requiring any preexisting easement, liens, or encumbrances to take second priority to the use of the property as a compensatory mitigation site; and
8. Any information required by applicable state or other laws (e.g., conservation easements).

5. DEMONSTRATING EFFECTIVENESS & DURABILITY *(continued)*

5d. Durability — Financial Protections

The mitigation program should require sufficient financial assurances connected to each compensatory mitigation project to ensure a high level of confidence that the compensatory mitigation will be successfully completed in accordance with applicable performance standards and for the full duration of the project's intended life. To demonstrate stability, adequate funding sources to provide for interim and long-term operation, management, monitoring, enforcement, documentation costs, and contingencies or remediation (if the project fails to meet performance standards) should be identified.

The amount of financing to deliver the mitigation is best determined by an appropriate cost-analysis for all elements of the mitigation, including acquisition, easement, restoration or enhancement, and long-term maintenance. Typical cost estimate components include land purchase price; taxes; site protection instrument; project planning; permits; construction activities; restoration materials; as built surveys; operation and maintenance costs; management, monitoring and reporting activities; reasonably foreseeable remedial actions; contingencies; and legal and administrative costs.

Examples of financial assurances include performance bonds, irrevocable trusts, escrow accounts, casualty insurance, letters of credit, endowments, and legislatively enacted dedicated funds for government-operated mitigation sites.

In cases where an alternative mechanism is available to ensure a high level of confidence that the compensatory mitigation will be provided and maintained (e.g. a formal, documented commitment from a government agency or public authority) financial assurances may not be necessary or may be reduced.

For any funding vehicle, proper portfolio management is critical to providing sufficient investment growth to keep pace with inflation. Overall success will be determined by establishing appropriate risk and return objectives, asset allocation guidelines and suitable investments for funding, and a framework for ongoing monitoring of investment performance. All funds should be held in dedicated accounts and managed based on agreed-to terms to assure that target ecological conditions will be attained and maintained as necessary. Public agencies are generally limited in their ability to protect long-term funds for being used for other purposes, thus the Service recommends any mitigation funds should be held by third parties.

Dedicated funds to maintain and monitor the conservation action will ensure transparency and maximize the potential to attain and maintain ecological durability. The Service recommends that the program specify the conditions under which financial assurances are to be released to any party including, as appropriate, linkage to achievement of performance standards, adaptive management, or compliance with special conditions.

6. DETERMINING METRICS & ACCOUNTING SYSTEMS

The methodologies, or metrics, used to determine the expected impacts of actions (debits) and the measures necessary to mitigate those impacts (credits) must be based on biological and/or habitat conditions and upon reliable, consistent, and repeatable methods and analysis resulting in a common "currency" between credits and debits. Ultimately, the metrics used must clearly tie back to species conservation.

A formal, consistent, rigorous but relatively simple methodology[4] to assess impacts should be used and applied to all land development activities that impact sage-grouse. The methodology should address direct impacts (habitat removal), indirect impacts and disturbance, potential significant cumulative effects, and ecological site conditions. Metrics that are comparable or the same across jurisdictional boundaries will allow for more biologically meaningful exchanges in a landscape context. Approaches such as distance-based disturbance bands, habitat weighting, and ecological potential are acceptable, especially in conjunction with defined thresholds of allowable impact in defined geographies.

Verification, monitoring, and adaptive management of metrics are important components of mitigation program accounting necessary to ensure success.

- *Verification* is the process(es) used to confirm that program rules have been followed and provides a standardized process for reporting and monitoring that is needed by agencies that oversee mitigation programs and must certify credits for sale or use. Complete, consistent, and accurate verification provides the public and credit buyers with evidence that the mitigation program is in compliance and delivering benefits.

- Monitoring of actions generating credits ensures practices are implemented and maintained and may be necessary throughout the life of the project, though frequency may vary based on the management needs of specific projects (e.g. restoration projects may require more frequent monitoring than preservation projects).

- To adaptively manage metrics, the program should establish clear thresholds to trigger future adjustments and include criteria and processes for making adjustments in a way that will not undermine existing credits or mitigation agreements.

A robust compensatory mitigation program will provide an accounting system[5] whereby credits and debits can be tracked. Registries developed for other environmental markets which function to issue, transact, and retire serialized credits represent current examples of robust accounting mechanisms. The accounting system should foster transparency, accountability, and credibility and facilitate the connections between compensatory mitigation providers at the lowest transaction costs.

[5] See Willamette Partnership's *General Crediting Protocol* for an example of an ecosystem credit accounting system.

7. MANAGING RISK

Predictions about effects and the effectiveness of compensatory mitigation measures carry varying degrees of risk and uncertainty. Programs should target mitigation measures that are expected to achieve a net gain for sage-grouse commensurate with the degree of risk and uncertainty associated with predicted effects. Increasing uncertainty of impacts from climate change means we need new approaches to assess multiple future scenarios, resilience of mitigation plans, to provide for adaptive management, and to ensure risk is properly managed. Overall, reducing uncertainty within a mitigation program increases regulatory predictability. The following risk management tools, in conjunction with site and financial protections, should be considered in a mitigation program.

7a. Adaptive Management

Adaptive management is an iterative approach to decision-making, providing the opportunity to adjust decision in light of learning with an overarching goal of reducing uncertainty over time. Incorporating adaptive management strategies into mitigation area management plans can help to manage risk and uncertainty for any type of mitigation area. Adaptive management processes require establishment of management benchmarks to ensure progress towards goals, protocols to monitor progress related to these benchmarks, and the resources and ability to make adjustments as needed to ensure mitigation objectives are achieved. The adaptive management plan should include triggers for identifying when corrective actions should be taken.

7b. Credit Release

One way to manage risk and uncertainty is by creating release schedules that only allow use of mitigation actions when specific success criteria are met. Success criteria should be designed to identify when risk and uncertainty have been substantially reduced. For third party mitigation sites, the Service recommends providing phased credit releases based on both ecological and administrative performance. A legally binding credit agreement should be in place between any party generating credits and the program administrator. The mitigation agreement should provide a schedule for credit releases as appropriate milestones are achieved. Failure to meet these milestones should result in suspension of credit release to ensure compliance.

Administrative criteria which may allow for initial credit release could include: site agreement and management plan have been approved, the site has been secured with an appropriate real estate instrument, and appropriate financial assurances have been established. Subsequent credits can be released for meeting ecological milestones (as determined through site monitoring) and financial milestones (e.g. endowments partially funded by portions of each credit sale). The credit release schedule should reserve a significant share of the total credits for release only after full achievement of performance standards.

7c. Ratios

Mitigation ratios (trading ratios, multipliers, proximity factors) may be used to address uncertainty or implement policy decisions to ensure net gain. Ratios can enable offset transactions to achieve net benefit for the species by ensuring the credit acquired is functionally greater than the debit.

Ratios may be determined based on several factors including temporal considerations (impact versus mitigation timing), functional quality and importance of proposed impacted areas, projected functional quality of proposed mitigation areas, likelihood of restoration success, degree of threat to proposed preservation areas, durability, etc.

However, we must be cautious in the over-use of ratios to make up for limited understanding of sage-grouse habitat restoration and our inability to accurately measure and compare the value of habitat types. Ratios should be reserved for dealing with the true uncertainty of any mitigation program and also for policy-based incentives (e.g. increasing trading ratios for acquiring credits outside an impact's service area). Any mitigation ratio used must be based on sound biological rationale that is easily explained, readily understood, and consistently applied. Documentation and justification for ratio values is important.

EXAMPLE

Multipliers can be built in to the debiting or crediting side of the metrics to create incentives for avoidance of impacts or preservation of habitat in high priority areas. Reserve ratios or retirement ratios can be used to set aside credits for unexpected events or to permanently retire a proportion of credits, never to be used as offsets, to insure net gain.

7. MANAGING RISK *(continued)*

7d. Reversals

Reversals may be caused by natural disturbances (unintentional reversal, such as wildfire) or anthropogenic disturbances (intentional reversal, such as development) which shorten the intended duration of compensatory mitigation. For intentional reversals, the Service recommends compensation by the party responsible for the reversal. To address this issue up front, the Service recommends establishing policies such that intentional reversals are prohibited to the extent possible, and the conservation benefits from a compensatory mitigation project are not diminished due to replacements made necessary by unforeseen intentional reversals.

Requiring the credit provider to be responsible for reversals outside of their control would likely make administration of a program more complex and decrease interest in providing credits. One recommended approach to address unintentional reversals is to establish insurance or a *reserve pool* where the amount of funding each site contributes to the pool is directly related to the amount of risk (e.g. from fire) of the site not providing habitat in the future.

Reserve pools can be established several ways, including:

- The compensatory mitigation program administrator requires that each individual mitigation provider sets aside a percentage of credits in reserve, never to be sold. In the event of an unintentional reversal, the administrator could draw from the pool of credits to make up for the lost conservation.
- An insurance premium, based on the number of credits sought and the likelihood of unintentional reversal (i.e. a natural disturbance that may lead to loss of habitat function), is added to the cost of compensatory mitigation for the debits requested. The insurance premium would then be used to generate additional compensatory mitigation projects that generate credits for the insurance pool. In the event of an unintentional reversal that generates unintentional debits, the compensatory mitigation program administrator would draw down credits from the pool to offset the debits.

CONCLUSION

The Service's primary goal for any sage-grouse compensatory mitigation program is to support conservation of the species by working with others in managing threats, protecting populations, and reversing declines. Implementation of robust and transparent compensatory mitigation programs and processes could contribute to reducing the need to list the species or simplify the effects of a listing and allow for well-sited actions that participate in the mitigation program to move forward smoothly. This will take a collaborative, unified approach between all stakeholders.

If we are able to work together on landscape-scale mitigation strategies for sage-grouse, we anticipate many benefits to accrue, including a streamlined permit process, increased public transparency and confidence, increased economic incentives and opportunities for landowners, and legal and scientific defensibility for actions taken under such strategies. Most importantly, we can reduce threats to the species in a manner consistent with the socio-economic needs of the local communities and states where sage- grouse occur.

APPENDIX I

Glossary

NOTE

The Service does not have formal definitions for a majority of these terms. Definitions were derived from existing policy and guidance where available but modified for the purposes of this document.

Additionality – A property of compensatory mitigation where the conservation outcomes are demonstrably above and beyond results that would have occurred if the mitigation had not taken place.

Baseline – the pre-existing condition of a defined area that can be quantified by an appropriate metric or metrics to determine level of function or value and re-measured at a later time to determine if the same area has increased, decreased, or maintained the same level of function or value.

Candidate Conservation Agreement (CCA) – a formal agreement between the Service and one or more federal or non-federal parties to address the conservation needs of proposed or candidate species, or species likely to become candidates for listing under the ESA, in which participants voluntarily commit to implementing specific actions that will help remove or reduce the threats to these species.

Candidate Conservation Agreement with Assurances (CCAA) – a formal agreement between the Service and one or more non-federal parties who voluntarily agree to manage their lands or waters to remove threats to candidate or proposed species and in exchange receive assurances that their conservation efforts will not result in future regulatory obligations in excess of those they agreed to at the time they entered into the agreement.

Compensatory Mitigation (Offset) – the preservation, enhancement, restoration and/or establishment of a resource to compensate for or offset unavoidable adverse impacts to the resource elsewhere.

Conservation Bank – a site or suite of sites established under a Conservation Bank Agreement that provides ecological functions and services expressed as credits that are conserved and managed in perpetuity for specified evaluation species and used to offset impacts occurring elsewhere to the same evaluation species. The establishment, operation, and use of a conservation bank require a conservation bank agreement between the Service and the bank sponsor (USFWS 2003 Conservation Banking Guidance). Ensuring that the required compensatory mitigation activities are completed and successful is the responsibility of the bank sponsor. The permittee transfers their liability for success of the mitigation to the bank sponsor through the transfer of credits. Conservation banks generally provide mitigation in advance of impacts.

Conservation Bank Agreement (CBA) – the legal document for the establishment, operation and use of a conservation bank. At a minimum, the Service and a bank sponsor (the individual or entity in charge of establishment and operation of a conservation bank) enter in to a CBA. This document may also be referred to as a Mitigation Bank Instrument (MBI), Conservation Bank Instrument (CBI), Conservation Bank Enabling Instrument (CBEI), or Bank Enabling Instrument (BEI).

Conservation Objectives Team (COT, COT Report) – a February 2013 report prepared by Service and state wildlife agencies. The COT Report identifies PACs, discusses principle threats to greater sage-grouse, and provides objectives, measures and options to ameliorate these threats.

Credit – a defined unit of trade representing the accrual or attainment of functions or value at a compensatory mitigation site. For example, a credit may be expressed as a measure of surface area (e.g., an acre or hectare), linear distance, number of individuals, stage of maturity of a particular habitat type, or other appropriate metric that can be consistently quantified and traded.

Debit – a defined unit of trade representing the loss of resource functions or value at an impact or project site. The unit of measure should be the same as that for a credit within a specific mitigation system.

APPENDIX I
Glossary

Durability – ability for mitigation measures to be effective at least as long as the impacts those measures are designed to offset. Durability is often addressed through legal, financial, and management mechanisms.

Effectiveness – Effective actions or plans proposed as compensatory mitigation demonstrate timeliness, ecological durability, and are accompanied by durable site protections and financial assurances that secure and protect the conservation status of the mitigation site and credits for at least as long as associated impacts persist.

Enhancement – manipulation of existing habitat to heighten, intensify, or improve a specific resource function(s). Enhancement results in a gain of selected resource function(s).

Habitat Credit Trading Systems (Habitat Credit Exchange) – A market-based system that facilitates the exchange between interested parties of credits that represent habitat that has been restored, enhanced, established, preserved or otherwise conserved for the purpose of offsetting losses of at-risk species habitat, habitat function, or habitat value elsewhere with the goal of achieving net species conservation benefits.

Incidental Take – take of listed species that results from, but is not the purpose of, carrying out an otherwise lawful activity. Incidental take is prohibited under the ESA and its implementing regulations, but may be authorized pursuant to section 7 or 10 of the ESA.

In Kind – (for sage-grouse) habitat of a similar structural and functional type to the habitat impacted.

In-lieu Fee – a site established as part of an in-lieu fee program that provides ecological functions and services expressed as credits that are conserved and managed for specific species and are used to offset impacts occurring elsewhere to the same species. In-lieu fee programs are sponsored by government agencies or environmental not-for-profit organizations that collect funds that are used to establish in-lieu fee sites. The establishment, operation, and use of an in-lieu fee program requires an agreement between the regulating agency and the in-lieu fee sponsor. Responsibility for ensuring that the required compensatory mitigation activities are completed and successful is transferred from the permittee to the in-lieu fee program sponsor through the transfer of credits.

Landscape-scale – for the purposes of this document, a landscape is defined as a large area encompassing an interacting mosaic of ecosystems and human systems that is characterized by a set of common management concerns.

Mitigation Ratio – typically, the relationship between compensatory offset for, and impacts to, individuals of species or habitat for species. Ratios (trading ratios, multipliers, proximity factors) may be used to address uncertainty or implement policy decisions.

Net Conservation Gain – the actual benefit or gain above baseline conditions, after deductions for impacts, in habitat function or value to species covered by a mitigation program.

No Net Loss – impacts caused by the project are balanced or outweighed by measures taken to avoid and minimize the project’s impacts and compensate any residual impacts so that no loss remains.

Off-Site – an area that is neither located on the same parcel of land as the impact site, nor on a parcel of land contiguous to the parcel containing the impact site.

Out of Kind – (for sage-grouse) habitat of a different structural and functional type from the impacted habitat.

Performance Standards – observable or measurable administrative or ecological (physical, chemical, or biological) attributes that are used to determine if a compensatory mitigation project meets the agreed upon objectives.

APPENDIX I
Glossary

Permittee Responsible Mitigation – a mitigation site that provides ecological functions and services established as part of the conservation measures associated with a permittee' s action. The permittee retains responsibility for ensuring that the required compensatory mitigation activities are completed and successful. Each permittee-responsible mitigation site is linked to the specific activity that required the offset. Permittee-responsible mitigation approved for a specific action is not transferable and cannot be used for other mitigation needs.

Prelisting Mitigation – (in this document) conservation measures benefitting a non-federally listed species that are recognized in a Service prelisting mitigation agreement and undertaken prior to the determination that the species to be benefited is a federally endangered or threatened species.

Preservation – maintenance or retention of existing habitat with specific resource function(s) for a species. This term usually implies legal protection of existing and functioning habitat, for example a parcel of land protected under a conservation easement.

Priority Areas for Conservation (PACs) – key areas that states have identified as crucial to ensure adequate representation, redundancy, and resiliency for conservation of its associated population or populations of greater sage-grouse. PACs are identified in the COT Report.

Program Administrator – The entity with enforcing authority for the establishment, operation, and management of a mitigation program.

Reserve Account (Reserve Pool) – a pool of issued credits, managed by the program administrator, intended to cover risks from intentional or unintentional reversals on mitigation sites.

Restoration – returning a site to its natural/historic habitat type with the same or similar functions.

Retired Credits (Retirement Ratio) – proportion of credits set aside and not ever to be used as compensatory mitigation.

Reversal – compensatory mitigation that does not persist for the full duration due to unplanned circumstances, whether through natural or man-made intentional or unintentional causes.

Service Area – the geographic area within which impacts to a species' habitat can be offset at a particular habitat offset site as designated in an agreement or program; specific to third party mitigation, the geographic area within which habitat credit trading occurs.

Split Estate – surface rights and subsurface rights (such as the rights to develop minerals) for a piece of land are owned by different parties.

Stacking (Credit Stacking) – generating multiple mitigation credit types on the same parcel of land.

Verification – process(es) used to confirm that mitigation program rules have been followed. Verification provides a standardized process for reporting and monitoring.

APPENDIX II
Questions Guide

NOTE

These questions, in conjunction with the principles, standards, and program elements outlined in the Framework, are intended to guide development of individual sage-grouse mitigation programs.

I. MITIGATION PROGRAM GOALS AND OBJECTIVES

1. How does the mitigation program aim to avoid impacts to sage-grouse and achieve a net conservation gain by mitigating for unavoidable impacts to sage-grouse across all habitats? At what scale(s) will this be measured?
2. How does the mitigation program address equitability (i.e. how will the mitigation hierarchy be applied across impact types and land ownerships in an equitable manner)?
3. What are other basic objectives of the program (e.g. implementable regardless of listing, cover other resources)?

II. COVERED ACTIVITIES

1. How are sage-grouse habitat classifications defined for the covered area (e.g., core, low density, occupied habitat, seasonal)?
2. Will any sage-grouse habitat type not be included in the mitigation program (and why)?
3. How will the program account for non-surveyed or unclassified habitats?
4. Will any other regulated resources be covered by the program (e.g. big game winter range, Bald and Golden Eagle Act, wetlands/Clean Water Act, etc.)?
5. What types of development activities will be covered?
6. What existing regulatory mechanisms relate to covered activities, and which entities provide this overview (e.g. permit requirements)?
7. Which development activities have been identified as threats to sage-grouse (e.g. *see* 2013 COT Report)?
8. How much demand for compensatory mitigation are development activities expected to create?
9. Does there need to be a process to include other development activities in the future?

III. MITIGATION PROGRAM GOVERNANCE

1. Is the program a stand-alone local or state-managed effort, or a jointly managed effort between state, federal, tribal and/or other agencies?
2. Who is in charge of administering different parts of the mitigation program?
3. What mechanism (agreement, legislation, etc.) identifies the responsible parties for managing the mitigation program?
4. How are relationships among different agencies and stakeholders managed?
5. How will the program operations be funded?
6. What compensatory mitigation transaction models will be supported (e.g. conservation banking, permittee-sponsored mitigation, credit exchange, in-lieu fee)?
7. How will any compensatory mitigation funds be managed and by whom?
8. What trigger points can be identified that would indicate that changes to the program are needed and how will changes be implemented?

APPENDIX II
Questions Guide

9. Is the mitigation program transparent and does it inform participants of the potential for information to be publicly disclosed by participation in these programs"?
10. How will information on impacts, offsets, and any credit trading be tracked?
11. How are the results reported to the Service or others?
12. Will the Service play a role in any part of the program (development, review, etc.)?
13. Will prelisting mitigation (for potential use in a post-listing scenario) be part of the program and if so, what will the agreement with the Service look like?
14. How will the program provide for coordination across jurisdictions (including across states)?

IV. MITIGATION HIERARCHY

A. Avoiding Impacts

1. What triggers review and entry into the mitigation hierarchy process?
2. Are there any avoidance or exclusion areas (e.g. NSO, lek buffers, etc.)?
3. What measures are used to determine if habitat is avoided? How are direct and indirect impact measures included?
4. What criteria or regulatory mechanisms are used to emphasize, require, and/or enforce avoidance? Specifically, what compliance measures are in place to ensure avoidance (e.g. permit denial)?
5. Is there a cap on disturbance, and at what scale and in which sage-grouse habitat types does it apply? Does it include direct and indirect impacts? What are the data source and methods used to measure avoidance?

B. Minimizing Impacts

1. Under what circumstances will minimization measures be employed?
2. What practices can developers use to minimize impacts?
3. What criteria or regulatory mechanisms are used to require and/or enforce minimization? Specifically, what compliance measures are in place to ensure impacts are minimized (e.g. permit denial)?
4. How are minimization measures monitored and are there triggers for adaptive management?

C. Rectifying Impacts

1. Is there an identified timeframe that rectification must occur?
2. How will the time lag between impact and rectification be offset?
3. What baseline will be used to determine whether rectification has occurred?
4. How are rectification measures monitored?
5. If rectification measures are not adequate who enforces compliance?
6. Who verifies that rectification is complete and adequate?

APPENDIX II

Questions Guide

D. Compensating (Offsetting) for Unavoidable, Residual Impacts

a) Impact (Debit) Assessment

1. How should impacts generally be measured, in other words, what constitutes a “debit” (e.g. functional acres, acres, number of birds)?
2. Will habitat measures take in to account rarity, vulnerability, or conservation priority?
3. Will impact assessments take in to account duration (i.e. temporary versus permanent impacts)?
4. From what baseline will impacts be calculated (e.g. current condition)?
5. How will the impact assessment method address direct impacts, indirect impacts, and cumulative effects?
6. Who can measure impacts? Will these calculations be verified?

b) Offset (Credit) Assessment

1. How should offsets generally be measured, in other words, what constitutes a “credit” (e.g. functional acres, acres, number of birds)?
2. From what baseline will offsets be calculated? In other words, are credits awarded on the difference between current and future condition (emphasizes enhancement and restoration), or just on future condition (emphasizes preservation), or on future condition with a minimum enhancement requirement?
3. How will risk and uncertainty of restoration and management factor into offset calculations?
4. How will duration of impacts (e.g. temporary versus permanent) factor into offset calculations?
5. Who can measure offsets? Will these calculations be verified and by whom?

c) Impact to Offset (Debit or Credit) Relationship

1. Will the quantification methods (metrics) for debits and credits be the same? If not, why?
2. How will the outcomes of the debit and credit metrics combine into a credit quantity to ensure that impacts are offset such that there is a net gain to sage-grouse (e.g. via ratios, multipliers)?
3. How will the timing of mitigation implementation (e.g. in advance of, concurrent with, or subsequent to impacts) factor into offset calculations (e.g. with ratios, caps on actions that result in time lags in critical areas, etc.)?
4. Under what circumstances would demonstration of functional mitigation in advance of impacts be required?
5. What criteria will be used to determine when in-kind or out-of-kind mitigation for habitat types (e.g. brood rearing, wintering, and nesting) is more appropriate?
6. What process is in place to adaptively manage the metrics?
7. What process is in place to approve new metrics?
8. How are service areas defined?
9. Will there be a mechanism to allow for trades to occur outside of service areas?
10. What mechanisms are in place to provide for or use credit available in other programs or states?

APPENDIX II
Questions Guide

d) Criteria for Compensatory Mitigation (Offset) Projects

1. What criteria are used for locating and prioritizing sites for compensatory mitigation?
2. Is there a preference for compensatory mitigation on a particular land ownership type (e.g. public, private) and why?
3. What pre-conditions must a site meet before being able to provide mitigation credits?
4. Will there be a minimum number of credits or site functionality before any credits are released?
5. How do other agreements (e.g. CCA, CCAA, SGI) affect eligibility to sell credits?
6. What constitutes on-site versus off-site mitigation, and when, if ever, is on-site mitigation preferred?
7. Does less than permanent protection count? If yes, how and why?
8. What is the process when impacts are proposed near or on compensatory mitigation sites?
9. Is credit provided for avoided loss? Under what circumstances?
10. What constitutes additionality (e.g., above and beyond legal requirements, above business as usual, etc.)? Does this differ by land ownership and if so, why?
11. What are the mechanisms for ensuring durability of protection on various land ownership types? How are split estates handled?
12. What conservation types (e.g., preservation, enhancement action, etc.?) and actions (e.g. juniper removal, fence marking) can generate credits?
13. How will preservation or restoration effect timing of the release of credits? Are credits released up front or based on administrative or ecological performance standards?
14. Who verifies credits (e.g., permitting agencies, third parties, etc.)?
15. Who approves the final mitigation agreement for a site and certifies release of credits?
16. How do you ensure that the credits represent the right conservation in the right locations?
17. What role, if any, can public funds or restricted conservation dollars play in mitigation (e.g., Farm Bill dollars)?
18. Can other resources be stacked on sage-grouse mitigation sites (e.g. carbon, wetlands)?
19. How will ongoing stewardship be ensured (e.g., proof of endowment or maintenance funds, when funds should be set aside, designation of a steward, qualifications of a steward)?
20. For each eligible conservation practice, what criteria will make sure it is implemented and maintained correctly?
21. What performance standards and monitoring techniques/durations will be applied at mitigation sites? Will there be standardized defaults, or will everything be site-specific?
22. What happens if performance standards are not being met either because of force majeure or things within a credit developer’s control? Specifically, how will wild fire be addressed?
23. What content needs to be in the monitoring reports and how often and to who are they submitted?
24. What constitutes success? Does it include presence of the species?

NEVADA SAGEBRUSH ECOSYSTEM PROGRAM

2014 Nevada
Greater Sage-Grouse
Conservation Plan

2014 Nevada Greater Sage-grouse Conservation Plan

Sagebrush Ecosystem Program
State of Nevada

October 1, 2014
As updated at the April 9, 2015 and May 14, 2015 SEC meetings

On April 22, 2013, the Sagebrush Ecosystem Council (SEC) recommended the development of the 2012 State Plan into a more comprehensive and detailed strategy. The SEC considered proposed revisions over a series of meetings starting in July 2013. Each SEC meeting was held in compliance with the Nevada Open Meeting Law, including multiple opportunities for public comment. The result of those efforts is this document, the 2014 Nevada Greater Sage-grouse Conservation Plan (2014 State Plan).

2014 Nevada Greater Sage-Grouse Conservation Plan

October 1, 2014
As updated at the April 9, 2015 and May 14, 2015 SEC meetings

Presented To:
Governor Brian Sandoval

Prepared Under the Direction of the:
Sagebrush Ecosystem Council

Allen Biaggi

1.0 INTRODUCTION

The greater sage-grouse (*Centrocercus urophasianus*; hereafter, sage-grouse) is a historically and culturally significant species in Nevada. Sage-grouse were a staple of the diet of Native American tribes in Nevada, including Northern Paiute and Western Shoshone (BLM 2013). In addition, sage-grouse play a prominent role in some tribal oral traditions (BLM 2013), as well in dances, customs, and celebrations (IDFG 1997, DOE 2007). Lewis and Clark noted the birds in their journey west in 1804 (IDFG 1997). Early pioneers dubbed them “sage chickens” and utilized them as an important food source over the next half century (IDFG 1997, DOE 2007). In Nevada, sage-grouse hunting laws began around 1890 (DOE 2007). From the early 1900s until the late 1920s, Nevada pursued reductions in the length of the hunting seasons and enforced bag limits due to decreasing bird populations (DOE 2007).

Sage-grouse increased in prominence as of species of interest in the West in the 1950s and 1960s due to a management need to learn more about basic sage-grouse biology (Stiver, personal communication 2014). Nevada has historically been a leader in sage-grouse conservation, including conducting one of the first ever scientific studies of sage-grouse in the O’Neil Basin and hosting the second ever Western Association of Fish and Wildlife Agencies (WAFWA) Sage-grouse Workshop in Elko (Stiver, personal communication 2014). State fish and game agencies began counting sage-grouse on breeding grounds, called “leks” as early as the 1930s (Stiver, personal communication 2014). Nevada has records of lek counts that date back to the 1950s (Stiver, personal communication 2014). In the later part of the twentieth century, Nevada continued its leadership role in sage-grouse conservation as a pioneer in sage-grouse monitoring techniques and scientific research, as well as by working with WAFWA to develop sage-grouse guidelines for habitat, population, and management (Stiver, personal communication 2014).

In 2000, then Governor Kenny Guinn appointed a task force representing various interest groups and agencies to develop a plan that would conserve and protect Nevada’s sage-grouse and their habitat. In October 2001 the Nevada Sage-grouse Conservation Strategy identified challenges, offered potential solutions, and laid the groundwork for the formation of local area working groups (LAWG) and Population Management Units (PMU; Figure 1). It provided guidance for developing conservation plans and subsequent legislative endorsements in 2004 and 2010 reinforced Nevada’s commitment to conserve the species.

From 2001 to 2004 the Governor’s Sage-grouse Conservation Team under leadership of the Nevada Department of Wildlife (NDOW) completed an intensive planning effort for the State in which LAWGs developed plans for their respective areas and PMUs. In June 2004, the *1st Edition of the Greater Sage-grouse Conservation Plan for Nevada and Eastern California* (2004 State Plan) was completed. Between 2004 and the present, resource management agencies have implemented conservation projects and instituted policies to support the conservation goals in the 2004 State Plan.

On March 23, 2010, the U.S. Fish and Wildlife Service (USFWS) determined that listing the sage-grouse was warranted under the Endangered Species Act of 1973, as amended (ESA), but precluded due to higher priority species. Consequently, sage-grouse were placed on the federal candidate species list. The USFWS later entered into a court settlement with several environmental groups, which included a schedule for making listing determinations on over 200 candidate species, including the sage-grouse. A proposed decision for sage-grouse is scheduled for September 2015.

In response, the Bureau of Land Management (BLM) and U.S. Forest Service (USFS) developed their National Greater Sage-grouse Planning Strategy in late 2011, a process to revise existing land use plans (LUPs) in order to provide regulatory mechanisms to conserve sage-grouse and their habitats. Secretary Salazar invited the states impacted by a potential sage-grouse listing to develop state-specific regulatory mechanisms to conserve the species which could be considered as an alternative in the BLM and USFS LUP revision process.

On March 30, 2012, Governor Sandoval fortified Nevada’s commitment to sage-grouse conservation, by issuing Executive Order 2012-09, which established the Governor’s Greater Sage-grouse Advisory Committee (Advisory Committee) with a directive to provide updated recommendations for sage-grouse conservation in Nevada in order to preclude the need to list sage-grouse under the ESA and provide an alternative for consideration in the BLM/ USFS LUP revision process for Nevada. Those efforts resulted in the *Strategic Plan for Conservation of Greater Sage-Grouse in Nevada* (2012 State Plan), completed on July 31, 2012, which consisted of a list of primary threats to sage-grouse in Nevada and recommendations to the Governor on strategies and actions to conserve sage-grouse in Nevada.

One of the main recommendations of the 2012 State Plan was the creation of the Sagebrush Ecosystem Program (SEP), which would consist of the Sagebrush Ecosystem Council (SEC) and the Sagebrush Ecosystem Technical Team (SETT; see Section 5.0). The SEC was originally established under Executive Order 2012-19, on November 19, 2012, and later codified under state statute NRS Chapter 232.162. The SETT began work on February 11, 2013. On April 22, 2013, the SEC directed the SETT to further develop the recommendation in the 2012 State Plan into a more comprehensive and detailed strategy. The SEC considered proposed revisions over a series of meetings starting in July 2013. Each SEC meeting was held in compliance with the Nevada Open Meeting Law, including multiple opportunities for public comment. The result of those efforts is this document, the *2014 Nevada Greater Sage-grouse Conservation Plan* (2014 State Plan).

The 2014 State Plan represents the best available scientific information, as well as stakeholder input, to develop a sage-grouse conservation plan specific to Nevada. This is meant to be a “working document” that will be updated as new science emerges and lessons are learned through implementation of the 2014 State Plan, through an adaptive management framework.

In addition to the 2014 State Plan, the SEP is in the process of developing a *Nevada Sage-grouse Strategic Action Plan* (SAP). The 2014 State Plan provides broad goals, objectives, and management actions to ameliorate the primary threats to sage-grouse in Nevada. The SAP will be a companion document to the 2014 State Plan and will go into greater detail and identify areas to focus conservation efforts in order to achieve the broad goals and objectives outlined in the 2014 State Plan. The SAP will look to identify funding sources to implement the management actions recommended in the 2014 State

Plan. The SAP will identify where the primary threats to sage-grouse habitat are located across the landscape and provide specific guidance on how to ameliorate these threats based on local area conditions, resistance and resilience regimes, and ecological site descriptions. The SAP will help guide how and where the management efforts identified in the 2014 State Plan are prioritized in order to achieve landscape-scale conservation of sage-grouse and the sagebrush (*Artemisia* spp.) ecosystem. The planning efforts of the Bi-State Distinct Population Segment Greater Sage-grouse will serve as a general template for the SAP in terms of the level of specificity needed for project planning and commitment to funding (Bi-state Technical Advisory Committee Nevada and California 2012, Bi-State Executive Oversight Committee 2014).

2.0 DEFINITIONS

Acts of Nature – An event resulting from natural processes of the earth which occur outside human control and may be unpredictable, such as wildfires or drought.

Adaptive Management - An adaptive approach that involves exploring alternative ways to meet management objectives, predicting the outcomes of alternatives based on the current state of knowledge, implementing one or more of these alternatives, monitoring to learn about the impacts of management actions, and then using the results to update knowledge and adjust management actions.

Anthropogenic Disturbance – Any human-caused activity or action or human-created physical structures that may have adverse impacts on sage-grouse or their habitats. The term anthropogenic disturbance and its associated conservation policies includes, but is not limited to the following project categories: mineral development and exploration and its associated infrastructure; renewable and non-renewable energy production, transmission, and distribution and its associated infrastructure; paved and unpaved roads and highways; cell phone towers; landfills; pipelines; residential and commercial subdivisions; activities undertaken pursuant to special use permits and right-of-way grants; and other infrastructure development. Livestock operations and agricultural activities and infrastructure related to ranch and farm businesses (e.g. water troughs, fences, etc.) are not included in this definition.

Conservation – The wise sustainable use, preservation, enhancement, or restoration of the natural environment; including: ecosystem processes, vegetation, and wildlife.

Conservation Credit System (CCS) – A pro-active solution to ensure impacts from human activities generate a net benefit for the species, while enabling human activities vital to the Nevada economy and way of life. The Credit System creates new incentives for 1) human activities to avoid and minimize impacts to important habitats for the species, and 2) private landowners and public land managers to preserve, enhance, and restore important habitats, including reducing the threat of wildfire to important habitats for the species.

Enhancement – Manipulation of existing habitat to improve specific habitat functionality.

Habitat – An area that provides food, cover, water, and space for an organism. It is the resources and conditions present in an area that are required by a species to carry out its life. Habitat implies more than just vegetation or vegetation structure; it is the sum of the specific resources that are needed by an organism. Other resources that influence habitat include physical and biological characteristics, such as: climate, precipitation, elevation, topography, water availability, soil type, etc.

Specific to this State Plan:

Suitable Habitat – Areas identified through the habitat suitability index (Section 6.0) with index values greater than 1.5 standard deviations below the mean value of the index. These areas are identified as generally meeting the needs for sage-grouse to survive and reproduce.

High Suitability Habitat – Areas identified through the habitat suitability index (Section 6.0) with index values greater than 0.5 standard deviations below the mean.

Moderate Suitability Habitat – Areas identified through the habitat suitability index (Section 6.0) with index values between 1.5 and 0.5 standard deviations below the mean.

Non-Habitat – Areas identified through the habitat suitability index (Section 6.0) with index values less than 1.5 standard deviations below the mean value of the index. These areas are identified as generally not meeting the needs for sage-grouse to survive and reproduce.

Habitat Quantification Tool (HQT) – The method for quantifying impacts ("debits") or benefits ("credits") to sage-grouse habitat characteristics generated by participants in the Nevada CCS. It is intended to provide an effective means for targeting credits and debits to the most beneficial locations for the sage-grouse, and tracking the contribution of the CCS to sage-grouse habitat and population goals.

Invasive Plants – A non-native plant that effectively reproduces, is able to outcompete native plants, may alter ecosystem processes, and may be difficult to control or eradicate. Invasive plants can be considered by the State Quarantine Officer for the designation of "noxious".

Lek – Traditional courtship display and mating areas attended by sage-grouse in or adjacent to sagebrush dominated nesting habitat. Leks are generally situated on gentle terrain in relatively open areas with less herbaceous and shrub cover than surrounding areas (Connelly et al 2004).

Noxious Weeds – Any species of plant which is currently or likely to become detrimental, destructive or difficult to control and is designated by the State Quarantine Officer as "noxious". These weeds are regulated by Nevada Revised Statute 555.130 – 555.201 and the designation and categorization of noxious weeds can be found in Nevada Administrative Code 555.010.

Population Management Units (PMUs) – General delineations of sage-grouse populations for management in Nevada. PMUs are based on aggregations of leks, understanding of habitats, and potential boundaries to populations (such as mountains and valleys). These were developed by NDOW for the 2001 State plan and refined in the 2004 State Plan (see Figure 1).

Preservation – Maintenance or retention of existing habitat quality and ecosystem functions currently used by or in close proximity to habitat used by sage-grouse through a variety of management tools, both active and passive.

Reclamation – Actions performed during or after an exploration project or mining operations to shape, stabilize, re-vegetate, or otherwise treat the land in order to return it to a safe, stable condition consistent with the establishment of a productive post-mining use of the land and the abandonment of a facility in a manner which ensures the public safety, as well as the encouragement of techniques which minimize the adverse visual effects (NRS Chapter 519A.100).

Rehabilitation – Re-vegetation of a site to achieve basic ecological functions, such as preventing soil erosion, but which does not return a site to its reference state according to its ecological site description.

Resource Selection Function (RSF) – Any model that yields values proportional to the probability of use of a resource unit. RSF models often are fitted using generalized linear models (GLMs) although a variety of statistical models might be used. RSFs were used in the development of the habitat suitability model (Section 6.0; Boyce et al. 2002).

Restoration – The reestablishment of ecologically important habitat or other ecosystem resource characteristics and function(s) at a site where they have ceased to exist, or where they exist in a substantially degraded state, and that renders a positive biological response by the habitat.

Sage-Grouse Management Area (SGMA) – The spatial extent of sage-grouse management in Nevada. The overarching objective of Nevada's plan is to achieve conservation through net conservation gain of sage-grouse habitat due to new anthropogenic disturbances within the SGMA.

Core Management Areas – Areas of high estimated space use in suitable sage-grouse habitat in the State of Nevada. These areas represent the strongholds (or "the best of the best") for sage-grouse populations in the State and support the highest density of breeding populations.

Priority Management Areas – Areas that are determined to be highly suitable habitat for sage-grouse in areas of estimated low space use and areas of non-habitat which overlap with areas of estimated high space use.

General Management Areas – Areas determined to be moderately suitable habitat for sage-grouse in areas of estimated low space use.

Non-Habitat Management Areas – Areas within the SGMA determined to be unsuitable for sage-grouse.

Site Specific Consultation Based Design Features – Measures or actions designed to minimize adverse effects to sage-grouse and their habitats due to disturbances.

Space Use Index – Continuous surface mapping developed based on lek attendance and density coupled with probability of sage-grouse occurrence relative to distance to nearest lek.

WAFWA Management Zones – Range-wide sage-grouse management delineations based on populations within floristic provinces. These were developed to guide sage-grouse conservation goals and range-wide management outlined in the 2006 Greater Sage-grouse Comprehensive Conservation Strategy developed by WAFWA.

3.0 CONSERVATION GOALS AND OBJECTIVES

The State's goal for the conservation of sage-grouse in the State of Nevada is to provide for the long-term conservation of sage-grouse by protecting the sagebrush ecosystem upon which the species depends. Redundant, representative, and resilient populations of sage-grouse will be maintained through amelioration of threats; conservation of key habitats; mitigation for loss of habitat due to anthropogenic disturbances; and restoration or rehabilitation of habitat degraded or lost due to Acts of Nature.

Achieving the State's goal for the conservation of sage-grouse will provide benefits for the sagebrush ecosystem and for many other sagebrush obligate species. Sage-grouse are known to be an "umbrella species" for many sagebrush obligate and associated species (Hanser and Knick 2011). The enhancement and restoration measures that bring resiliency and restore ecological functions to sagebrush ecosystems will also serve to ensure quality habitat for sage thrasher, sage sparrow, Brewer's sparrow, sagebrush vole, pygmy rabbit, pronghorn antelope, mule deer, and many other species.

The State's goal will be met through specific conservation objectives for anthropogenic disturbances and Acts of Nature, principally large acreage wildland fires and subsequent invasion or potential domination by non-native species. This combined strategy creates the regulatory framework through which sage-grouse habitat can be conserved and the decline of sage-grouse populations can be stopped in the State of Nevada. This section of the Plan details related policies and an adaptive management approach that will provide guidance to achieve these objectives.

The guiding principles that create the balanced foundation and vision for a coordinated, management approach to conserve sage-grouse and the sagebrush ecosystem in Nevada are as follows:

- Conserve sage-grouse and their habitat in Nevada while maintaining the economic vitality of the State.
- Due to the broad reach of sage-grouse habitat, effective management and implementation of sage-grouse conservation actions must be conducted through a collaborative, interagency approach that engages private, non-governmental, local, state, Tribal and federal stakeholders to achieve sufficient conservation of the sage-grouse and their habitat.
- Monitoring and adaptive management will be employed at all levels of management in order to acknowledge potential uncertainty upfront and establish a sequential framework in which decision making will occur in order to learn from previous management actions.

3.1 Anthropogenic Disturbances

3.1.1 <u>Conservation Objective</u> – Net conservation gain due to new anthropogenic disturbances

The overarching objective of Nevada's plan is to achieve conservation through net conservation gain of sage-grouse habitat due to new anthropogenic disturbances within the Sage-Grouse Management Area (SGMA; Figure 2) in order to stop the decline of sage-grouse populations. Net conservation gain is defined as the State's objective to maintain the current quantity and quality of sage-grouse habitat within the SGMA at the state-wide level by protecting existing sage-grouse habitat or by mitigating for loss due to anthropogenic disturbances. Mitigation requirements are determined by the Conservation Credit System. This objective will be measured by the credit to debit ratio.

Anthropogenic disturbance is defined here as any human-caused activity or action or human-created physical structures that may have adverse impacts on sage-grouse or their habitat. The term anthropogenic disturbance and its associated conservation policies will include, but not limited to the following project categories: mineral development and exploration and its associated infrastructure; renewable and non-renewable energy production, transmission, and distribution and its associated infrastructure; paved and unpaved roads and highways; cell phone towers; landfills; pipelines; residential and commercial subdivisions; activities undertaken pursuant to special use permits and right-of-way grants; and other infrastructure development. Livestock operations and agricultural activities and infrastructure related to ranch and farm businesses (e.g. water troughs, fences, etc.) are not included in this definition, though Section 7.5 and Appendix A address how to minimize impacts to sage-grouse and their habitat from these activities.

3.1.2 <u>Conservation Policies</u> – "Avoid, Minimize, Mitigate"

The State of Nevada's overriding policy for all management actions within the SGMA is to "avoid, minimize, and mitigate" impacts to sage-grouse habitat.

This is a fundamental hierarchical decision process that seeks to:

Avoid – Eliminate conflicts by relocating disturbance activities outside of sage-grouse habitat in order to conserve sage-grouse and their habitat. Avoidance of a disturbance within sage-grouse habitat is the preferred option. If impacts are not avoided, the adverse effects will need to be both minimized and mitigated.

Minimize – Impacts will be minimized by modifying proposed actions or developing permit conditions to include measures that lessen the adverse effects to sage-grouse and their habitat. This will be accomplished through Site Specific Consultation Based Design Features (Design Features), such as reducing the disturbance footprint, seasonal use limitations, co-location of structures, etc. Minimization does <u>not</u> preclude the need for mitigation of a disturbance. Any disturbance in habitat within the SGMA will require both minimization and mitigation.

Mitigate – If impacts are not avoided, after required minimization measures are specified, residual adverse effects on designated sage-grouse habitat are required to be offset by implementing mitigation actions that will result in replacement or enhancement of the sage-grouse habitat that will result in net conservation gain of habitat from the disturbance activity. This will be accomplished through the Conservation Credit System.

Proposed anthropogenic disturbances within the SGMA will trigger timely consultation with the SETT for assessment of impacts to sage-grouse and their habitats and compliance with SEC and other relevant agency policies. All currently mapped sage-grouse habitat is located within the SGMA. Specifics of the SETT Consultation will be detailed in a Memorandum of Understanding (MOU) between the applicable State and Federal agencies, still under development. SETT Consultation is designed to provide a regulatory mechanism to ensure that sage-grouse conservation policies are applied consistently throughout the State and streamline the federal permitting process.

Determination of sage-grouse habitat will be based on the Nevada Habitat Suitability Map (Figure 3)[1]. At the onset of a proposed project, habitat evaluations or “ground-truthing” of the project site and its surrounding areas shall be conducted by a qualified biologist with sage-grouse experience using methods as defined in Stiver et al (2010), or other mutually agreed to scientifically valid techniques, to confirm habitat type. Evaluations can be conducted by the SETT or NDOW at the request of the project proponent.

The specific steps for the implementation of the “avoid, minimize, mitigate” policy are as follows:

Avoid

Project proponents must first seek to avoid disturbance in sage-grouse habitat within the SGMA. If the project is located entirely outside of habitat, but within the SGMA it will still be analyzed for indirect effects, such as noise and visual impacts. A project will only be considered to have avoided impacts if it is physically located in non-habitat and it is determined to have no indirect impacts affecting designated habitat within the SGMA. If this is determined, no further consultation with the SETT is required.

It is important to note that the avoid step is not an “all or nothing” concept. If the entirety of a project cannot be relocated to non-habitat, alternatives will be explored to relocate portions of the project to non-habitat. (For example, if a mine cannot be relocated into non-habitat, power distribution lines associated with the project may be relocated to non-habitat.) This may reduce minimization and mitigation requirements for the project proponent.

Anthropogenic disturbances should be avoided within the SGMA. If avoidance cannot be reasonably accomplished, the project proponent must demonstrate why it cannot be reasonably accomplished (as described in Table 3-1) in order for the SETT to consider minimization and mitigation alternatives. The process to demonstrate that avoidance cannot be reasonably accomplished (the “avoid process”) is

---

[1] Higher resolution maps are available at: http://sagebrusheco.nv.gov/uploadedFiles/sagebrusheconvgov/content/HSM/3-%20NV%20Management%20Categories%20Version%202.pdf

determined by four management categories (Figure 4), which consider both sage-grouse breeding population density and habitat suitability within the SGMA. This approach was taken in order to minimize impacts to areas with higher estimated sage-grouse use and habitat quality. Definitions and methods for developing the management categories are provided in Section 6.0.

The burden of proof to demonstrate that avoidance cannot reasonably be accomplished within the SGMA will be on the project proponent and will require the project proponent to demonstrate the specified criteria listed in Table 3-1 as determined by the management categories the proposed project is located in. Exemptions to the avoid policy will be granted if all the criteria in Table 3-1 are met. A higher burden of proof is set for project proponents to demonstrate that avoidance cannot be reasonably accomplished in areas that have higher densities of sage-grouse populations and suitable habitat.

Table 3-1. The Avoid Process for Proposed Anthropogenic Disturbances within the SGMA

Anthropogenic disturbances should be avoided in habitats within the SGMA. If project proponents wish to demonstrate that a disturbance cannot be avoided, exemptions will be granted if the criteria listed in the table can be met for the applicable management category.

Core Management Areas (“best of the best”)	Priority Management Areas	General Management Areas	Non-habitat Management Areas
• Demonstrate that the project cannot be reasonably accomplished elsewhere – the purpose and need of the project could not be accomplished in an alternative location, or that locating the project elsewhere is not technically or economically feasible; • Demonstrate that the individual and cumulative impacts of the project would not result in habitat fragmentation or other impacts that would cause sage-grouse populations to decline through consultation with the SETT; • Demonstrate that sage-grouse population trends within the PMU are stable or increasing over a ten-year rolling average; • Demonstrate that project infrastructure will be co-located with existing disturbances to the greatest extent possible; • Develop Site Specific Consultation Based Design Features to minimize impacts through consultation with the SETT; and, • Mitigate unavoidable impacts through compensatory mitigation via the Conservation Credit System. Mitigation rates will be higher for disturbances within this category.	• Demonstrate that the project cannot be reasonably accomplished elsewhere – the purpose and need of the project could not be accomplished in an alternative location, or that locating the project elsewhere is not technically or economically feasible; • Demonstrate that project infrastructure will be co-located with existing disturbances to the greatest extent possible. If co-location is not possible, siting should reduce individual and cumulative impact to sage-grouse and their habitat; • Demonstrate that the project should not result in unnecessary and undue habitat fragmentation that may cause decline in sage-grouse populations within the PMU through consultation with the SETT; • Develop Site Specific Consultation Based Design Features to minimize impacts through consultation with the SETT; and, • Mitigate unavoidable impacts through compensatory mitigation via the Conservation Credit System.	• Demonstrate that the project cannot be reasonably accomplished elsewhere – the purpose and need of the project could not be accomplished in an alternative location, or that locating the project elsewhere is not technically or economically feasible; • Demonstrate that project infrastructure will be co-located with existing disturbances to the greatest extent possible; • Develop Site Specific Consultation Based Design Features to minimize impacts through consultation with the SETT; and, • Mitigate unavoidable impacts through compensatory mitigation via the Conservation Credit System.	• Demonstrate that the project will not have indirect impacts to sage-grouse and their habitats. If it cannot be demonstrated, the project proponent will be required to develop Site Specific Consultation Based Design Features to minimize impacts and compensatory mitigation will be required.

Core Management Areas

The Core Management Areas support high densities of sage-grouse and areas of high estimated space use in suitable habitat (See Section 6.0 for details on technical language). These areas include approximately 85% of space use by sage-grouse in the State of Nevada. These areas represent the strongholds (or "the best of the best") for sage-grouse populations in the State of Nevada and support the highest density of breeding populations. Thus, the management strategy is to conserve these areas by avoidance of anthropogenic disturbances in order to maintain or improve current sage-grouse population levels.

Project proponents must seek to avoid disturbances within the SGMA. If the project proponent wishes to demonstrate that avoidance cannot be reasonably accomplished within these areas, exemptions will be granted to this restriction as part of the SETT Consultation. The project proponent must demonstrate that all of the following criteria listed below (also see Table 3-1) are met as part of the SETT Consultation process in order to be granted an exemption:

- Demonstrate that the project cannot be reasonably accomplished elsewhere – the purpose and need of the project could not be accomplished in an alternative location, or that locating the project elsewhere is not technically or economically feasible;
- Demonstrate that the individual and cumulative impacts of the project would not result in habitat fragmentation or other impacts that would cause sage-grouse populations to decline through consultation with the SETT;
- Demonstrate that sage-grouse population trends within the PMU are stable or increasing over a 10-year rolling average;
- Demonstrate that project infrastructure will be co-located with existing disturbances to the greatest extent possible;
- Develop Site Specific Consultation Based Design Features to minimize impacts through consultation with the SETT; and
- Mitigate unavoidable impacts through compensatory mitigation via the Conservation Credit System. Mitigation rates will be higher for disturbances within this category.

Priority Management Areas

The Priority Management Areas encompass areas that are determined to be highly suitable habitat for sage-grouse by the Nevada Habitat Suitability Model and areas of high space use that are not contained within the Core Management Areas (See Section 6.0 for details on technical language).

Management in these areas provides more flexibility to project proponents, though avoidance in these areas is still the preferred option and project proponents are encouraged to develop outside of these areas whenever possible. Anthropogenic disturbances will be permitted in these areas if the criteria listed below (also see Table 3-1) are met as part of the SETT Consultation process:

- Demonstrate that the project cannot be reasonably or feasibly accomplished elsewhere – the purpose and need of the project could not be accomplished in an alternative location, or that locating the project elsewhere is not technically or economically feasible;

- Demonstrate that project infrastructure will be co-located with existing disturbances to the greatest extent possible. If co-location is not possible, siting should reduce individual and cumulative impacts to sage-grouse and their habitat;
- Demonstrate that the project should not result in unnecessary and undue habitat fragmentation that may cause declines in sage-grouse populations within the PMU through consultation with the SETT;
- Develop Site Specific Consultation Based Design Features to minimize impacts through consultation with the SETT; and
- Mitigate for unavoidable impacts through compensatory mitigation via the Conservation Credit System.

General Management Areas

The General Management Areas encompass areas determined to be suitable habitat for sage-grouse, though less suitable than Priority Management Areas and are not contained within the Core Management Areas (See Section 6.0 for details on technical language). Management of these areas provides the greatest flexibility to project proponents. Anthropogenic disturbances will be permitted in these areas if the criteria listed below (also see Table 3-1) are met as part of the SETT Consultation process:

- Demonstrate that the project cannot be reasonably or feasibly accomplished elsewhere – the purpose and need of the project could not be accomplished in an alternative location, or that locating the project elsewhere is not technically or economically feasible;

- Demonstrate that project infrastructure will be co-located with existing disturbances to the greatest extent possible;

- Develop Site Specific Consultation Based Design Features to minimize impacts through consultation with the SETT; and

- Mitigate for unavoidable impacts through compensatory mitigation via the Conservation Credit System.

Non-Habitat Management Areas

The Non-Habitat Management Areas encompass areas determined to be unsuitable for sage-grouse by the Nevada Habitat Suitability Model (See Section 6.0 for details on technical language). As specified above, all proposed projects within the SGMA, including in non-habitat within SGMAs must conduct habitat evaluation or ground-truthing to confirm presence or absence of sage-grouse habitat. If areas are confirmed by habitat evaluations to be non-habitat, an analysis for indirect impacts on sage-grouse within their habitat in the SGMA will be required to determine if Site Specific Consultation Based Design Features to minimize impacts and compensatory mitigation are necessary as part of the SETT Consultation process (also see Table 3-1).

Minimize

If a project cannot avoid adverse effects (direct or indirect) to sage-grouse habitat within the SGMA, the project proponent will be required to implement Site Specific Consultation Based Design Features (Design Features) that minimize the project's adverse effects to sage-grouse habitat to the extent practicable.

Minimization will include timely consultation with the SETT to determine which Design Features would be most applicable to the project when considering site conditions, types of disturbance, etc. Some general examples could include: reducing the footprint of the project, siting infrastructure in previously disturbed locations with low habitat values, noise restrictions near leks during breeding season, and washing vehicles and equipment to reduce the spread of invasive species. Land use specific Design Features are included in Appendix A.

A list of Design Features for the project must be specified and agreed upon by the SETT and project proponent prior to the start of the project and will become part of the permit/ contract requirements issued for the project. The project proponent will be required to implement, maintain, and monitor the required Design Features in good working order throughout the duration of the project.

Mitigate

Mitigation involves the successful restoration, enhancement, or preservation of sage-grouse habitat and is designed to offset the negative impacts caused by an anthropogenic disturbance. Mitigation will be required for all anthropogenic disturbances impacting sage-grouse habitat within the SGMA. Mitigation requirements will be determined by the State's Conservation Credit System (Section 8.0).

Options for mitigation will be identified in the State's Strategic Action Plan. The State's Strategic Action Plan will identify prioritized areas on public and private lands to implement a landscape scale restoration effort. The plan will identify where the primary threats to sage-grouse habitat are located throughout the State and provide management guidance for how to ameliorate the threats based on local area conditions and ecological site descriptions. The prioritization will include efforts to use mitigation funding in areas where sage-grouse will derive the most benefit, even if those areas are not adjacent to or in the vicinity of impacted populations. This Strategic Action Plan will be updated at least every five years to reflect improvements in understanding, science, and technology for mitigation activities.

3.1.3 Adaptive Management

The SETT, in close coordination with applicable federal and state agencies, will evaluate and assess the effectiveness of these policies at achieving the objective of net conservation gain and will provide a report to the SEC annually. The objective will be considered to have been met if there is a positive credit to debit ratio within the Conservation Credit System on an annual basis. If the State falls short of its objective, the SEC will reassess and update polices and management actions based on recommendations from the SETT using the best available science to adaptively manage sage-grouse habitat.

3.2 Acts of Nature – Fire and Invasive Plants

3.2.1 Conservation Objectives –

The overarching objectives of Nevada's plan is to achieve conservation through the following short and long term objectives for Acts of Nature in order to stop the decline of sage-grouse populations and restore and maintain a functioning sagebrush ecosystem:

Short Term:

- *Reduce the amount of sage-grouse habitat loss due to large acreage wildfires and invasion* or potential domination *by non-native plants.*

Long Term:

- *Maintain an ecologically healthy and intact sagebrush ecosystem that is resistant to the invasion of non-native plants and resilient after disturbances, such as wildfire.*
- *Restore wildfire return intervals to within a spatial and temporal range of variability that supports sustainable populations of sage-grouse and other sagebrush obligate species.*

The Greater Sage-grouse Advisory Committee, using the best available science, identified fire and invasive plant species, principally cheatgrass (*Bromus tectorum*), as the primary threat to sage-grouse and their habitat in the State of Nevada. The State acknowledges these threats must be adequately addressed in order to achieve the conservation goal for sage-grouse within the State of Nevada; however, it is not economically or ecologically feasible to restore all fire damaged or invasive species dominated landscapes at this point, nor is it possible to prevent all fires. The State will put forth a best faith effort to reduce the rate of sage-grouse habitat loss due to fire and invasive plant species. This objective will be measured by evaluating the amount of habitat lost due to fire over a five year rolling period. This will include an evaluation of the amount of habitat gained through post-fire sagebrush re-establishment for those communities with higher resistance and resilience, and the amount of habitat lost post fire which is subsequently dominated by invasive plant species.

3.2.2a Conservation Policies – Fire Management: Paradigm Shift

In order to address the threats of fire and invasive species, which has long challenged land managers throughout the western United States, the State proposes a paradigm shift. This would entail a more proactive, rather than reactive approach, to stop the dominance of invasive species and restore fire to within a range of variability to support sustainable populations of sage-grouse. For specific management actions associated with these policies, refer to Section 7.1 of this State Plan.

3.2.2b Conservation Policies – Invasive Plants: Prevent, Detect, Control, Restore, and Monitor

While wildfire is commonly the vector for the spread of invasive plants, such as cheatgrass, invasive plants are currently widespread throughout the Great Basin and can spread without the aid of wildfire. In order to address the general threat of invasive plants, the State proposes a policy of Prevent, Detect, Control, Restore, and Monitor. For specific management actions associated with these policies, refer to Section 7.1 of this State Plan.

3.2.3 Adaptive Management

Fire and the subsequent reestablishment of plant species (native or not) is a natural process, and consequently this threat is extremely challenging across the western United States as humans are still limited in our ability to directly control this cycle. However, scientific understanding of ecological processes and resource management techniques continues to improve. Adaptive management approaches, committed to by the State, will provide an opportunity to continue to gain a greater understanding of the ecological mechanisms that drive these processes and will subsequently lead to improvements in resource management practices that reduce the occurrence of catastrophic wildfire and minimize the risk of crossing ecological thresholds due to the invasion and subsequent potential domination by invasive annual grasses.

The SETT will evaluate and assess the effectiveness of these policies at achieving the stated short and long term objectives and will provide a report to the SEC annually. The objectives will be met if there is a decrease or leveling off of the amount of habitat loss due to the effect of wildland fire within the SGMA over a five year period. If the State and federal agencies fall short of this objective, the SEC will reassess and update polices and management actions based on recommendations from the SETT using the best available science to adaptively manage sage-grouse habitat.

4.0 DESIRED HABITAT CONDITIONS FOR GREATER SAGE-GROUSE IN NEVADA

The desired habitat conditions for sage-grouse describe what is generally considered to be the highest quality seasonal habitat for greater sage-grouse, specific to Nevada. The desired habitat conditions do not specify what is and what is not habitat, but depict the characteristics of seasonal habitats that sage-grouse in Nevada are using most successfully, based on research, data and observations in Nevada and the Great Basin. The desired habitat conditions are based on current knowledge of sage-grouse selection and demographic rates related to habitat conditions in Nevada and the Great Basin. Management to work towards these desired habitat conditions must be implemented using professional judgement that assesses ecological site descriptions (including current state and potential), adaptive management, and knowledge of authorized land uses and plans. Vegetation community responses to management techniques can be highly variable and may take years to reach desired conditions depending on a multitude of factors. Vegetation communities go through natural and human influenced successional stages over time that may or may not be progressing sites towards the desired habitat conditions. Therefore, monitoring and data collection must be conducted over a sufficient period of time to allow for an accurate accounting of whether or not a site is making progress toward the desired conditions.

The desired habitat conditions will be used to evaluate management actions and site conditions in sage-grouse habitat to ensure that 1) habitats are maintained if meeting desired conditions, or 2) habitats are trending toward these conditions if they are not being met. Management actions in sage-grouse habitats will include site-specific resource objectives (Swanson et al. 2006) using these desired habitat conditions as guidelines, while taking into account ecological site descriptions tied to state and transitions models and other locally relevant resource values and relevant information about management context and commitments. Progress of management actions will be evaluated through long-term monitoring for adaptive management. When habitat within the State is identified as not meeting these desired conditions and there are opportunities and resources available, the State will seek to work with private and public land managers to assess the causal factors and recommend adjustments in management to work towards the desired conditions with site specific resource objectives. **The desired habitat conditions in table 4-1 should not be used to conduct land health assessments and are not regulatory, but are intended to help guide planning for current and future management using adaptive management as a part of the process.** In implementation, managers must have flexibility to manage for these desired sage-grouse habitat conditions along with other desired conditions on the site, taking into consideration existing permitted uses and corresponding management plans. Also, some sites do not have the potential to meet desired sage-grouse habitat conditions, which is why resource objectives must be specific to the site.

The State of Nevada recognizes that a resilient and resistant sagebrush ecosystem should be heterogeneous (a mosaic of multiple seral phases) across the landscape and that achievement of any desired habitat conditions resulting in a large-scale homogenous landscape is not optimum. Thus, the State will work with land managers and advisors to work towards achieving or maintaining a resistant and resilient landscape informed by the desired conditions in Table 4-1 and ecological site descriptions, and to incorporate new science, adaptive management, and incentives in the future that will allow this to occur.

The desired conditions in Table 4-1 should not be reviewed, measured, or managed for, independently. Sage-grouse habitat suitability should be determined by the relationship among several indicator values including ecological site descriptions (including current state and potential) along with the relative abundance of habitat types across the landscape. These conditions apply to an area being used by sage-grouse for the appropriate life stage (microsites) and not across the entire site or landscape. The desired conditions for each seasonal habitat should only be assessed during the appropriate season of use (dates can vary annually based on climatic conditions) and in areas spatially mapped as the relevant seasonal habitat (expected from USGS in May 2015). Habitat types may not be mutually exclusive and therefore may have to be managed to meet multiple conditions or selected for the more limiting habitat in the area. It is important to understand that the desired conditions described for these habitat types are based on average plant productivity, structural data, supporting scientific literature, and expert opinion relative to sage-grouse use of sagebrush communities and they may not apply to all sagebrush communities in the planning area (Davies et al. 2006). These measures also do not account for inter-annual climate variation (e.g., precipitation) (Davies et al. 2006). Herbaceous vegetation, in particular, varies dramatically year to year; measurements for a single given year should not necessarily be used to adjust management decisions or actions. When evaluating herbaceous vegetation in areas grazed in different seasons in different years, it is important to evaluate conditions across the years of rotation, recognizing that effective management for robust healthy plants may leave more or less residual in a specific season of any one year. Individual indicator values do not define site suitability and overall site suitability descriptions require an interpretation of the relationships between the indicators, ecological site descriptions (including current state and potential), and other factors. In order to provide recommendations for management changes and adaptive management, professional expertise and judgment are required to properly assess current conditions. This should include but not be limited to inter-annual climate variation, and authorized uses and their associated plans.

These desired habitat conditions were developed by a team consisting of representatives from the USFWS, NDOW, USFS, USGS, and BLM. The team reviewed the Connelly et al. (2000) guidelines adding considerable detail and making adjustments based on regionally and locally derived data and analysis by the USGS. The State of Nevada’s Science Work Group provided input on the science behind the desired habitat conditions.

Desired Habitat Conditions for Greater Sage-Grouse.

Site-specific objectives should be defined based on ecological site descriptions and current ecological state.

Life Requisite	Habitat Indicator	Objective	Notes
GENERAL/LANDSCAPE-LEVEL			
All Life Stages	Rangeland Health Indicator Assessments	Conduct assessments in sage-grouse habitat and develop site-specific objectives informed by assessments	Pellant et al. 2005
Cover (Nesting)	Seasonal Habitat Needed	>65% of the landscape in sagebrush dominated cover	Aldridge and Boyce 2007
	Annual Grasses	<%5	Blomberg et al. 2012
Security (Nesting)	Conifer Encroachment	<3% phase I (>0- <25%cover) No phase II (25–50% cover) No phase III (>50% cover)	Casazza et al. 2011 USGS (In prep) (A)
Cover and Food (Winter)	Conifer Encroachment	<5% phase I (>0 - <25% cover) No phase II (25–50% cover) No phase III (>50%)	USGS (In prep) (A) USGS (In prep) (B)
	Sagebrush Extent	>85% sagebrush dominated land cover	USGS (In prep) (A) Doherty et al. 2008
LEK (Seasonal Use Period: 1 March – 15 May)

	Sagebrush Height	>9.8 inches (25 centimeters) above snow depth	Connelly et al. 2000 USGS (In prep) (C)

[1] Applicable to Phase I and Phase II pinyon and/or juniper.

[2] Defined as structures that provide nesting resource for Sage-grouse predators using best available science. Does not include fences.

[3] Field collection data for these seasonal habitat delineations should only be taken in the areas mapped as that habitat type (maps expected from USGS in May 2015) and during the appropriate seasonal use period. Seasonal use periods are standardized for the purposes of this table, but may fluctuate annually due to climatic conditions.

[4] Species richness should include some forb species, with consideration given to sage-grouse preferred forb species listed in Stiver et al. In Press.

[5] Site does not have to meet PFC but should be showing progress in trending toward proper functioning condition or have an upward trend if functioning at risk.

[6] Applies to grasses within sagebrush-shrub communities adjacent to riparian area. Sage-grouse generally select for perennial grass heights that are greater than what is randomly available in a given site (USGS unpublished data). Selected heights in Nevada on average range from 4" - 8" (average droop height of live plants) depending upon resistance and resilience mapping and ecological site descriptions (USGS unpublished data). Generally, sites in the northern portion of the management area trend toward the upper end and those in the southern portion trend toward the lower end of the height range (USGS unpublished data).

5.0 IMPLEMENTATION RESPONSIBILITIES

The creation of the Sagebrush Ecosystem Program (SEP) was one of the main recommendations of the 2012 Governor's Sage-grouse Advisory Committee. The SEP consists of the Sagebrush Ecosystem Council (SEC) and the Sagebrush Ecosystem Technical Team (SETT). The program is established under the Department of Conservation and Natural Resources – Division of State Lands. The program is a collaborative, multi-stakeholder approach, charged to carry out programs to preserve, restore, and enhance sagebrush ecosystems in the State of Nevada. In addition, the SEP will work with Local Area Working Groups (LAWGs) and Conservation Districts to help identify and implement on-the-ground sage-grouse and sagebrush ecosystem conservation efforts. Also, the SEP will work with local governments to avoid conflicts with sage-grouse habitat, including but not limited to urbanization issues.

Sagebrush Ecosystem Council (SEC)

The SEC was originally established under Executive Order 2012-19 and later codified under state statute NRS Chapter 232.162. The SEC consists of a nine voting member board, appointed by the Governor with representatives from the following interests: agriculture, energy, general public, conservation and environmental, mining, ranching, local government, Native American tribes, and Board of Wildlife Commissioners. In addition, the state directors of the Nevada Departments of Conservation and Natural Resources (DCNR), Wildlife (NDOW), and Agriculture (NDA), as well as the state directors for the federal agencies of BLM, USFWS, and HTNF serve as ex-officio members. The SEC is responsible for determining policy associated with the sagebrush ecosystem and sage-grouse.

The objective of the SEC is to establish and guide a consistent, transparent process to coordinate disturbance and conservation activities and set policy in the SGMA in order to provide for a resilient and resistant sagebrush ecosystem and stable or increasing sage-grouse populations.

The specific duties of the SEC include:

- Consider the best science available in its determinations regarding the conservation of sage-grouse and sagebrush ecosystems in this State;
- Establish and carry out strategies for: 1) the conservation of the sage-grouse and sagebrush ecosystems in this State; and 2) managing land that includes those sagebrush ecosystems, taking into consideration the importance of those sagebrush ecosystems and the interests of the State;
- Establish and carry out a long-term system for carrying out strategies to manage sagebrush ecosystems in this State using an adaptive management framework and providing for input from interested persons and governmental entities;
- Oversee the SETT;
- Establish and set policy for the Conservation Credit System (CCS);
- Solicit suggestions and information and, if necessary, prioritize projects concerning the

enhancement of the landscape, the restoration of habitat, the reduction of nonnative plants and the mitigation of damage to, or the expansion of, scientific knowledge of sagebrush ecosystems;

- If requested, provide advice for the resolution of conflict concerning the management of the sage-grouse or a sagebrush ecosystem in this State;
- Coordinate and facilitate discussion among persons, federal and state agencies, and local governments concerning the maintenance of sagebrush ecosystems and the conservation of the sage-grouse;
- Provide information and advice to persons, federal and state agencies and local governments concerning any strategy, system, program or project carried out under this State Plan;
- Provide direction to state agencies concerning any strategy, system, program or project carried out pursuant to this State Plan and resolve any conflict with any direction given by another state board, commission, or department jointly with that board, commission or department, as applicable;
- Submit semi-annual program progress reports to the Governor;
- Pursuant to the "Inter-Tribal Council of Nevada, Inc. Resolution & Letter of Support," (Appendix C) integrate Tribal participation in the statewide conservation effort, and acknowledge traditional Tribal ecological knowledge when available to update SGMA;
- Establish policies for the identification and prioritization of landscape-scale enhancement, restoration, fuel reduction, and mitigation projects based upon ecological site potential, state and transition models, and other data that will contribute to decision making informed by science to increase resiliency; and
- Encourage and facilitate land management education and training for all user groups of sage-grouse habitat.

Sagebrush Ecosystem Technical Team (SETT)

The SETT is a multi-disciplinary, interagency team with representation from DCNR – Divisions of State Lands and Forestry, NDOW, and NDA. The SETT serves as staff to the SEC and advises them on the best available science.

The objective of the SETT is to implement a multi-disciplinary approach for the administration of this State Plan that incorporates various scientific and technical expertises and provides a well-defined process for assessing impacts and permitting activity in the SGMA.

The specific duties of the SETT include:

- Serve as staff to the SEC and advise the SEC on the best available science in order for them to set policy;
- Develop a comprehensive State Plan based on the recommendations from the Governor's Sage-

grouse Advisory Council;

- Oversee the day-to-day implementation of the goals, objectives, and management actions established under this State Plan. Propose revisions to the State Plan as needed;
- Coordinate the development of the CCS. In accordance with SEC policy, administer and operate the CCS once it is established;
- Work with the USGS and other technical experts to development sage-grouse habitat and management maps;
- Establish and manage a process in cooperation with applicable federal and state agency partners to update sage-grouse habitat and management maps using the best available science;
- Coordinate with the BLM and USFS and other federal and state agencies on the development of the Nevada and Northeastern California Greater Sage-grouse Land Use Plan Amendment (LUPA) and Environmental Impact Statement (EIS);
- Enter into an MOU with the BLM and USFS for agency coordination on sage-grouse management and administration of the CCS;
- Compile and submit state-wide data for the USFWS data call for the sage-grouse listing decision;
- Work with scientific and technical experts for advice on the best available science for implementing and updating management actions;
- Identify and prioritize landscape-scale enhancement, restoration, fuel reduction, and mitigation projects based upon ecological site potential, state and transition models, and other data that will contribute to decision making informed by science to increase resiliency following wildfire;
- Provide timely consultation for project proponents who want to conduct activities in the SGMA to avoid, minimize, and mitigate impacts to sage-grouse. This will likely include robust ground-truthing for the presence or absence of habitat. Foster and maintain collaborative processes with state and federal agencies to expedite state and federal permitting, while providing for the conservation of sage-grouse;
- Secure grants and other funding opportunities to implement habitat enhancement and restoration projects;
- Develop and oversee a monitoring and adaptive management program and provide recommendations to the SEC on how to update policies based on new information learned; and
- Establish a geographic database repository to maintain the inventory of development and mitigation projects, population data, and monitoring results.

Local Area Working Groups (LAWGs)

The LAWGs provide all stakeholders with an opportunity to work together in actively managing and restoring landscapes across boundaries. Even with collaboration there is a realization that to be successful there is a need for more investment from all sources to achieve sage-grouse conservation objectives. LAWG membership includes representation from private land owners, tribes, federal land management agencies, local governments, conservation districts, USFWS, USGS, NDOW, NGO, USDA-ARS, UNR, NRCS, DOD, sportsmen, mining, energy, Off-Highway Vehicle (OHV) users, agricultural and environmental interests.

The SEP will work with the LAWGs to:

- Develop and implement site-specific plans to accomplish enhancement and restoration projects in areas that are identified by the SEP as important areas for sage-grouse conservation;
- Monitor and adaptively manage conservation actions;
- Identify potential habitat enhancement and restoration projects; and
- Provide local, site-specific expertise on a variety of issues.

Conservation Districts Program (CDP)

The CDP provides administrative support to the State Conservation Commission, which develops policy and regulations for Nevada’s twenty-eight locally elected conservation districts. The CDP is comprised of a program coordinator and three staff specialists stationed in Elko, Ely, and Winnemucca. The CDP’s role in the implementation of this State Plan is to assist in the development of on-the-ground conservation projects.

The SEP will work with the CDP to:

- Implement on-the-ground conservation and mitigation projects identified by the SEP and LAWGs, including perusing grants and other funding opportunities. Provide recommendations to the SEP on possible additional projects; and
- Facilitate communication between individual CDs, SEP, LAWGs, and other stakeholders in order to more effectively achieve on-the-ground conservation.

Local Governments

Thirteen of Nevada’s seventeen counties, as well as several cities are located within the SGMA.

The SEP will work with local governments:

- When a county or city considers a change to its master plan for a land use of higher intensity affecting the SGMA.
- To address any potential conflicts with sage-grouse habitat.

6.0 MAPPING

The SEP contracted with the USGS to serve as the lead technical and science advisor for the development of habitat suitability index (HSI) for sage-grouse in Nevada using resource selection function (RSF) modeling. The SEP used the HSI to develop habitat and management maps to be implemented through this State Plan. The SETT assembled an Expert Review Team, comprised of local sage-grouse technical experts from the UNR, BLM, NDOW, USFWS, and HTNF to advise the SETT on technical aspects of the mapping process.

Methods

The State's process for developing spatially explicit maps for sage-grouse habitat and sage-grouse management areas was completed in four stages: 1) development of the HSI; 2) classification of the HSI into suitability categories; 3) development of a space use index; and 4) merging the habitat suitability categories and space use index to develop management categories. The methods for each of these stages are outlined below.

Habitat suitability index

Model averaged RSFs were used to develop HSIs that ranked areas of the State based on a continuum of sage-grouse selection, from highly selected for to strongly avoided. The modeling is driven by actual location data obtained using radio-telemetry information, informed by >31,000 telemetry locations from >1,500 radio-marked sage-grouse across 12 study areas within Nevada and California collected over a 15-year period, and by environmental factors including land cover composition, water resources, habitat configuration, elevation, and topography, each at multiple spatial scales that are relevant to sage-grouse movement patterns. The modeling process contrasted these environmental factors for sites used by sage-grouse (telemetry data) with available sites (randomly generated locations). Contrasting the environmental factors of used versus available sites provided information about what factors were correlated with greater sage-grouse selection or avoidance (e.g., streams, pinyon-juniper).

RSFs were applied to calculate an overall probability of use per pixel[2]. This created a single sage-grouse HSI and resulted in a surface of predicted use by sage-grouse across Nevada. This surface, the HSI, is represented by probability values that range across a continuous spectrum of 0.0 to 1.0 (Figure 5).

Habitat Suitability Categories

To identify suitable habitat, the HSI described above was classified into three categories of suitability (high, moderate, and non-habitat) using cutoff values based on the standard deviation (SD) from the mean HSI ($\bar{x}$) value. High suitability habitat was comprised of all HSI values greater than 0.5 SD below $\bar{x}$. Moderate suitability habitat was comprised of HSI values between 1.5 and 0.5 SD below $\bar{x}$. Non-suitable habitat was comprised of HSI values 1.5 SD below $\bar{x}$. This bottom cut-off point was validated by a cost-benefit ratio looking at the trade-off between additional area to telemetry points. The equalization

---

[2] Pixels are the 30 x 30 meter resolution of the RSFs.

point occurs at 1.5 SD. The resulting habitat categories were then aggregated at the 1 km scale to account for corridors and smoothed at the 1.2 km scale to remove "islands" (Figure 3).

Space use index

An index of space use was developed based on lek attendance and density coupled with probability of sage-grouse occurrence relative to distance to nearest lek. This index was then categorized into two categories: high use and low to no use. High use consisted of areas that included up to 85 percent of the highest space use index density and low-to-no use consisted of areas with less than 15 percent.

Management Categories

To create a management prioritization for the implementation of this State Plan, the habitat suitability classes were intersected with the space use categories as follows:

> **Core Management Areas** – areas of suitable sage-grouse habitat that are found within areas of estimated high space use;
>
> **Priority Management Areas** – high suitability habitats that are found in areas of estimated low space use and areas of non-habitat that overlaps with areas of estimated high space use;
>
> **General Management Areas** – moderate suitability habitats that are found in areas of estimated low space use; and
>
> **Non-habitat Management Areas** – non-suitable habitats that are found in areas of estimated low space use (Figure 4).

Full methods for the development of the Nevada HSI, Habitat Suitability Map, and Management Category Map are detailed in "Spatially Explicit Modeling of Greater Sage-Grouse Habitat in Nevada and Northeastern California: A Decision Support Tool for Management" (Coates et al. 2014).

The Nevada sage-grouse habitat and management mapping process is a product of the SETT and is a collaborative group process with state and federal agency review and input and with the USGS serving as the scientific contractor on the habitat suitability model.

Map revisions

This mapping effort is iterative and is intended to inform and better define aspects of the State Plan. To that end, the habitat and management mapping process will be reviewed and refined every 3 to 5 years. New or improved spatial data (*e.g.*, additional sage-grouse telemetry data, updated or improved vegetation community data) will be incorporated during the refinement process. The review and refinement process will be scientifically based and include review and input from SETT, NDOW, BLM, USFS, and USFWS. Other stakeholders will be encouraged to participate in the process by submitting relevant information to the listed agencies. It is anticipated that the habitat suitability modeling processes will be the basis for refinements, unless more rigorous methods are developed.

Project assessment under SETT Consultation will be based on the map that is current at the commencement of the review process. If a new map becomes available after the review process has begun, the previous version of the map will continue to be used. If the project proponent proposes changes in scope of the project, then the assessment will be based on the revised map. In addition, individual projects will typically include on the ground habitat determinations for the presence or absence of habitat.

7.0 THREAT ASSESSMENT—GOALS, OBJECTIVES, AND MANAGEMENT ACTIONS

Threats to sage-grouse and their habitats in Nevada were based on those identified in USFWS' 2010 proposed rule for sage-grouse and further developed in their Conservation Objectives Team Report, as well as from input by local areas experts. The list of threats and proposed actions was originally determined by the Advisory Committee and further developed in greater detail by the SEP.

7.1 Fire and Invasive Plants

In 2012, Nevada's Greater Sage-grouse Advisory Committee, using the best available science, identified fire and invasive plants, principally cheatgrass, as the primary threat to sage-grouse and their habitat in the state of Nevada. Wildland fires and the subsequent invasion or potential domination by cheatgrass and other invasive plants continue to create large-scale habitat loss and fragmentation (Figure 6 and Figure 7). This current rate of habitat loss is not sustainable for long-term sage-grouse population persistence.

While the vast majority of fires in sage-grouse habitat are suppressed in the initial attack phase, the continued loss of large areas in sage-grouse habitat occurs most often during periods of 'Extreme Fire Danger Conditions' when fire behavior has the greatest impact on suppression capabilities. These 'Extreme' conditions can exist simultaneously over large areas of the western U.S, creating a shortage of regional/national firefighting assets due to pre-existing large fires with greater values at risk (Murphy et al. 2013).

In Nevada and throughout the western United States, the years in which the highest number of acres burned occurred after wet productive growing seasons that produced abundant fine fuels. Consecutive wet years can add to residual fine fuels. An unprecedented series of four wet years in 1995-1998 was followed by an unprecedented three years in 1999-2001 during which more than 2.75 million acres burned in Nevada (Littell et al. 2009). Woody fuels become most flammable when lack of fire or a fire surrogate vegetation management allows woody fuel to accumulate. Many areas of Nevada that prehistorically burned every few decades have not burned for over a century (Gruell and Swanson 2013).

The State acknowledges these threats must be adequately addressed in order to achieve the conservation goal for sage-grouse and actions must be taken to increase overall preparedness, strategically locate fuels management projects using resistance and resilience concepts (Chambers et al. 2014), increase local suppression capabilities, and improve rehabilitation/restoration capabilities.

To this end, the State has begun to address these threats by creating the Sagebrush Ecosystem Program, composed of the Sagebrush Ecosystem Council, with its attendant Sagebrush Ecosystem Technical Team, to develop and approve a state plan that facilitates best available science review and technology transfer to State and local agencies and to work in coordination with federal land managers and other public and private partners. In addition, the State has also approved and is implementing the Nevada

Division of Forestry's (NDF) Wildland Fire Protection Program, which allows for full implementation of Nevada Revised Statute, Chapter 472, improving delivery of financial, technical and wildland firefighting equipment/human resources to Nevada counties in fuel reduction planning and implementation, wildfire management and suppression and short and long term restoration of burned areas.

As well, the SAP, to be developed subsequently to this State Plan, will draw on concepts of resistance and resilience as a multi-scale approach to prioritize management actions for sage-grouse. Chambers et al (2014) outlines the role of these concepts relative to fire cycle and the role of annual invasive grasses. The SETT will participate in the interagency collaborative Fire, Invasive Assessment Team (FIAT) that has developed a step-down process (FIAT 2014) based on Chambers et al. 2014 to identify management projects focused in key sage-grouse habitat to address the continual threat of fire and invasives, as well as conifer encroachment. Projects identified through the FIAT will be incorporated into the SAP, as appropriate.

Nevada Revised Statute (NRS) Chapter 555 and Nevada Administrative Code (NAC), Chapter 555 address both noxious and invasive plants, their status, and any regulations regarding the control of such plants. The State has established a priority list of noxious weeds that require some form of control. Other widespread invasive plants, such as cheatgrass, while not on the noxious weed priority lists, pose a significant threat to Nevada's landscapes and habitats and will be addressed on a priority basis, particularly when they compromise sage-grouse desired habitat conditions (see Section 4.0).

The introduction of exotic invasive plant species in Nevada has likely been occurring since the early European settlers arrived and has been intentionally and unintentionally occurring since that time. While some species may go seemingly unnoticed, many currently pose significant threats to the sagebrush ecosystem, wildlife habitats, and our landscape in general. While all of these identified species are currently considered by the State as invasive plants, some warrant further declaration as 'noxious'. Noxious weeds are defined in NRS 555.130 as: "Any species of plant which is likely to be detrimental, destructive or difficult to control, but is not already introduced and established in the State to such an extent as to make its control or eradication impracticable in the judgment of the State Quarantine Officer". Plants that do not meet this definition are generally considered to be invasive or nuisance weeds. Cheatgrass falls into the 'invasive' category due to its expansive footprint within Nevada's sagebrush ecosystem.

Cheatgrass is an exotic species from the Middle East that was introduced in North America in the late nineteenth century and has become one of the most adaptive and dominant invasive plants in the Western U.S. This is especially true following fire and other major ground disturbing activities in sagebrush ecosystems, particularly at lower elevations and precipitation zones in Nevada.

Many factors will be considered when prioritizing treatments for fire and invasive plants (i.e. noxious weed presence, sage-grouse breeding densities, habitat suitability (abundance, quality, and connectivity), existing additional threats, resistance, resilience, ecological site description, state and transition models, etc.). Additionally, further prioritization may be determined by the type of action required (conservation related, prevention based, or restoration or rehabilitation activities), presence of or proximity to sage-grouse habitat, and the amount of funding available for treatment in a given year.

Goals, Objectives, and Management Actions

The overarching direction of Nevada's plan is to stop the decline of sage-grouse populations and restore and maintain a functioning sagebrush ecosystem. Currently, it is not economically or ecologically feasible to restore all fire damaged or invasive plant dominated landscapes, nor is it possible to prevent all fires, though the State acknowledges that this threat must be addressed in order to provide for the conservation of sage-grouse. In order to achieve this goal, the State will take a phased approach through a series of short term and long term objectives and management actions. The State will first seek to reduce the amount of habitat loss, with the long-term objective of restoring ecosystem functions and processes. This will require a concerted and consistent commitment to achieve these objectives over the long-term.

The State has already taken steps to achieve these objectives through statewide adoption and implementation of the Nevada Division of Forestry's Wildland Fire Protection Program, creating a tiered system that gives equal priority to cooperative pre-suppression fire prevention projects; adopting and incorporating National Wildfire Coordination Group (NWCG) approved training and firefighting techniques that can help preserve habitat; and, cooperative post-suppression rehabilitation and restoration activities in and around areas of important habitat.

Goal 1: Ameliorate the threat of fire and invasive plants in order to provide for the conservation of sage-grouse and their habitat.

Short term objectives and management actions:

Objective 1.1: Reduce the amount of sage-grouse habitat loss due to large acreage wildfires and invasion or potential domination by non-native plants.

Pre-suppression

In order to address the threat of fire and invasive plants, which continues to challenge land managers throughout the western United States, the State proposes a paradigm shift. This entails a shift in focus from the current suppression-centric approach to a more nuanced, cost effective, and proactive approach focusing on pre-suppression activities; which if adequately supported, will contribute greatly to Federal, State and local efforts to stop the dominance of invasive plants, reduce catastrophic wildfire incidence, and restore fire to within a range of variability to support sustainable populations of sage-grouse in Nevada.

Management Action 1.1.1a: Develop, and provide sustainable, predictable federal, state, and local funding sources for pre-suppression activities (including maintenance) separate from funding for suppression and post-fire rehabilitation activities.

Management Action 1.1.1b: Dedicate funding to plan and implement cost effective pre-suppression activities with an emphasis on strategic, scalable cooperative projects informed by best available science; utilize cost efficient methods and tools; and follow up with effective, repeatable monitoring.

Management Action 1.1.1c: Make decisions regarding pre-suppression planning and fuels management projects based on best available science. This information will be incorporated into the planning process to inform locations of landscape and local scale fuels management projects and to provide protection to areas of sage-grouse habitat that have compromised resilience, resistance, and heterogeneity.

Management Action 1.1.1d: Prioritize pre-suppression fuels management projects, fire prevention planning, and invasive plant control activities in and around Core and Priority Management Areas. Pre-suppression projects will be identified, designed and prioritized so that they facilitate firefighter safety, protect private property, prioritize important sage-grouse habitat, and work to maintain natural resource functions.

Management Action 1.1.1e: Establish, maintain, and fund an effective, repeatable pre-suppression monitoring and adaptive management program that informs future project planning and implementation.

Suppression

State and federal agencies will provide safe, cost-effective fire management programs that support the conservation of sage-grouse habitat through collaborative planning, coordination, training, staffing, resource allocation, and fire management oversight.

Management Action 1.1.2a: Support robust, coordinated, and rapid fire suppression management using a diversity of agencies, including federal, state, tribal and local government, as well as creating, empowering and training (to latest Nevada and National Wildfire Coordinating Group (NWCG) standards) Rural Fire Associations, Fire Protection Districts and Wildfire Support Groups.

Management Action 1.1.2b: Support and improve interagency wildfire prevention activities and education statewide, including: interagency agreement updates, wildfire workshops, demonstration projects, and public service announcements on wildfire and sage-grouse habitat loss.

Management Action 1.1.2c: When prioritizing wildland firefighting actions in the Sage Grouse Management Area (SGMA), give priority to Core Management Areas, followed by Priority and General Management Areas during fire operations.

Management Action 1.1.2d: Use wildland fire strategically to accomplish resource management objectives. Fire may not have to be suppressed in all instances. Resource and fire managers should consider beneficial fire use if located in areas that may benefit sage-grouse habitats, but only if:

- it would not risk the net spread of invasive plants;
- human lives, property, and important natural resource functions are not at risk;

- wildland fires exhibit prescribed/desired fire behavior characteristics and are located in designated sage-grouse habitats appropriate for beneficial fire use.

Management Action 1.1.2e: Manage wildland fires in sage-grouse habitat to retain as much habitat as possible. Interior unburned islands of vegetation in areas of habitat should be protected through follow-up mop-up of the island's perimeter and interior, when fire crew safety is not at risk.

Post-Fire Restoration/ Rehabilitation

Emergency stabilization (ES) and burned area rehabilitation (BAR) funding streams are instrumental in the process of stabilizing soils and reestablishing adapted perennial vegetation on federal lands post-fire. Currently, these programs provide funding for rehabilitation treatment immediately post-fire, which does not reflect the need to accommodate for poor initial success due to lack of precipitation and other environmental variables.

Management Action 1.1.3a Work with federal, tribal, and local governments to develop dedicated funding sources that allow for up to five years of additional post-fire restoration treatments in order to better ensure projects meet goals and objectives.

Management Action 1.1.3b Until such time as dedicated funding sources for multi-year post-fire restoration treatments can be developed, federal, state, tribal, and local governments should submit budget requests and projections that reflect the need for funding that will cover actual and contingent yearly costs associated with successful multiyear post-fire rehabilitation efforts.

Management Action 1.1.3c: Use the concepts of resistance and resilience and products developed by BLM's FIAT (Fire and Invasives Assessment Team) group to determine if post-fire restoration actions are necessary to trend towards sage-grouse desired habitat conditions (see Section 4.0).

Management Action 1.1.3d: Control the spread of invasive plants post-fire.

Management Action 1.1.3e: Use collaborative and strategic approaches in post-fire rehabilitation efforts in sage-grouse habitat. Federal, state, tribal and local agencies should coordinate and collaborate on rehabilitation projects in sage-grouse habitat where responsibilities and land ownership interests intersect.

Management Action 1.1.3f: Design post-fire restoration treatments in Core, Priority, and General Management Areas to trend towards sage-grouse desired habitat conditions (see Section 4.0). Consider the use of native plant materials based on availability and probability of success. When native plant materials are not available or the probability of success is low, use non-native plant materials that will best work towards achieving sage-grouse desired habitat conditions. All seed used on rehabilitation and restoration projects must be labeled source identified or certified seed, as appropriate. All mulch, straw or gravel/earth materials used in rehabilitation and restoration projects must be certified weed free to the North American Invasive Species Management Association (NAISMA) standards.

Management Action 1.1.3g: Monitor post-fire restoration treatments to ensure long term persistence of restored habitat, and that the monitoring continues at least until treatment objectives are met.

Invasive plants

While wildfire is commonly the facilitator for the domination of invasive plants, such as cheatgrass, invasive plants are currently widespread throughout the Great Basin and can spread without the aid of wildfire. In order to address the general threat of invasive plants, the State will pursue a strategy of Prevent, Detect, Control, Restore, and Monitor, using the best available science. The Nevada Department of Agriculture (NDA) will utilize its EDDMapS program to assist the State in the implementation of these efforts.

Management Action 1.1.4a**:** *Prevent* the establishment of invasive plants into uninvaded sage-grouse habitat. This will be achieved by conducting systematic and strategic detection surveys, data collection, and mapping of these areas and engaging in early response efforts if invasion occurs. This will be achieved by further developing federal and state partnerships and working with counties, cities, and local groups, such as Weed Control Districts, Cooperative Weed Management Areas, and Conservation Districts. This is a priority for invasive plant control in the state of Nevada.

Management Action 1.1.4b: Apply Design Features to proposed anthropogenic disturbance (see Appendix A) in order to minimize land disturbance and prevent the spread of invasive plants.

Management Action 1.1.4c: Require anthropogenic disturbance proponents to monitor for the existence of invasive plants pre-disturbance and to report all findings to the NV EDDMapS database. Pre- and post-disturbance activities must include prevention strategies prior to entering sites, control, restoration, and monitoring for a minimum of three years or until the site is deemed noxious and invasive weed free following the disturbance. All sites must be certified weed free prior to any relinquishment of obligations that authorized the disturbance.

Management Action 1.1.4d: *Detect* new invasive plant infestations, whether it is a single plant or a small patch. If it can be detected and mapped early in the invasion and control begins immediately, then the likelihood for eradication will increase dramatically. NDA will use its EDDMapS program to assist in the effective and efficient implementation of this action.

Management Action 1.1.4e: Within sage-grouse habitat, and where funding may be a limiting factor, prioritize the control of invasive plants that are compromising attainment of sage-grouse desired habitat conditions (see Section 4.0).

Management Action 1.1.4f: Rehabilitate sites that are ecologically functioning, but at risk of crossing an ecological threshold and becoming nonfunctional due to already being compromised by invasive plants, to trend towards sage-grouse desired habitat conditions(see Section 4.0). Rehabilitation may include re-vegetating sites with native plants cultivated locally or locally adapted, or non-native plant species where appropriate. Any rehabilitation project where invasive plants already occur or may be found in close proximity should include an invasive plant treatment and monitoring component within the plan.

Management Action 1.1.4g: Use ecological site descriptions and associated state and transition models to identify target areas for resiliency enhancement or restoration. Maintaining or enhancing resilience should be given top priority. In the Great Basin sagebrush-bunchgrass communities, invasion resistance and successional resilience following disturbance are functions of a healthy perennial bunchgrass component. Therefore a combination of active and passive management will be required to ensure this functionality. Areas that are in an invaded state that will likely transition to an annual grass monoculture if a disturbance occurs and are located within or near sage-grouse habitat should be prioritized for pre-fire management favoring native and adapted perennials and post-fire restoration efforts to increase resistance and resilience.

Management Action 1.1.4h: Engage climatological and meteorological professionals and their agencies to identify opportunities to increase both effectiveness and efficiency in the timing of restoration activities. Additional activities could include weather augmentation through cloud seeding, and assistance with both short term and longer term weather prediction model guidance or shorter term weather indicators.

Management Action 1.1.4i: Monitor and adaptively manage to ensure effectiveness of efforts to prevent, detect, control and restore. Use the resource mapping functions within EDDMapS to identify and map infestations as well as any prevention, restoration, or rehabilitation efforts.

Long term objectives and management actions:

Objective 2a: Maintain an ecologically healthy and intact sagebrush ecosystem that is resistant to the invasion of non-native species and resilient after disturbances, such as wildfire.

Objective 2b: Restore wildfire return intervals to within a spatial and temporal range of variability that supports sustainable populations of sage-grouse and other sagebrush obligate species.

Management Action 1.2.1 Develop consistent and dedicated funding sources in order to provide a consistent commitment to pre-suppression, suppression, post-fire restoration, and invasive plant management actions described above.

Management Action 1.2.2: Work collaboratively with federal, state, tribal, and local governments, as well as private entities to consistently implement the management actions described above.

Management Action 1.2.3: Monitor all management actions to evaluate and assess their effectiveness at achieving objectives and use this knowledge to adapt management plans.

Management Action 1.2.4: Emphasize continued research and provide funding for research and monitoring to enhance knowledge and understanding of how to further reduce the prevalence of catastrophic wildfire. Minimize the risk of crossing ecological thresholds due to the invasion and subsequent potential domination by invasive annual grasses, use fire behavior prediction to optimize fire management, and improve rehabilitation/ restoration techniques.

7.2 Pinyon-Juniper Encroachment

In Nevada, pinyon and juniper (P-J) woodlands are composed of single leaf pinyon pine (*Pinus monophylla*) and Utah juniper (*Juniperus osteosperma*) (Figure 8). In northwestern Nevada pinyon and Utah juniper are replaced with western juniper (*J. occidentalis*). P-J woodlands currently cover 13% of Nevada, or approximately 9.1 million acres (Mitchell and Roberts 1999). Of the 9.1 million acres in Nevada, approximately 64% is found on BLM land, 26% on USFS land, 5% on private land, and the remaining 5% on other lands (DOD, NRC, USFWS, BIA, etc.)(DCNR-NDF 2010).

From a historical standpoint, the area occupied by pinyon or juniper has increased 125 to 625 percent since 1860. The increase in trees is a result of infill into shrub-steppe communities that contained low numbers of trees, and expansion of P-J into areas that previously did not support trees. (Miller et al. 2008). Potential reasons for the expansion may include: altered fire regimes, improper livestock grazing, natural range expansion, and changing climate (Romme et al. 2009).

In Nevada, P-J encroachment is ranked as the second highest threat to sage-grouse, after fire and invasive plants. This continued woodland expansion is a challenge for land and wildlife managers, with two primary concerns being the continuing steady conversion of sagebrush habitat to woodland and increased risk of large area destructive wildfires that may convert woodlands to monocultures of invasive annual grasses and other weedy species.

Pinyon – Juniper Woodland Encroachment into Sagebrush Communities – Characterization
P-J woodland encroachment is characterized by three phases (Miller et al 2005):

- Phase I – Trees are present but shrubs and herbaceous vegetation are the dominant vegetation that influences ecological processes on the site;
- Phase II – Trees are co-dominant with shrubs and herbaceous vegetation and all three vegetation layers influence ecological processes on the site; and
- Phase III – Trees are the dominant vegetation and the primary plant layer influencing ecological processes on the site.

If a wildfire occurs before Phase III is reached, the original vegetation community has an opportunity to return to the site via successional pathway that is dependent upon the fire's surviving plant species, seed produced by the remaining shrubs, surviving herbaceous vegetation, or their viable seed remaining in the soil seed bank. This return to the original community is also dependent on the native plants being abundant enough to out compete any on-site invasive annual grasses like cheatgrass or medusahead grass (*Taeniatherum caput-medusae*) and perennial invasive weeds (e.g. knapweeds, etc.) following the fire.

With time, and little or no fire, these invaded brush communities become Phase III woodlands, characterized by very little understory, the only evidence of the former plant community being skeletons of sagebrush and other woody brush species and a sparse population of weakened herbaceous plants . At this point, run-off from the soil surface of spaces between trees increases, due to the loss of herbaceous ground cover. In turn, the increased rate and speed of soil erosion can trigger difficult to reverse changes to the biogeochemical cycles of the plant community. If a fire burns through the woodland at this point, the potential for the area to return to a sagebrush plant community is greatly reduced, particularly if cheatgrass, medusahead, or perennial invasive weeds are present in the understory.

The risk of conversion to annual and perennial invasive plants increases as trees grow from phase II to phase III, with the threshold occurring at about >40% relative cover of trees compared to <60% cover of shrubs and herbaceous plants. Prior to this threshold, fire sustains long-term sagebrush ecosystem resilience. After this threshold, fire leads to potential domination by invasive annuals or perennials without effective re-vegetation by perennial grasses (Miller et al. 2005).

In the Great Basin there are approximately 100,000 + acres a year moving into Phase III woodlands. (Miller et al.2008). At this rate of encroachment, management of sagebrush habitats becomes a race between a potentially permanent loss of sagebrush habitat to P-J woodland versus how much Phase I and II woodlands can reasonably be treated each year before they reach Phase III.

Land managers have to consider removal of trees from areas that historically have been sagebrush dominated as a priority activity. Numerous studies have documented the expansion of P-J woodlands into sagebrush communities (Cottam and Stewart 1940; Adams 1975; Burkhardt and Tisdale 1976; Tausch et al. 1981; Tausch and West 1988, 1995; Gedney and others, 1999; Miller and Rose 1995, 1999; Miller et al. 2005). In recent years, research has looked at woodland dynamics and new approaches to measure the extent that P-J has replaced or are encroaching sagebrush communities, versus dynamics on sites that have supported woodlands in the past (Miller et al.2008).

Another area of recent research increasing land managers understanding of vegetation dynamics and increasing decision making options is the inclusion of concepts of resistance and resilience. These concepts can be used in conjunction with sage-grouse habitat requirements to develop lists of appropriate management actions and to identify effective management strategies at landscape scales (Wisdom and Chambers 2009 & Chambers et al. 2014).

Pinyon – Juniper Woodland Encroachment into Sagebrush Communities – Greater Sage-grouse Impacts

The continued expansion of woodland has become a primary threat to greater sage-grouse and other sagebrush obligate wildlife species. In the instance of sage-grouse, woodland expansion contributes to the loss of important seasonal habitats. It also increases raptor presence and predation associated with the coniferous trees (Commons et al. 1999). Several studies demonstrate that sage-grouse avoid areas encroached by P-J, show that P-J removal will increase sage-grouse habitat quality, and provide some evidence that sage-grouse will return to an area once P-J is removed:

- During both the breeding and summer seasons, sage-grouse preferred cover types with less than 5% juniper canopy cover compared to those same cover types with greater than 5% juniper canopy cover. (Freese 2009).

- Juniper can also indirectly influence sage-grouse avoidance of habitats through its influences on plant community compositional and structural changes, such as a reduction in the herbaceous understory (Knapp and Soule 1998, Miller et al. 2000).

- Sage-grouse avoided conifers at the 0.65 km scale (850m x 850m). Sage-grouse avoided mixed sagebrush/tree (≤40 trees/ha) at scales of 7.3 and 159.2 ha. Avoidance was most statistically supported when patch widths exceeded 200 m (Doherty 2008).

- Sage-grouse avoid areas encroached by P-J at scales of 7.9 ha to 226.8 ha (Casazza et al 2011).

- Recent modeling efforts by the Sage-grouse Initiative have shown that no leks remained active when P-J cover exceeded >4% and recommended focusing P-J removal treatments in Phase I stands (Baruch-Mordo et al 2013).

- Research focused on treatment effectiveness indicated that mechanical tree thinning increased native understory biomass by 200 percent (Brockway et al 2002).

- Removal, by cutting, of pinyon- juniper trees/shrubs in association with brush-beating to reduce height of mountain big sagebrush and deciduous brush resulted in doubling numbers of male sage grouse counted on treatment leks in years 2 and 3 post-treatment (Commons 1999).

Goals, Objectives, and Management Actions

Goal 1: Establish and maintain a resilient sagebrush ecosystem and restore sagebrush vegetation communities in order to provide for the conservation of sage-grouse and their habitat.

Objective 1.1: Reduce the expansion of P-J woodlands into otherwise suitable sage-grouse habitat.

Management Action 1.1.1: Inventory and prioritize areas for treatment of Phase I and Phase II encroachment that is contiguous with suitable sage-grouse habitat in Core, Priority, and General Management Areas in order to achieve sage-grouse desired habitat conditions (Table 4.1). Treat areas that have the greatest opportunity for recovery to suitable sage-grouse habitat based on ecological site potential.

Management Action 1.1.2: Prioritize areas for treatment of Phase III pinyon-juniper encroachment in strategic areas only to break up continuous, hazardous fuel beds, create movement corridors, or connect habitats. Treat areas that have the greatest opportunity for recovery to suitable sage-grouse habitat based on ecological site potential. Old growth trees should be protected on woodland sites.

Management Action 1.1.3: Aggressively implement plans to remove Phase I and Phase II encroachment in areas contiguous with suitable sage-grouse habitat. Only treat areas in Phase III encroachment to reduce the threat of severe conflagration, create movement corridors, or connect habitats. Phase III treatments may need additional rehabilitation/restoration actions if perennial understory vegetation is absent.

Management Action 1.1.4: Allow temporary road access to P-J encroached treatment areas. Construct temporary access roads where access is needed with minimum design standards to avoid and minimize impacts. Remove and restore temporary roads upon completion of treatment.

Management Action 1.1.5: Seek sufficient resources to address habitat loss and degradation in the next ten years.

Management Action 1.1.6: Share project funding among all appropriate agencies and jurisdictions by designing and completing NEPA for large-scale, watershed-based treatments over a period of years.

***Management Action 1.1.7*:** Incentivize and assist in the development of bio-fuels and other commercial uses of pinyon and juniper resources, where utilization is appropriate and can expand site-specific restoration and rehabilitation goals and objectives

Management Action 1.1.8: Increase the incentives for private industry investment in biomass removal, land restoration, and renewable energy development by authorizing stewardship contracts for up to 20 years.

Management Action 1.1.9: Work with federal, state, local, tribal, and private partners to treat at least 100,000 acres annually. Monitor, adaptively manage, and report progress to the Nevada Sagebrush Ecosystem Council.

Management Action 1.1.10: Use pre-suppression fuels management treatments in strategic areas so fire in P-J areas can be managed appropriately.

Management Action 1.1.11: Work with federal, state, and local fire management partners to pre-plan for fire use and prescribed natural fire where and when appropriate.

7.3 Predation

Predation is a natural factor operating on all sage-grouse populations. Historically, given appropriate quality and quantity of habitat, sage-grouse populations have persisted despite naturally high levels of predation with which they evolved (Schroeder and Baydack 2001, Hagen 2011). Prey species have evolved ways to avoid predation such as coloration that conceals them, behavioral adaptations, and specialized reproductive strategies. Sage-grouse populations typically mitigate impacts of predation through cryptic nesting, increased chick production, re-nesting efforts, and response to annual habitat variation. When population levels become depressed below a particular threshold, quantity and quality of habitat may be diminished, or predator populations may become abundant enough to serve as a limiting factor, the behaviors and life-history strategies of prey species may not be able to compensate for losses from predators depending on numerous factors influencing predator densities and effects. These factors include: predator search efficiency, prey switching, and food subsidies (Cote and Sutherland 1997, Schroeder and Baydack 2001, Hagen 2011).

Predator Species

Predators can affect sage-grouse during various life stages in three ways: 1) nesting success, 2) survival of chicks during the first few weeks after hatch, and 3) annual survival of breeding age birds (Schroeder and Baydack 2001). Table 7-1 outlines potential predator species in Nevada that may influence each life stage.

Table 7-1 Potential Sage-grouse Predator Species in Nevada

	Life Stage		
Predator Species	**Nest**	**Chick**	**Juvenile and Adult**
American badger (*Taxidea taxis*)	X		X
Bobcat (*Lynx rufus*)	X		
Coyote (*Canus latrans*)	X		X
Fox (*Vulpes* spp.)	X		
Great Basin gopher snake (*Pituophis catenifer*)		X	
Raptors (*Buteo* spp., *Aquila* spp. *Circus* spp, etc.)			X
Common raven (*Corvus corax*)	X	X	
Weasels (*Mustela* spp.)	X	X	

(Connelly et al. 2004, Coates et al. 2008, Lockyer et al. 2013)

None of these predators depend on sage-grouse as their primary prey species. Many depend primarily on rodents or lagomorphs but will opportunistically consume sage-grouse, especially during specific life phases (e.g. badgers during the nesting season (Coates and Delehanty 2010)).

The common raven (*Corvus corax*) is identified as the most frequent predator during nesting season in sage-grouse predator studies conducted recently in the Great Basin (Coates et al. 2008, Lockyer et al. 2013). Raven populations have increased over 200 percent from 1992 to 2012 in both the Great Basin and in Nevada, based upon USGS Breeding Bird Survey results (Sauer et al. 2014). Subsidized food sources such as landfills and road kill; elevated nest platforms provided by transmission lines; and landscape alterations such as transitions to annual grasses, can increase raven populations (Boarman 2003, Boarman and Heinrich 1999, Webb et al. 2004). Raven abundance is often tied to habitat quality, particularly in areas where recently burned areas abut unburned habitat (Howe et al. 2014, Coates et al., In Review). Raven control has been shown to be an effective, short-term, tool during the early nesting season to gain increased survival through the nesting and early brood life cycle stages (Coates et al. 2007) when ravens are the limiting factor affecting nest success. Long-term effects at the population level are still not understood.

Given that ravens have been found to be increasing across the West and juvenile survival of ravens is tied to anthropogenic subsidies (Webb et al. 2004), localized lethal efforts are not likely to be successful in reducing state-wide populations (Webb et al. 2004). Thus, effective raven management needs to also include efforts to reduce food, water, and nesting subsidies.

Current State Predation Management Efforts for Sage-grouse

The following presents information on the State of Nevada's current predator control efforts to benefit sage-grouse populations.

Predator control
NDOW is partnered with USDA-APHIS-Wildlife Services for predator control focusing on carnivores (primarily badgers and coyotes) and ravens. NDOW currently has a depredation permit from the FWS for 2,500 ravens. Much of the take under this permit is conducted using poisoned eggs (hard-boiled chicken eggs that contain DRC-1339, an avicide). Poisoned eggs are placed at specific leks for ravens as a means of limiting raven populations during the sage-grouse nesting season. (See Appendix D for additional details regarding FWS depredation permits for ravens.)

Road kill removal
In cooperation with NDOT, county road crews, USFWS, and UNR, NDOW has hired wildlife technicians to experimentally remove road carrion from three treatment areas in northern Nevada, in and around priority sage-grouse nesting habitat.

Landfill management
NDOW is working in cooperation with city and county municipalities, private entities, and the USFWS in Eureka, Humboldt, and Lander Counties to improve waste stream policies to minimize access by predator species and to increase the frequency of food waste and dead animal pit burials.

Goals, Objectives, and Management Actions

Goal 1: Reduce sage-grouse mortality due to predation where predation mortality is likely additive or is a limiting factor influencing sage-grouse population.

The following three objectives should be carried out concurrently as part of an integrated predator management plan.

The management actions identified under Objective 1.1 should be carried out at the state-wide level, or at a more localized, targeted scale, as appropriate.

Objective 1.1: Reduce anthropogenic subsidies to ravens, such as food sources (e.g. road kill, landfills), and nesting substrates (e.g. power lines), especially cognizant in landscapes with heterogeneous land cover, such as burned and unburned areas.

Management Action 1.1.1*:* Coordinate with NDOT and local governments to identify high density road kill areas to focus interagency road kill removal efforts. Provide information to agency staff that explains the need for the effort and outlines disposal options and procedures.

Management Action 1.1.2*:* Work with city and county governments to develop and adopt procedures that minimize availability of refuse in the urban interface that acts as food and water sources for predators.

Management Action 1.1.3*:* At landfills and waste transfer facilities, work with Nevada Division of Environmental Protection and facility managers to develop and adopt procedures that eliminate food and water sources for predators.

Management Action 1.1.4*:* Work with livestock owners, land managers, and regulatory authorities to develop and implement effective methods to reduce or eliminate exposed animal carcasses or other livestock by-products that may provide a food subsidy for predators.

Management Action 1.1.5*:* Collaborate with and provide informational material to stakeholders, such as Nevada Association of Counties, League of Cities, sportsmen's groups, Nevada Cattlemen's Association, and the general public on raven subsidy issues; such as refuse in urban areas, livestock carcasses and by-products, and wildlife carcasses (coyote, squirrels, rabbits).

Management Action 1.1.6*:* Research and develop management techniques to limit or reduce the availability of water subsidies to ravens. This may be very challenging and will likely require new technologies and techniques given Nevada's arid environment, distance between natural water sources, and the need for anthropogenic watering sites accessible to both livestock and wildlife.

Management Action 1.1.7: Reduce and eliminate artificial hunting perches and nesting substrate for aerial predators (e.g., removal of non-operational fences and power lines, installation of anti-perch devices on new power lines). Consideration for retrofit of existing power lines can be done on a case by case basis, where technology and economic factors allow.

Management Action 1.1.8: Encourage continued research in the development of more effective perching and nesting deterrent options.

Management Action 1.1.9: Monitor the effects of efforts to reduce anthropogenic subsidies on raven populations and adapt management accordingly.

Objectives 1.2 and 1.3 should be implemented in localized areas where predation has been identified as a limiting factor on sage-grouse population. Use the "Process to Prioritize Integrated Predator Management Projects" (See Appendix E) before engaging in Objectives 1.2 and 1.3.

Objective 1.2: Maintain or improve habitat integrity by increasing visual cover to reduce detection by predators or by reducing fragmentation to limit habitat for ravens.

Management Action 1.2.1: Maintain a mosaic of shrub cover conditions with areas of nesting habitat having ≥20% sagebrush cover and ≥30 percent total shrub cover to provide increased cover for nesting and escape (Gregg et al. 1994, Coates and Delehanty 2010) and decrease opportunities for large fires using pre-suppression strategies.

Management Action 1.2.2: Maintain residual grass cover in nesting habitat to provide cover for nesting and escape (Gregg et al. 1994, Gregg and Crawford 2009, Coates and Delehanty 2008). This factor is more important if shrub cover is low.

Management Action 1.2.3: Where appropriate, begin recovery of degraded sites to reduce fragmentation by decreasing edge of non-native annual grasses next to intact Core or Priority Management Areas and to reduce fragmentation.

Management Action 1.2.4: Minimize disturbance activities near leks during lek season (i.e., when males are inattentive and most vulnerable to predation) and near nest sites during nesting season that may result in adults flushing off nests or away from young. (In this instance, disturbance activities are anything that may cause birds to flush such as startling noise [explosions], road traffic, human presence, etc.). Use seasonal restrictions on activities, when appropriate, to minimize disturbances.

Objective 1.3: Conduct targeted predator control, based on monitoring and adaptive management. Objective 1.3 should be implemented pursuant to steps to achieve objectives 1 and 2.

Management Action 1.3.1: From the outcome of the Process to Prioritize Integrated Predator Management Projects (see Appendix E), establish a predator control program based on biological assessments appropriate to local conditions. Conduct predator control to coincide with the life stage impacted by predation. Program development needs to include specific goals and objectives and identification of triggers or endpoints for management practices. Monitor pre- and post-treatment predator numbers or densities as appropriate, and effects of predator control on sage-grouse vital rates (e.g. nest success, chick survival) and adapt control strategies accordingly.

Management Action 1.3.2: When conducting raven control programs using DRC-1339, the methods outlined in Coates et al. (2007) should be followed. The following points should be evaluated when conducting raven control programs:

- The assumed ratio of number of ravens removed to baited eggs placed
- Need for pre-baiting to accustom ravens to their presence
- Length of time eggs should be left in the environment
- Spacing of egg and number of eggs placed together
- Consideration to implement treatment yearly, based on monitoring of raven population response
- Treatment should be conducted early in sage-grouse incubation period (within the first 40 days following first average nest initiation for the season) to coincide with greatest raven predation period (Coates and Delehanty 2008, Lockyer 2013)

The SETT will work with subject experts (USGS, NDOW, Wildlife Services) to develop a standardized protocol for effective raven removal efforts.

Management Action 1.3.3*:* Consider option to oil or addle eggs in nests of territorial ravens found on anthropogenic structures as part of raven control program, when appropriate.

Management Action 1.3.4: Document success through a rigorous monitoring, analysis, and reporting of population responses to control efforts. For raven control programs, if there is a demonstrated benefit to sage-grouse via scientifically valid documentation, submit a request to USFWS for increased allowable take of ravens, assuming personnel availability from NDOW and Wildlife Services to appropriately identify locations and conduct work.

7.4 Wild Horses and Burros Management

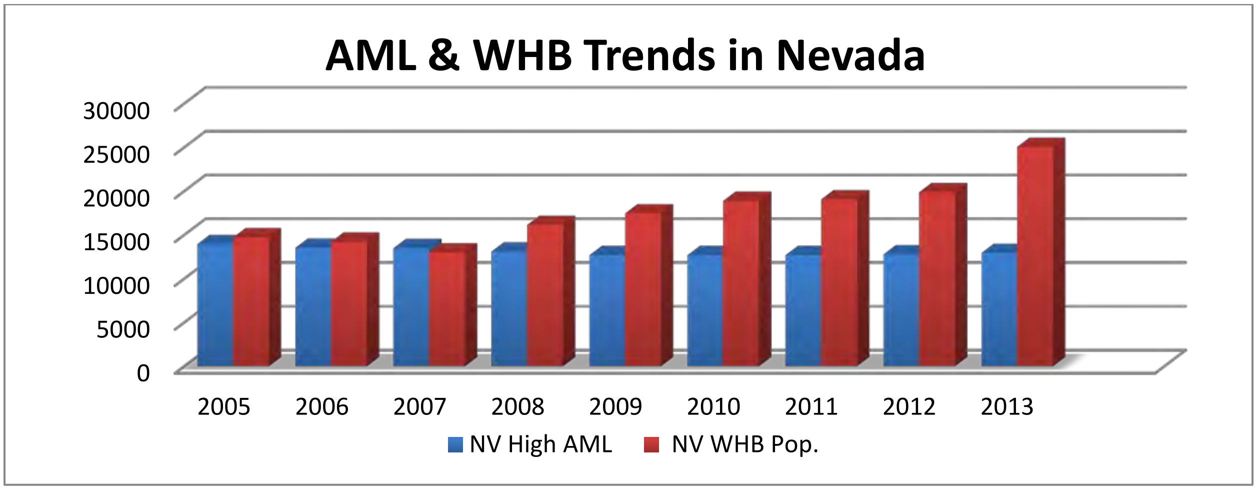
The State of Nevada supports multiple uses on public lands and the responsible and active management of those lands uses, including wild horses and burros, which are protected by the Wild Free-Roaming Horses and Burros Act (the Act) of 1971. While that Act protects them from harassment and unjustified removal or destruction, it also allows for the proper management of wild horse and burro populations within the Herd Management Areas (HMA) on BLM land and Wild Horse and Burro Territories (WHBT) on USFS land that are within Herd Areas (HA). Proper management of herd populations serves to protect their health as well as that of the habitat they and other species rely upon. The Act acknowledges the need to maintain the wild horses and burros within established Appropriate Management Levels (AML). This State supports the Act as it was initially authorized and offers recommendations for alternative management actions necessary to attain and maintain herd sizes that promote the continued health and diversity among wild horses and burros and allows for a sustainable sagebrush ecosystem that is mutually beneficial to all land uses and users.

How HA, HMA, WHBT, and AML were established

Under the Act, BLM and USFS are required to manage wild horses and burros only in HA where they were found when the Act passed in 1971. Through land use planning, the BLM and USFS evaluated each HA to determine if it had adequate food, water, cover, and space to sustain healthy and diverse wild horse and burro populations over the long-term. The areas which met these criteria were then designated as HMA and WHBT (BLM 2013, BLM 2014) (Figure 9).

BLM and USFS also evaluated each HMA to determine how much forage is available for use. The available forage is then allocated among wildlife, wild horses and burros and domestic livestock. The number of horses and burros which can graze without causing damage to the range is called the AML (BLM 2013, BLM 2014).

Nevada's annual AML as compared to Wild Horse and Burro (WHB) population estimates ([http://www.blm.gov/wo/st/en/prog/whbprogram/herd_management/Data.html 2/28/1014](http://www.blm.gov/wo/st/en/prog/whbprogram/herd_management/Data.html))



Current estimates of wild horses from the BLM and USFS are as follows (Shepherd 2014, BLM 2013):

- National: 37,300
- Nevada: 24,000-26,500
- National AML: 26,600
- Nevada AML: 12,688
- 84.3 percent of Nevada HMA are at or exceed AML
- 70 of the 83 HMA statewide are at or exceed AML
- 49 of the 62 HMA overlapping sage-grouse habitat are at or exceed AML
- 10 of the 14 WHBT overlapping sage-grouse habitat are at or exceed AML
- Nationally, over 50,000 horses are currently held in captivity in either short term holding facilities or long term private pastures

Wild horses are capable of increasing their numbers by 18 percent to 25 percent annually, resulting in the doubling of wild horse populations about every 4 years (Wolfe et al. 1989; Garrott et al. 1991). Wild horses are a long-lived species with survival rates estimated between 80 and 97 percent (Wolfe et al. 1980; Eberhardt et al. 1982; Garrrott and Taylor 1990) and they are a non-self-regulating species. There are 62 HMA and 14 WHBT that overlap with sage-grouse habitat in Nevada (BLM 2013, BLM 2014).

While nationally more than 220,000 wild horses and burros have been adopted by private citizens since the program began in 1971, the levels of adoption have decreased dramatically since 2007 (Shepherd, personal communication). In 2013 nationally there were 4,221 horses removed and 2,400 were either adopted or sold. In 2013 in Nevada there were 2,787 horses removed and 89 were adopted or sold (Shepherd 2014). In order to maintain current population levels in Nevada (most are currently near or exceeding the high range of AML), approximately 4,300 – 6,600 horses would need to be removed annually statewide, in the absence of using effective population growth suppression techniques.

The State of Nevada will work closely with federal agencies to develop new, and expand on existing strategies, policies, and best management practices to attain sustainable wild horse and burro populations within HMA and WHBT. The State of Nevada will also engage Congressional representatives and their staff to secure assistance in the implementation of the management activities authorized within the Act.

Goals, Objectives, and Management Actions

Goal 1: Support, promote, and facilitate full implementation of the Wild Free-Roaming Horses and Burros Act of 1971, as amended, including to preserve and maintain a thriving natural ecological balance and multiple-use relationship, without alteration of its implementation by subsequent Congresses or Presidential administrations.

Recognizing that if action is not taken until herd health has become an issue, the range and water resources are likely to be in a highly degraded and potentially irreversible state. Non-active management (e.g. let nature take its course, wait until horse health or resource conditions are critical) is not acceptable management. Non-management will negatively impact or potentially create irreversible habitat impacts within the SGMA; therefore, use all tools available to actively manage wild horses and burros within HMA and WHBT.

Objective 1.1: Maintain healthy and diverse wild horse and burro populations in the State of Nevada in a manner that maintains or is actively managed to trend towards sage-grouse desired habitat conditions, as applicable (see Table 4.1).

Management Action 1.1.1: Focus expenditures of appropriated funds on management of wild horses and burros on public lands over care in captivity.

Management Action 1.1.2: Even if current AML is not being exceeded, yet habitat within the SGMA continues to become degraded, at least partially due to wild horses or burros, established AML within the HMA or WHBT should be reduced through the NEPA process and monitored annually to help determine future management decisions. Unless already meeting the lowest established AMLs, during periods of drought, AML should be reduced to remain consistent with the declining levels of available forage).

Management Action 1.1.3: Methods that were used to initially establish AML should be reevaluated to determine if they are still sufficient to maintain or achieve sage-grouse desired habitat conditions, as applicable (see Table 4.1).

Management Action 1.1.4: Use professionals (botanists, rangeland ecologists, wildlife biologists, hydrologists, etc.) from diverse backgrounds to conduct land health, and riparian proper functioning condition assessments.

Management Action 1.1.5: Conduct annual site specific wild horse and burro grazing response indices (Swanson et al. 2006) assessments, and habitat objective assessments.

Management Action 1.1.6: When implementing management activities, water developments, or rangeland improvements for wild horses or burros, consider both direct and indirect effects on sage-grouse and use the applicable Site Specific Consultation Based Design Features (Design Features; see Appendix A) to minimize potential impacts or disturbances.

Management Action 1.1.7: To expedite recovery time and enhance restoration efforts following wildfire or sage-grouse habitat enhancement projects, consider a significant reduction and temporary removal or exclusion of all wild horses and burros within or from burned areas where HMA and WHBT overlap with sage-grouse Core, Priority, and General Management Areas. Wild horse grazing behaviors and specialized physiological requirements make unmanaged grazing on recently burned/treated areas problematic for reestablishment of burned or seeded vegetation (Arnold and Dudzinski 1978, Rittenhouse et al. 1982, Duncan et al. 1990, Hanley 1982, Wagner 1983, Menard et al. 2002, Stoddart et al. 1975, Symanski1994).

Management Action 1.1.8: If current AML is being exceeded, consider emergency short-term measures to reduce or avoid degradation of sage-grouse habitat from HMAs or WHBTs that are in excess of established AMLs within the SGMA.

Plan for and implement an immediate reduction in herd size to a level that would enable the area to trend towards desired habitat conditions in Table 4.1 and to preserve and maintain a thriving natural ecological balance and multiple-use relationship in that area. Consider lowering the AML levels to prevent future damage.

Management Action 1.1.9: If monitored sites are not meeting sage-grouse desired habitat conditions, as applicable in Table 4.1, even if AML is being met, and it is determined that wild horses or burros are the primary causal factor, then implement protective measures as applicable in addressing similar emergencies (e.g. fire, flood, drought, etc.).

Management Action 1.1.10: Consider exclusionary or controlled use pasture fencing of riparian or other mesic sites and implement water developments (following the Design Features as described in Appendix A) to ensure dispersal or avoidance of sites heavily impacted by wild horses (Feist 1971, Pellegrini 1971, Ganskopp and Vavra 1986, Naiman et al. 1992). A water source should be provided, as horses traditionally do not leave known water sources just because they are fenced.

Management Action 1.1.11: As climate data become available, adjust wild horse and burro and rangeland management practices to allow for Core, Priority, and General Management Areas to sustain or restore the sagebrush ecosystem resiliency and resistance.

Management Action 1.1.12: Collaborate with weather and climate professionals and agencies (UNR, DRI, NOAA, etc.) to proactively manage the rangeland resources and adjust, as necessary, the current wild horse and burro management policies. Ensure that sufficient ongoing public and political education is provided.

Objective 1.2: Evaluate conflicts with HMA designations in SGMAs and modify LUPs to avoid negative impacts on sage-grouse.

Management Action 1.2.1: Even if current AML is not being exceeded, yet habitat within the SGMA continues to become degraded, at least partially due to wild horses or burros, reduce established AMLs within the HMA or WHBT and monitor resource objectives annually to help determine future management decisions. Unless already meeting the lowest established AMLs, during periods of drought, AML should be reduced to levels that are consistent with the declining levels of available forage. *(same as Management Action 1.1.2)*

Management Action 1.2.2: Ensure that Herd Management Area Plans and WHBT plans are developed or amended within the Core, Priority, and General management areas, identified in the State's management areas map, taking into consideration the sage-grouse desired habitat conditions (see Table 4.1).

Management Action 1.2.3: Conduct herd management activities, as originally authorized, to avoid conflicts between the potential implementation of regulations within the Wild Free-Roaming Horses and Burros Act and the Endangered Species Act

Goal 2: As authorized in the Wild Free-Roaming Horses and Burros Act of 1971: Achieve and maintain wild horses and burros at or below established AML within the SGMA and mange for zero horse populations in non-designated areas within the SGMA to reduce impacts to sage-grouse habitat.

Objective 2.1: Meet established AML in all HMA and WHBT in Core, Priority, and General Management Areas within five years.

Management Action 2.1.1: Focus expenditures of appropriated funds on management of wild horses and burros on public lands over care in captivity. *(same as Management Action1.1.1)*

Management Action 2.1.2: Even if current AMLs are not being exceeded, yet habitat within the SGMA continues to become degraded, at least partially due to wild horses or burros, reduce established AMLs within the HMA or WHBT and monitor resource objectives annually to help determine future management decisions. Unless already meeting the lowest established AML, during periods of drought, AMLs should be reduced to a level that is consistent with maintaining or trending towards sage-grouse desired habitat conditions, as applicable (see Table 4.1). *(same as Management Action 1.1.2)*

Management Action 2.1.3: *Reevaluate m*ethods that were used to initially establish AML to determine if they are still sufficient to maintain or trend towards sage-grouse desired habitat conditions, as applicable (see Table 4.1). (same as Management Action 1.1.3)

Management Action 2.1.4: Given their capability to increase their numbers by 18%-25% annually, resulting in the doubling in population every 4-5 years (Wolfe et al. 1989; Garrott et al. 1991), conduct wild horse gathers to attain the lowest levels of AML. This in combination with continued and expanded use and development of effective forms of population growth suppression techniques will enable AML to be maintained for longer periods and reduce the frequency of gathers and associated cost and effort.

Management Action 2.1.5: If current AMLs are being exceeded, consider emergency short-term measures to reduce or avoid degradation of sage-grouse habitat from HMA or WHBT that are in excess of established AML within the SGMA.

Plan for and implement an immediate reduction in herd size to a level that would enable the area to trend towards the desired habitat conditions, as applicable in Table 4.1 and to preserve and maintain a thriving natural ecological balance and multiple-use relationship in that area. Consider lowering the AML to prevent future damage. *(same as Management Action 1.1.7)*

Management Action 2.1.6: Prioritize gathers for removal or population growth suppression techniques in HMA, HA, and WHBT first within the State's Core Management Areas and then within the Priority and General Management Areas. Additional prioritization should be given for HMA and WHBT that are near AML or where a reduction would serve the most beneficial purpose. Proactively and adaptively manage herd sizes taking into consideration climate variability and other natural phenomena, similar to the restrictions placed on livestock managers.

Goal 3: Support and conduct science based research and monitoring to more efficiently and effectively maintain AML in HMA and WHBT.

Objective 3.1: Implement more effective methods to conduct surveys and monitor wild horse and burro activities, populations, and responses to different herd management techniques.

Management Action 3.1.1: Work with professionals from other federal and state agencies, researchers at universities, and others to continue to develop, expand, and test more effective population growth suppression techniques, including contraception options.

Management Action 3.1.2: Implement a telemetry monitoring program for wild horses. Research regarding the direct interactions between, and indirect effects of wild horses on sage-grouse, has been identified as a need that could further assist the agencies in the development of habitat selection maps (Beever and Aldridge et al. 2011) as well as offer a general understanding of the intensity, timing, and duration of use by wild horses within the SGMA.

Management Action 3.1.3: Investigate the use of automated or time-lapse cameras or other monitoring methods to differentiate horse and livestock use impacts at key areas such as late brood-rearing habitats, use appropriate management methods where combined use does not meet resource objectives. Subsequently, make management changes based upon monitoring data and resource objectives.

7.5 Livestock Grazing

Farming and ranching on private lands in unison with authorized livestock grazing on public lands has been a long standing arrangement for many private landowners in the State of Nevada. Historically, many homesteaders began to farm and ranch much of Nevada's riparian and mesic landscapes due to the availability of surface water or springs. Once developed, many of these mesic areas were expanded by the artificial spreading of water or irrigation. These larger, irrigation induced, privately and publicly owned meadows served to support many species of wildlife in addition to livestock. This expansion of late brood rearing habitat and an increase in sagebrush acreage due to an absence of fire after consumption of fine fuels, (Burkhardt and Tisdale 1976) may be causes of sage-grouse population expansion in the late 1800s and early 1900s (Gruel and Swanson 2012). Today, by allowing for the authorized use of proper and targeted livestock grazing on public lands, private landowners and wildlife habitat managers can serve to protect or even benefit each other if managed properly (by reductions in fuels, targeted grazing of specific habitats and cheatgrass, etc.). The State of Nevada recognizes and supports this long standing beneficial relationship and the property interests associated with grazing permits (Figure 10).

Livestock grazing (primarily sheep and cattle) has occurred on the Nevada landscape for over 170 years at varying levels. Many variables have contributed to the growth and reduction of the size and number of homesteads, as well as the number of livestock using the range, over the past century. The State supports the proper management of livestock grazing on allotted public lands in Nevada. Davies et al. (2011, p. 2575) concluded based on literature review that "Though appropriately managed grazing is critical to protecting the sagebrush ecosystem, livestock grazing per se is not a stressor threatening the sustainability of the ecosystem. Thus, cessation of livestock grazing will not conserve the sagebrush ecosystem."

Dependent on many factors, livestock grazing can have a negative effect, a positive effect, or a neutral effect on sage-grouse habitat (Davies et al. 2009; Knopf 1996; Oakleaf 1971; Svejcar et al. 2014; Whitehurst and Marlow 2013). If implemented appropriately, the recommended actions listed in this section will assist landowners and land managers in managing appropriately to avoid or minimize negative impacts to sage-grouse habitat due to livestock grazing. The actions should also help to maintain the existing resistance and resilience of sagebrush communities and to protect the future persistence and sustainability of the diversity of other sage-grouse habitat types within the sagebrush ecosystem for those who depend on it.

The State supports grazing practices that incorporate a high level of flexibility through adaptive management to achieve the overall management and resource objectives agreed upon by the permittee and the land manager. The State will provide technical support to landowners through its combined resources and through partnerships with other governmental agencies and private industry. The State will continue to support the further understanding and development of rangeland management, resource conservation, rehabilitation, restoration, and protection that can be applied and supported, at least in part, by permittees and other land managers.

The State encourages private landowners to develop and implement conservation plans that serve to maintain or strengthen financial viability that also work to conserve or protect the renewable natural resources of Nevada, including sage-grouse and other wildlife species habitat.

The State will continue to support current, and development of new, public outreach and educational programs that assist with the proper understanding and implementation of the actions listed below to achieve the goals and objectives within this plan.

The State will also work with federal land managers and livestock owners to develop acceptable procedures to conduct consistent rangeland or resource monitoring with appropriate frequency. This should allow for greater flexibility in administering adaptive management decisions to achieve targeted goals and objectives.

The State encourages federal agencies to ensure that any loss of grazing allotment rights that were not directly attributable to the permittees actions or inactions are mitigated to attain a no-net-loss of AUMs.

Conservation Goal, Objective, and Management Actions

Goal 1: Ensure that existing grazing permits maintain or enhance sage-grouse habitat. Utilize livestock grazing when appropriate as a management tool to improve sage-grouse habitat quantity and quality, or to reduce wildfire threats. Based on a comprehensive understanding of seasonal sage-grouse habitat requirements, and in conjunction with the need for flexibility in livestock operations, make cooperative, timely, seasonal range management decisions to meet vegetation management objectives, including fuels reduction.

Objective 1.1: In sage-grouse habitat, manage for vegetation composition and structure that maintains or is actively managed to trend towards sage-grouse seasonal desired habitat conditions, as applicable (see Table 4.1), enhancing resilience and resistance based upon the ability of the ecological site to respond to management. This objective recognizes spatial and temporal variations across seral stages.

Management Action 1.1.1: Within sage-grouse habitat, incorporate sage-grouse desired habitat conditions, as applicable (see Table 4.1), and management considerations into all BLM and Forest Service grazing allotments through allotment management plans (AMP), multiple use decisions, or permit renewals or Forest Service Annual Operating Instructions.

Implement appropriate prescribed grazing actions, at scales sufficient to influence a positive response in sage-grouse habitats, such as NRCS Conservation Practice Standard 528 for prescribed grazing (NRCS 2011).

Management Action 1.1.2: In sage-grouse habitat, work cooperatively on integrated ranch planning within sage-grouse habitat so operations with deeded land, and BLM or Forest Service allotments, can be planned as single units, providing flexibility and adaptive management across all ownerships and not altering stocking rates on operations for progressive management decisions.

Management Action 1.1.3: Continue the use of land health assessments on BLM-administered lands or the Sierra and Central/Eastern Nevada Riparian Field Guides and the Resource Implementation Protocol for Rapid Assessment Matrices on Forest Service-administered lands in sage-grouse habitat to evaluate current conditions as compared to sage-grouse desired habitat conditions described in Table 4.1. Incorporate the results of BLM and Forest Service monitoring and land health assessments into future management applications to ensure the maintenance or active management to trend towards sage-grouse desired habitat conditions. Incorporate terms and conditions into grazing permits and adjust these as needed through monitoring and adaptive management to meet sage-grouse desired habitat conditions.

Management Action 1.1.4: Where current permitted livestock grazing is identified as the causal factor of not meeting the desired habitat conditions, implement management actions (grazing decisions, Annual Operating Instructions [Forest Service only], AMP/Conservation Plan development, or other agreements) to modify grazing management to trend towards desired habitat conditions, as applicable in Table 4.1. Consider singly, or in combination, changes in:

- Season, timing (duration) or rotation of use;
- Distribution of livestock use;
- Intensity of use;
- Type of livestock (e.g., cattle, sheep, horses, llamas, alpacas and goats; Briske et al. 2011); and
- Numbers/ AUMs of livestock and other ungulates (includes temporary nonrenewable (TNR) use, and nonuse).

Before imposing grazing restrictions or seeking changes in livestock stocking rates or seasons of permitted use, federal agencies in coordination with grazing permittees must identify and implement all economically and technically feasible livestock distribution, forage production enhancement, weed control, prescribed grazing, off-site water development by the water rights holder, shrub and pinyon/juniper control, livestock salting/supplementing, and riparian pastures and herding. (Eureka County Master Plan 2010)

Management Action 1.1.5: At a minimum, use grazing management strategies for riparian areas and wet meadows to maintain or trend towards riparian Proper Functioning Condition (PFC) and promote brood rearing/summer desired habitat conditions, as described in Table 4.1, within sage-grouse habitat. Within sage-grouse habitat, manage wet meadows to maintain a component of available perennial forbs with diverse species richness to facilitate brood rearing and stabilizing riparian species (Burton et al. 2011) near where water flows to achieve or maintain PFC. Use Ecological Site Descriptions (ESD) or locally relevant information about soils, hydrology, soil moisture, and site potential to set realistic objectives and evaluate assessments and monitoring data (Swanson et al. 2006). Also conserve or enhance wet meadow complexes to maintain or increase amount of edge and cover near that edge to minimize elevated mortality during the late brood rearing period (Hagen et al. 2007; Kolada et al. 2009a; Atamian et al. 2010) as observed throughout the stream/watershed and not limited to only easily accessible sites.

Some defined areas of concentrated livestock use may be necessary to protect and enhance the overall riparian area.

Management Action 1.1.6: Authorize new water development for diversion from spring or seep sources only when sage-grouse habitat would not be net negatively affected by the development. This includes developing new water sources for livestock as part of an AMP/conservation plan to improve sage-grouse habitat.

Management Action 1.1.7: Analyze springs, seeps and associated pipelines to find mutually beneficial enhancement opportunities for livestock and wildlife that restores functionality to riparian and mesic areas within sage-grouse habitat, and allow them to be developed.

Management Action 1.1.8: In sage-grouse habitat, encourage and allow vegetation treatments that conserve, enhance, or adaptively restore resilience and resistance over time. This includes adaptive management as part of an AMP/Conservation Plan to improve sage-grouse habitat.

Management Action 1.1.9: Evaluate the role of existing seedings that are currently composed of primarily introduced perennial grasses that are in and adjacent to sage-grouse habitat to determine if additional efforts should be made to restore sagebrush or to improve habitat quality for sage-grouse. If these seedings are part of an AMP/Conservation Plan or if they provide value in conserving, enhancing, or protecting the rest of the sage-grouse habitat, then no restoration may be necessary. Assess the compatibility of these seedings for sage-grouse habitat or as a component of a grazing system during the land health assessments (Davies et al. 2011), or other analyses such as the Humboldt-Toiyabe Resource Implementation Protocol for Rapid Assessment Matrices (USDAFS - HTNF 2007).

Management Action 1.1.10: In sage-grouse habitat, ensure that the design of any new structural range improvements and the location of supplements (salt or protein blocks) to enhance sage-grouse habitat or minimize impacts in order to maintain or trend towards sage-grouse desired habitat conditions, as applicable (see Table 4.1). Structural range improvements, in this context, include but are not limited to: cattle guards, fences, exclosures, corrals or other livestock handling structures; pipelines, troughs, storage tanks (including moveable tanks used in livestock water hauling), windmills, ponds/reservoirs, solar panels and spring developments. Potential for invasive species establishment or their increase following construction must be considered in the project plan and then monitored, treated, and rehabilitated post-construction.

Management Action 1.1.11: Locate salting and supplemental feeding locations, and temporary or mobile watering and new handling facilities (corrals, chutes, etc.) at least 1/2-mile from riparian zones, springs, meadows, or 1 mile from active leks in sage-grouse habitat, unless the pasture is too small or another location offers equal or better habitat benefits. The distance should be based on local conditions.

Management Action 1.1.12: To reduce sage-grouse strikes and mortality, remove, modify or mark fences in high risk areas within sage-grouse habitat based on proximity to lek, lek size, and topography (Christiansen 2009; Stevens 2011). Consideration of the utility of the fence should also be taken into consideration to ensure that its removal does not promote degradation of the overall management for habitat or other desired conditions (Swanson et al. 2006).

Management Action 1.1.13: In sage-grouse habitat, monitor, treat and, if necessary, restore sites with invasive species associated with existing range improvements (Gelbard and Belnap 2003; Bergquist et al. 2007). State listed noxious weeds (NRS Chapter 555) should be given the highest priority. In general, monitor, map, treat (using integrated pest management and associated tools), and restore sites that have invasive and noxious weed species, especially those associated with disturbance activities.

Management Action 1.1.14: Consider all options to allow responsible management of livestock grazing on an allotment before any voluntary withdrawal of a grazing permit is considered, in conformance with the multiple use sections of the Taylor Grazing Act. All permit relinquishments should be voluntary.

Management Action 1.1.15: Prior to implementation, establish project monitoring sites where vegetation treatment is planned and monitor at least annually during the recovery period. To ensure effective recovery, monitoring should continue for a number of years immediately following the livestock exclusion period and following livestock reintroduction, depending on local site conditions.

Management Action 1.1.16: When conditions, i.e., climatic variations (such as drought) and wildfire, require unique or exceptional management, work to protect sage-grouse habitat on a case by case basis and implement adaptive management to allow for vegetation recovery that meets resistance, resilience, and sage-grouse life cycle needs in sage-grouse habitat as needed on an individual allotment basis.

Management Action 1.1.17: During the annual grazing application, work with permittees to avoid consistent concentrated turn-out locations for livestock within approximately 3 miles of known lek locations during the March 1 to May 15 period. During the March 1 to May 15 period, avoid domestic sheep use, bedding areas, and herder camps within at least 1.24 miles (2 kilometers) of known lek locations. Utilize land features and roads on maps provided to the permittee to help demarcate livestock use avoidance areas. Require terms and conditions language for affected livestock grazing permits regarding livestock turnout locations during the lekking period. During the lekking period, use best management practices to avoid livestock aggregation around the lekking grounds.

Management Action 1.1.18: Strive to improve and maintain regular communication at the allotment level between land management agency and the permittee to encourage proper management techniques. Land management agencies should coordinate with relevant state, local and tribal government agencies and permittees to conduct regular trend monitoring at the allotment level. Actively pursue and implement cooperative permittee monitoring, such as described in Perryman et al. 2006, Swanson et al. 2006.

Management Action 1.1.19: Promote and implement proper livestock grazing practices that promote the health of the perennial herbaceous vegetation component. Perennial grasses, especially, are strong competitors with cheatgrass (Booth et al. 2003; Chambers et al. 2007; Blank and Morgan 2012). Field research has demonstrated that moderate levels of livestock grazing can increase the resiliency of sagebrush communities, reduce the risk and severity of wildfire, and decrease the risk of exotic weed invasion (Davies et al. 2009 and Davies et al. 2010).

Management Action 1.1.20: To reduce the risk of fire and enhance restoration in large contiguous blocks of cheatgrass-dominated sagebrush or sage-grouse habitats that are next to highly flammable cheatgrass dominated lands, create local NEPA documented plans to use tools (e.g. dormant season TNR AUM authorizations and stewardship contracted grazing), to reduce fuels in areas dominated by invasive plants (Schmelzer et al. 2014) especially after high production growing seasons with favorable moisture. Use adaptive management to allow the use of TNR during other seasons, if science emerges demonstrating effectiveness of such practices. Planning should be conducted on an allotment specific basis, and may be contained in AMPs, multiple use decisions, or permit renewals.

Management Action 1.1.21: To aid in planning adaptive management for the purpose of maintaining health of important forage plants (perennials needed for resilience and resistance), cooperatively strategize how various areas in sage-grouse habitat allotments can be managed differently each year to achieve positive grazing response index scores (Perryman et al. 2006; Reed et al. 1999; Wyman et al. 2006; and USDA USFS 1996) and meet resource objectives.

7.6 Anthropogenic Disturbances

Anthropogenic disturbances, as defined in Section 3.0 of this State Plan, are a threat to sage-grouse and their habitat in Nevada; however these activities are a vital part of Nevada's economy. The State of Nevada seeks a balanced approach that allows for the preservation of Nevada's economy, while conserving and protecting sage-grouse populations and the sagebrush ecosystem upon which they need to survive. Nevada's strategy is to provide consultation for project planning to first avoid and minimize impacts to sage-grouse (see Section 3.0) and then to offset residual impacts through compensatory mitigation via the Conservation Credit System (see Section 8.0).

Anthropogenic disturbances can negatively impact sage-grouse both directly and indirectly, and through various mechanisms. Anthropogenic disturbances can directly impact sage-grouse by causing direct loss of habitat, avoidance behavior to infrastructure (Doherty et al. 2008) and to otherwise suitable habitat (Lyon and Anderson 2003, Holloran 2005, Kaiser 2006, Doherty et al. 2008), direct mortality through collision with infrastructure (Beck et al. 2006, Stevens et al. 2012) and mosquitos carrying the West Nile virus (Walker and Naugle 2011) associated with certain artificial ponds created by development (Zou et al 2006), and negative impacts to survival and reproduction (Lyon and Anderson 2003, Holloran 2005, Kaiser 2006, Aldridge and Boyce 2007, Holloran et al. 2007). Indirect impacts on sage-grouse demographics can be caused by noise produced from operations (Braun et al. 2002, Holloran 2005, Kaiser 2006, Blickley et al. 2012), vehicle traffic on associated roads (Lyon and Anderson 2003), and increased predation by raptors perching on associated power lines (Ellis 1984). Moreover, anthropogenic disturbances can lead to an increase in the presence of cheatgrass and other invasive plant species (Bradley and Mustard 2006, Manier et al. 2014). In addition, habitat fragmentation resulting from cumulative effects of multiple anthropogenic disturbances across the landscape has been shown to have long term negative impacts on sage-grouse populations (Johnson et al. 2011, Knick and Hanser 2011, Knick et al. 2013).

Mining

Mining is a vital part of the State of Nevada's economy both currently and historically. The initial discovery of the Comstock Lode silver ore deposit in Virginia City in the 1850s was central to the settling and development of Nevada, as well as a major reason for Nevada's admission into the United States in 1864. The Nevada Department of Taxation currently estimates the net assessed mineral value in the State to be approximately $5.1 billion (State of Nevada 2014) and the Nevada Bureau of Mines and Geology (NBMG) estimates the total production value at $10.76 billion (NBMG 2014)[3]. The annual tax revenue collected in fiscal year 2013 was approximately $236 million (State of Nevada 2014). It is estimated that Nevada's mining economic output contributes a 6% share of Nevada's statewide GDP (Nevada Mining Association 2011).

The primary type of mineral exploration and development in the state of Nevada is locatable minerals, including gold, silver, and copper. Locatable mineral development and exploration is governed under the

---

[3] The State of Nevada 2014 estimate is for FY 12-13 (June 2012 – July 2013) and the NBMG estimate is for calendar year 2012. Both estimates also include geothermal energy and petroleum production.

General Mining Law of 1872 and is a non-discretionary activity on federal lands. Additional federal, state, and local laws also govern locatable minerals. Salable and non-energy leasable mineral exploration and development also occurs, though to a lesser extent. Salable mineral materials, which are common varieties of construction materials and aggregates, such as sand, stone, and gravel are governed under the Materials Acts of 1947. Government and non-profit organizations may obtain these resources free of charge for community purposes on BLM and USFS administered lands. The Nevada Department of Transportation and local governments are the primary users of gravel and sand resources on federal lands in Nevada. Non-energy leasable minerals, such as potassium and sodium, which are governed under the Mineral Leasing Act of 1920 are also present, however there are currently no leases in sage-grouse habitat in Nevada (BLM 2013).

The extent of mining activities across the state of Nevada overlaps with the range of sage-grouse habitat. There are approximately 2 million acres of locatable mineral claims in sage-grouse habitat in Nevada (BLM 2013). The total “footprint” of mining in Nevada is estimated at 169,029 and 181,340 acres by BLM and NDEP respectively (Johnson personal communication 2014, Holmgren personal communication 2014). Mining and its associated facilities and infrastructure may result in habitat fragmentation, direct habitat loss, and indirect impacts decreasing the suitability of otherwise suitable habitat (USFWS 2013). The specific impacts of mining on sage-grouse and their habitat have not been studied in the peer reviewed literature (Manier 2013).

Non-Renewable Energy Production

There is currently little oil and gas development in Nevada. Oil production in Nevada has been on a steady decline and is currently limited to approximately 336,000 barrels of oil production annually (Nevada Division of Minerals 2014a). Within sage-grouse habitat it is limited to two major basins, including the Railroad Valley and Pine Valley, with Railroad Valley being the predominant oil-producing valley in Nevada (BLM 2013). However, with recent federal approval of oil and gas exploration in, Nevada (BLM 2014), coupled with the emergence of new technologies, there may be potential for increased oil and gas production in the State pending results of exploration.

In a comprehensive literature review of the impacts of energy development, principally oil and gas, on sage-grouse conducted by Naugle et al (2011), all studies reported negative effects, while no positive impacts to sage-grouse populations or habitat were reported. Negative responses of sage-grouse were consistent regardless of whether lek dynamics or demographic rates were studied (Naugle et al. 2011). The specific direct and indirect impacts are described above.

Renewable Energy Production

The development, transmission, and distribution of renewable and non-renewable energy are a high priority for the state of Nevada. Shifting national and state energy policies, as well as Nevada’s favorable conditions for different types of renewable energy resources, renewable energy development is likely to increase in the State. The SEP supports Nevada’s Renewable Portfolio Standard goal of 25% of Nevada’s energy coming from renewable sources by 2025. In addition, the Nevada Public Utilities Commission this year ruled in accordance with Nevada S.B. 123 requiring the retirement of no less than 300 MW of coal-fired electrical generating capacity on or before December 31, 2014, and not less than

250 MW of coal-fired electrical generating capacity on or before December 31, 2017 (Public Utilities Commission of Nevada 2014).

Renewable energy resources in Nevada include geothermal, wind, solar, and biomass. Nevada has vast geothermal resources and is leading the way in geothermal energy development in the United States. As of the end of 2013, of the 3442 MW of installed generating capacity in the U.S. (Matek 2014), Nevada contributes 586 MW (Nevada Division of Minerals 2014b), representing approximately 17% of total installed capacity in the U.S. Nevada is outpacing the rest of the country in developing geothermal projects. Nevada accounted for approximately 41% of the total number of projects under development in the U.S. since 2011 (Matek 2014). Nevada currently has 22 operating geothermal plants at 14 different locations (Nevada Division of Minerals 2014b). There are significant geothermal resources in northern Nevada that coincide with the sage-grouse habitat range. Recent geothermal projects that coincide with sage-grouse habitat include the Tuscarora, McGinness Hills, and Jersey Valley Geothermal Power Plants.

Wind energy is one of the fastest growing renewable energy sectors in the U.S.; however the potential viability for development of this resource in Nevada is currently limited. Analysis conducted as part of BLM's Wind Energy Development Programmatic EIS showed most of Nevada's wind power classification rated as poor to fair, with only small pockets classified as good to outstanding (BLM 2005). Some of those pockets however, overlap with sage-grouse habitat. Currently there is one wind generation facility in Nevada, the Spring Valley Wind Project; an approximately 150 MW facility located approximately 30 miles east of Ely, NV.

The BLM, as part of a Programmatic EIS for Solar Energy Development, developed Solar Energy Zone (SEZ), defined as an area well suited for utility scale production of solar energy. Five SEZs were identified for Nevada; all located in Clark, southern Nye, and Lincoln counties, outside the range of sage-grouse (BLM 2012). There are currently no solar energy rights of ways within sage-grouse habitat in Nevada (BLM 2013).

There is currently no significant commercial conifer biomass energy economy in Nevada (BLM 2013); however considering that pinyon-juniper expansion is one of the major threats facing sage-grouse in Nevada, the SEP encourages exploring and incentivizing biomass energy development in the State.

Renewable energy development can negatively impact sage-grouse both directly and indirectly through various mechanisms. Impacts to sage-grouse from geothermal energy development have not been assessed in the scientific literature because the development has been too recent to identify immediate and lag effects (Knick et al. 2011). There are currently no commercial solar projects operating in sage-grouse habitats at this time, so the impacts cannot be assessed. There has been one study on the effects on sage-grouse from wind energy developments recently completed in south-central Wyoming, which demonstrated that the relative probabilities of sage-grouse nest and brood success decreased with proximity to wind turbines (LeBeau 2012). Wind energy generation also requires tall structures, which can provide artificial nesting and perching substrate for sage-grouse predators (Knight and Kawashima 1993). Renewable energy development requires many of the same features for construction and operation as non-renewable energy, so it is anticipated that the potential impacts from direct habitat loss, habitat fragmentation through roads and power lines, noise, and increased human presence would most likely be similar to those for non-renewable energy production (USFWS 2010).

Infrastructure
Infrastructure, whether related to energy production, mining, or any other purpose, can adversely impact sage-grouse. Infrastructure can result in habitat loss and fragmentation as well as sage-grouse avoidance of otherwise suitable habitat. In addition, infrastructure can provide a source for the spread of invasive species and provide artificial subsidies for predators (USFWS 2013). Infrastructure most common in Nevada includes transmission lines, distribution lines and roads. Other types of infrastructure may also include, but is not limited to, pipelines, communication towers, and fences.

Transmission and distribution lines (hereafter collectively referred to as power lines) are necessary for transmitting energy from power production facilities and distributing that power to homes and businesses. Power lines may directly impact sage-grouse through habitat loss and fragmentation (Knick et al. 2013), as well as direct mortality due to collisions (Beck et al. 2006). Indirect habitat loss due to avoidance of vertical structures, presumably due to increases in predator populations is also a concern (Manier 2013). Power lines have been shown to decrease male lek attendance (Ellis 1985) and probability of lek persistence (Walker et al. 2007), as well as causing avoidance behavior of brood-rearing habitat (LeBeau 2012). Power lines have been shown to increase predator distributions and hunting efficiency resulting in increased predation on sage-grouse (Connelly et al. 2004). Preliminary results from a ten-year study on the impacts of the Falcon-Gonder transmission line on sage-grouse population dynamics in Eureka County, Nevada show a significant negative effect of the transmission line on nest success and female survival, weak negative effect on male survival, and no support for impacts on nest site selection and female nesting propensity (Gibson et al. 2013). Nest success and female survival, along with chick survival, are the demographic rates that have been shown to be important for population growth (Taylor et al. 2012).

Roads are widespread through the sage-grouse range and can impact sage-grouse through a variety of mechanisms. A study along I-80 in Wyoming and Utah between 1970 and 2003 found no leks within 1.25 miles of the interstate, and fewer birds on leks within 4.7 miles of the interstate, than further distances (Connelly et al. 2004). Roads can negatively impact sage-grouse through direct mortality due to vehicle collision, decreased male lek attendance due to increased traffic (Holloran 2005), avoidance behavior (Lyon and Anderson 2003, LeBeau 2012), and reduced nest initiation rates (Lyon and Anderson 2003). Roads can also facilitate the spread of invasive species (Gelbard and Belnap 2003).

Goals, Objectives, and Management Actions

Goal 1: Manage anthropogenic disturbance development in a manner that provides for the long-term conservation of sage-grouse and their habitat, while balancing the need for continued development of the resources.

Objective 1.1: Achieve net conservation gain of sage-grouse habitat due to new anthropogenic disturbances and any associated facilities and infrastructure within the Sage-Grouse Management Area (SGMA) in order to maintain stable or increasing sage-grouse populations.

Management Action 1.1.1: All new proposed anthropogenic disturbances within the SGMA will trigger timely SETT Consultation for application of the "avoid, minimize, mitigate" process (see Section 3.0). This will serve as a centralized impact assessment process that provides consistent evaluation, reconciliation and guidance for project development.

Management Action 1.1.2: Avoid new anthropogenic disturbance activities and its associated facilities and infrastructure within the SGMA. Locate activities, facilities, and infrastructure in non-habitat wherever possible. Avoidance of a disturbance within sage-grouse habitat is the preferred option. If avoidance cannot be reasonably accomplished, the project proponent must demonstrate why it cannot be reasonably accomplished in order for the SETT to consider minimization and mitigation alternatives. The process to demonstrate that avoidance cannot be reasonably accomplished (the "avoid process") is determined by the four management categories. (See Table 3-1 for more details on the avoid process.) If development cannot be sited in non-habitat, it should occur in the least suitable habitat.

Management Action 1.1.3: If adverse impacts to sage-grouse and their habitat cannot be avoided, require project proponents to minimize impacts by employing Site Specific Consultation-Based Design Features (Design Features; see Appendix A) appropriate for the project. This may include seasonal operational restrictions, noise restrictions, clustering disturbances, and placing infrastructure in previously disturbed locations.

Management Action 1.1.4: Technically evaluate and where reliability is not adversely impacted, seek to site new linear features in existing corridors (Figure 11) or, at a minimum, co-locate with existing linear features in Core, Priority, and General Management Areas.

Management Action 1.1.5: Reduce and eliminate artificial hunting perches and nesting substrate for aerial predators. This can be achieved by installing anti-nesting and anti-perching devices on new power lines (see Section 7.3) or burying power lines. Bury distribution power lines of up to 35kV where ground disturbance can be minimized, and where technically and economically feasible. Where technology and economic factors allow, bury higher kV power lines (see Appendix A). Sage-grouse desired habitat conditions (see Section 4.0) will be incorporated when reclaiming the site.

Management Action 1.1.6: Encourage continued research in the development of more effective perching and nesting deterrent options (see Section 7.3).

Management Action 1.1.7: Aggressively engage in rehabilitation/weed control efforts during pre- and post-project construction.

Management Action 1.1.8: If impacts from anthropogenic disturbances cannot be avoided and after minimization options have been exhausted, residual adverse impacts are required to be offset through compensatory mitigation. Mitigation obligations will be determined through the Conservation Credit System (see Section 8.0).

Objective 1.2: Explore options to minimize impacts from existing and abandoned anthropogenic disturbances and associated infrastructure.

Management Action 1.2.1: While SETT Consultation and the "avoid, minimize, mitigate" process do not apply retroactively to existing anthropogenic disturbances, encourage existing operators to incorporate the Design Features outlined in Appendix A and contact the SETT for timely input on techniques and practices to avoid and minimize existing impacts to sage-grouse and their habitat.

Management Action 1.2.2: Inventory abandoned mine sites within sage-grouse habitat, where practical, and reclaim sites to trend towards sage-grouse desired habitat conditions (see Section 4.0). Coordinate with the Abandoned Mine Lands Program on this effort.

Management Action 1.2.3: Work with the energy industry to explore opportunities to install anti-nesting and anti-perching devices on existing power lines and tall structures and to bury existing power lines where technology and economic factors allow.

Management Action 1.2.4: Inventory power lines and utility structures that are no longer in use and look for opportunities to decommission the lines and reclaim the sites to trend towards sage-grouse desired habitat conditions (see Section 4.0).

7.7 Recreation & Off-Highway Vehicle Activities

Nevada offers some of the most robust recreational and OHV experiences in the nation due, in large part, to its high percentage of accessible federally managed public lands. Recreation, in all of its forms, creates a significant benefit to local and statewide economies. Extensive networks of roads and trails offer recreationists excellent access to most of Nevada's expansive basin and range high desert ecosystems. This extensivity of roads and trails may also create impacts on sagebrush habitats and sage-grouse that may be difficult to measure.

While recreational and off-highway vehicle use is one of the many acceptable multiple-uses on our federal public lands, it also requires frequently reviewed and updated policies that allow for greater adaptive management. This may assist in ongoing efforts to protect and preserve sensitive land forms, plants, and animals from levels or types of disturbance that create unnatural or unduly negative impacts. Potential impacts on sage-grouse and their habitat associated with recreational activities include but are not limited to: increases in noise levels, distribution of invasive plants, generation of fugitive dust, and effects on predator prey relationships (Manier 2013).

In Nevada, the recent creation of the Commission on Off-Highway Vehicles provides a mechanism and a funding source to educate users on how to responsibly use off-highway vehicles. Educational efforts will focus on minimizing adverse effects due to uses in or near sage-grouse habitats during certain seasons and times of day. It may also provide a funding source to allow the State to join with the federal agencies to better plan, develop, and manage a coordinated and designated system of off-road vehicle trails in Nevada. The off-highway vehicle registration system allows state law enforcement personnel to access vehicle registration information and identify vehicle titleholders in instances where state or federal laws pertaining to off-road access or use are violated.

Conservation Goals, Objectives, and Management Actions

Goal 1: Conserve sage-grouse and their habitat while allowing for continued recreational access to public lands.

Objective 1.1: Avoid or minimize recreation and OHV negative direct and indirect impacts to sage-grouse and their habitats and monitor sites for potential impacts.

Management Action 1.1.1: Establish appropriate ambient noise levels for undisturbed sage-grouse leks. Noise restrictions should generally apply between the hours of 6:00 p.m. to 9:00 a.m. as these are the hours most critical for communications of sage-grouse and auditory detection of predators (Patricelli et al. 2010, Blickley et al. 2012, Patricelli et al. 2013).

Management Action 1.1.2: Take measures to minimize or reduce activities and to avoid an ambient noise level increase >10 dB at the edge of leks during the lekking season generally, March 1 through May 15 from one hour before sunrise until 9:00 a.m.

Management Action 1.1.3: Assist in efforts to enhance collaborative monitoring through volunteer organizations, recreational groups, etc., to collect data that would assist in the protection, enhancement, or restoration of sage-grouse habitats.

Management Action 1.1.4: Support studies that further the understanding of the relationship between recreational uses and their potential impacts on sage-grouse.

Management Action 1.1.5: Utilize sage-grouse habitat mapping to inform state and federal recreation management plans.

Management Action 1.1.6: Where feasible locate recreation trails strategically to create or augment fuel breaks in the margins of sage-grouse habitats and landscapes and not create roads or trails where they cause net negative direct and indirect impacts.

Objective 1.2: Support and implement efforts to reduce the potential for additional sage-grouse habitat fragmentation from unauthorized 'trail making'.

Management Action 1.2.1: Support and promote efforts by state, local, and federal agencies and recreational groups to promote educational campaigns that encourage responsible OHV and recreation activities that avoid or minimize negative impacts to sage-grouse and their habitat, including the spread of invasive species.

Management Action 1.2.2: Work with state, local, and federal agencies and recreational groups to inventory unauthorized trails in Core, Priority, and General Management Areas and where feasible restore trails to trend towards sage-grouse desired habitat conditions (see Table 4-1).

Objective 1.3: Promote the leveraging of funding from all sources when addressing sage-grouse habitat enhancement, restoration, or preservation projects.

Management Action 1.3.1: Develop a database to share with interested agencies and groups to maximize efforts and leverage funding.

Management *Action 1.3.2:* Encourage and support the Commission on Off-Highway Vehicles to expend OHV registration funds to enhance, restore, or protect sage-grouse habitat.

8.0 CONSERVATION CREDIT SYSTEM

The Nevada Conservation Credit System (CCS)[4] is a pro-active solution that provides net conservation benefits for sage-grouse, while balancing the need for continued human activities vital to the Nevada economy and way of life. The CCS creates new incentives for private landowners and public land managers to preserve, enhance, restore, and reduce impacts to important habitat for the species.

The CCS is a market-based mechanism that quantifies conservation outcomes (credits) and impacts from new anthropogenic disturbances (debits), defines standards for market transactions, and reports the overall progress from implementation of conservation actions throughout the sage-grouse range within Nevada. The CCS establishes the policy, operations, and tools necessary to facilitate effective and efficient conservation investments. The CCS is intended to provide regulatory certainty for industries by addressing compensatory mitigation needs whether or not the species is listed under the ESA.

Goal and Scope

The goal of the CCS is to achieve net conservation gain of sage-grouse habitat due to new anthropogenic disturbances within the Sage-grouse Management Area (SGMA; Figure 2), in order to stop the decline of sage-grouse populations. Proposed anthropogenic disturbances, as defined in Section 3.0 of this plan, must seek to avoid, minimize, and mitigate impacts to sage-grouse habitat. After all practicable economically and technically feasible possibilities to avoid and minimize impacts to sage-grouse habitat have been exhausted, residual adverse impacts are required to be offset by mitigation requirements as determined through the CCS.

Anthropogenic disturbances occurring on BLM and USFS lands within the SGMA require timely consultation with the SETT. Private landowners are not required to mitigate anthropogenic disturbances on their land, but are welcome to voluntarily generate, sell, or purchase credits in the CCS. The CCS scope can be expanded in the future to support additional conservation needs or to include other states within the sage-grouse range.

Roles and Responsibilities

The *DCNR Division of State Lands*, holds ultimate authority over CCS design, operations, and management. The *SEC* oversees CCS operations and approves changes to the program. *The Administrator* manages the CCS's day-to-day operations, ongoing program improvements, facilitates transactions, and reports programmatic results. CCS operations are also informed by *Resource Managers* (e.g. BLM, NDOW, USFS, USFWS) and by a *Science Committee* to ensure it functions according to current laws, policies, and regulations and is consistent with the best available science.

Credit Developers are landowners, land managers, organizations, or agencies, that generate, register, or sell credits in the CCS. *Credit Buyers* are entities that purchase mitigation credits to offset impacts from new anthropogenic disturbances or to meet other conservation objectives.

---

[4] For more information please refer to *The Nevada Conservation Credit System Manual* on the Sagebrush Ecosystem Program's Website: http://sagebrusheco.nv.gov/CCS/ConservationCreditSystem/

What are Credits and Debits?

Credits are the currency of the CCS. A credit represents a verified *"functional acre"* that meets the durability criteria defined by the CCS, such as committing to a Customized Management Plan that outlines actions to maintain habitat performance and to limit risks from future impact for the duration of the project. A functional acre is based on habitat quality ("function") relative to optimal conditions, and quantity (acres). This is determined through the Habitat Quantification Tool (HQT; see below).

Debits are similar to credits, but are the quantified and verified units of functional acres lost due to a new anthropogenic disturbance.

Generating and Purchasing Credits

The steps for generating and purchasing credits are depicted below. Blue chevrons signify the steps undertaken to generate credits and green chevrons represent the purchase of credits.

Calculating Credits and Debits

Habitat Quantification Tool (HQT)[5]

The HQT is a method to estimate habitat quality and quantify debits and credits. The HQT uses a set of metrics, applied at multiple spatial scales, to evaluate vegetation and environmental conditions related to sage-grouse habitat quality and quantity. The HQT enables the CCS to create incentives to generate credits in the most beneficial locations for the sage-grouse, and to minimize impacts to existing high quality habitat.

The HQT is used to calculate scores for each type of seasonal habitat. Habitat condition is expressed in functional acres, relative to optimal conditions. The functional acre score is adjusted to account for indirect effects of the local area surrounding the site. Mitigation ratios are then applied.

Mitigation Ratios

Mitigation ratios incorporate biologically significant factors that cannot currently be incorporated into the HQT. They enable offset transactions to achieve a net benefit for the species by ensuring the functional acres of credit acquired is greater than the functional acres of debit. The mitigation ratios create incentives for avoidance of impacts and preservation, enhancement, and restoration of habitat in important areas. This includes avoiding and protecting seasonal habitats that are scarce for a particular population. Mitigation ratios are determined by the:

- Habitat Importance Factor: The value is influenced by the location of a credit or debit site in Core, Priority, or General Management Areas (Figure 4)
- Seasonal Habitat Scarcity Factor: This is determined by the portion of seasonal habitat type (nesting, late-brood rearing, and winter) impacted.

---

[5] For more information please refer to *The Habitat Quantification Tool Scientific Methods Document* on the Sagebrush Ecosystem Program's Website: http://sagebrusheco.nv.gov/CCS/ConservationCreditSystem/

Debits are adjusted based on proximity to potential credit sites (Proximity Factor) to determine the credit obligation that must be purchased to offset a debit project. Credit obligation increases if the credits purchased are located outside the same population as the debits. This incentivizes mitigation in close proximity to debit sites.

Regulatory Assurances

Verification

Credit and debit projects require verification to ensure that calculations represent a true and accurate account of on-the-ground implementation and habitat function and assurances that projects are maintained over time. *Third-party Verifiers*, trained and certified by the Administrator, conduct independent checks using the HQT methods. *Credit Verification* is required before credit release and every fifth year. *Debit Verification* is required before the project begins, during project implementation, and when debits end or decrease. Periodic spot checks and audits are also required.

Reserve Account

The *Reserve Account* is a pool of credits, functioning like an insurance fund, that replace credits that are invalidated due to a force majeure event, mismanagement, or competing land uses. A percentage of credits from each credit transaction are deposited into the reserve account. Factors that determine the Reserve Account contribution are: base contribution, probability of wildfire, and probability of competing land uses. In the case of unintentional credit reversal due to force majeure or competing land use events, the Administrator withdraws credits from the reserve account to cover the invalidated credits at no cost to the Credit Developer for a limited duration until the original credits are replaced.

Additionality and Stacking of Multiple Payments

Projects that generate credits must be additional to activities that would occur in the absence of the CCS. On private and public lands, a credit project is additional if the land manager is not already performing or planning to perform conservation actions using funding sources other than the CCS. *Stacking* allows a Credit Developer to receive multiple payments for conservation actions on the same area of land, but only receive credit for the additional conservation benefits.

Durability

The CCS uses *performance assurances* on private and public lands to ensure the durability of credits generated throughout the life of the credit project. Performance assurances are implemented through contract terms and financial instruments. The *durability of projects on public lands* is safeguarded using land protection mechanisms (e.g. right-of-ways), financial instruments (e.g. contract performance bonds) and the Reserve Account.

Additional Policy Considerations

The *Service Area*, the area in which credits can be exchanged, for the CCS is the SGMA.

Baseline is the starting point from which credits and debits are measured. Credits and debits represent the change from baseline that results from implementing a project. *Credit baseline* is a state-wide standard for each seasonal habitat type equivalent to the average habitat functionality. Project sites must be at the credit baseline, at a minimum to begin generating credits. *Debit baseline* is the pre-project habitat function value for each seasonal habitat type for a proposed debit project.

Credit release occurs when performance criteria milestones which increase habitat function are achieved on a credit site. Specific performance criteria are defined in each project's *Customized Management Plan*. Credit release can occur in single or multiple increments depending on credit project type; including: *preservation projects*, *enhancement projects*, and *restoration projects*.

The CCS requires that the *project life* of a credit project must be equal to or greater than the duration of the impacts of the debit project it is offsetting.

Credit variability may occur due to annual climatic or other natural conditions affecting habitat functionality. As a result, a *tolerance threshold* of above or below 10% habitat function is applied.

9.0 MONITORING AND ADAPTIVE MANAGEMENT

Monitoring and adaptive management are key components of successful resource management plans in order to derive the greatest environmental benefit given limited agency resources. Incorporation of these strategies in the planning process will help ensure management actions identified in this State Plan are implemented and effective at achieving the intended goals and objectives for the benefit of sage-grouse. Adaptive management allows for information learned through monitoring to be integrated into iterative decision making that can be adjusted as outcomes from management actions become better understood (Williams et al. 2009). Management that does not achieve intended goals and objectives can be modified through adaptive management and contribute to the emerging understanding of management action response, sage-grouse habitat requirements, sage-grouse behavior, and sagebrush ecosystem processes.

Monitoring

Two main categories of monitoring will occur for the State Plan: 1) inventory monitoring and 2) management action monitoring. These are described below. Within each of these categories, additional concepts will need to be considered: short and long-term monitoring, monitoring at multiple scales (e.g., site, landscape) (Swanson et al. 2006), and, for management action monitoring, monitoring for implementation and for effectiveness.

Inventory monitoring assesses the status/extent/condition of sage-grouse populations (e.g., sage-grouse population trends over time), sage-grouse habitats (e.g., gain/loss of sage-grouse habitats over time), and of the threats to sage-grouse (as identified in the State Plan, e.g., how many acres of PJ encroachment are occurring each year). Inventory monitoring provides a quantified understanding of changes in condition and extent of sage-grouse populations, habitat, and threats over time and space, can help prioritize efforts, and can help evaluate success in meeting short and long-term goals and objectives. Many of the state and federal agencies already provide a level of inventory monitoring appropriate for the needs of the state plan and this will be incorporated into the state's monitoring plan- more detail is provided below.

This State Plan identified many management actions to address specific threats. Monitoring of management actions is necessary to ensure that individual actions are accomplishing what they are intended to do. The state will require that monitoring plans be developed for all management actions that occur under direction of the State Plan, including those intended to ameliorate threats outlined in Section 7.0. These plans will include monitoring for implementation and monitoring for effectiveness. Monitoring associated with the Conservation Credit System (see Section 8.0) is detailed in the Habitat Quantification Tool Scientific Methods Document[6] {currently under development}.

---

[6] For more information please refer to The Habitat Quantification Tool Scientific Methods Document on the Sagebrush Ecosystem Program's Website: http://sagebrusheco.nv.gov/CCS/ConservationCreditSystem/[7] Scale of Management Action Monitoring is dependent on management action details specified in Section 7.0

Management Action monitoring for implementation includes: 1) a brief description of the project and the work completed, 2) pre- and post-project photographs, 3) short term monitoring of weather (especially precipitation and when it occurs) and other events (e.g., fire, floods, insects, infestations, etc.) and on-going management (e.g., season of livestock use or livestock, horse, and wildlife population levels) (Swanson et al. 2006), 4) lessons learned during implementation, 5) discussion of impacts to uses and other resources, 6) recommendations on the implementation of future projects, 7) maintenance performed, and 8) accounting of expenditures.

Management Action monitoring for effectiveness can play a key role in demonstrating the accountability, success, and value of management investments. Effectiveness monitoring is designed to determine if the project is effective at meeting its biological and ecological goals and objectives. Project-scale effectiveness monitoring measures environmental parameters to ascertain whether management actions were effective in creating the desired change(s) in habitat conditions and species response. There are at least three important reasons to conduct project-scale effectiveness monitoring on a management action or a change in management: 1) to determine the biotic and abiotic changes resulting on, and adjacent to, the treatment area; 2) to determine if treatment and management actions were effective in meeting the objective(s); and 3) to learn from the management actions and to incorporate new knowledge in future treatment design.

The following concepts should be addressed in all monitoring plans:

- Identify the site conditions and the reasons for implementing management action(s) at the site.
- Set monitoring objectives and indicators – these should quantitatively or qualitatively evaluate the project objectives that will be used to evaluate project implementation and effectiveness in meeting objectives. Effectiveness in meeting objectives will need to be evaluated for both habitat changes and when appropriate and feasible, sage-grouse response.
- Identify anticipated site attribute changes in response to the management action, target values, and time frame under which changes are anticipated. Swanson et al. (2006) explain characteristics of useful and effective resource objectives (**S**pecific, **M**easureable, **A**chievable, **R**elevant, and **T**rackable).
- Select monitoring sites and determine appropriate, effective methods. Include control or reference sites in method design. Baseline data on these will allow before, after, with, and without comparisons.
- Monitoring will be conducted for a minimum of three years or until management objects are met. If, as part of the treatment, grazing was restricted for a time period, post-treatment, monitoring should be conducted for three year following resumption of grazing practices. In addition, monitoring will be conducted at 10 years post-treatment as a follow-up for long-term monitoring.
- Any monitoring plans will be prepared jointly between a project proponent, relevant stakeholders (such as permittees), and land management agency, with final approval from the land management agency.

See resources listed at end of this section for development on monitoring plans.

Adaptive Management

Adaptive management as it relates to sage-grouse and their habitats is a structured, iterative process of robust decision making in the face of uncertainty, with an aim to reduce uncertainty over time through continued monitoring. Because adaptive management is based on a learning system, it improves long term management outcomes. The challenge in using the adaptive management approach lies in finding the correct balance between gaining knowledge to improve management in the future and achieving the best short-term outcomes based on current knowledge (Allan and Stankey 2009).

> "An adaptive management approach involves exploring alternative ways to meet management objectives, predicting the outcomes of alternatives based on the current state of knowledge, implementing one or more of these alternatives, monitoring to learn about the impacts of management actions, and then using the results to update knowledge and adjust management actions" (Williams et al. 2009).

Adaptive management takes monitoring to the next level by establishing, prior to implementation, a framework from which an iterative implementation and learning process can be instituted. Adaptive management implements "learning by doing" and provides flexibility to act in the face of uncertainty.

The following are additional steps to monitoring that need to be addressed to successfully implement adaptive management (Adapted from Williams et al. 2009):

- Identify and record potential drivers of change in the system, threats to the system, and opportunities for beneficial actions. These should be incorporated in the model of response for each management action.
- Development of "models" or hypotheses of the expected response and rationale.
- Development of how management actions should be adjusted following results from monitoring (this should include a set of potential alternatives to management based on the outcome of specific monitoring, allowing for flexibility while based on best available science).
- Implementation of iterative adjustments to management actions following implementation of actions and results of monitoring, following the process outlined in previous bullet.
- Project and management plans should incorporate the ability to change methods when monitoring of the projects or management actions indicate or when new science from research or other monitoring project emerges.

Consideration of when adaptive management is appropriate:

- Decision making must be able to be made in an iterative process
- Monitoring data must be available to decision makers
- It is not appropriate when risks associated with learning based-decision making are too high (i.e., if risk of management action is unknown and worst case scenario has irreversible consequences) in comparison to the risks of not doing so (i.e., the consequences of doing nothing).

See resources listed at end of this section for development on adaptive management plans.

Incorporation of Monitoring and Adaptive Management into the State Plan

A multi-scale monitoring approach is necessary as sage-grouse are a landscape species and conservation is scale dependent to the extent that management actions are implemented within or across seasonal habitats to benefit populations. The state should track the extent of threats to sage-grouse (e.g., fire, pinyon-juniper encroachment, etc.), through inventory monitoring, as well as the efforts to manage the threats (e.g., number of acres of pinyon-juniper treated), through management action monitoring to promote effective species management and understand whether the state is making progress towards the goals and objectives outlined in this plan. Many of the components of inventory monitoring are already being monitored by state and federal agencies. The SETT will work to compile annual monitoring reports that provide a synopsis of these monitoring efforts and metrics relevant to the state plans goals and objectives. The state will engage with stakeholders responsible for these components to facilitate when possible and ensure monitoring occurs. For components that are not currently under the purview of other state and federal agencies, the SETT will work to engage relevant stakeholders to develop a monitoring program. The SETT will develop a comprehensive database to store all monitoring information which will be accessible to the public.

To meet the need for the management action monitoring requirement, all management actions overseen by the SEP will develop monitoring plans following guidance provided in this section. If participating in projects developed by BLM/USFS, NDOW, NDA, NDF, or other agencies, projects should include similar aspects to those outlined here, if not all. As well, all management actions should be reviewed and those appropriate for the adaptive management process should additionally develop an adaptive management plan in coordination with the monitoring plan.

Table 9.1 presents the components (sage-grouse threats, habitats, and populations) that will be monitored to be able to better understand the level of threat to sage-grouse and sagebrush ecosystems and what can be done to respond to the threat for sage-grouse. Elements for inventory monitoring and management action monitoring are outlined as well as the relevant agencies from which monitoring information will be gathered. Monitoring information will be collected across the extent of SGMA and provided at the site, landscape, PMU and state levels and by core, priority, and general management areas. In addition, known changes in extent between years will be documented and total extent of treatments will be summarized.

Additional monitoring components may be identified in the future for inclusion in the annual monitoring report (above and beyond those monitoring components listed in Table 9.1). As additional threats to sage-grouse and sage-grouse habitats are identified, components and leading indicators should be included in inventory monitoring and management action monitoring to better assess and understand the severity of threat and progress in ameliorating the threat.

In addition to the annual monitoring report and database, the state of Nevada will develop a methods document for monitoring plans and adaptive management plans that provide recommended, standardized protocols and methods for objective based monitoring that are consistent with other land jurisdictions and agencies, including BLM, USFS, NDOW, and others.

Table 9.1. Inventory and Management Action Monitoring for the State Plan

Monitoring Component	Agency/Entity	Inventory Monitoring Elements	Management Action Monitoring Elements[7]
Sage-grouse Parameters			
Sage-grouse habitats	NDOW, BLM, USFS, SETT CCS	• Land Health Assessments (BLM) (site, landscape, and state scale) • Resource Implementation Protocol for Condition Assessment Matrices (USFS) • Sagebrush landscape cover (BLM EIS)[8] (landscape scale) • CCS- functional acres lost due to debit projects, functional acres gained due to credit projects (concept of net conservation gain)	• Treatment conducted and effectiveness of treatments (these would be treatments not included in subsequent monitoring components, e.g., meadow restoration)
Sage-grouse populations	NDOW, BLM, USGS	• Lek, lek cluster, PMU counts, populations and trends (all scales) • Telemetry data collection (site to landscape scale- project dependent)	• At this point, the state plan does not outline management actions directly influencing sage-grouse numbers. Management actions outlined directly affect habitat and indirectly affect populations.
Threat			
Fire	BLM, USFS, NDF, NDOW[9]	• Number of fire starts per year • Number and size of fires in each vegetation community, and resistance and resilience classes	• Number of fires "successfully" suppressed (<1,000 acres) • Number of catastrophic fires • Fuels management treatments (conducted and effectiveness of treatments) • Rehabilitation efforts for each fire (implementation and effectiveness of treatments) • Document coordination efforts that aid in efficient and effective fire pre-suppress and suppression management
Cheatgrass	SETT will coordinate with researchers to	• Extent (spatial distribution, acres, and density of	• Treatments conducted and effectiveness of treatments

---

[7] Scale of Management Action Monitoring is dependent on management action details specified in Section 7.0

[8] As part of the Greater Sage-grouse Northern California and Nevada Sub-regional EIS/LUPA, the BLM/USFS have developed a Monitoring Framework (Appendix E of that document) that outlines monitoring for habitat loss, habitat degradation, and population trend (in coordination with NDOW) at the 1st, 2nd, and 3rd order scale (Stiver et al. 2010).

[9] NDOW is engaged with BLM on post -fire treatment monitoring and provides monitoring in conjunction with these agencies post ES&R efforts.

Monitoring Component	Agency/Entity	Inventory Monitoring Elements	Management Action Monitoring Elements[7]
	determine extent BLM, USFS, NDOW, Nevada Cheatgrass Action Team	invasion)	(includes restoration efforts or efforts to improve resilience/resistance)
Noxious weeds[10] Medusahead Hoary cress (*Cardaria draba*) Russian knapweed (*Acroptilon repens*) Leafy spurge (*Euphorbia esula*) Perennial pepperweed (*Lepidium latifolium*) Canada thistle (*Cirsium arvense*) Rush skeleton weed (*Chondrilla juncea*) Yellow starthistle (*Centaurea solstitialis*) Musk thistle (*Carduus nutans*) Spotted knapweed (*Centaurea maculosa*) Scotch thistle (*Onopordum acanthium*) Mediterranean sage (*Salvia aethiopis*) **Other weeds** Red Brome (*Bromus rubens*) Rattlesnake chess (*Bromus briziformis*) Halogeton (*Halogeton gomeratus*) Purple mustard (*Chorispora tenella*)	NDA, NDOW, University of Nevada Cooperative Extension, and SETT	• Extent (spatial distribution, acres, and density of invasion)	• Treatments conducted and effectiveness of treatments
Pinyon-Juniper encroachment	BLM, USFS, NDF, NDOW, SETT, all stakeholders (including researchers at University of Nevada, Reno, and USGS)	• Extent (spatial distribution, acres, and density of invasion)	• Treatments conducted and effectiveness of treatments
Predation	NDOW, Wildlife Services, NDA, and SETT,	• Baseline data collected prior to treatments- data will likely be site specific, not SGMA wide (road kill inventories, raven counts, habitat parameters, etc.)	• Treatments conducted and effectiveness of treatments • Documentation of coordination efforts with city counties, landfills waste managers, livestock owners, research on perching and nest deterrent technology
WHB populations	BLM, USFS	• HMA/WHBT populations • Extent of resources	• Gathers conducted • Treatments conducted and

Monitoring Component	Agency/Entity	Inventory Monitoring Elements	Management Action Monitoring Elements[7]
		damaged by WHB • Understand their timing of use on seasonal habitats • Trend monitoring regarding maintenance of a thriving natural ecological balance for adjusting AML (BLM 2010)	effectiveness of treatments
Livestock grazing	BLM, USFS, permittees and stakeholders	• Allotment standards and guidelines • Dates of use or intensity of use by allotment • Monitoring of attainment of management objectives (Swanson et al. 2006)	• Documentation of changes in management prescriptions to improve management, when appropriate
Anthropogenic disturbances	SETT, BLM, USFS, other federal agencies, all stakeholders	• CCS- functional acres lost due to debit projects, functional acres gained due to credit projects (concept of net conservation gain) • Surface acres impacted • Indirect acres impacted • Identification of existing infrastructure that could be retrofitted, as appropriate (inclusion on the list does not require retrofitting, simply identifying the opportunity)	• Management actions to mitigation for anthropogenic disturbances will be accounted for under the appropriate threat or under habitat and in reporting will be noted as credit projects. • Documentation of implementation of Site Specific Consultation Based Design Features
Recreation and OHVs	SETT, BLM, USFS, Commission on Off-Highway Vehicles and other stake holders	• Permitted activities • Extent of authorized and unauthorized recreational trails and facilities	• Treatments conducted to restore areas impacted by recreational activities and effectiveness of treatments • Documentation of coordination efforts with recreational groups
Weather Variability	NOAA, DRI, State Climatologist, NRCS Water and Climate Center, USGS BLM, USFS, and other stakeholders	• U.S. Drought Monitor • Hydrologic Report • Climate data records (current and historic)	• Tracking changes in management actions due to weather variability
Land Ownership	All agencies	• Tracking of land ownership changes	• Tracking of how changes in management actions due to land ownership affects habitat

Existing monitoring and adaptive management plans and methods

There are several key plans and methods that have been developed for use in Nevada and across the range of the sage-grouse. These should be referenced in the development of resource objectives, management action monitoring plans, and adaptive management plans. The following are recommended for consideration in the State Plan:

Monitoring

Swanson, S., Bruce, B., Cleary, R., Dragt, B., Brackley, G., Fults, G., Linebaugh, J., McCuin, G., Metscher, V., Perryman, B., Tueller, P., Weaver, D. and Wilson, D. 2006. Cooperative monitoring

The state of Nevada recognizes the value of monitoring as well as the time and effort required to do so. Given limiting staffing and resources of agencies, the SETT will encourage and facilitate cooperative monitoring by interested stakeholders. The BLM has established a cooperative monitoring agreement for grazing allotment permittees to help conduct rangeland health assessments on their permitted allotments (See Appendix F). In compilation of the first annual monitoring report and through discussions with stakeholders, the SETT will work to develop similar cooperative monitoring agreements for additional resources with additional agencies and will facilitate development of such to meet the needs for training and quality control.

APPENDICES

Appendix A:

Site Specific Consultation Based Design Features

Site Specific Consultation Based Design Features

Site Specific Consultation Based Design Features (here after Design Features) are used to minimize impacts to sage-grouse and its habitat due to disturbances on a project by project and site by site basis. Design Features in the State of Nevada's plan apply to all newly proposed projects and modifications to existing projects. Existing projects within SGMA are not currently subject to Design Features; however all Design Features listed below, according to program area, are required to be considered as part of the SETT Consultation process. The State of Nevada recognizes that all Design Features may not be practical, feasible, or appropriate in all instances considering site conditions and project specifications, nor is this list completely exhaustive. Therefore, the SETT in coordination with the project proponent, will consider all of the listed Design Features on a site-specific basis taking into consideration the best available science references for guidance in planning and implementation. If certain Design Features are determined to not be practical, feasible, or appropriate for the specific project site, the SETT will document the reasons the Design Features were not selected. The SETT may also consider additional Design Features that may minimize impacts to sage-grouse and its habitat that are not specifically listed here and document the reasons for selecting the additional Design Features.

Roads

These Design Features apply to all new roads, whether a component of a mining/ energy project or for any other purpose.

- Do not construct new roads where roads already in existence, could be used or upgraded to meet the needs of the project or operation.

- Design roads to an appropriate standard, no higher than necessary, to accommodate their intended purpose and level of use.

- Locate roads outside of key sage-grouse seasonal habitat, such as leks and late brood rearing habitat areas. New roads that are located within 3 miles of a lek should have seasonal restrictions from March 1 to May 15 from 1 hour before sunrise to 9 a.m.

- Coordinate road construction and use among ROW or SUA holders.

- Avoid constructing roads within riparian areas and ephemeral drainages (note that such construction may require permitting under section 401 and 404 of the Clean Water Act).

- Construct road crossings at right angles to ephemeral drainages and stream crossings.

- Work with local governments to enforce speed limits and design roads to be driven at speeds appropriate to minimize vehicle/wildlife collisions.

- Establish trip restrictions (Lyon and Anderson 2003) or minimization through use of remote access technology, such as telemetry and remote well control if applicable (e.g., Supervisory Control and Data Acquisition).

- Restrict vehicle traffic to authorized users on newly constructed routes by employing traffic control devices such as signage, gates, fencing etc.

- Dust abatement on roads and pads will be based on road use, road condition, season, and other pertinent considerations.

- Close and rehabilitate duplicate roads by restoring original landform and establishing desired vegetation, in cooperation with landholders and where appropriate authority exists to do so.

Mineral Resources

Fluid Minerals

Operations

- Cluster disturbances associated with operations and facilities as close as possible, unless site specific conditions indicate that disturbances to sagebrush habitat would be reduced if operations and facilities locations would best fit a unique special arrangement.

- Minimize site disturbance though site analysis and facility planning.

- Use directional and horizontal drilling to reduce surface disturbance.

- Place infrastructure in already disturbed locations where the habitat has not been restored.

- Apply a phased development approach with concurrent reclamation through a coordination process among relevant parties.

- Place liquid gathering facilities outside of Core Management Areas. Have no tanks at well locations within Core Management Areas to minimize truck traffic, and perching and nesting sites for ravens and raptors.

- Pipelines should be under or immediately adjacent to the road.

- Reduce motor vehicle travel during field operations through development and implementation of remote monitoring and control systems plans.

To reduce predator perching, limit the construction of vertical facilities and fences to the minimum number and amount needed.

- Site or minimize linear ROWs or SUAs to reduce disturbance to sage-grouse habitats.

- Co-locate new utility developments (power lines, pipelines, etc.) and transportation routes with existing utility or transportation corridors where adequate spacing separation can be achieved in order to preserve grid reliability and ongoing maintenance capability.

- Bury distribution power lines of up to 35kV where ground disturbance can be minimized. Where technology and economic factors allow, bury higher kV power lines.

- Power lines, flow lines, and small pipelines should be co-located under or immediately adjacent to existing roads.

- Permanent structures, which create movement (e.g., pump jack) should be designed or sited to minimize impacts to sage-grouse.

- Preclude sage-grouse access to pits and tanks through use of practical techniques (e.g. covers, netting, birdballs, location, etc.).

- Equip tanks and other above-ground facilities with structures or devices that discourage nesting or perching of raptors, corvids, and other predators.

- Control the spread and effects of non-native, invasive plant species Nevada Department of Agriculture listed noxious weeds (NAC 555.010, classes A through C, inclusive) and undesirable non-native plant species (Gelbard and Belnap 2003, Bergquist et al. 2007) (e.g., by washing vehicles and equipment, minimize unnecessary surface disturbance). All projects within SGMA should have a noxious weed management plan in place prior to construction and operations.

- Use only closed-loop systems for drilling operations and no reserve pits.

- Reduce the potential for creating excessive or unintended mosquito habitat and associated risk of West Nile Virus impacts to sage-grouse. This can be implemented through minimizing pit and pond construction and, where necessary, size of pits and ponds (Doherty 2007).

- Remove or re-inject produced water to reduce habitat for mosquitoes that vector West Nile virus. If surface disposal of produced water continues and West Nile virus has been identified as a concern in the project area, use the following steps for reservoir design to limit favorable mosquito habitat (Dohery 2007):

    – Overbuild size of ponds for muddy and non-vegetated shorelines.

    – Build steep shorelines to decrease vegetation and increase wave actions. Ponds with steep shorelines will be equipped with NDOW approved wildlife escape ramps.

    – Avoid flooding terrestrial vegetation in flat terrain or low lying areas.

    – Construct dams or impoundments that restrict down slope seepage or overflow.

    – Line the channel where discharge water flows into the pond with crushed rock.

    – Construct spillway with steep sides and line it with crushed rock.

    – Treat waters with larvicides to reduce mosquito production where water occurs on the surface if necessary.

- Limit noise to less than 10 decibels above ambient measures one hour before sunrise until 9:00 a.m. within 3 miles of a lek during active lek season, March 1 to May 15 (Patricelli et al. 2010, Blickley et al. 2012, Patricelli et al. 2013).

- Require noise shields when drilling during the lek, nesting, brood-rearing, or wintering season.

- Fit new transmission towers with anti-perch devices (Lammers and Collopy 2007).

- Design and construct fences consistent with NRCS fence standards and specifications Code 382 and, where appropriate, use fence markers (Sage Grouse Initiative 2013).

- Locate new compressor stations outside priority habitats. Otherwise design them to reduce noise that may be directed towards priority habitat.

- Implement site keeping practices to preclude the accumulation of debris, solid waste, putrescible wastes, and other potential anthropogenic subsidies for predators of sage-grouse (Bui et al 2010).

- Locate man camps outside of priority habitats.

Reclamation

- Include objectives for ensuring habitat rehabilitation to meet sage-grouse habitat needs in reclamation practices/sites (Pyke 2011). Address post reclamation management in reclamation plans such that goals and objectives are to protect and improve sage-grouse habitat needs.

- Reseed all areas requiring reclamation with a seed mixture appropriate for the soils, climate, and landform of the area to ensure recovery of the ecological processes and habitat features of the potential natural vegetation, and to prevent the invasion of noxious weeds or other exotic invasive species. Long-term monitoring is required to determine success.

- Maximize the area of interim and concurrent reclamation on long-term access roads and well pads, including reshaping, topsoiling and re-vegetating cut-and-fill slopes. In coordination with appropriate agencies, consider development of fuel breaks in reclamation design.

- Restore disturbed areas at final reclamation to the near pre-disturbance landforms and the desired plant community.

- Irrigate interim reclamation if necessary for establishing seedlings more quickly and if water rights are available.

- Utilize mulching techniques to expedite reclamation and to protect soils.

- Ensure that all authorized ground disturbing projects have vegetation reclamation standards suitable for the site type prior to construction and ensure that reclamation to appropriate sage-grouse standards are budgeted for in the reclamation bond.

Locatable Minerals

For consistency, sage-grouse Design Features for locatable minerals shall be considered in association with state and federal permitting requirements including bonding, if applicable.

Operations

- Cluster disturbances associated with operations and facilities as close as possible unless site specific conditions indicate that disturbances to sagebrush habitat would be reduced if operations and facilities locations would best fit a unique special arrangement.

- Minimize site disturbance though site analysis and facility planning.

- Place infrastructure in already disturbed locations where the habitat has not been restored.

- Apply a phased development approach with concurrent reclamation through a coordination process among relevant parties.

- Reduce motor vehicle travel during field operations through development and implementation of remote monitoring and control systems plans.

- To reduce predator perching, limit the construction of vertical facilities and fences to the minimum number and amount needed.

- Site or minimize linear ROWs or SUAs to reduce disturbance to sage-grouse habitats.

- Co-locate new utility developments (power lines, pipelines, etc.) and transportation routes with existing utility or transportation corridors where adequate separation can be achieved in order to preserve grid reliability and ongoing maintenance.

- Bury distributive power lines of up to 35 kV where ground disturbance can be minimized. Where technology and economic factors allow, bury higher kV power lines.

- Preclude sage-grouse access to pits and tanks through use of practical techniques (e.g. covers, netting, birdballs, location, etc.).

- Equip tanks and other above ground facilities with structures or devices that discourage nesting or perching of raptors, corvids, and other predators.

- Control the spread and effects of Nevada Department of Agriculture listed noxious weeds (NAC 555.010, classes A through C, inclusive) and undesirable non-native plant species (Gelbard and Belnap 2003, Bergquist et al. 2007). All projects within SGMA should have a noxious weed management plan in place prior to construction and operations.

- Reduce the potential for creating excessive or unintended mosquito habitat and associated risk of West Nile Virus impacts to sage-grouse. This can be implemented through minimizing drill and process pit and pond construction and, where necessary, size of drill and process pits and ponds (Doherty 2007).

- Reduce habitat for mosquitoes that vector West Nile virus. If West Nile virus has been identified as a concern in the project area, limit favorable mosquito habitat.

- Limit noise to less than 10 decibels above ambient measures one hour before sunrise until 9:00 a.m. within 3 miles of a lek of a lek during active lek season, March 1 through May 15 (Patricelli et al. 2010, Blickley et al. 2012, Patricelli et al. 2013).

- Require noise shields when drilling during the lek, nesting, brood-rearing, or wintering season.

- Fit new transmission towers with anti-perch devices (Lammers and Collopy 2007).

- Design and construct fences consistent with NRCS fence standards and specifications Code 382 and, where appropriate, use fence markers (Sage Grouse Initiative 2013).

- Implement site keeping practices to preclude the accumulation of debris, solid waste, putrescible wastes, and other potential anthropogenic subsidies for predators of sage-grouse (Bui et al 2010).

- Locate man camps outside of priority sage-grouse habitats.

Reclamation

- Include objectives for ensuring habitat rehabilitation to meet sage-grouse habitat needs in reclamation practices/sites (Pyke 2011). Address post reclamation management in reclamation plans such that goals and objective are to protect and improve sage-grouse habitat needs.

- Reseed all areas requiring reclamation with a seed mixture appropriate for the soils, climate, and landform of the area to ensure recovery of the ecological processes and habitat features of the potential natural vegetation, and to prevent the invasion of noxious weeds or other exotic invasive species. Long-term monitoring is required to determine success.

- Maximize the area of interim and concurrent reclamation on infrastructure related disturbances through reshaping/regrading, topsoiling and re-vegetating cut and fill slopes. In coordination with appropriate agencies, consider development of fuel breaks in reclamation design.

- Ensure that all authorized ground disturbing projects have vegetation reclamation standards suitable for the site type prior to construction and ensure that reclamation to appropriate sage-grouse standards are budgeted for in the reclamation bond.

- Irrigate interim reclamation as necessary during dry periods when valid water rights exist.

- Utilize mulching techniques to expedite reclamation.

Salable and Non-Energy Minerals

Operations

- Cluster disturbances associated with operations and facilities as close as possible unless site specific conditions indicate that disturbances to sagebrush habitat would be reduced if operations and facilities locations would best fit a unique special arrangement.

- Minimize site disturbance though site analysis and facility planning.

- Place infrastructure in already disturbed locations where the habitat has not been restored.

- Apply a phased development approach with concurrent reclamation through a coordination process among relevant parties.

- Reduce motor vehicle travel during field operations through development and implementation of remote monitoring and control systems plans.

- To reduce predator perching, limit the construction of vertical facilities and fences to the minimum number and amount needed.

- Site or minimize linear ROWs or SUAs to reduce disturbance to sage-grouse habitats.

- Co-locate new utility developments (power lines, pipelines, etc.) and transportation routes with existing utility or transportation corridors where adequate separation can be achieved in order to preserve grid reliability and ongoing maintenance.

- Bury distributive power lines of up to 35 kV where ground disturbance can be minimized. Where technology and economic factors allow, bury higher kV power lines.

- Preclude sage-grouse access to pits and tanks through use of practical techniques (e.g. covers, netting, birdballs, location, etc.).

- Equip tanks and other above ground facilities with structures or devices that discourage nesting or perching of raptors, corvids, and other predators.

- Control the spread and effects of Nevada Department of Agriculture listed noxious weeds (NAC 555.010, classes A through C, inclusive) and undesirable non-native plant species (Gelbard and Belnap 2003, Bergquist et al. 2007).. All projects within SGMA should have a noxious weed management plan in place prior to construction and operations.

- Reduce the potential for creating excessive or unintended mosquito habitat and associated risk of West Nile Virus impacts to sage-grouse. This can be implemented through minimizing pit and pond construction and, where necessary, size of pits and ponds Where West Nile virus has been identified as a concern, restrict pond and impoundment construction to reduce or eliminate threats from West Nile virus (Doherty 2007).

- Remove or re-inject produced water to reduce habitat for mosquitoes that vector West Nile virus. If surface disposal of produced water continues and West Nile virus has been identified as a concern in the project area, use the steps described under "Fluid Minerals" for reservoir design to limit favorable mosquito habitat (Doherty 2007).

- Limit noise to less than 10 decibels above ambient measures one hour before sunrise until 9:00 a.m. within 3 miles of a lek during active lek season, March 1 through May 15 (Patricelli et al. 2010, Blickley et al. 2012, Patricelli et al. 2013).

- Require noise shields when drilling during the lek, nesting, brood-rearing, or wintering season.

- Fit new transmission towers with anti-perch devices (Lammers and Collopy 2007).

- Design and construct fences consistent with NRCS fence standards and specifications Code 382 and, where appropriate, use fence markers (Sage Grouse Initiative 2013) around sumps.

- Implement site keeping practices to preclude the accumulation of debris, solid waste, putrescible wastes, and other potential anthropogenic subsidies for predators of sage-grouse (Bui et al. 2010).

- Locate man camps outside of priority sage-grouse habitats.

Reclamation

- Include objectives for ensuring habitat rehabilitation to meet sage-grouse habitat needs in reclamation practices/sites (Pyke 2011). Address post reclamation management in reclamation plans such that goals and objective are to protect and improve sage-grouse habitat needs.

- Reseed all areas requiring reclamation with a seed mixture appropriate for the soils, climate, and landform of the area to ensure recovery of the ecological processes and habitat features of the potential natural vegetation, and to prevent the invasion of noxious weeds or other exotic invasive species. Long-term monitoring is required to determine success.

- Reclamation In coordination with appropriate agencies, consider development of fuel breaks in reclamation design.

- Maximize the area of interim and concurrent reclamation on infrastructure related disturbances through reshaping/regrading, topsoiling and re-vegetating cut and fill slopes. In coordination with appropriate agencies, consider development of fuel breaks in reclamation design.

- Ensure that all authorized ground disturbing projects have vegetation reclamation standards suitable for the site type prior to construction and ensure that reclamation to appropriate sage-grouse standards are budgeted for in the reclamation bond.

- Restore disturbed areas at final reclamation to near pre-disturbance landform and the desired plant community.

- Irrigate interim reclamation as necessary during dry periods when valid water rights exist.

- Utilize mulching techniques to expedite reclamation.

Fuels and Fire Management and Post-Fire Rehabilitation

- Fire and fuels operations should focus on protecting and enhancing occupied sage-grouse habitats. This includes taking into account the feasibility and cost of future rehabilitation efforts during Wildland Fire Decision Support Tree planning and general fire operations in all occupied sage-grouse habitats

Fuels Management

- Design fuels treatment objective to protect existing sagebrush ecosystems, modify fire behavior, restore ecological function, and create landscape patterns which most benefit sage-grouse habitat.

- Incorporate resilience and resistance and other best available science concepts into fuels treatment planning activities

- Provide training to fuels treatment personnel on sage-grouse biology, habitat requirements, and identification of areas used locally.

- Fuels treatment project design in sagebrush and pinyon-juniper encroached sagebrush habitats must be based on the best available science. At a minimum, project proponents will consider best available science including: use of site appropriate state and transition models; ecological site characteristics; and, the evaluation of resilience to disturbance and resistance to invasive annual grasses.

- Ensure the proposed prescription burning plans meet the need of the resource via a comprehensive review by proponents, fire managers, wildlife biologists and resource managers, at a minimum.

- Use prescriptive fire use on project sites where state and transition models, ecological site descriptions and existing high site resilience/resistance are used as principle components of the prescription planning process. The desired outcome of all prescription fire use in appropriate sagebrush habitat is to minimize undesirable long-term effects on vegetation or soils (e.g., minimize mortality of desirable perennial herbaceous species and reduce risk of annual grass invasion).

- Ensure proposed sagebrush treatments are planned with full interdisciplinary input pursuant to NEPA and coordination with NDOW and SETT, and that treatment acreage is conservative in the context of surrounding sage-grouse seasonal habitats and landscape.

- Ensure that treatments are configured in a manner that promotes use by sage-grouse.

- Incorporate roads and natural fuel breaks into fuel break design

- Utilize supervised livestock grazing as a tool to reduce fuels and control non-native species. Targeted grazing needs to be conducted within the framework of the sage-grouse desired habitat conditions (Table 4-1).

- Power-wash all vehicles and equipment involved in fuels management activities prior to entering the area to minimize the introduction of undesirable or invasive plant species.

- Design vegetation treatments in areas of high fire frequency, which facilitate firefighter safety, reduce the potential acres burned, and reduce the fire risk to sage-grouse habitat. Additionally, develop maps for sage-grouse habitat, which spatially display existing fuels treatments that can be used to assist suppression activities.

- For implementing specific sage-grouse habitat rehabilitation projects in annual grasslands, first give priority to sites which are adjacent to or surrounded by Core Management Areas or that reestablish continuity between priority habitats. Annual grasslands are a second priority for rehabilitation when the sites are not adjacent to Core Management Areas, but within two miles of Core Management Areas. The third priority for annual grassland habitat restoration projects are sites beyond two miles of Core Management Areas. The intent is to focus restoration outward from existing, intact habitat. Within these criteria, projects should be prioritized based on probability of success based on current condition, ecological site and state-and-transition modeling if available.

- As funding and logistics permit, rehabilitate annual grasslands to a species composition characterized by perennial grasses, forbs, and shrubs with the goal of establishing a functional ecological site based on state-and-transition modeling and ecological site descriptions..

- Emphasize the use of native plant species, recognizing that non-native species may be necessary depending on the availability of native seed and prevailing site conditions

- Based on ecological site descriptions, remove encroaching pinyon and juniper trees from areas within at least 3 kilometers (1.86 miles) of occupied sage-grouse leks (Connelly et al. 2000) and from other limiting habitats at least 850 meters (e.g., nesting, wintering and brood rearing) to reduce the availability of perch sites for avian predators, as resources permit (Connelly et al 2000, Casazza et al. 2011).

- Protect wildland areas from wildfire originating on private lands, infrastructure corridors, and recreational areas.

- Reduce the risk of vehicle- or human-caused wildfires and the spread of invasive species by installing and maintaining fuel breaks or planting perennial vegetation (e.g., green-strips) paralleling road rights-of-way. Strategically place and maintain pre-treated strips/areas (e.g., mowing, herbicide application, targeted grazing, etc.) to aid in controlling wildfire, should wildfire occur near SGMA or important restoration areas (such as where investments in restoration have already been made).

- All fuels management projects should include short and long term monitoring to ensure success and provide for adaptive management. Multiple re-vegetation entries may be required to ensure success.

Fire Management

- Compile state and local government/District/Forest level information into state-wide sage-grouse tool boxes. Tool boxes will contain maps, listing of state and local resource advisors, contact information, local guidance, and other relevant information for each state and local government/District/Forest, which will be aggregated into a state-wide document. Update the toolbox annually or continually.

- Provide localized maps to dispatch offices and extended attack incident commanders for use in prioritizing wildfire suppression resources and designing suppression tactics.

- Assign a state or local resource advisor with sage-grouse expertise, or who has access to sage-grouse expertise, to all extended attack fires in or near sage-grouse habitat. Prior to the fire season, provide training to sage-grouse resource advisors on wildfire suppression organization, objectives, tactics, and procedures to develop a cadre of qualified individuals. Involve state wildlife agency expertise in fire operations through:

  – instructing resource advisors during preseason trainings;

  – qualification as resource advisors;

  – coordination with resource advisors during fire incidents;

  – contributing to incident planning with information such as habitat features or other key data useful in fire decision making.

- On critical fire weather days, pre-position additional local, state, and federal fire suppression resources to optimize a quick and efficient response in sage-grouse habitat areas.

- Encourage local resources (volunteer fire departments and country equipment) to respond to initial attack efforts and further encourage these agencies to obtain required ICS training to be able to run incidents for longer periods when needed during critical fire periods.

- During periods of multiple fires, ensure line officers, in consultation with state and local resource advisors are involved in setting priorities.

- To the extent possible, locate wildfire suppression facilities (i.e., base camps, spike camps, drop points, staging areas, heli-bases, etc.) in areas where physical disturbance to sage-grouse habitat can be minimized. These include disturbed areas, grasslands, near roads/trails or in other areas where there is existing disturbance or minimal sagebrush cover.

- Power-wash all firefighting vehicles, to the extent possible, including engines, water tenders, personnel vehicles, and all-terrain vehicles (ATV) prior to deploying in or near sage-grouse habitat areas to minimize noxious weed spread. Minimize unnecessary cross-country vehicle travel during fire operations in sage-grouse habitat.

- Minimize burnout operations in key sage-grouse habitat areas by constructing direct fire line whenever safe and practical to do so.

- Utilize retardant, mechanized equipment, and other available resources to minimize burned acreage during initial attack.

- As safety allows, conduct mop-up where the black adjoins unburned islands, dog legs, or other habitat features to minimize sagebrush loss.

- Adequately document fire operation activities in sage-grouse habitat for potential follow-up coordination activities.

- Coordinate and utilize local fire suppression resources to the maximum extent possible.

- Eliminate “burning out” islands and fingers of unburned sage-grouse habitat, unless lives and property are at risk.

Post-Fire Rehabilitation

- Emphasis should be on fall re-vegetation to ensure greatest likelihood of success.

- All post-fire rehabilitation projects should include short- and long-term monitoring to ensure success and provide for adaptive management. Multiple re-vegetation entries may be required to ensure success. Emphasize the use of native plant species in post-fire rehabilitation, recognizing that non-native species may be necessary depending on the availability of native seed and prevailing site conditions. Selected species maintain site ecological function based on pre-burn conditions and anticipated threat of invasive and noxious weed establishment. Use ecological site descriptions and state-and-transition models if available.

- Reseed all burned areas requiring rehabilitation with a seed mixture appropriate for the soils, climate, and landform of the area to ensure recovery of the ecological processes and habitat features of the potential natural vegetation, and to prevent the invasion of noxious weeds or other exotic invasive species. Long-term monitoring is required to determine success.

- Power-wash all vehicles and equipment prior to entering sage-grouse habitat rehabilitation/restoration areas to minimize noxious weed spread. Minimize unnecessary cross-country vehicle travel during rehabilitation/restoration operations in sage-grouse habitat.

- Consider Integrated Pest Management (IPM) practices to ensure greater initial control of invasive and noxious plant species.

- Sage-grouse seasonal habitat requirements must be considered when selecting re-vegetation materials in all burned potential and current sage-grouse habitat.

- Prioritize shrub island plantings in large burn areas which may lack sufficient shrub seed sources, in order to ensure the reestablishment of the shrub component.

Vegetation Management

- Avoid sagebrush removal in sage-grouse breeding or wintering habitats.

- Maintain all remaining large intact sagebrush patches, particularly at low elevations, through active management, in order to increase resistance and resilience to reduce the risk of being lost to wildfire.

- Limit habitat treatments in winter ranges to actions that maintain or expand current or needed levels of sagebrush available in winter.

Lands and Realty

Leases and Permits

- Permits and leases must include stipulations to minimize impacts to sage-grouse and sage-grouse habitats based upon the specific activity and ensure no net loss of sage-grouse habitat.

Right-of-Ways (ROWs)

- Work with existing rights-of-way holders to encourage installation of perch guards on all poles where existing utility poles are located within 5 km (3.2 miles) of known leks (Coates et al. 2013).

- Use existing utility corridors and consolidate rights-of-way to reduce habitat loss, degradation, and fragmentation. Install new power lines within existing utility corridors.

- Where sage-grouse conservation opportunities exist, BLM field offices and Forests should work in cooperation with rights-of-way holders to conduct maintenance and operation activities, authorized under an approved ROW grant, to avoid and minimize effect on sage-grouse habitat.

- When renewing or amending ROWs, assess the impacts of ongoing use of the ROW to sage-grouse habitat and incorporate stipulations, which minimize such impacts to the extent allowed by law.

- Conduct pre-application meetings with the BLM or Forest Service and SETT for all new ROW proposals consistent with the ROW regulations (43 CFR 2804.10) and consistent with current renewable energy ROW policy guidance (WO-IM-2011-061, issued February, 2011). Assess the impact of the proposed ROW on sage-grouse and its habitat, and implement the following: Ensure that reasonable alternatives for siting the ROW outside of sage-grouse habitat or within a BLM designated utility corridor are considered and analyzed in the NEPA document; and identify technically feasible best management practices, conditions, (e.g., siting, burying power lines) that may be implemented in order to eliminate or minimize impacts.

- Maximize the area of interim reclamation on long-term access roads and well pads including reshaping, top-soiling and re-vegetating cut and fill slopes.

- Authorize ROWs for wind energy development projects by applying appropriate Design Features as specified in the BLM Wind Energy Development EIS (BLM 2005), land use restrictions, stipulations, and mitigation measures.

- Bury distribution power lines of up to 35kV where ground disturbance can be minimized. Where technology and economic factors allow, bury higher kV power lines.

- Where existing leases or rights-of-way (ROWs) have had some level of development (road, fence, well, etc.) and are no longer in use, reclaim the site by removing these features, without interfering with valid pre-existing rights, and restoring the habitat.

- Within designated ROW corridors encumbered by existing ROW authorizations: new ROWs should be co-located to the extent practical and feasible with the entire footprint of the proposed project adjacent to or within the existing disturbance associated with the authorized ROWs taking into account operational requirements and safety.

- Subject to valid, existing rights, where new ROWs associated with valid existing rights are required, co-locate new ROWs within existing ROWs or where it best minimizes sage-grouse impacts. Use existing roads, or realignments as described above, to access valid existing rights that are not yet developed. If valid existing rights cannot be accessed via existing roads, then build any new road constructed to the minimum standard necessary.

- Upon project completion, roads used for commercial access on public lands would be reclaimed, unless, based on site-specific analysis, the route provides specific benefits for public access and does not contribute to resource conflicts.

- Construct new power lines outside of sage-grouse habitat wherever possible. If power lines cannot be sited outside of sage-grouse habitat, site power lines in the least suitable habitat possible or bury power lines, where technology and economic factors allow.

- Remove power lines that traverse important sage-grouse habitats when facilities being serviced are no longer in use or when projects are completed.

- Install anti-perching and anti-nesting measures on new tall structures, such as power lines, commensurate with the design of the structures.

Travel and Transportation

- Work with local government to enforce speed limits and design roads to be driven at speeds appropriate to minimize vehicle/wildlife collisions.

- Conduct rehabilitation of roads, primitive roads, and trails not designated in travel management plans where such plans exist and have been approved for implementation. This also includes primitive route/roads that were not designated in wilderness study areas and within lands managed for wilderness characteristics that have been selected for protection, with due consideration given to any historical significance of existing trails.

- When reseeding roads, primitive roads, and trails, use appropriate seed mixes and consider the use of transplanted sagebrush in order to trend towards achieving sage-grouse desired habitat conditions (Table 4-1). Where invasive annual grasses are present, herbicides may be used to enhance the effectiveness of any seeding and to also establish islands of desirable species for dispersion.

- Use existing roads, or realignments to access valid existing rights that are not yet developed. If valid existing rights cannot be accessed via existing roads, then any new roads would be constructed to the minimum standard necessary to support the intended use.

- Work with local governments to minimize upgrading of existing routes that would change route category (road, primitive road, or trail) or capacity unless the upgrading would have minimal impact on sage-grouse habitat, is necessary for motorist safety, or eliminates the need to construct a new road, while providing for the intended use.

- Manage on-road travel and OHV use in key grouse areas to avoid disturbance during critical times such as winter and nesting periods.

- Consider road removal, realignment, or seasonal closures where appropriate to avoid degradation of habitat and /or to avoid disturbance during critical periods of the sage-grouse life cycle.

Recreation

- Special recreation permits must have stipulations to minimize impacts to sage-grouse and sage-grouse habitat based upon the specific activity and ensures net conservation gain of sage-grouse habitat.

- Issue special recreation permits with appropriate distance and timing restrictions to minimize impacts to seasonal sage-grouse habitat.

- Develop trail mapping, and educational campaigns to reduce recreational impacts on sage-grouse, including effects of cross country travel.

- Where feasible, locate recreation trails strategically to create or augment fuel breaks in the margins of sage-grouse habitats and landscapes and not create roads or trails where they cause net negative direct and indirect impacts.

- Take measures to minimize or reduce activities and to avoid an ambient noise level increase >10 dB at the edge of leks during the lekking season generally, March 1 through May 15 from one hour before sunrise until 9:00 a.m. (Patricelli et al. 2010, Blickley et al. 2012, Patricelli et al. 2013).

Energy Development and Infrastructure

- Adopt standards outlined in *Nevada Energy and Infrastructure Development Standards to Conserve Greater Sage-grouse Populations and Their Habitats,* April 2010, pgs. 25-29 (Appendix G).

Wild Horses and Burros

- When conducting NEPA analysis for wild horse and burro management activities, water developments or other rangeland improvements for wild horses in sage-grouse habitat, address the direct and indirect effects to sage-grouse populations and habitat. Implement any water developments or rangeland improvements using the criteria for wild horses and burros year around use and ensure that it is consistent with the necessary rights and right of ways in sage-grouse habitats. Incorporate the NRCS water development standards and additional criteria listed below, including Codes 614, 574, 533, 642, and 516.

Livestock Grazing and Range Management

• Where applicable and as part of a ranch management plan, use the Natural Resource Conservation Service (NRCS) Conservation Practice Standards and Specification listed below[11]. In addition, use the recommendations additions to the standards developed by NRCS and NDOW as part of NRCS' Sage-grouse Initiative and further expanded by the state of Nevada in this document:

- Code 645: Upland Wildlife Habitat Management
- Code 528: Prescribed Grazing
    - Emphasize rest periods or seasonal deferment when appropriate as part of the grazing management plan and restoration.
- Code 614: Water Facilities
    - Avoid placement where existing sagebrush cover will be reduced near a lek, in nesting habitat, or winter habitat whenever possible. NDOW recommends structures be at least 1 mile from a lek.
- Code 574: Spring Development
    - Springs may be developed as long as valid water claims or rights exist and development shows a net benefit to overall habitat management within a SGMA.
- Code 533: Pumping Plant
    - NDOW recommends the structure should not be placed within 3 miles of a lek to avoid disturbance to nesting sage-grouse.
- Code 642: Water Well
    - Well placement should encourage dispersion of livestock and provide for a neutral or no net negative impact to habitat within a SGMA. Further water developments will decrease concentrated livestock and wildlife use and further protect sagebrush habitats.
- Code 516: Livestock Pipeline
    - Pipelines shall be replaced as needed to provide for better dispersion of livestock.
    - Pipelines shall be replaced along existing pipelines, roadways, or fences.
    - Replacement and maintenance of pipelines shall use the least invasive techniques and extensive work requiring heavy equipment shall be done in a manner consistent with season of use by the sage-grouse (i.e. replacing improvements in sage-grouse winter habitat during the summer and replacing improvements in breeding and nesting habitat during the fall)
    - Replacement of improvements shall be allowed in order to not jeopardize existing and valid claims and rights.
- Code 410: Grade Stabilization Structure
    - If possible, avoid the installation of these structures during the late summer brood rearing period. NDOW recommends structure placement in mid-September through late November.
- Code 382: Fence
    - If possible, fencing should not be constructed near a lek and should be avoided in winter habitats near ridges. To make a fence more visible, use white tipped metal fence posts,

---

[11] These USDA; NRCS Conservation Practice Codes as well as others can be found at: http://www.nrcs.usda.gov/wps/portal/nrcs/detailfull/national/technical/references/?cid=nrcs143_026849

securing flagging or reflectors to the top fence wires, or slide sections of PVC pipe over the top wire (Stevenson and Reece 2012).

- Relocate or modify existing water developments (including locating troughs to further disperse livestock) that are having a net negative impact on sage-grouse habitats. Any changes to existing water developments must be conducted in accordance with State Water Law and in close consultation with the water right owner in order to avoid a "taking" of private property water rights.

- All troughs should be outfitted with the appropriate type and number of wildlife escape ramps.

- All field and district offices should apply BLM IM 2013-094 or similar methodology until superseded related to drought management planning.

Surface Disturbing Activities – General

- During the period specified, based upon site-specific conditions manage discretionary surface disturbing activities and uses to prevent disturbance to sage-grouse during life cycle periods. Seasonal protection is identified for the following:

  -Seasonal protection within three (3) miles of active sage-grouse leks from March 1 through June 15 during lekking hours of 1-hour before sunrise until 9:00 a.m.

  -Seasonal protection of sage-grouse suitable wintering areas from November 1 through March 31;

  -Seasonal protection of sage-grouse suitable brood-rearing habitat from May 15 to August 15.

- Implement appropriate time-of-day or time-of year restrictions for future construction or maintenance activities in known sage-grouse habitat

- Reseed all areas requiring reclamation with a seed mixture appropriate for the soils, climate, and landform of the area to ensure recovery of the ecological processes and habitat features of the potential natural vegetation, and to prevent the invasion of noxious weeds or other exotic invasive species. Long-term monitoring is required to determine success.

- Minimize the footprint of disturbances to avoid or minimize the potential for invasive plant infestations. When possible, do not remove native vegetation. Monitor, report, and treat all disturbance sites that become occupied by invasive plants, primarily cheatgrass, and all state listed noxious weeds. Pre- and post-disturbance activities must include prevention strategies prior to entering sites. Treatments, restoration, and monitoring are required for a minimum of three years or until the site is deemed noxious and invasive weed free following the disturbance. Reporting should be sent to the Nevada Department of Agriculture via the EDDMapS link on their website.

- Maximize the area of interim reclamation on long-term surface disturbing activities to including reshaping, top-soiling and re-vegetating areas no longer being disturbed within the overall project foot print.

Miscellaneous

- In Wilderness and Wilderness Study Areas (WSA), the state of Nevada will work with the federal land management agencies to investigate the use of mechanized equipment in those areas in conformance with the Wilderness Act, Federal Land Policy and Management Act, and National Forest Management Act. The State will also support congressional efforts to investigate and responsibly use additional techniques (including mechanized) to protect or restore areas that exhibit unique or emergency circumstances (fire, P/J expansion, invasive weeds infestations, excessive fuels, etc.) in order to protect the area from long term resource damage..

- Work with federal, state, and local governments and project proponents to minimize anthropogenic subsidies for predators, including ravens.

Appendix B:

Development Process and Justification for Desired Habitat Conditions

for Greater Sage-Grouse in Nevada

Greater Sage-Grouse Proposed Desired Habitat Conditions

Questions and Answers

1. How were the Proposed Desired Habitat Conditions for GRSG developed?
   The proposed Desired Habitat Conditions are a synthesis of existing data across the state of Nevada and portions of the Bi-State in California. The U.S. Geological Survey was primarily responsible for much of the synthesis and in translating often complex habitat relationships and GRSG responses into the proposed desired habitat conditions which could be summarized and applied on the ground. A team consisting of representatives from the U.S. Fish and Wildlife Service, BLM, Nevada Department of Wildlife, and U.S. Forest Service reviewed the Connelly et al. 2000 guidelines and also reviewed a bibliography of Nevada-based research made available by the U.S. Geological Survey. The team then went through each Connelly et al. 2000 guideline and reviewed it with respect to localized data. The Connelly et al. 2000 guidelines remained as a default unless refined by new information. In March 2015, the Science Work Group met and further revised the State Plan section 4.0 and the desired habitat conditions table.

2. Why are the Proposed Desired Habitat Conditions for GRSG different from Connelly et al. 2000 guidelines?
   The Connelly et al. 2000 guidelines were a strong synthesis of research until that time. The guidelines themselves suggest that studies which define GRSG habitat on a more region-specific basis should be used where supported by research. These proposed desired habitat conditions respond to more localized data than the Connelly et al. 2000 guidelines, which relied heavily on data from the eastern half of the range of GRSG where a perennial grass component is more dominant, and where large-scale ecological changes such as invasive grasses and conifer encroachment are largely absent. The proposed desired habitat conditions reflect those differences.

3. What are the differences between the Proposed Desired Habitat Conditions for GRSG and Connelly et al. 2000 guidelines?
   While numerous differences exist, they are driven primarily by three elements: 1) the reduced role of perennial grasses for nest concealment as revealed by many nesting habitat studies throughout Nevada; 2) the increased habitat fragmentation and degradation as a result of invasive grasses and conifer encroachment; and 3) the elevated importance of late-summer brood-rearing habitats in the lower precipitation zones of Nevada. The proposed desired habitat conditions also reflect recent research into more complex aspects of habitat juxtaposition, such as the interspersion of meadow habitat with adjacent sagebrush cover, and the attempt to quantify other scale-dependent relationships such as the degree of conifer encroachment.

4. Are the Proposed Desired Habitat Conditions for GRSG supported by science?
   The proposed desired habitat conditions are supported by numerous studies throughout Nevada from the Bi-State area in southwestern Nevada and California through the Elko District into northeastern Nevada. Much of the synthesis of research which resulted in these proposed desired habitat conditions for GRSG was conducted by the U.S. Geological Survey.

5. Are the Proposed Desired Habitat Conditions for GRSG consistent with the BLM National Technical Team report (NTT)?

   The NTT report suggests the use of local and state seasonal GRSG desired habitat conditions when they are available and references the habitat recommendations from Connelly et al. 2000 if they are not.

6. What is the rationale for eliminating the residual cover standard (7 in/18cm) from GRSG nesting habitat?

   Localized data indicate that sagebrush canopy cover was the primary indicator of nesting success within Nevada. Research indicates that the primary deterrent to successful nesting was predation, specifically by common ravens, an aerial predator. Thus, the research demonstrated that overhead concealment was the primary indicator of nesting success and that the lateral concealment component of perennial grasses drove nesting success only when sagebrush canopy was deficient.

7. What is the difference between tall trees and power lines?

   These differ in degree of impact. Generally, power lines are larger and have much greater visibility. They contribute to fragmentation and provide potential predators with larger scale, more pervasive access to habitats.

RESOLUTION
OF
INTER-TRIBAL COUNCIL OF NEVADA, INC.

SAGE GROUSE MANAGEMENT AREA ON TRIBAL LANDS

WHEREAS, The Inter-Tribal Council of Nevada, Inc., is organized and operates in accordance with its Constitution and By-Laws, amended in November 1974; and

WHEREAS, the purposes of Inter-Tribal Council of Nevada, Inc. (ITCN), are stated in its Constitution, Preamble; and

WHEREAS, the Executive Board, a body comprised of the twenty-seven (27) representatives of the federally recognized member tribes in the State of Nevada and whose Charter is ratified by these same tribes; and

WHEREAS, the Inter-Tribal Council of Nevada has a continuing interest in the health, education and well-being of their Indian people; and

WHEREAS, the Inter-Tribal Council of Nevada respects the sovereign to sovereign relationship between the Tribes and the State of Nevada and the federal government; and

WHEREAS, a Memorandum of Agreement may be sought on behalf of each individual Tribe to further develop the efforts needed for the management, monitoring, and surveying for sage grouse.

ITCN Executive Board

Appendix D:

Cooperation of State and Federal Agencies for Depredation Permits for Common Raven

Cooperation of State and Federal Agencies for Depredation Permits for Common Raven

The USFWS can authorize depredation permits for the 'take' of common ravens, which are protected under the Migratory Bird Treaty Act. Currently in the State of Nevada, there are permits that authorize the 'take' of approximately 5,000 ravens annually, which constitutes five percent of the estimated 100,000 resident ravens (2003 estimate, Wildlife Services) in Nevada. NDOW is authorized to take 2,500 ravens; USDA-APHIS-Wildlife Services (WS) is authorized to take 1,500, and other private sources around 1,000. NDOW's permit is specifically authorized for the protection of sage-grouse and other game species. WS' permit is authorized for the protection of livestock. Other permits are authorized for the protection of property, public health and welfare (power companies, landfills, etc.). The most recent population estimate for Nevada is 190,000 ravens (2013 estimate, WS). This may potentially lead to an increase in permit allocations in the future if they can be justified

WS is a federal agency that works cooperatively with the Nevada Department of Agriculture's Division of Animal Industry. Its primary objective is to protect livestock and farming interests from damage caused by predators or other nuisance species. WS is authorized to perform their duties on federal land and may enter into agreements with state, tribal, county, or private landowners to conduct their business. Predator control is a major component of their duties.

Specific to ravens, WS certified applicators are the only ones authorized by the EPA to either apply or directly supervise those applying the avicide DRC-1339 to execute the federal depredation permit authorized by the USFWS for the taking of migratory birds.

Currently, WS and NDOW are working jointly to reduce raven densities with the aim to enhance sage-grouse recruitment rates, which can be affected by raven predation of sage-grouse eggs and chicks. NDOW designates priority areas for treatment and WS treats hard-boiled chicken eggs with DRC-1339 and places them within the priority areas. Monitoring and data collection is done by both agencies as well as other partners to inform future implementation of the program and determine the efficacy of the protocols used.

Appendix E:

Process to Prioritize Integrated Predator Management Projects

Process to Prioritize Integrated Predator Management Projects

The following frame work will be used to prioritize where Objective 1.1, 1.2, and 1.3 are implemented across the state.

Step 1: State level mapping for ravens and sage-grouse. This should be an ongoing process updated every few years.

a. Contract with USGS to conduct landscape level modeling to estimate location of high raven occupancy (following methods for Raven Selection Probability Function (RSPF) as described in Coates et al., In Review).
   If funding is not available to conduct modeling, regional biologists would submit areas of concern for evaluation.

b. Conduct modeling of sage-grouse nesting habitat

c. Intersect areas of raven concern with areas of sage-grouse nesting habitat. Select 5-15 sites to be evaluated at the site level. Until map of nesting habitat for sage-grouse in Nevada is available, the Core Management Area should be used.

Step 2: Site level analysis. This step should be conducted annually.

a. Conduct raven surveys at 5-15 sites identified during Step 1 following a selected raven survey protocol to determine raven densities.
b. Evaluate sage-grouse demographic data, as available, to determine if nest success is a limiting factor. Areas identified for potential raven removal should be prioritized for sage-grouse demographic data collection as feasible.
c. Use information from the above two steps to identify 2-5 project sites for Integrated Predator Management around the State. Sites that have identified nest success as limiting to the populations due to raven predation should be prioritized for treatment. Sites that have greater than 0.46 ravens per km^2 should be prioritized for treatment (Coates et al., In Review). Exact number of project locations should be determined by number of raven take permits available, funding for projects, and personnel to carry out work.

Once Prioritized Integrated Predator Management Project locations are identified, the following steps should be completed.

1. Develop Integrated Predator Management Program for each project location.
    a. Develop anthropogenic subsidies control plan for project location following recommendations in Predation Goal 1 Objective 1.
    b. Develop habitat integrity improvement plan for project location recommendations in Predation Goal 1 Objective 2.
    c. Develop predator control plan for project location following recommendations in Predation Goal 1 Objective 3.
        i. Develop treatment regime for project area

        1. Determine/set parameters of predator control area (where damage is occurring)
        2. Determine/set parameters of predator control project timing (when resource is vulnerable)
        3. Establish species to be targeted and methods/techniques which are acceptable
        4. Determine what constitutes a “corrected” situation (when does project end, e.g. stop lethal control once raven density is below density thresholds or a lack of population response to actions is determined)
    ii. Establish predator monitoring regimes
        1. Pre-treatment monitoring of predator numbers (frequency, number & type).
        2. Treatment monitoring of predator numbers (frequency, number & type).
        3. Post-treatment monitoring of predator numbers (frequency, number & type).
    iii. Establish sage-grouse monitoring regimes
        1. Monitor sage-grouse population trends/demographic rates to determine effectiveness of predator control practices.

Appendix F:

Template Cooperative Monitoring Agreement

COOPERATIVE MONITORING AGREEMENT

1. Introduction

The Joint Cooperative Monitoring Agreement is instituted under the authority of the Memorandum of Understanding between the U.S. Department of the Interior, Bureau of Land Management (BLM) and the Public Lands Council dated January 30, 2004.

The BLM and ______[*cooperator*] enter into this agreement with the intent to strengthen their partnership in monitoring of the ________ Allotment. Resource objectives will be a central feature of this agreement because they will become the target and guide regarding what and how to monitor, and for what reasons. Resource objectives will be measurable and attainable statements of the desired resource attributes.

The BLM and ______[*cooperator*] expect the monitoring plan to evolve over time. New data will provide input on how to better interpret and apply the monitoring results. This will enable the parties to optimize the application of cooperative techniques throughout the monitoring partnership. The parties will work together to determine how the monitoring results will be used to refine and redirect the strategies and tactics for both the monitoring and management plans.

2. Existing Management Objectives

The ________ Allotment was evaluated through a Rangeland Health Evaluation and Assessment document in _____[*year*]. Allotment-specific objectives were brought forward through the Final Multiple Use Decision (FMUD) for each key management area for upland areas, riparian zones, wildlife habitat, and wild horse and burro management. These objectives were established to be in conformance with the current Land Use Plan (LUP) and the Standards for Rangeland Health. Objectives under the LUP, Rangeland Program Summary, and Allotment Evaluation are attached. Also attached are the __________ Resource Advisory Council Standards and Guidelines (RAC S&Gs).

3. Existing Monitoring Data/Information and Additional Data Needs to Address Established Resource Objectives

a. Established Monitoring Methodologies

Short-term	**Long-term**
Actual Use Information	Trend (Frequency study)
Use Pattern Mapping	Production/Composition/Ecological Status
Key Species Utilization at long-term	Cover

upland monitoring sites	
Riparian Utilization	Weed Inventory
	Water Quality
	Climate data
	Wild Horse & Burro Census
	Riparian Proper Functioning Condition (PFC) Assessment

b. Additional Studies Needed

Short-term	Long-term
None	Upland Soil Site Stability
	Photo Trend Monitoring
	Riparian Multiple Indicator Monitoring (MIM)

4. **Future Monitoring Attributes and Protocols**

   a. Key Management Areas, Critical Area, or Designated Management Areas have been selected for the _________ Allotment utilizing BLM protocols. The site(s) will be reconfirmed jointly. If a site is not reconfirmed as an appropriate monitoring site, consideration must be given to the historical data associated with the site and a determination should be made whether or not to continue monitoring this site to retain trend information.

   b. Monitoring by the BLM and the cooperator will be consistent with BLM protocol and technical references. Short and long-term monitoring studies will allow for measurement(s) towards specific objective(s).

   c. Any updates to technical references/BLM protocol will be incorporated for use under this cooperative monitoring agreement in the future. If additional monitoring studies become available that will supplement studies already occurring for measuring an objective, this cooperative monitoring agreement will be updated.

5. **Frequency and Timing of Monitoring (cooperator/agency specific for each cooperative monitoring agreement and cooperator interest)**

   a. Short-term monitoring will be collected on an annual or semi-annual basis, unless otherwise stipulated. Long-term monitoring will be measured at 3-10 year intervals unless otherwise stipulated or if observations indicate a more rapid than expected rate of change. Observers will be consistent in the plant phenology or time of year in which data are collected. If new sites are established, data collection will follow BLM protocol, BLM technical references, and this Cooperative Agreement.

b. The following monitoring studies will be conducted as appropriate in order to measure progress towards meeting the objectives and for determining if the RAC S&Gs are being met.

Short-term monitoring (Upland triggers or indicators):

Study	**Responsible Party**	**Collection Period**
Actual Use	Cooperator	Annually
Trigger Monitoring	Cooperator	Annually
Key Area Utilization	BLM	Semi-annually
Landscape Appearance (Ranchers' Monitoring Guide)	Cooperator	Annually
Use Pattern Mapping	BLM	As grazing management changes, funding, and priorities dictate
Climate	BLM and Cooperator	Annually

Long-term monitoring (Upland objectives):

Study	**Responsible Party**	**Collection Period**
Frequency	BLM	Every 5-10 years
Photo Trend	Cooperator	Annually
Production/Composition	BLM	Every 5-10 years
Line Intercept	BLM	Every 5-10 years
Line-Point Intercept	BLM	Every 5-10 years

Short-term monitoring (Riparian triggers or indicators):

Study	**Responsible Party**	**Collection Period**
Utilization/Stubble Height	BLM	Every 3-5 years
Stream Bank Alteration	BLM	Every 3-5 years

Long-term monitoring (Riparian objectives):

Study	**Responsible Party**	**Collection Period**
PFC (assessment)	BLM	Every 5-10 years
Multiple Indicator Monitoring	BLM	Every 5-10 years

c. Each party will contact the other party prior to collecting monitoring data on the ___________ Allotment in order to further promote a cooperative and collaborative working environment.

d. If a cooperator is interested, they may request to collect additional monitoring studies from those assigned above after adequate training and verification by the BLM.

e. Parties are encouraged to conduct monitoring efforts together, where possible.

6. Data Analysis

a. The BLM and the Permittee will meet to discuss the monitoring data collected. Each party will be provided copies of the monitoring data collected each given year for the associated monitoring file.

b. The BLM and the Cooperator will meet periodically to discuss the monitoring data collected.

c. The BLM and the Cooperator will review data analysis jointly and discuss any future changes that may be needed in order to address resource concerns.

7. Agreement Implementation

a. Collection of monitoring data specified in this cooperative agreement will occur at appropriate times immediately upon signature of this agreement. Data share between the parties will occur by the end of each calendar year.

BLM Authorized Officer____________________ Date_________________________

Appendix G:

Nevada Energy and Infrastructure Development Standards to Conserve Greater Sage-grouse Populations and their Habitats, excerpt page 25-29

VII. Standards to Avoid or Minimize Impacts to Sage-grouse (All Energy Developments)

It is important to note here that some recommendations differ for non-migratory and migratory populations of sage-grouse. For the purposes of this document, non-migratory populations of sage-grouse are those where the majority of individuals do not make long distance movements between or among seasonal ranges (individuals travel <10 km one way between seasonal ranges). Migratory populations are those in which a preponderance of individual grouse move ≥10 km one way between seasonal ranges (derived from Connelly et al. 2000).

A. Site Selection

1. The NGSCT considers Category 1 habitats (leks and nesting habitat) irreplaceable and Category 2 habitats (quality winter and brood rearing habitats) critical to the long term persistence of sage-grouse populations. Energy or transmission development should be avoided within Category 1 and 2 sage-grouse habitats.
2. Energy development is strongly discouraged from occurring in Category 3 habitats; however, if unavoidable, projects in these habitats should be situated to minimize impact through placement in the least suitable portion of habitat.
3. Renewable energy developers are encouraged to pursue project development activities within Category 4 and 5 habitats within the range of sage-grouse in Nevada.
4. Project proponents should focus on previously disturbed sites in high potential wind resource areas. These areas could be described as those with prior disturbances including, but not limited to, previously burned areas, dense pinyon and juniper woodlands, areas converted to agriculture and areas within existing linear rights of way (transmission corridors).
5. If habitat categories have not been identified for a certain area, energy facilities and transmission lines should not be sited within 3 miles of the nearest active lek location for non-migratory populations[3].
   a. To the greatest extent possible, energy developers should work closely with NDOW and pertinent federal agency biologists to determine important nesting, brood rearing and winter habitats and avoid those areas.
6. Where populations of sage-grouse are considered migratory, energy facilities and transmission lines should not be sited within 3 miles of the nearest active lek location and should not be sited within the associated nesting habitat for that particular population.
   a. Consideration should also be given to movement corridors between breeding, nesting, brood-rearing or winter habitat. These movement corridors may not be well defined unless significant radio marking investigations have been conducted for a particular population. It is recommended that these investigations take place where project proponents are proposing developments in likely movement corridors for sage-grouse.
7. No development should occur within a 0.6 mile (1 km) radius around seeps, springs and wet meadows within identified brood rearing habitats.

---

[3] Holloran (2005) found that natural gas development within 3 – 5 km (approximately 2 - 3 miles) of active sage-grouse leks led to dramatic declines in breeding populations. Walker et al. (2007) also found that coal-bed natural gas development within 0.8 km and 3.2 km had strong negative effects on sage-grouse and detected effects as far as 6.4 km. Johnson et al. (In Press) found that few leks were located within 5 km (≈3 miles) of developed land and trends in male attendance were lower for those leks with more developed land within 5 km or 18 km.

B. Pre-Development Planning and Survey Requirements (All Energy Related Developments)

Each proposed energy facility requires some level of detailed individual evaluation. Unique habitat conditions can and do exist due to local variations in wildlife populations and movement patterns, habitats, area topography, facility design, and weather (Alberta Fish and Wildlife Division 2005). The level of pre-project planning and the need for certain surveys or monitoring depends on the seasonal habitat that the project is located in and the importance of the particular habitat. It is the intent of the NGSCT to complete mapping of habitat categorizations in 2010. The following are standards recommended by the NGSCT for pre-project planning and surveys:

1. Identify the cover type of habitat and habitat category of proposed development by using R-value classifications, current seasonal habitat delineations and previous telemetry information. These habitat types and categories should be determined on a site specific basis through consultation with NDOW.
2. A remote assessment (utilizing GIS applications) of present habitat condition should be conducted. This assessment should include vegetative classification, seasonal habitat layers, aerial photos, fire polygons and other man-made structures on the landscape including transmission lines, roads or other anthropogenic features.
3. If the project happens to occur in Category 1 or 2 habitats, a comprehensive monitoring plan should be developed and approved by NDOW that addresses demographics and seasonal movement patterns. The Western Agencies Sage and Columbian Sharp-tailed Grouse Technical Committee provides sound recommendations in their Interim Guidelines for Evaluating the Impacts of Energy Development (Appendix A).
4. In Category 3 or 4 habitats, field investigations should be conducted by the applicant to determine the actual condition of the habitat and the approximate extent of use by sage-grouse through consultation with NDOW. The potential for habitat improvement should be identified and a restoration or habitat enhancement plan should be developed.
5. If a project is located in Category 5 habitats, surveys (radio-marking of individuals in adjacent sage-grouse populations or stratified random pellet counts) should be considered to determine if sage-grouse move through the area between seasonal habitat patches. If movement across the area is detected, then recommendations should be made to preserve movement patterns by grouse.

C. Project Development (All Energy Related Developments)

Through this guidance document, we hope to eliminate more direct impacts to sage-grouse populations through avoidance of Category 1 through 3 habitats. However, unless Greater Sage-grouse habitats are afforded increased protection from federal land management agencies such as the BLM, it is likely that some form of renewable energy development will occur within these types of habitats. The NSGCT recognizes that there are projects in the advanced stages of permitting or development which have obtained final or near-final siting approvals from federal, state and/or private entities, and that the siting and/or mitigation commitments for such projects may not be consistent with some of this document's recommendations. Where this is the case, and where the project has worked with federal and state agencies on matters relevant to wildlife prior to the release of this document, the NSGCT respects agreements that have already been made with regard to siting and mitigation measures. We hope that project proponents in these situations can use the recommended guidance contained in this document to minimize the effects of development where possible. However, if sage-grouse are listed as a threatened or endangered species by the U.S. Fish and Wildlife Service in the future, then projects on federal lands would be subject to section 7 consultation. Prior agreements may be subject to further review.

It is important to note here that some recommendations differ for non-migratory and migratory populations of sage-grouse. For the purposes of this document, non-migratory populations of sage-grouse are those where the majority of individuals do not make long distance movements between or among seasonal ranges (individuals travel <10 km one way between seasonal ranges). Migratory populations are those in which a preponderance of individual grouse move ≥10 km one way between seasonal ranges (derived from Connelly et al. 2000). If a project were approved in Category 1 through 3 habitats, the following represents guidelines suggested by the NGSCT:

1. Where sage-grouse populations are non-migratory energy facilities should not be constructed within 3 miles of the nearest active lek site (see Chapter 1, Section C).
2. Where populations of sage-grouse are considered migratory, energy facilities should not be constructed within 3 miles of the nearest active lek location and should not be sited within the associated nesting habitat for that particular population.
3. If construction within 3 miles of an active sage-grouse lek is absolutely unavoidable, conduct construction activities from 15 July to 30 November to avoid disturbing sage-grouse during the breeding, nesting, early brood rearing and winter periods.
    a. If pumping stations are placed within 3 miles of an active lek, consideration should be given, and attempts made to place these features in an area where noise would least impact the actual lek using topography to help mask noise.
4. Avoid practices that remove sagebrush cover in these habitat categories as they may be the most important areas to sage-grouse using these habitats.
5. No development or infrastructure features should be placed within 0.6 miles (1 km) of identified late brood rearing habitats, especially meadow complexes and springs. These features can provide a competitive advantage for avian predators; therefore increasing sage-grouse mortality during a period when birds may be susceptible.
6. A comprehensive monitoring plan approved by the Nevada Department of Wildlife will be required to monitor sage-grouse demographics, vital rates and movement patterns before, during and after the construction phase within Category 1 – 3 habitats. The Western Agencies Sage and Columbian Sharp-tailed Grouse Technical Committee provide sound recommendations in their Interim Guidelines for Evaluating the Impacts of Energy Development (Appendix D).
7. Within Category 1-3 sage-grouse habitats, a company representative should be on site to oversee compliance during construction and provide environmental training to on-site personnel. This individual is responsible for overseeing compliance with all protective measures and coordination in accordance with the permitting authority and resource agencies should have the authority to issue a “stop work order” if deemed necessary.
8. Human Activity (Daily Operations/Maintenance)
    a. Vehicle trips should be limited to those times that would least impact nesting or wintering grouse:

        i. Vehicle trips should not occur on a regular basis within 3 miles of an active lek or in identified nesting habitats from 01 March through 15 May.
            1) If vehicle trips are required during the lekking period, vehicles should only be operated from 10:00 a.m. to 5:00 p.m. daily.
        ii. Public access to construction areas should be limited if construction activities are occurring from 01 March through 15 May.

D. Associated Infrastructure (Transmission Lines, Road, Substations, Fences, etc.)

The infrastructure associated with utility scale energy developments can potentially be as detrimental as the facility itself. Roads, transmission lines, substations, fences and vehicle traffic can all eliminate or create disturbance within sage-grouse habitats. Even though a wind generation facility or geothermal power plant may not be constructed in optimal sage-grouse habitats, it is likely that roads and/or transmission lines associated with the facility will be. The following guidelines apply to associated infrastructure:

1. Transmission lines should not be sited within 3 miles of the nearest active lek location or in nesting habitat that occurs outside lek buffers.
    a. In instances where transmission line placement is within 3 miles of the nearest active lek location and cannot be avoided, apply standards 5-9 in this section.
        i. Attempt to place the line in the least suitable habitat within a 3 mile radius of the nearest active lek.
        ii. Consider placing the transmission line to the west of the nearest active lek so that avian predators are at a disadvantage (i.e., looking into the sun) in the early morning hours.
2. Roads and below ground infrastructure (i.e. buried power lines, pipelines) should not be sited within 0.6 miles (1 km) of the nearest lek site. These features are a concern because their construction directly removes potential nesting habitat and act as vectors for invasive plant species establishment (e.g., cheatgrass).
3. To the greatest extent practical, transmission lines should be placed near existing highway corridors at “minimum safe distances” designated by the BLM or project proponent to reduce direct and indirect effects to sage-grouse.
4. In all instances where structures are to be placed in sage-grouse habitat, especially nesting habitat, preliminary surveys should be conducted to identify sage-grouse nesting areas and all attempts should be made to avoid these areas.
5. Structures should be constructed with the least amount of perching or nesting substrate possible by avoiding such things as external ladders and platforms.
6. Use tubular tower designs with pointed tops rather than lattice designs.
    a. This should be applied as a standard design within the range of sage-grouse in Nevada regardless of habitat categorization.
7. In addition to tubular towers, conventional perch and nesting deterrents should be utilized in adherence to the Migratory Bird Treaty Act. Perching and nest deterrents include:
    a. devices installed on support towers;
    b. actual physical maintenance through hazing; and/or
    c. physical removal of nest structures.
8. Avoid removing sagebrush cover whenever feasible, especially in identified winter habitats.
9. Avoid use of guy wires whenever possible.

   a. In some circumstances, use of guy wires may facilitate tower design features which minimize perching and nest building (e.g. guyed V tubular tower). The overall benefit to sage-grouse of these designs is likely to compensate for any direct affect to sage-grouse from guy wire strikes; however, guy wires should be marked with devices (e.g. spiral vibration damper, FireFly™ bird flight diverter) to increase the visibility of the wires to avian species, thus minimizing strikes.

10. To reduce the impact of new fences on sage-grouse, new fence proposals (including those for emergency stabilization and rehabilitation) should be carefully evaluated for sage-grouse collision risk (BLM IM 2010-022).
    a. In the process of prioritizing areas for flagging or marking fences, state wildlife agency personnel shall be consulted (BLM IM 2010-022).

E. Post Project Development

1. Monitoring
   a. Within Category 1 through 3 sage-grouse habitats, a comprehensive monitoring plan will be required that addresses demographics, vital rates and seasonal movement patterns. The Western Agencies Sage and Columbian Sharp-tailed Grouse Technical Committee provide sound recommendations in their Interim Guidelines for Evaluating the Impacts of Energy Development (Appendix D).
   b. Information gained from monitoring can be used to help develop future mitigation measures.
2. Noxious Weed Prevention
   a. Roads and the footprint of wind turbine pads, geothermal energy plants, and transmission lines should be monitored at least annually for any noxious weeds and, if found, treated with appropriate techniques.
3. Noise Reduction
   a. Noise levels from geothermal facilities, oil and gas pumping stations or gas pipeline compressor stations should not exceed 55 decibels (dBa) at leks. Several noise muffling techniques and equipment are available.
      i. Noise mufflers should be installed at gas compressor stations;
      ii. Noise barriers should be installed around oil and gas pumping stations;
      iii. Temporary noise shields should be constructed around portions of the drilling rigs and used on standard construction equipment.
4. Decommissioning
   a. Any roads that were built, primarily for construction only, should be decommissioned post construction to deter dispersed vehicle use within sagebrush habitats and the creation of new roads.
      i. Decommissioned roadways should be restored, to the greatest extent practicable, to the pre-existing vegetative condition.
   b. Developers should restore pathways of buried transmission lines or pathways to a desired vegetative condition.

In addition, many knowledgeable and dedicated individuals from the Nevada Governor's Office and various other state agencies, U.S. Fish and Wildlife Service, U.S. Bureau of Land Management, U.S. Forest Service and citizens of the State of Nevada provided guidance, insight and support that was essential to ensure the Nevada Conservation Credit System (Credit System) is aligned with the needs of key constituents and is a viable component for species conservation.

The consulting team was led by Environmental Incentives, LLC and included Ecometrix Solutions Group and Environmental Defense Fund.

The Nevada Conservation Credit System incorporates design, organization, and content from documents developed by Environmental Incentives, LLC, Willamette Partnership, and Environmental Defense Fund, among others. In particular, the Nevada Conservation Credit System operations were adapted from the Colorado Habitat Exchange Manual Version 0.95. Thus, in accordance with the Open Content License from that document: This content was created in part through the adaptation of procedures and publications developed by Environmental Incentives, LLC (www.enviroincentives.com), Environmental Defense Fund (www.edf.org), and the Willamette Partnership (www.willamettepartnership.org), but is not the responsibility or property of any one of these entities.

Open Content License

The Credit System has been developed with an eye toward transparency and easy extension to address multiple environmental issues across geographic regions. As such, permission to use, copy, modify and distribute this publication and its referenced documents for any purpose and without fee is hereby granted, provided that the following acknowledgement notice appears in all copies or modified versions: "This content was created in part through the adaptation of procedures and publications developed by Environmental Incentives, LLC, Environmental Defense Fund, and Willamette Partnership, but is not the responsibility or property of any one of these entities."

IMPLEMENTATION TIMELINE

As of October 2014, the Nevada Conservation Credit System (Credit System) is open for *credit project* enrollment and development. The Credit System *Administrator* – the Nevada Sagebrush Ecosystem Technical Team - is working with landowners to validate potential credit sites to determine if they are eligible to produce credits and estimating the expected credits generated by the proposed projects using the Habitat Quantification Tool (HQT) and site-specific *Management Plans*. The Nevada Sagebrush Ecosystem Program (SEP) encourages landowners and other parties interested in developing credits to contact the Nevada Sagebrush Ecosystem Technical Team (SETT) to get started. All application fees are waived through the end of 2014.

In January 2015, the Credit System will begin evaluating *debit projects* for *credit obligations* and start the process of awarding credits to *offset* debit projects. The Credit System's policies and technical requirements will be updated systematically through a formal, annual adaptive *management process*. Significant updates are anticipated during the years of implementation, as the Nevada Sagebrush Ecosystem Program gains transactional experience. Any changes will only apply to new credit and debit projects, thus credits awarded and credit obligations fulfilled through the Credit System will not be impacted by future updates to the Credit System.

The Credit System can be used to meet regulatory requirements established by State of Nevada statute NRS Chapter 232.162, and are intended to fulfill *compensatory mitigation* requirements currently under development for anthropogenic disturbances to greater sage-grouse habitat on Bureau of Land Management (BLM) and U.S. Forest Service (USFS) lands in the State of Nevada. However, the Credit System does not currently provide *participants* with federal regulatory assurances in the event that greater sage-grouse is listed as threatened or endangered under the Endangered Species Act (ESA). In the future, the Credit System intends to provide regulatory assurances by developing a programmatic *agreement* with the U.S. Fish and Wildlife Service (USFWS).

INTRODUCTION TO THIS MANUAL

The Nevada Conservation Credit System Manual (Credit System Manual) provides the necessary materials and information for understanding and participating in the Nevada Conservation Credit System (Credit System). The table below provides a summary of the contents of the Credit System Manual. The Credit System Administrator will use this document to guide *Credit System operations* and policies over time. Landowners and other parties interested in generating credits, and any parties interested in purchasing credits through the Credit System should refer specifically to guidance provided in *Section 2: Technical and Policy Considerations*, regarding specific technical and policy considerations that arise during the generation and *transfer* of credits to *Credit Buyers* and the determination of credit obligations for debit projects.

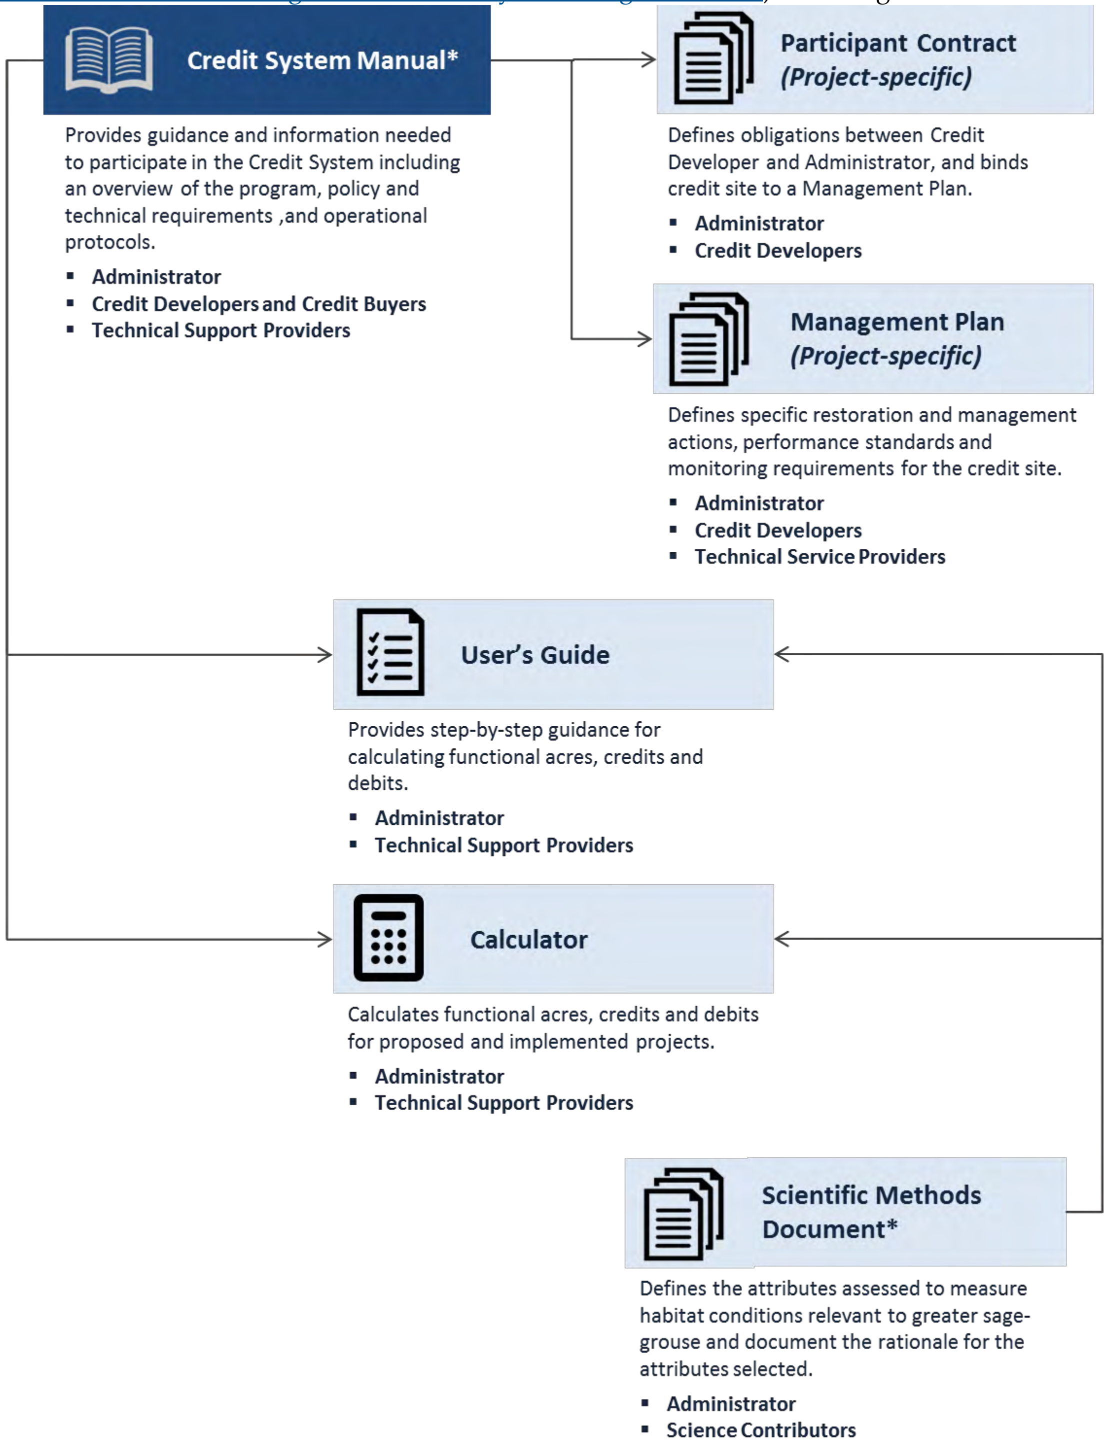
CREDIT SYSTEM MANUAL CONTENTS

Section 1: Credit System Overview	Provides an overview of the objectives, scope and primary participants of the Credit System.
Section 2: Policy & Technical Elements	Summarizes the primary policy and technical requirements necessary to develop credits and offset credit obligations, and govern the Credit System.
Section 3: Credit System Operations	Defines the detailed steps, tools and timing to: ▪ Quantify and verify credits generated and credit obligations from individual project sites, including fulfilling ongoing *verification* requirements. ▪ Obtain credits and use them to mitigate debit projects (credit obligations), or define and report the effectiveness of *management actions* not used to offset impacts. ▪ Systematically evaluate new information, report results and improve the accuracy and efficiency of the Credit System over time.
Appendix A: Glossary	Defines key terms used throughout the Credit System Manual.
Appendix B: Forms and Instructions	Lists forms to be filled out by Credit System participants and submitted to the Credit System Administrator. Contact the Sagebrush Ecosystem Technical Team for form and guidance documents.

The first use of a term defined in the glossary in *Appendix A* is in italic font.

CREDIT SYSTEM TOOLS & DOCUMENTS

Several tools and documents are used to describe and operationalize the Credit System. The primary tools and documents are summarized in **Error! Reference source not found.** and the most recent versions are available on the Credit System website (https://www.enviroaccounting.com/NVCreditSystem/Program/Home) or through the Administrator.



Credit System Manual*

Provides guidance and information needed to participate in the Credit System including an overview of the program, policy and technical requirements ,and operational protocols.

- **Administrator**
- **Credit Developers and Credit Buyers**
- **Technical Support Providers**

Participant Contract *(Project-specific)*

Defines obligations between Credit Developer and Administrator, and binds credit site to a Management Plan.

- **Administrator**
- **Credit Developers**

Management Plan *(Project-specific)*

Defines specific restoration and management actions, performance standards and monitoring requirements for the credit site.

- **Administrator**
- **Credit Developers**
- **Technical Service Providers**

User's Guide

Provides step-by-step guidance for calculating functional acres, credits and debits.

- **Administrator**
- **Technical Support Providers**

Calculator

Calculates functional acres, credits and debits for proposed and implemented projects.

- **Administrator**
- **Technical Support Providers**

Scientific Methods Document*

Defines the attributes assessed to measure habitat conditions relevant to greater sage-grouse and document the rationale for the attributes selected.

- **Administrator**
- **Science Contributors**

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 1: CREDIT SYSTEM OVERVIEW

Greater sage-grouse (*Centrocercus urophasianus*) populations have declined significantly from historic numbers[1], in Nevada and throughout their current range (which includes 11 US states and 2 Canadian provinces). The decline of greater sage-grouse populations is largely attributable to the degradation, fragmentation and loss of habitat caused by wildfire, particularly in the western portion of the species range, and by the increased prevalence of invasive species and conifer encroachment. Additionally, anthropogenic disturbances resulting from infrastructure, mineral and energy development, improper grazing practices and other human activity contribute to habitat loss for the species[2].

In 2010, the U.S. Fish and Wildlife Service (USFWS) announced the finding that listing the greater sage-grouse as threatened or endangered under the Endangered Species Act is warranted, but precluded by higher priority listing actions[3]. By September 2015, the USFWS must propose whether or not to list the greater sage-grouse as threatened or endangered. This listing could significantly impact Nevada's economy and way of life. One component of Nevada's proactive conservation strategy is the development of the Nevada Conservation Credit System (Credit System).

The SEP was established in 2013 and its purpose is to protect and enhance Nevada's sagebrush ecosystems, culture and economy by promoting good stewardship, as stated in the Sagebrush Ecosystem Council mission statement. The Credit System provides a mechanism to achieve sage-grouse conservation goals while preserving the integrity of the culture and economy of the State of Nevada.

The Credit System is an innovative solution to greater sage-grouse habitat protection that ensures habitat impacts from anthropogenic disturbances are fully compensated by long-term enhancement and protection of habitat that result a net benefit for the species, while allowing appropriate anthropogenic disturbances that are vital to the Nevada economy and the Nevada way of life. The Credit System creates new incentives 1) to avoid and minimize impacts from anthropogenic disturbances to important species habitat, and 2) for private landowners and public land managers to preserve, enhance, and restore habitat, while reducing threats to important habitat for the species. The Credit System is a performance-driven and market-based approach to species conservation that quantifies benefits from enhancement and protection of habitat (*credits*) and negative impacts to habitat from anthropogenic disturbances (*debits*), operationalizes market transactions, and reports net benefit from all transactions processed by the Credit System.

1.1 CREDIT SYSTEM GOALS & PRINCIPLES

The goal of the Credit System is for impacts from anthropogenic disturbances to be offset by enhancement and protection that results in a net benefit for greater sage-grouse habitat in the State of Nevada. In the future, the Credit System may be expanded to support the *stewardship* and *restoration* of Nevada's sagebrush ecosystem overall and other sagebrush obligate species, in addition to the greater sage-grouse.

[3] "Endangered and Threatened Wildlife and Plants; 12-Month Findings for Petitions to List the Greater Sage-Grouse (Centrocercus urophasianus) as Threatened or Endangered," 50 Federal Register 17. Volume 75, No. 55 (23 March 2010), pp. 13910-13911.

GUIDING PRINCIPLES

The Credit System enables the stewardship and restoration of a resilient and resistant sagebrush ecosystem. The Credit System works within the regulatory *mitigation* hierarchy, where anthropogenic disturbance impacts are first avoided, then minimized, and then the residual unavoidable impacts are mitigated using the Credit System. The following principles guide the development and operation of the Credit System and are meant to provide clarity and guidance in cases where the Credit System Manual is silent or unclear.

- Produce high quality conservation where it makes a significant ecological and biological difference.
- Enable decision-making based on the best available science.
- Create an efficient marketplace, where each transaction is anticipated to result in a net benefit for greater sage-grouse.
- Foster transparency, accountability, and credibility.
- Improve the effectiveness and efficiency of the Credit System over time.

1.2 GEOGRAPHIC & PARTICIPANT SCOPE

The geographic scope of the Credit System is consistent with the current Sage-Grouse Management Area (SGMA), the 2014 SGMA map is provided in Figure 2 as an example. The range of the Bi-State Distinct Population Segment of the greater sage-grouse in the State of Nevada is not included in this Credit System.

Proposed anthropogenic disturbances to habitat on State of Nevada, BLM, USFS, and local government lands within the SGMA require consultation with the SETT and the appropriate federal agency, as defined in the 2014 Nevada Greater Sage-Grouse Conservation Plan[4]. This consultative process will determine when residual unavoidable impacts require compensatory mitigation through the Credit System. Private landowners are not required to mitigate anthropogenic disturbances on their land; however, they are encouraged to voluntarily participate in the Credit System by generating or purchasing credits. The Credit System scope can be expanded in the future to support additional conservation needs and to correspond with revisions to habitat and management maps.

Figure 2: Sagebrush Ecosystem Program Sage-grouse Management Area Map, 2014

1.3 ORGANIZATIONAL STRUCTURE & ROLES

The organizational structure and interactions between the participants in the Credit System are depicted in Figure 3 below, followed by a description of each participant. Additional detail regarding the governance structure and roles is provided in *Section 2.1.1: Program Governance.*

Nevada Division of State Lands (NDSL): NDSL is a division of the Nevada Department of Conservation and Natural Resources, and holds the ultimate responsibility to ensure the Credit System functions as designed.

---

[4] http://sagebrusheco.nv.gov/uploadedFiles/sagebrusheconvgov/content/home/features/2014_ConsolidatedStatePlan.pdf

Oversight Committee: The Sagebrush Ecosystem Council (SEC) is a legislatively established council comprised of representatives from conservation interests, industry, ranching, and government which is responsible for overseeing the operations of the Credit System and making policy decisions.

Administrator: The SETT is responsible for managing the day-to-day operations of the Credit System, including facilitating and overseeing all credit generation and transaction activities. The SETT ensures consistent operations, issues credits, and reports results.

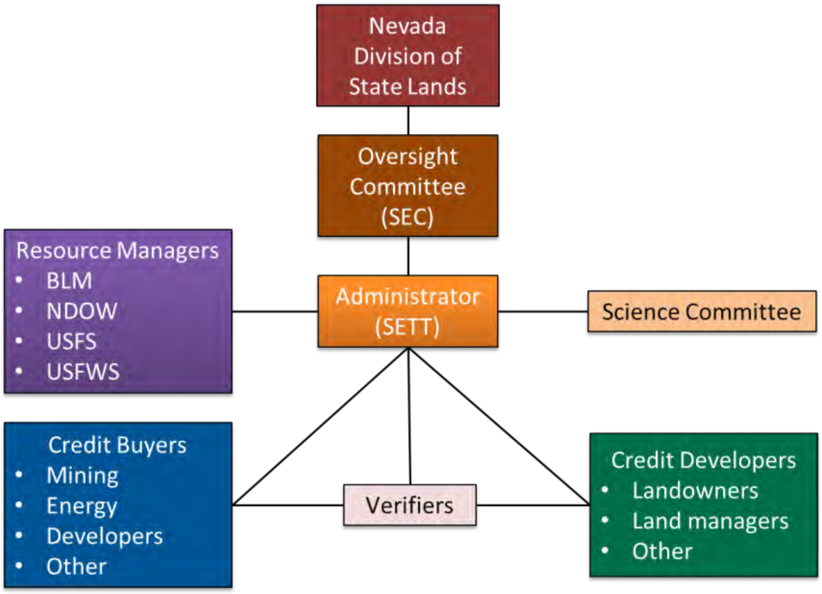

Figure 3: Operational structure of the Nevada Conservation Credit System

Resource Managers: Agencies that manage greater sage-grouse populations or habitat areas within the scope of the Credit System, and ensure that the Credit System functions according to current law, policy, and regulations.

Science Committee: Species and ecology scientists and experts who inform science-related policy decisions and development of technical products and tools, like the HQT. The Science Committee makes recommendations to the Administrator, based on the best-available science regarding the greater sage-grouse and its habitat.

Verifiers: State, local and federal agency staff or private contractors who assess the accuracy of credit and debit calculations. Verifiers must be trained and certified by the Administrator and must meet qualifications established by the Oversight Committee.

Credit Developers: Landowners or managers, organizations, or agencies, that produce, register, or sell credits in the Credit System. *Credit Developers* may also be facilitators, such as conservation banking companies or other types of *Aggregators*, who work with multiple landowners to implement credit projects, develop Management Plans, secure *financial assurances*, and register and sell credits.

Credit Buyers: Entities that purchase credits to meet credit obligations or to meet other conservation objectives.

Technical Support Providers ***(Not included in Figure*** **3*)***: Individuals and entities with technical expertise in conservation planning and project design, who understand how to use the Credit System tools and forms. Technical Support Providers may be hired by Credit Developers or Credit Buyers to help design credit projects and estimate credit obligations, use the HQT to estimate credits and debits, and submit all required materials to the Administrator. There is no formal process to designate or certify a Technical Support Providers.

1.4 HABITAT QUANTIFICATION & CREDIT SYSTEM CURRENCY

Credits are the currency of the Credit System. A credit consists of verified habitat value that is made durable for the defined duration of the project through financial assurances and contract requirements to maintain habitat performance standards as defined in a site-specific Management Plan. Credits are primarily awarded for meeting performances standards, not for implementing conservation practices.

Credits are used to offset debits, which represent units of greater sage-grouse habitat value lost by anthropogenic disturbances. The credit obligation is the quantity of credits required to offset a debit project.

The Credit System measures habitat value in units of *functional acres*. Function refers to the role of the habitat in providing life history requirements for greater sage-grouse, and includes the direct and indirect effects of anthropogenic disturbances. Function is expressed as a percent function in relation to fully-functioning habitat for greater sage-grouse. Functional acres are the product of percent function and acres within the relevant area assessed as illustrated in Figure 4.

The Credit System uses the HQT to quantify functional acres for both credit and debit sites. A summary of the HQT and credit and debit calculation is provided below, and the concepts below are described in detail in the *HQT Scientific Methods Document*, and the following sections of this Manual: *Section 2.3.4: Calculating Credit Baseline Habitat Function*, *Section 2.5.4: Calculating Debit Baseline Habitat* and *Section 2.2: Habitat Quantification and Credit and Debit Calculation*.

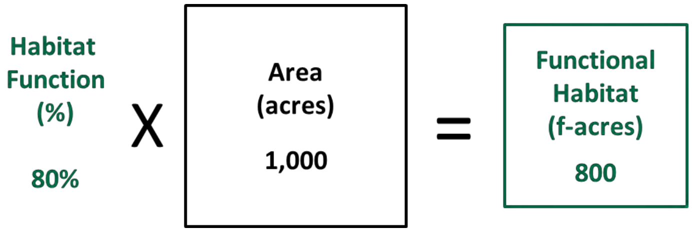

Figure 4: Illustration of functional acre concept

Habitat Quantification Tool

The HQT quantifies *habitat function* for greater sage-grouse habitat in the State of Nevada. The HQT generates a percent function and a number of functional acres for each seasonal habitat type (breeding, late brood-rearing, and winter) within the area assessed.

The HQT accounts for habitat characteristics or attributes that influence sage-grouse habitat selection across multiple scales. These habitat characteristics were based on different orders of selection (Johnson 1980, Stiver et al. 2010) that represent four spatial scales at which habitat attributes influence where greater sage-grouse reside and obtain resources necessary for survival and reproduction[5]. The HQT assessed habitat quality at four orders.

Key Terms

Credit: A quantifiable unit of a greater sage-grouse habitat conservation value measured as the difference between credit baseline functional acres and post-project functional acres multiplied by a mitigation ratio, and secured by contract requirements, a project-specific Management Plan and financial assurances.

Credit Obligation: Quantify of credits that must be acquired to offset debits generated by a debit project.

Debit: A quantifiable unit of loss to greater sage-grouse habitat value from an impact measured as the difference between debit baseline functional acres and post-project functional acres multiplied by a mitigation ratio.

Habitat Function: The ability for habitat to provide life history requirements for greater sage-grouse considering needs across multiple spatial scales. Function is expressed as a percentage in relation to fully functioning habitat for greater sage-grouse.

---

[5] While the term 'selection' may be interpreted as relating to individual bird behavior, in this context the term is applied broadly to describe the four geographic scales at which sage-grouse occur, are organized into populations and use habitat (per Johnson 1980, Connelly et al 2003, Stiver et al 2010). These four scales also correspond to scales at which sage-grouse policy and management are

Range-wide Scale (1st order): The range considered by the Credit System is the geographic range of the sage-grouse population in Nevada.

Landscape Scale (2nd order): Landscape selection is based on the availability of seasonal habitats needed to support a population or subpopulation.

Local Scale (3rd order): Local selection is based on suitability of the habitat within their home range and the effects of anthropogenic disturbances.

Site Scale (4th order): Site selection is based on vegetation structure and composition that provide forage and cover.

See the *HQT Scientific Methods Document* for additional information on the attributes measured at each scale (order), and the methods used to measure those attributes.

Credits, Debits and Credits Obligations

Credits and debits represent the difference between baseline functional acres and post-project functional acres, multiplied by a mitigation ratio that incorporates biologically significant factors that are not captured through the HQT. Figure 5 illustrates how baseline is subtracted from the post-project habitat value to determine the functional acres above baseline for a credit project. Figure 6 illustrates how the functional acres above baseline are multiplied by a mitigation ratio to determine the number of credits generated by the credit site. Debits are calculated in a similar way; however the post-project functional acres are subtracted from the baseline functional acres to determine the loss in habitat value.

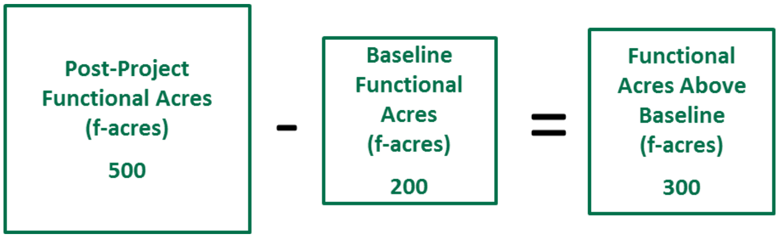

Figure 5: Illustration of functional acres above baseline for a credit project

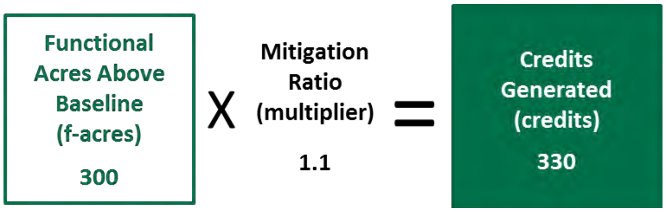

Figure 6: Illustration of the credits generated from a credit project

The HQT generates functional acre values for each seasonal habitat type (breeding, late brood-rearing and winter), and unique mitigation ratios are also generated for each habitat type. The change in habitat value for each seasonal habitat is tracked and reported by the Credit System; however only the most valuable habitat type is used to determine the credits or debits generated from the site. Guidance for determining the mitigation ratio for each seasonal habitat type is provided in *Section 2.2.2: Mitigation and Proximity Ratios*, and the calculation to determine the seasonal habitat type of greatest value is illustrated in *Section 2.2.3: Credits and Debit Calculation*.

The amount of credits required to offset a debit project, the credit obligation, is the number of debits generated by the project adjusted by a proximity ratio, determined by the proximity between the debit site and the offsetting credit site. Guidance for determining the proximity ratio and the credit obligation for a debit project is provided in *Section 2.2.2: Mitigation and Proximity Ratios*.

1.5 CREDIT SYSTEM OPERATIONS OVERVIEW

---

typically implemented (Stiver et al. 2010). Throughout this document, orders of selection will be identified by their descriptive terms (e.g., site scale, local scale, landscape scale).

This section provides an overview of the steps used to generate and transfer credits between accounts for credit and debit projects, and for the Administrator to manage the program. These processes are defined in detail in [*Section 3: Credit System Operations*]() of this Credit System Manual. Specific tools, forms, and guidance that are tailored to the Credit System are included in [*Appendix B*]().

Figure 7: Overview of the process steps to generate and purchase credits

The steps for generating and transacting credits are depicted in Figure 7, above. Blue chevrons signify the steps undertaken to generate credits, green chevrons represent the steps to buy credits to offset credit obligation or for conservation purposes, and the orange Track and Transfer connector represents the steps and platform within which transactions occur.

GENERATING CREDITS

The following steps outline the process to generate, verify and register credits from a credit project under the Credit System.

1. **Select & Validate Site:** Credit Developers may select any project site on private or public land that provides verified benefit to greater sage-grouse habitat, as determined by the Credit System's *credit site eligibility* requirements. The Credit Developer completes a Validation Checklist to determine whether eligibility requirements are met and submits to the Administrator for approval or rejection and commentary. This stage provides a screen to minimize investment and cost to participants for sites that may not be eligible to generate credits.
2. **Implement & Calculate Credit:** Credit Developers design the project, quantify the expected number of credits using the HQT, implement conservation practices, and refine calculations based on *conditions* on-the-ground.
3. **Verify Conditions:** All projects undergo third-party verification to confirm that protocols were followed correctly and projected credits are appropriately calculated, according to actual on-the-ground conditions.
4. **Register & Issue:** Once a project has been verified, supporting documentation is submitted to the Administrator where it is reviewed for completeness before credits are registered and issued to the Credit Developer's account on the Credit System Registry. Upon issuance, credits are given a unique serial number so they can be tracked over time.
5. **Track & Transfer:** Issued credits are tracked by the Administrator using the Credit System Registry and are either transferred to a Credit Buyer's account or held in other accounts. After transfer, the Credit Developer is responsible for meeting the *monitoring*, reporting and verification requirements of each project for the life of the project (described in [*Step D3 in Section 3*]()). Credit Developers annually confirm that *performance standards* are met and additional *credit releases* are triggered, where applicable.

ACQUIRING CREDITS

The following steps outline the process to purchase credits under the Credit System.

1. **Indicate Initial Interest:** Credit Buyers become aware of the opportunity or requirement to participate in the Credit System and contact the Administrator to provide basic information. Additional assistance and technical support is available, if desired.
2. **Determine Credit Need:** Credit Buyers determine the duration and amount of credit needed to best meet their needs. If fulfilling a regulatory offset, Credit Buyers determine credit amount needed by estimating and verifying debit baseline and post-project conditions of the debit site in accordance with the relevant regulatory instrument and the HQT, and the geographic location of credit offsets.
3. **Acquire Credits:** Credit Buyers contact the Administrator and confirm needed credit quantities. The price, terms and conditions are all set by the Credit Buyer and Credit Developer, or Administrator. The Administrator provides notice when credits have been transferred between accounts.
4. **Track & Transfer:** Credits are tracked using unique serial numbers that identify the source of each credit, the HQT version used to estimate credits, and the current owner. Once credits are transferred to a Credit Buyer's account, the Credit Buyer can use that information for internal and external reporting.

MANAGING THE CREDIT SYSTEM

The Credit System is managed by an Administrator, using a transparent and inclusive management process to improve the efficiency and effectiveness of the Credit System over time. The Oversight Committee acts as a board of directors for the Credit System, and is responsible for adopting any changes made to the Credit System through a defined management process. This process follows the steps depicted in Figure 8.

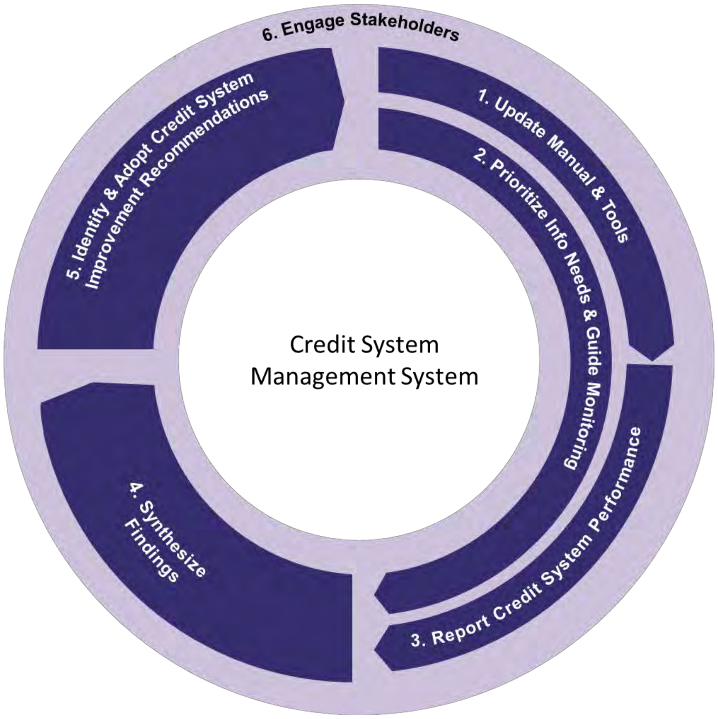

Figure 8: Overview of Credit System Management

1. **Update Manual & Tools:** Administrator updates this Credit System Manual, as well as tools, forms, and related guidance to ensure practical experience and new scientific information result in increased efficiency and effectiveness.
2. **Prioritize Information Needs & Guide Monitoring:** In coordination with the Science Committee and federal land management agencies, the Administrator identifies and prioritizes research and monitoring needs, coordinates funding efforts, and oversees monitoring and research.
3. **Report Credit System Performance:** Administrator develops the Annual Performance Report to summarize credit awards, debits and habitat improvements achieved. Routine reporting of accomplishments is essential to ensure transparency and drive accountability.

4. **Synthesize Findings:** Administrator synthesizes relevant research, monitoring and operational findings to inform Credit System improvements. Synthesizing findings into information that is directly related to the operations of the Credit System is essential to inform management decisions. Incorporating the best available science and other new information into the program and HQT ensures the calculation of credits and debits is accurate, improves project selection and design decisions, and improves accountability.
5. **Identify & Adopt Credit System Improvement Recommendations:** Administrator develops operational and technical improvement recommendations which are reviewed and acted upon by the Oversight Committee to ensure the Credit System continues to motivate effective actions over time. Creating and transparently adopting clear recommendations to improve the Credit System is the most critical step in the annual Credit System management process. The transparency of this adjustment process enables Credit Developers, Credit Buyers and other stakeholders to participate in the process and gain knowledge of the reasoning for adjustments as adopted.
6. **Engage Stakeholders:** Throughout the year, the Administrator engages stakeholders to keep them informed of progress and solicit input for how to improve the Credit System. Consistent stakeholder engagement is necessary to ensure the Credit System operates efficiently, increases understanding, and facilitates accountability.

All of the steps described in Section 1.4 above are defined in detail in *Section 3: Credit System Operations*. *Section 2: Policy and Technical Elements* defines the primary policy and technical requirements that enable consistent application of the Credit System by all participants.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 2: POLICY & TECHNICAL ELEMENTS

This section of the Credit System Manual defines specific policy and technical requirements and additional considerations for generating credits for sale, determining debits and credit obligations, and managing the Nevada Conservation Credit System (Credit System). Table 1 below provides a summary of these requirements and considerations, including the primary audience and brief description.

Table 1: Summary of Policy & Technical Considerations

Credit System Elements		Primary Audience	Element Description & Guidance
2.1 Program Governance			
2.1.1	Governance Roles	**Administrator**	▪ The Administrator facilitates day-to-day operations, participant engagement, and program reporting and improvement
2.1.2	Implementation of State Policy		▪ State of Nevada policy that established the Credit System, and requires mitigation for anthropogenic disturbances which impact greater sage-grouse habitat to be determined by the Credit System
2.1.3	Federal Regulatory Predictability		▪ Credit System is designed to accommodate different regulatory mechanisms and provide certainty to Credit Buyers and Credit Developers
2.1.4	Accounting System & Reporting		▪ Rigorous accounting system tracks functional acres, credits and debits ▪ Annual Performance Report includes Credit System performance and program improvements
2.1.5	Adaptive Management		▪ Formal, structured programmatic adaptive management approach that deals with uncertainty and leverages management experience and research results
2.1.6	Participant Confidentiality		▪ As a State-run program, certain information must be disclosed upon request by a member of the public; however, published information protects *participant confidentiality* by aggregating information and removing identification information
2.1.7	Reserve Account Management and Use of Financial Assurances		▪ *Reserve account* serves as an insurance mechanism for the overall Credit System by allowing the Administrator to temporarily cover invalidated credits until they are *remediated* or replaced ▪ Financial assurances are used to remediate unintentional *reversals*, or to replace credits lost due to unintentional and intentional reversals that cannot be remediated
2.2 Habitat Quantification and Credit and Debit Calculation			
2.2.1	Habitat Quantification Tool	**Credit Developers & Credit Buyers**	▪ Percent function and an amount of functional acres for each seasonal habitat type are generated for each *map unit* within a project boundary, including the area indirectly impacted by debit projects ▪ Field sampling must be collected during specific times of the year for breeding and late brood-rearing habitat
2.2.2	Mitigation & Proximity Ratios		▪ Credit and debit ratios determined by management importance and limiting seasonal habitat ▪ Debits are adjusted by a proximity ratio, determined by the proximity between the debit site and offsetting credit site
2.2.3	Credit and Debit Calculation		▪ Total credits and debits generated by a project represent the difference between baseline and post project functional acres multiplied by a mitigation ratio

2.3 Credit Additionality Provisions

2.3.1	Credit Service Area	**Credit Developers**	▪ All sites must be located within the current SGMA
2.3.2	Credit Project Types		▪ Habitat stewardship ▪ Habitat restoration
2.3.3	Credit Site Eligibility		▪ Site must be located in the *Service Area* ▪ *Participant Contract* with Administrator is required and must attest to ownership or use rights and past stewardship ▪ *Additionality* must be demonstrated and post-project habitat functionality must meet minimum habitat function requirements ▪ No evidence of an imminent threat of direct or indirect disturbance ▪ Necessary financial assurances must be complete ▪ Credit Developer must attest to the accuracy of the information
2.3.4	Calculating Credit Baseline Habitat Function		▪ Local-scale, pre-project habitat function combined with a site-scale, regional standard habitat function for each seasonal habitat type
2.3.5	Developing Credits on Public Lands and Other Land Designations		▪ Additional benefit is required above and beyond what would have been achieved by planned and funded public *conservation actions*, and existing land designations
2.3.6	Partnering with Federal Programs on Private Lands		▪ Additional benefit is required ▫ **During Federal Contract:** Allocation of credits proportionate to non-federal contribution ▫ **Following Federal Contract:** Full credit for long-term extensions or agreements following expiration of federal contract
2.3.7	Stacking Credit Types		▪ Credits from other conservation programs can be generated on a Conservation Credit System credit site if the credit site can demonstrate additional benefits based on specific conservation and management practices
2.3.8	Integration with CCA/CCAAs		▪ Credits can be generated in combination with enrollment in CCA/CCAAs if they demonstrate additionality of specific conservation and management practices

2.4 Credit Durability Provisions

2.4.1	Credit Site Protection	**Credit Developers**	▪ Participant Contract with Administrator and accompanying Management Plan is required for all credit projects ▪ Additional site protection measures such as easements reduce reserve account contribution and thus increase generated credits available for sale
2.4.2	Credit Project Duration		▪ Minimum 10 year with 5 year term increments afterwards, up to in perpetuity
2.4.3	Reserve Account Contrition		▪ Contribution amount determined by base contribution, probability of adverse impacts from wildfire, and probability of *competing land uses*
2.4.4	Credit Release		▪ **Stewardship Projects:** One or more habitat function performance standards triggers credit releases ▪ **Restoration Projects:** Combination of one performance standard defined by management actions and multiple habitat performance standards triggers credit releases

2.4.5	Credit Site Verification		▪ Before initial credit release, before increased credit releases if applicable, every 5th year, and periodic spot checks ▪ Site-specific verification variability tolerance is defined as a percentage below site-scale habitat function
2.4.6	Financial Assurances		▪ Financial instrument contains sufficient funds for management of credit project ▪ Financial penalty or instrument provides appropriate funds to disincentivize intentional reversals and replace invalidated credits
2.5 Credit Obligation Provisions and Credit Investment Strategies			
2.5.1	Debit Service Area	**Credit Buyers**	▪ All sites must be located within the current SGMA
2.5.2	Debit Project Types		▪ Anthropogenic disturbances to greater sage-grouse habitat on state and federal lands within the current SGMA
2.5.3	Mitigation Hierarchy and Permit Requirements		▪ Credits are used to offset debits that occur when disturbances are proven unavoidable and minimization does not provide for complete *direct or indirect impact* avoidance ▪ Debit projects must fulfill regulatory requirements of relevant public agency permitting process
2.5.4	Debit Project Duration		▪ Time until verification confirms that habitat function impacted by a debit project returns to pre-project habitat function and an additional set period of time to allow greater sage-grouse to begin to use the site, up to in perpetuity, and can be different for different portions of a debit project
2.5.5	Calculating Debit Baseline Habitat Function		▪ Local-scale, pre-project habitat function combined with site-scale, pre-project habitat function
2.5.6	Debit Site Verification		▪ Before construction, at time when debits are reduced or end, and periodic spot checks
2.5.7	Credit Investment Strategies		▪ Strategies include direct credit purchase, reverse auctions, requests for proposals, and selection from list of credit development opportunities

2.1 PROGRAM GOVERNANCE

This section describes the Credit System's governance, enforcement, accounting and adaptive management procedures pursuant to NRS 321.594, as well as other relevant state and federal policies and assurances. The Administrator is the primary audience of this section.

2.1.1 GOVERNANCE ROLES

The Credit System uses a governance structure that includes an Oversight Committee, Administrator and Science Committee to ensure that the program is managed consistently and policy and technical requirements are improved over time without causing uncertainty for regulators or participants. Information regarding the key duties and responsibilities for each of these entities are provided below.

Oversight Committee

The SEC serves as the Credit System Oversight Committee. State of Nevada statute NRS 232.162 established the SEC; it also directed the SEC to institute and oversee a program to mitigate damage to sagebrush ecosystems. Statute NRS 232.162 also defines the membership, duties, and other aspects of the SEC, including the oversight of any team within the Division of State Lands of the Department of Natural Resources and Conservation, which provides technical services concerning sagebrush ecosystems. The SEC contains nine voting members representing specific constituencies that are appointed by the Governor, and six ex-officio members representing specific State and Federal agencies.

The SEC is responsible for overseeing the operations of the Credit System, making high-level Credit System management decisions, and conducting other critical ongoing duties described in Table 2.

Table 2: Key Responsibilities of the Oversight Committee

	Oversight Committee Key Responsibilities
Ensure Program Performance	▪ Pursues the memorandum of understanding (MOU) with BLM and potentially programmatic agreements with USFWS and other participating agencies; and participates in negotiations with USFWS and other participating agencies to amend the agreements as necessary. ▪ Oversees Administrator's implementation of the Credit System policy and technical components. ▪ Evaluates annual reports from the Administrator that include assessment of the effectiveness of credit projects in relation to both species habitat and overall programmatic performance goals of the Credit System and provide reports to USFWS, BLM and other participating agencies as necessary. ▪ Executes annual audit, or contract for the auditing of, the Administrator's finances and operations, and determine if corrective actions are needed to ensure finances and operations are sufficiently in order for the ongoing, consistent operations of the Credit System.
Ensure Programmatic Adaptive Management	▪ Considers and adopts Credit System improvement recommendations provided by the Administrator and participants. Specifically approves any changes to the Credit System Manual and HQT. ▪ Gains input from the Administrator and Science Committee on new scientific information to be incorporated into the Credit System's tools and processes as necessary and at least annually. ▪ Evaluates and approves adaptive management actions.
Participant Oversight	▪ Resolves disputes among Credit System participants that cannot be resolved independently or in consultation with the Administrator.

Administrator

The SETT serves as the Administrator of the Credit System. As Administrator, the SETT implements the Credit System, making day-to-day management decisions based on the direction detailed in this Credit System Manual and authority granted in the BLM MOU and programmatic agreements with USFWS and other agencies.

Table 3 outlines the key responsibilities of the SETT, and is aligned with the processes described in *Section 3: Credit System Operations*. The SETT will develop and maintain a comprehensive work plan to guide the allocation of resources, and define procedures to consistently and efficiently facilitate transactions.

Table 3: Key Responsibilities of the Administrator

	Administrator Key Responsibilities
Program Administration & Credit Accounting	▪ Manages day-to-day Credit System operations. ▪ Manages all Credit System tools, guidance and forms. ▪ Manages credit accounts and the complete ledger of all credits and debits. ▪ Manages accounting of reserve account credits.
Credit Developer & Credit Buyer Engagement	▪ Responds to inquiries of interest from Credit Buyers and Credit Developers, connecting them to relevant resources as desired. ▪ Ensures any necessary outreach to Credit Developers and Credit Buyers occurs.
Adaptive Management & Reporting	▪ Implements Credit System adaptive management process. ▪ Compiles Improvement Recommendations throughout the year, develops the annual Synthesis of Findings, and develops the Annual Performance Report. ▪ Brings products developed through the adaptive management process to the Oversight Committee for consideration. ▪ Makes improvements to the Calculator, User's Guide, Forms and Guidance Documents consistent with direction defined in the Manual and HQT. Informs Oversight Committee on operational changes so that the Oversight Committee can elect to review and provide alternative direction.
Compliance & Enforcement	▪ Performs quality control review on information submitted by Verifiers and Credit System participants. ▪ Ensures programmatic compliance of the Credit System with relevant USFWS, BLM, Nevada Department of Wildlife (NDOW) and other relevant agency policies. ▪ Works with Credit Developers to implement corrective actions through *remedial action plans* when appropriate in cases of intentional and unintentional reversals. ▪ Enforces contract compliance and any associated penalties in cases of intentional reversals.
Financial & Contracting Support	▪ Manages funds, contracts, and partnerships for monitoring. ▪ Confirms financial assurances are in place for credit projects. ▪ May facilitate credit auctions or Request for Proposals for Credit Buyers. ▪ May administer contract payments between Credit Buyers and Credit Developers.
Science & Technical Support	▪ Creates and gains input from the Science Committee on new scientific information to be incorporated into the Credit System's tools and processes. ▪ Defines questions to guide monitoring and research investments, and Science Committee input. ▪ Trains and certifies Verifiers. ▪ Evaluates results of any effectiveness monitoring established for credit and debit projects.

Science Committee

The Science Committee consists of species and ecology scientists and experts whose purpose is to inform the development and revision of HQTs for species and habitat included in the scope of the Credit System. The Sciences Committee contributes to prioritizing and defining monitoring efforts to improve HQTs and the Credit System, and informing the conservation and species recovery objectives that influence and guide Credit System design.

The Science Committee is composed of a minimum of four and a maximum of seven biologists, rangeland ecologists or other qualified scientists with recognized knowledge and expertise on the species and habitat. One position on the Science Committee will be held by the NDOW upland game staff specialist responsible for greater sage-grouse. The SETT appoints members of the Science Committee and members commit to serve two-year terms. Specific duties of the Science Committee include:

- Compile and analyze the latest and best-available science regarding the species and habitat, and make recommendations to the SETT regarding how that new information may be used to update the HQT through the Credit System adaptive management process; and
- Assist the SETT with making changes to the HQT through the Credit System adaptive management process.

As of November 2014, the Science Committee has not been created. A Technical Review Group made up of six greater sage-grouse scientists and experts advised the development of the initial version of the HQT. Several members of the Technical Review Group shared interest in participating in the Science Committee. The Science Committee will be created in early 2015.

2.1.2 IMPLEMENTATION OF STATE OF NEVADA POLICY

In 2012, under Governor Brian Sandoval, the 2012 Strategic Plan for Conservation of Greater Sage-Grouse in Nevada was developed and recommended the creation of Sagebrush Ecosystem Program, including the SEC and the SETT. The SEC was originally established under Executive Order 2012-19, on November 19, 2012, and later codified under State of Nevada statute NRS Chapter 232.162, which also directed the SEC to establish a crediting program for compensatory mitigation of sagebrush ecosystems[6].

The Credit System was developed to fulfill NRS Chapter 232.162 requirements and is included in the updated 2014 Nevada Greater Sage-Grouse Conservation Plan, which states mitigation requirements for anthropogenic disturbances that impact habitat will be determined by the Credit System, as approved by the SEC on October 1, 2014.

2.1.3 FEDERAL REGULATORY PREDICTABILITY

The Credit System is designed to accommodate different regulatory mechanisms to ensure that efforts taken to facilitate conservation of the greater sage-grouse are recognized and certainty is provided to Credit Buyers and Credit Developers.

BLM Compensatory Mitigation

The Credit System is expected to be included in the BLM/USFS Land Use Plans for the Northeastern California-Nevada Sub Region as the tool for defining and fulfilling compensatory mitigation requirements for anthropogenic disturbances to greater sage-grouse habitat on BLM and USFS lands in the State of Nevada. The proposal in the Nevada Alternative of the Draft Environmental Impact Statement for the Northeast California/Nevada Sub Region states that disturbances within the SGMA [on Nevada BLM and USFS lands] will trigger evaluations and consultation with the SETT. Credits are expected to be purchased to meet credit obligations established when disturbances are proven unavoidable and minimization does not provide for complete direct or indirect impact avoidance.[7] As of November 2014, the Sagebrush Ecosystem Program is working with BLM and USFS to develop a MOU to define roles and responsibilities for implementation of the Credit System on BLM and USFS lands.

---

[6] The establishment of the Credit System by the Sagebrush Ecosystem Council is outlined in State statue (NRS 232.162 (7)(e)), and the administration of the Credit System by the Division of State Lands of the State Department of Conservation and Natural Resources is authorized in State statute (NRS 232.162).

[7] US Fish and Wildlife Service. Greater Sage-Grouse Range-Wide Mitigation Framework Version 1.0. September 3, 2014. Page 6.

USFWS Pre-Listing and Endangered Species Act

The Credit System is intended to be consistent with the Greater Sage-Grouse Range-Wide Mitigation Framework[8] (Mitigation Framework), and as such, the Credit System aims to provide regulatory certainty to both Credit Buyers and Credit Developers.

The Sagebrush Ecosystem Program intends for credits generated prior to the listing decision to be considered prelisting mitigation credits and treated as measures to mitigate the impact of *incidental take*, should greater sage-grouse be listed. As of November 2014, the Sagebrush Ecosystem Program is working with the USFWS to enter into a prelisting mitigation agreement that authorizes the use of Credit System credits for mitigation purposes. This agreement would signify that the Credit System can be integrated with other regulatory mechanisms to provide incidental take protection assurances to Credit Developers and Credit Buyers.

The Credit System could be used in listing scenarios as follows:

- In the event of a threatened (not endangered) listing, USFWS may create a 4(d) rule that would exempt a number of activities from ESA restrictions. These would be activities that USFWS determines to minimize the impacts to listed species to the extent that additional federal protections are not required. If a 4(d) rule is issued, it may be possible for activities using mitigation from the Credit System, both credit and debit projects, to be exempt from take requirements. Note that a 4(d) rule could also include exemptions for some agricultural and ranching activities to reduce the burden on farmers and ranchers.
- In the event of either a threatened or endangered listing, and if the Credit System is not included as an exemption in a 4(d) rule, take protection for Credit Buyers may be secured using Incidental Take Permits or Certificates of Participation issued through individual or regional Habitat Conservation Plans (HCPs) created for greater sage-grouse in the State of Nevada, or permittee-responsible mitigation. Any of these regulatory take coverage mechanisms could use the Credit System by specifying that the credit obligation for all debit projects will be determined and offset using the Credit System.
- In the event of either a threatened or endangered listing, and if the Credit System is not included as an exemption in a 4(d) rule, take protection for Credit Developers may be secured using additional types of regulatory mechanisms. More discussion on these regulatory mechanisms is needed and currently underway.

2.1.4 ADMINISTRATIVE TRANSACTION FEES

The Administrator collects transaction fees from Credit Buyers at transfer of credits between accounts (e.g. between Credit Developer and Credit Buyer accounts) in order to cover administrative costs incurred by the Administrator. Administrative costs range from the evaluating and awarding credits to credit projects and verification of credit and debit projects throughout their duration, to executing the annual Credit System adaptive management process. The Administrator maintains and publishes the fee structure and amounts, and regularly reviews the fee structure and amounts through the Credit System adaptive management process. Changes to the fee structure and amounts must be approved by the Oversight Committee. Fees are expected to include a per transfer component and a per credit component.

---

[8] US Fish and Wildlife Service. Greater Sage-Grouse Range-Wide Mitigation Framework Version 1.0. September 3, 2014. Page 5. http://www.fws.gov/greatersagegrouse/documents/Landowners/USFWS_GRSG%20RangeWide_Mitigation_Framework20140903.pdf

2.1.5 ACCOUNTING SYSTEM & REPORTING

The Credit System employs a rigorous accounting system that operates on an annual cycle. Credits and debits are tracked according to Credit System reporting and verification standards. See *Section 2.4.2 Credit Project Duration*, *Section 2.4.5 Credit Site Verification*, *Section 2.5.3 Debit Project Duration* and *Section 2.5.5 Debit Site Verification* for more information on credit and debit project reporting and verification standards. The Credit System accounting and reporting system uses the following key tools:

- **Credit System Registry:** Tracks functional acres, credits, debits, and other transactional information.
- **Annual Performance Reports:** Use Credit System Registry outputs and the Credit System adaptive management process to report on the change in functional acres, and the number of credits and debits generated each year, along with other information needed by state and federal regulatory agencies.

Tracking & Accounting

The Credit System tracks the functional acres impacted by anthropogenic as well as those enhanced and protected by credit projects. Each credit is tracked on the Credit System Registry and related to the specific debit project it is used to offset, if applicable. This tracking facilitates annual reporting, verifies the Credit System always generates more credits than debits in any given year, and provides information necessary for effective adaptive management.

The Credit System accounting structure can also account for the functional acres impacted by natural disturbances, such as wildfire, and management actions that do not generate credits for offset. Tracking functional acres impacted by natural disturbances and management actions facilitates a complete understanding of the state of habitat for the greater sage-grouse and provides useful data for adaptive management of the Credit System and other conservation strategies. The quantification of functional acres for calculating credits and debits is accomplished using the HQT, which uses vegetation characteristics collected in the field along with desktop analyses. Pre-natural disturbance vegetation characteristics would not be available and it would not be practical to collect post-natural disturbance vegetation characteristics for large natural disturbances, therefore a proxy assessment of vegetation characteristics would need to be used and there are options that would provide relatively accurate results. See *Section 2.2.1: Habitat Quantification Tool* for additional information on the HQT.

The Administrator will use a basic version of the Credit System Registry initially. Depending on transaction volume and cost, the Administrator may elect to develop a robust Credit System Registry or utilize an established environmental registry to efficiently track large volumes of transactions.

Annual Performance Reports

The Administrator will use the Credit System Registry and adaptive management process to report annually on the performance of the Credit System. See *Section 3.3: Managing the Credit System* for detailed information about the annual reporting process. Annual reports are expected to include the following information:

- Total functional acres lost by anthropogenic disturbances, and natural disturbances if tracked
- Total functional acres protected by credit projects, and management actions if tracked
- Total number of debit and credit projects statewide that are enrolled in the Credit System
- Total debits and credits generated by enrolled projects, and by WAFWA Zone and PMU
- Total credits held in the reserve account
- A description of any credit reversals that occurred over the course of the previous year, including a brief summary of the method and status of replacing invalidated credits
- A description of anticipated improvements to be made to Credit System operations identified through the adaptive management process

2.1.6 ADAPTIVE MANAGEMENT

The Credit System uses a formal, structured adaptive management approach to dealing with uncertainty, using the experience of management and the results of research as an ongoing feedback loop for continuous improvement. The Oversight Committee and Administrator are responsible for implementing the annual adaptive management process with support from the Science Committee and other stakeholders, as described in *Section 3.3: Managing the Credit System*.

The annual adaptive management process focuses on improving the effectiveness of Credit System Manual policy and technical elements, the HQT, and individual management actions used to generate credits by:

- Evaluating Credit System performance data related to changes in functional acres and the volume of credits relative to debits in the Credit System to improve the Credit System Manual and HQT;
- Identifying priorities and conducting research and monitoring, including comparing project success to overall population dynamics; and
- Collecting input on the application and results of 1) the Manual policy and technical elements, and 2) HQT scoring from Credit System participants and cooperating public agencies.

Each year, adaptive management findings are synthesized and improvement recommendations are produced by the Administrator. Significant changes are approved by the Oversight Committee through a public meeting process. Any changes will only apply to new credit and debit projects, thus credits awarded and credit obligations fulfilled through the Credit System will not be impacted by future updates to the Credit System.

2.1.7 PARTICIPANT CONFIDENTIALITY

Some Credit Developers may be concerned about the Credit System publicly disclosing personal information. However, it may also be necessary for federal and state agencies to evaluate individual actions in order to properly assess the effectiveness of the Credit System in reducing threats and providing net benefit to the species. Furthermore, the Credit System is run by the State of Nevada; therefore, certain information must be disclosed to the public in response to Freedom of Information Act (FOIA) requests.

The Credit System will annually publish a Performance Report that describes overall Credit System performance. This Performance Report will be provided to relevant federal and state agencies. To the maximum extent possible under federal, state, and local law, the Credit System will protect against disclosure of personal and confidential information from participants by using a case by case review and determination. Personal and confidential information may include: names, contact information, general and legal description of the enrolled property, grazing practices, land use practices, commercial activities on the land, recreational activities on the land, site-specific species sightings, and site-specific species habitat condition.

Disclosure of Information

In the event that a request for information is made to the Administrator that would result in the possible disclosure of personal or commercial confidential information, the Credit Developer or Credit Buyer will be notified of the request. Additionally, the Credit Developer or Credit Buyer will be provided the opportunity to state in writing why a release of the requested information would constitute a clearly unwarranted invasion of privacy or cause substantial harm to their commercial interest. The USFWS will provide a notice when a FOIA request for records concerning the Credit System is made, and allow the Administrator, Credit Developer or Credit Buyer to prepare a notification requesting that any confidential personal or commercial information be withheld.

2.1.8 RESERVE ACCOUNT MANAGEMENT AND USE OF FINANCIAL ASSURANCES

The Credit System creates a reserve account of credits and requires credit projects to provide financial assurances so that the Administrator can ensure the Credit System generates net benefit even if specific credit projects do not fulfill performance standards throughout the duration of each credit project. Credit projects that do not fulfill performance standards are considered credit reversals.

The reserve account is not a financial assurance method to hold a Credit Developer financially responsible in the event of project failure. Rather, the reserve account includes verified, released credits that are providing greater sage-grouse benefits and have not used to offset debit projects. The reserve account serves as an insurance mechanism for the overall Credit System. Each credit transaction contributes a percentage of credits generated based on the probability of the credits being invalided as described in *Section 2.4.3: Reserve Account Contribution*.

Financial assurances are fiscal mechanisms used to ensure that funds are available for the implementation and long-term management of each credit project, including remedial actions in the event of unintentional reversals, and to promptly replace credits that have been sold but become invalidated due to intentional reversals. Financial assurances can consist of contract terms, such as financial penalties for intentional reversals, and financial instruments, such as long-term stewardship funds and contract surety bonds. See *Section 2.4.6: Financial Assurances* for additional information on financial assurance requirements and guidance.

Reserve Account Management

The Administrator manages the reserve account and uses credits in the reserve account to temporarily cover credits invalidated due to unintentional or unintentional causes as described in this section. Credits in the reserve account are never used to offset debit projects. Credits withdrawn from the reserve account to temporarily cover invalidated credits are transferred back into the reserve account after the invalidated credits that they were withdrawn to temporarily cover are remediated or replaced using financial assurances associated to the invalidated credits. Term credits in the reserve account are permanently withdrawn from the reserve account when the term of the credits has expired.

The Administrator reviews the balance of the reserve credits at least annually. The Administrator at any time may propose adjustments to the required reserve account allocation to be approved by the Oversight Committee as part of the Credit System adaptive management process. The Administrator can propose the required contributions be adjusted upward or downward as needed to account for insufficient or excessive amounts of reserve credits.

Use of Reserve Account and Financial Assurances

Depending on the specific cause and circumstances of a reversal, invalidated credits can be replaced using a combination of the reserve account and financial assurances, as illustrated in Figure 9 below.

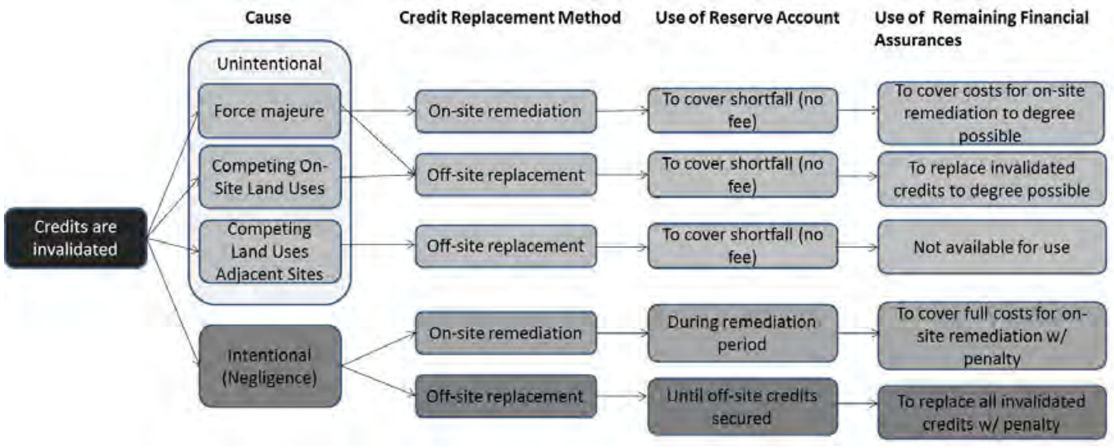

Figure 9: Credit invalidation replacement process

Unintentional reversals

Force Majeure

When credits generated by a credit site are invalided by an extraordinary event or circumstance beyond the control of the Credit Developer, such as wildfire, the Credit Developer is not liable and thus the financial assurances secured for intentional reversals are not available to the Administrator to replace the invalided credits. Instead, the Administrator withdraws credits from the reserve account to cover the invalidated credits at no cost to the Credit Developer. In cases where the credit site can be fully or partially recovered within a reasonable amount of time and cost, the Credit Developer has the option to develop a remedial action plan that is approved by the Administrator. In this situation, financial instruments secured for long-term management and unintentional reversals may be used to pay for activities included in the remedial action plan. See *Section 2.4.6: Financial Assurances* for additional information on financial assurance requirements. If only a portion of the credits are recovered following a *force majeure* event, then payments from financial instruments secured for long-term management and unintentional reversals are reduced according to the amount of credits actually being generated on the ground. The Administrator may use the remaining amount in the project site's financial instruments to purchase credits elsewhere. Any dedicated reserve account credits are returned to the reserve account if the invalidated credits are remediated, assuming all requirements of those reserve account credits are still being met.

In cases where the credit site cannot be recovered within a reasonable amount of time and cost, the Credit Developer has the option to cancel the contract without penalties, but retains the ability to re-enroll the site as a different project at a later time. If the contract is canceled, payments to the Credit Developer cease immediately and the Administrator uses the remaining amount in the project site's financial instrument for long-term management and unintentional reversals to purchase credits from a different credit site.

Competing On-site Land Uses

In the case of an unintentional reversal due to competing land uses on-site, such as *split estate* minerals development, the Administrator will withdraw credits from the reserve account to cover the invalidated credits at no additional cost to the Credit Developer. Similar to the policies described for force majeure events, if the impact of the competing land use reduces credit generation on a credit site, payments are reduced according to the amount of credits actually being generated. The Administrator uses the remaining funds in the project site's financial instrument to purchase credits elsewhere to the extent feasible. If the impact of the competing land use results in the credit site not being able to generate credits as expected, the contract can be canceled without penalties. If the contract is canceled, payments to the Credit Developer cease immediately and the Administrator uses the remaining amount in the project site's financial instrument to purchase credits from a different credit site.

Competing Land Uses on Adjacent Sites

There may be cases where verification shows that competing land uses on sites adjacent to enrolled credit project sites have occurred, which impairs the ability of the enrolled credit project site to generate benefit for the species. The effect of competing land uses on sites adjacent to the enrolled credit project sites are determined using the anthropogenic disturbance curves defined in *Section 3.3.1: Cumulative Anthropogenic Disturbances* in the *HQT Scientific Methods Document*. These occurrences are out of the direct control of the Credit Developer. Therefore in cases of unintentional reversals due to competing land uses on adjacent sites, the Administrator will withdraw credits from the reserve account to cover the invalidated credits at no cost to the Credit Developer. In these cases, the remaining financial assurances for the credit project site are not available to the Administrator to purchase replacement credits. The Credit Developer must continue to maintain habitat function at the project site-scale according to the performance requirements stated in the credit project's Management Plan.

Intentional Reversals

In the case of an intentional reversal, such as not implementing management activities to achieve habitat quality as defined in the Management Plan or intentional mineral development, all payments to the Credit Developer immediately cease. The Credit Developer and Administrator determine if a remedial action plan can be developed or if credits must be replaced off-site. The Credit Developer is responsible to the Administrator for the entire cost of purchasing replacement credits from a different credit site, any associated legal fees, and an additional 10% administrative fee (i.e. contract penalty). If there is a time lag between the intentional reversal and the recovery of the site, or a time lag between the intentional reversal and when the Administrator secures new credit contracts, the Administrator will withdraw from the reserve account for a limited duration to prevent any gaps in coverage for sold credits. The credit withdrawal from the reserve account ceases as credits are acquired to cover the remainder of the contract.

2.1.9 RECOGNITION AND SUPPORT OF EXISTING GREATER SAGE-GROUSE CONSERVATION PROGRAMS

To the extent appropriate, the Administrator may work with the sponsors of existing greater sage-grouse conservation programs to make Credit System tools and operations, such as the HQT, credit accounting and transfer protocols, verification protocols and credit investment strategies available to such programs. The terms under which the Credit System will be available to such programs shall be set forth in agreements between the Administrator and the program sponsors.

2.2 HABITAT QUANTIFICATION AND CREDIT AND DEBIT CALCULATION

This section describes how to calculate Credit System credits, debits and credit obligations, which are the amount of credits required to offset the debits generated by a debit project. The credit obligation is the number of debits generated by a debit project adjusted by a proximity ratio, determined by the proximity between the debit site and offsetting credit site. Credit Developers and Credit Buyers are the primary audience of this section.

Credits and debits represent the functional acre difference between baseline functional acres and post-project functional acres, multiplied by a mitigation ratio that incorporates biologically significant factors that are not captured through the HQT. This section begins with an overview of the HQT, which is used to quantify functional acres for both credit and debit sites. The difference in baseline functional acres and post-project functional acres is the starting point for calculating credits and debits, and guidance for determining baseline functional acres is provided in *Section 2.3.4: Calculating Credit Baseline Habitat Function* and *Section 2.5.4: Calculating Debit Baseline Habitat Function* for credit and debit sites, respectively. Following the overview of the HQT, guidance is provided for determining the mitigation ratio for credit and debit sites, and the credit obligation for debit projects. Lastly, an example calculation of credits and debits beginning with baseline and post-project functional acres is provided.

2.2.1 HABITAT QUANTIFICATION TOOL

The HQT quantifies habitat function for greater sage-grouse habitat in the State of Nevada. Habitat function refers to the role of the habitat in providing life history requirements for greater sage-grouse, and includes the direct and indirect effects of anthropogenic disturbances. Habitat function is expressed as a percent function in relation to fully-functioning habitat for greater sage-grouse, and is multiplied by the area (acres) assessed to calculate functional acres associated to the area assessed.

HQT Framework for Quantifying Habitat Function

The HQT was developed to account for habitat characteristics or attributes which influence sage-grouse habitat selection across multiple scales. These habitat characteristics were based on different orders of selection (Johnson 1980, Stiver et al. 2010), which represent four spatial scales at which habitat attributes influence where sage-grouse reside and obtain resources necessary for survival and reproduction[9]. The HQT assessed habitat quality at four orders.

Range-wide Scale (1st order): The range considered by the Credit System is the geographic range of the sage-grouse population in Nevada.

Landscape Scale (2nd order): Landscape selection is based on the availability of seasonal habitats needed to support a population or subpopulation.

Local Scale (3rd order): Local selection is based on suitability of the habitat within their home range and the effects of anthropogenic disturbances.

Site Scale (4th order): Site selection is based on vegetation structure and composition that provide forage and cover.

See the *HQT Scientific Methods Document* for additional information on the attributes measured at each scale (order), and the methods used to measure those attributes.

---

[9] While the term 'selection' may be interpreted as relating to individual bird behavior, in this context the term is applied broadly to describe the four geographic scales at which sage-grouse occur, are organized into populations and use habitat (per Johnson 1980, Connelly et al 2003, Stiver et al 2010). These four scales also correspond to scales at which sage-grouse policy and management are typically implemented (Stiver et al. 2010). Throughout this document, orders of selection will be identified by their descriptive terms (e.g., site scale, local scale, landscape scale).

Functional Acre Calculation

The HQT generates a percent function and a number of functional acres for each seasonal habitat type (breeding, late brood-rearing, and winter) for each *map unit* delineated within a project site. Map units are sub-divisions of the project area based on unique vegetation communities and vegetation structure. Map units are delineated based on variation in habitat attributes assessed by the HQT, such as sagebrush canopy cover, forb abundance and distance to sagebrush cover. Guidance for delineating map units within a credit or debit site is provided in the *HQT Scientific Methods Document*.

The HQT generates a local-scale habitat function score and site-scale habitat function scores for each seasonal habitat type. The product of the local-scale habitat function and site-scale habitat function scores for each seasonal habitat type determines overall habitat function for each seasonal habitat type for a map unit. The overall habitat function for each seasonal habitat type is multiplied by the acreage of the map unit to produce a functional acre value for each seasonal habitat type. Table 4 provides an example calculation of functional acres for each seasonal habitat type for a single map unit.

Table 4: Example calculation of functional acres for a single map unit

Seasonal Habitat Type	Local-Scale Habitat Function	Site-Scale Habitat Function	Overall Habitat Function	Acres	Functional Acre Values
Breeding	80%	60%	48%	500	240
Late Brood-Rearing	80%	0%	0%	500	0
Winter	80%	45%	36%	500	180

Application of the HQT

The Credit System uses the functional acre difference between baseline functional acres and post-project functional acres for each seasonal habitat type as the starting point for calculating credits and debits for each map unit delineated within a project site, including the area indirectly impacted by a debit project. Guidance for determining baseline functional acres is provided in *Section 2.3.4: Calculating Credit Baseline Habitat Function* and *Section 2.5.4: Calculating Debit Baseline Habitat Function* for credit and debit sites, respectively.

The HQT is used consistently throughout the life of a credit project to 1) substantiate the release of credits at the point that the project meets habitat function thresholds, and 2) verify that conditions are being maintained as expected over time. For debit projects, the HQT is used to determine pre-project functional acres before impacts occur, to determine post-project functional acres after impacts occur, and is used as necessary over time to determine if impacts are increased or reduced. Pre-project HQT results for debit projects can be used for up to 5 years after a site has been verified as long as the habitat function is believed to be similar to the previous assessments and no significant changes have occurred on the project site.

Field Data Collection Timing

Site-scale vegetation measurements required by the HQT must be collected during specific times of the year to accurately measure the function of breeding, late brood-rearing, and winter habitat. These vegetation measurements are primarily related to sagebrush, forbs and grasses. The forbs and grasses necessary to sustain greater sage-grouse are often different, or differ in availability, during specific greater sage-grouse life cycle stages. To ensure accurate quantification of the functionality for each seasonal habitat on a site, field work for the collection of forbs and grasses needs to occur during an appropriate season.

Permissible Windows

Credit Developers and Credit Buyers must collect data during the following permissible windows in order for functional acre scores to be official and approved by the Administrator:

Breeding: April 1st through June 15th
Late brood-rearing: July 1st through September 15th
Winter: Anytime

The permissible window may need to be shifted each year due to annual variation in climatic conditions. Shifts of the permissible window will be limited to significant departures from mean climatic conditions, and to no more than a 3 week shift forward or backward from the standard windows above. If the permissible window is shifted, the Administrator will post an announcement on the Nevada Conservation Credit System Website as soon as a determination is made.

Date Confirmation

Credit Developers and Credit Buyers may request written confirmation from the Administrator that their planned field work is scheduled within permissible windows in order in to ensure functional acre scores based on the field data collected will be accepted by the Administrator.

Field Data Outside of Permissible Windows for Planning Purposes

Credit Developers and Credit Buyers may collect field data outside the permissible windows to estimate credit generation and credit obligations for **project planning purposes only**, such as to negotiate options contracts between Credit Developers and Buyers. Credits will not be released for sale based on field data collected outside of permissible windows. Similarly, debit projects are not permitted to develop any area where field data has not been collected during a permissible window when it is needed to generate accurate quantification of habitat function. All credit and debit amounts must be finalized based on field data collected during a permissible window.

All preliminary estimates of habitat function collected outside the permissible windows will be clearly indicated as such. These estimates should also include an indication of when field work will occur during the permissible window. Credit Developers and Credit Buyers should make conservative estimates when using field data collected outside of permissible windows (e.g. under-estimate credits, over-estimate debits). In particular, estimates for forbs, grasses and other attributes that are affected by specific growing seasons should be conservative in order to minimize risk in planning decisions and capital investments.

2.2.2 MITIGATION AND PROXIMITY RATIOS

A mitigation ratio is applied to the functional acre difference between baseline functional acres and post-project functional acres for each map unit within a credit or debit project respectively. See *Section 2.2.1: Habitat Quantification Tool* for additional information on calculating functional acres, and guidance for determining baseline functional acres is provided in *Section 2.3.4: Calculating Credit Baseline Habitat Function* and *Section 2.5.4: Calculating Debit Baseline Habitat Function* for credit and debit sites, respectively. The mitigation ratio incorporates biologically significant factors that are not incorporated into the quantification of functional acres using the HQT.

The mitigation ratio enables credits acquired to offset debits generated by debit projects to achieve net benefits for greater sage-grouse by ensuring the total functional acres of credit acquired are greater than the functional acres of debit. The mitigation ratio incentivizes avoidance of impacts, while encouraging enhancement and protection of habitat in high priority areas.

The mitigation ratio is defined for each map unit delineated within a credit or debit project, including the area indirectly impacted by a debit project, and is based on multiple factors described below. The mitigation ratio is applied to the difference between baseline functional acres and post-project functional acres associated to each map unit for both credit and debit projects, as illustrated in Figure 10. See *Section 2.3.4: Calculating Credit Baseline Habitat Function* and *Section 2.5.4: Calculating Debit Baseline Habitat Function* for determining baseline for credit and debit projects respectively.

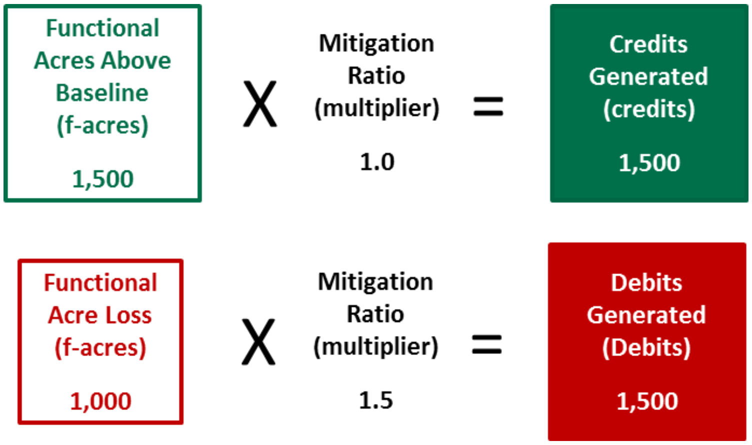

Figure 10: Illustration of calculation of debit and credits

The amount of credits required to offset a debit project, or the credit obligation, is the number of debits generated by the project adjusted by a proximity ratio, determined by the proximity between the debit site and offsetting credit site. The proximity ratio incentivizes credit sites used for mitigation to be in close proximity to debit sites.

Credit and Debit Mitigation Ratios

The Credit System applies a mitigation ratio to credit and debit sites to incorporate 1) estimated space use by greater sage-grouse, and 2) limiting seasonal habitat impacted, negatively or positively.

Management Importance Factor

The management importance factor incorporates estimated space use by greater sage-grouse into the calculation of credits and debits. The management importance factor is determined by the Core, Priority or General Management Area for which the credit or debit is located within, as defined by the Sagebrush Ecosystem Program's Management Categories map depicted in Figure 11. The Core Management Area is the highest conservation priority and the General Management Area is the lowest conservation priority under the management importance factor. Table 5 and Table 6 below provide the management importance factor values for debit and credit sites, respectively. These values will be reevaluated by the SEC after testing pilot projects.

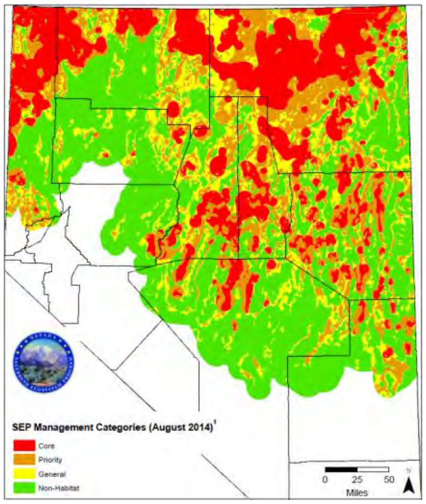

Figure 11: Sagebrush Ecosystem Program's Management Categories map

Table 5: Debit Site Management Importance Factor Values

Category	Factor Value
Core	2.0
Priority	1.5
General	1.0

Table 6: Credit Site Management Importance Factor Values

Category	Factor Value
Core	1.1
Priority	1.0
General	0.85

In accordance with the 2014 Nevada Greater Sage-Grouse State Plan Table 3-1, disturbances located in Non-Habitat Management Areas require evaluations to determine whether the disturbance will cause an indirect impact to Core, Priority, or General Management Areas. If the evaluation determines that an indirect impact will occur in a Core, Priority or General Management Area, the management importance factor of that area is applied to the indirect disturbance area of the debit project.

If a single map unit crosses two or more management importance categories, the management importance factor value used is an area-weighted average based on the management categories included in the map unit (see Figure 15 for an example of calculating an area-weighted average value).

Limiting Seasonal Habitat Factor

Greater sage-grouse depend on different types of habitat to accommodate different phases of their life cycle - breeding, late brood-rearing and winter. If one or more of these habitat types is impacted to the point that it can no longer support the corresponding life cycle phase, then the entire area is potentially no longer suitable for the greater sage-grouse. The limiting seasonal habitat factor incorporates the effect of a credit or debit project on each seasonal habitat type relative to the amount of the specific seasonal habitat currently available to the affected population within and surrounding the project site. The proportion of seasonal habitat affected by a credit or debit project is determined using a seasonal habitat map that excludes all disturbed habitat and non-habitat within and surrounding the project site due to existing anthropogenic disturbances, recent fire, and other factors. Including concepts of existing anthropogenic disturbances and recent fire into limiting habitat helps to provide the relative value of these habitats when some has already been lost to disturbance. See *Section 3.2.3: Limiting Seasonal Habitat* in the *HQT Scientific Methods Document* for additional information including the analysis method and area within and surrounding the project included in the analysis.

A limiting seasonal habitat factor value is incorporated in the mitigation ratio if the project impacts a seasonal habitat type with less than the proportions defined in Table 7, within and surrounding the project site.

Table 7: Limiting seasonal habitat proportion of analysis window thresholds

Breeding & Winter	**Late Brood-Rearing**
Proportion of Analysis Window	Proportion of Analysis Window
<40%	<4%

If the project impacts a limiting seasonal habitat, as defined in Table 7, the equation associated with that seasonal habitat type in Table 8 is used to determine the limiting seasonal habitat factor value.

Table 8: Limiting seasonal habitat factor value equations

Breeding & Winter	**Late Brood-Rearing**
Ratio Equation	Ratio Equation
$(.4\text{-}proportion)*100$	$\frac{1}{proportion}$

Combining Factors to Determine Credit and Debit Mitigation Ratio

The management importance and limiting seasonal habitat factors are summed to determine the overall mitigation ratio for a site, as per Equation 1.

Equation 1: Combining factor values to determine overall debit or credit mitigation ratio

$$\begin{aligned}&\mathbf{\mathit{Mitigation\ Ratio}}\\&\quad = \mathbf{\mathit{Habitat\ Importance\ Factor\ Value}}\\&\quad + \mathbf{\mathit{Limiting\ Seasonal\ Habitat\ Factor\ Value}}\end{aligned}$$

Proximity Ratio

The credit obligation is the number of credits that must be purchased to offset the debits generated by a debit project. The credit obligation is the number of debits calculated using the debit ratio above adjusted by a proximity ratio, determined by the proximity between the debit site and offsetting credit site.

The proximity ratio incentivizes debit projects to offset their credit obligation (purchase credits) in close proximity to debit sites in order to increase the likelihood that the mitigation serves the same populations of birds that are adversely impacted by the debit site. The WAFWA Management Zones and the NDOW PMU maps illustrated in Figure 12 and Figure 13. respectively are used to determine whether the debit and credit sites 1) have no population connection, 2) are connected through population dispersal, or 3) impact and benefit a single population.

- If the debit and credit sites are located within one PMU, they are considered to be relevant to a single population.
- If the debit and credit sites are located within the same WAFWA management zone, but not the same PMU, they are considered to be connected through population dispersal.
- Finally, if the debit and credit sites are located in different WAFWA management zones they are considered to have no population connection.

The proximity ratio value associated with each of these categories is in the Table 9.

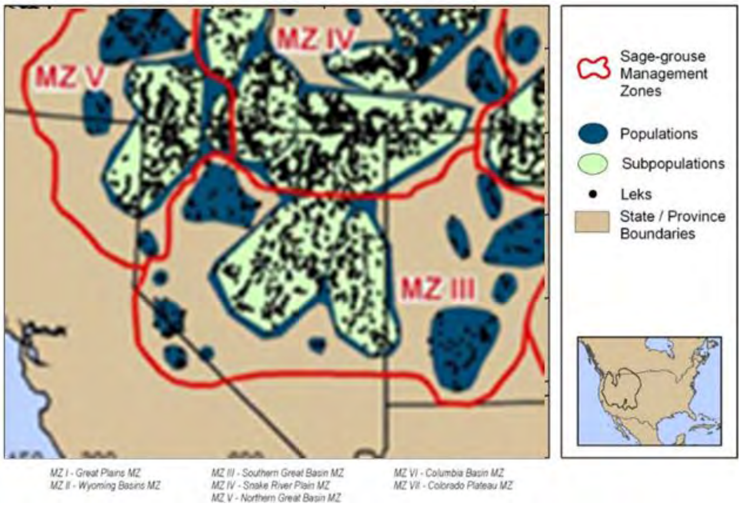

Figure 12: WAFWA Management Zones for Greater and Gunnison sage-grouse

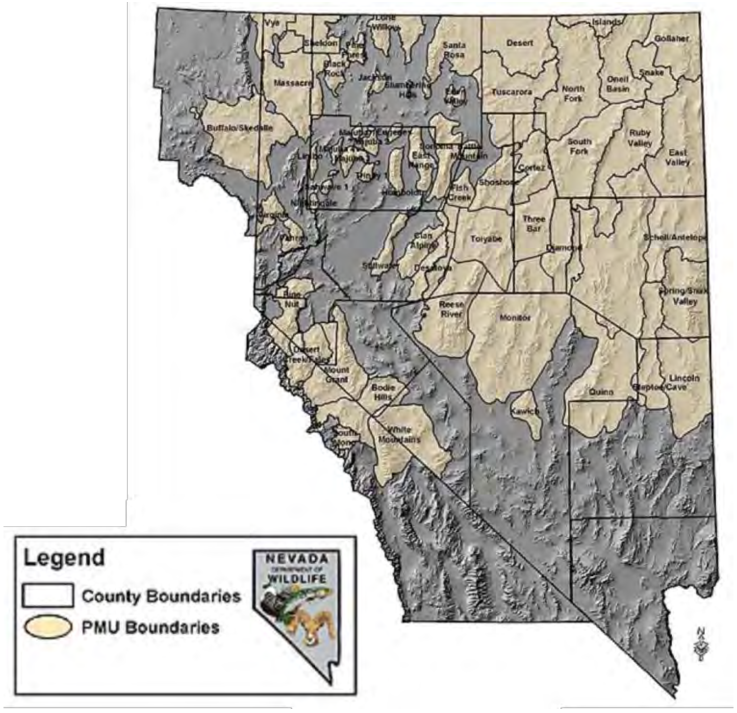

Figure 13: NDOW Population Management Units

Table 9: Proximity Ratio Values

Category	Factor Value
No population connection between credit and debit sites (different WAFWA Management Zone)	1.50
Credit and debit sites connected through population dispersal (same WAFWA Management Zone)	1.25
Credit and debit sites located within a single population (same PMU, even if in different WAFWA Management Zones)	1.00

Preferred conservation areas are expected to be defined and incorporated into the State of Nevada's strategic action plan in 2015. After preferred conservation areas are defined, waiving the proximity ratio for debit projects that acquire credit offsets from these areas but outside of the PMU or WAFWA zone for which the debit is located will be considered. This exception will be considered as an additional method to prioritizing mitigation in areas that best serve the greater sage-grouse at a landscape-scale instead of focusing exclusively at the individual population level.

Credit Obligation

The credit obligation for each debit project is determined by multiplying the number of debits by the proximity ratio, as per Equation 2.

Equation 2: Credit obligation for debit projects

$$Credit\ Obligation = Debits\ *\ Proximity\ Factor\ Value$$

2.2.3 CREDIT AND DEBIT CALCULATION

The amount of credits and debits generated from a project is determined by the greatest benefit for credit projects or the greatest impact for debit projects. The greatest benefit or impact from a project is the sum of the greatest benefit or impact determined for each delineated map unit within a credit or debit project. The greatest benefit or impact associated with each map unit is the largest product of the difference between baseline functional acres and post-project functional acres and the unique mitigation ratio associated to each seasonal habitat type. See *Section 2.2.1: Habitat Quantification Tool* for additional information on calculating functional acres, and guidance for determining baseline functional acres is provided in *Section 2.3.4: Calculating Credit Baseline Habitat Function* and *Section 2.5.5: Calculating Debit Baseline Habitat Function* for credit and debit sites, respectively.

An example calculation of the credits generated from a credit project with three map units is provided in Table 10. The left most group of columns contain the difference between baseline functional acres and post-project functional acres for each seasonal habitat type, and the next group of columns moving the right contains the unique mitigation ratio for each seasonal habitat type. The next group of columns to the right contains the potential credit value of each seasonal habitat type, which is the product of the difference between baseline functional acres and post-project functional acres and the unique mitigation ratio for each seasonal habitat type. The last column contains the credits generated by each map unit, which is the highest seasonal habitat credit value circled in red. The sum of the credits generated by each map unit is the total credits generated by the project.

Table 10: Example credit calculation for a project with three map units and enhancement and protection of limiting late brood-rearing habitat

Map Unit	Breeding F-Acres Above Baseline	Late Brood-Rearing F-Acres Above Baseline	Winter F-Acres Above Baseline	Breeding Mitigation Ratio	Late Brood-Rearing Mitigation Ratio	Winter Mitigation Ratio	Breeding Value	Late Brood-Rearing Value	Winter Value	Credits Generated
Map Unit 1	6	15	3	.95	25.95	.95	6	389	3	390
Map Unit 2	15	0	20	.95	25.95	.95	14	0	19	19
Map Unit 3	10	0	7	.95	25.95	.95	10	0	7	10
									Total Project	**419**

2.3 CREDIT PROJECT REQUIREMENTS & ADDITIONALITY PROVISIONS

This section describes requirements including additionality provisions for credit projects to ensure credit projects provide benefits beyond those that would be achieved if the project and associated management actions had not taken place. Additionality provisions address credit projects on public lands, credit projects that have received public funds, and *stacking* of multiple credit types. Credit Developers are the primary audience of this section. Specifics related to Credit Buyers are outlined in *Section 2.5: Credit Obligation Provisions and Credit Investment Strategies*.

2.3.1 CREDIT SERVICE AREA

Figure 14: Greater sage-grouse service area

The Credit System service area is the mapped geographic region where credits can be generated and will be tracked and reported. The service area designation has important implications for the viability of the Credit System transactions and for the ability of the Credit System to generate a net benefit for greater sage-grouse habitat from the impacts from anthropogenic disturbances.

The current SGMA is the Credit System service area, and the 2014 SGMA map is provided in Figure 14 as an example. The boundaries of this management area are based on the range of the species in the State of Nevada and are aligned with State of Nevada development project review requirements for greater sage-grouse.

While the Service Area broadly defines the domain of the Credit System, mitigation ratios establish incentives to offset debits using credits generated in close proximity to debit sites. *Section 2.2.2: Mitigation and Proximity Ratios* describes how the WAFWA Management Zones and the NDOW PMUs, depicted in the Figure 12 and Figure 13 respectively, are incorporated into the proximity ratio. In addition, three Management Categories are also incorporated into the mitigation ratios to encourage the generation of credits and discourage debits in Core and Priority Management Areas, which are estimated to have high space-use by greater sage-grouse. Credits and debits will be tracked in the Credit System Registry and reported by the Administrator by WAFWA Zones and PMUs.

2.3.2 CREDIT PROJECT MANAGEMENT ACTION TYPES

To achieve conservation needs and facilitate recovery of greater sage-grouse, the Credit System defines two credit project management action types:

1) **Habitat Stewardship** – Maintenance of high quality habitat currently used by or in close proximity to habitat used by greater sage-grouse, or manipulation of existing habitat to increase specific habitat functionality. An example project could be placing a conservation easement on existing high quality habitat and committing to maintaining that high quality for the full duration of the credit project. Another example project could be, and improvement of medium quality habitat through a prescribed grazing plan on existing rangeland, and committing to maintaining the post-project habitat function for the duration of the credit project.
2) **Habitat Restoration** – The reestablishment of ecologically important habitat and other ecosystem resource characteristics and functions at a site where they have ceased to exist or where they exist in a substantially degraded state. Examples include the reestablishment of useable greater sage-grouse habitat on abandoned mining claims, eradication of cheatgrass, removal of power line towers no longer in use, or restoration of a wet meadow that is currently not functioning properly.

Riparian Properly Functioning Condition Assessment

A riparian properly functioning condition (PFC) assessment is required for riparian areas included in a credit project. The results of the assessment in report format including the information from the field forms, map, riparian plant list, and photographs must be included in the Management Plan associated with the credit project. The assessment is intended to inform the Credit Developer and Administrator of the ecosystem health of the riparian areas and thus the risk of generating credits from those areas. The Credit Developer is not required to implement management actions to increase the functioning condition of riparian areas. However, the habitat function of riparian areas as measured by the HQT is likely to decrease when those areas are nonfunctional or functional at risk. Credit Developers are encouraged to implement management actions to achieve properly functioning condition to reduce the risk (as identified by the PFC assessment) of credits becoming invalidated.

2.3.3 CREDIT SITE ELIGIBILITY

To be eligible to participate in the Credit System, credit sites must meet the eligibility criteria defined below.

Service Area

All credit sites must be located within the Credit System Service Area. See *Section 2.3.1 Credit Service Area* consideration for additional information.

Ownership & Stewardship

Credit Developers must attest to their current ownership, tenure or use rights, and past land management and land uses over the previous 10 years. . On federal lands, credit developers must have an approved request or application depending on the land protection instrument.

Minimum Performance Standards

The Credit System requires that credit sites meet minimum performance standards related to habitat function and space use for the greater sage-grouse in order to be eligible to generate and release credits. The following minimum performance standards are based on post-project habitat function and must be met at all three scales in order to ensure credit sites are fulfilling the needs of greater sage-grouse at each scale:

- **Landscape-scale** – Credit projects must be located within the Core, Priority or General Management Areas using the SEP's current Management Categories map.
- **Local-scale** – Anticipated local-scale, post-project habitat function (area-weighted average across all map units) determined using the HQT must be greater than or equal to 20%.
- **Site-scale** – Anticipated site-scale post-project habitat function (area-weighted average across all map units using maximum seasonal habitat function associated to each map unit) determined using the HQT must be greater than or equal to the relevant site-scale regional standard habitat functions plus 10% (area-weighted average across all map units using the relevant seasonal habitat type regional standard habitat function). See *Section 2.3.4: Calculating Credit Baseline Habitat Function* for

Area-weighted average is the sum of products of Habitat Function and Area for each map unit divided by total area.

Step 1: Calculate product of habitat function and area, and total area

	Habitat Function	Acres	Product of Habitat Function and Area
Map Unit #1	70%	100	70
Map Unit #2	50%	500	250
Total		**600**	**320**

Step 2: Divide the sum of products of habitat function and area for each map unit by total area

Area-weighted Average Habitat Function = 320/600 **= 53%**

Figure 15: Definition of and an example calculation of area-weighted average habitat function for a credit site with two map units

site-scale regional standard habitat functions, and Figure 15 for additional detail on calculating area-weighted averages.

Additionality

Credit Developers must demonstrate that the performance standard defined for the credit site in the Management Plan exceeds what is otherwise required by federal, state, and local regulations and statutes. Credit Developers must also describe how federal funds have been previously or are currently used to support the development and management of the credit project site. Credit Developers must demonstrate that the credit project site will provide additional benefit to the species above and beyond those generated through the application of existing federal funds or participation in other credit markets. See *Sections 2.3.5* through *2.3.8* for additional information on additionality provisions.

No Imminent Threat

There cannot be evidence supporting imminent threat of direct or indirect disturbance by land uses that will cause the habitat function of the total credit site to be less than the minimum performance standard referenced above as measured by the HQT. Recently acquired subsurface rights, development plans (e.g. a building permit recently submitted or National Environmental Policy Act (NEPA) documents currently under development), or development designations (e.g. renewable energy zone or transmission corridor) would constitute proof of imminent threat that may disqualify a credit site from participating in the Credit System. Proper grazing practices are not anticipated to pose an imminent threat of disturbance. However, in order to develop credits on public land within a grazing allotment, the Credit Developer must either be the permittee or have an agreement with the permittee that are necessary to ensure grazing practices are compatible with the performance standards defined in the Management Plan associated with the credit project.

Site Protection

Credit Developers must show evidence of site protection for the duration of the contract period. A Participant Contract that commits to maintain habitat function above the minimum performance standard is the minimum level of site protection. The Participant Contract includes contractual language and references any other legally binding agreements, such as conservation easements.

Financial Assurances

Credit Developers must commit to financial assurances in the form of contract terms and financial instruments. Financial assurances are specifically defined in each Credit Developers' Participant Contract with the Credit System and associated Management Plan. See *Section 2.4.6: Financial Assurances* for additional information.

Accuracy

Credit Developers must attest to the accuracy of the information provided in all documentation.

2.3.4 CALCULATING CREDIT BASELINE HABITAT FUNCTION

Credit project baseline habitat function is the starting point from which the functional acre difference relative to post-project functional acres is calculated. The difference between a project's post-project functional acres and the baseline functional acres are multiplied by the mitigation ratio to determine the credits generated for each map unit within a credit project. The resulting sum of the functional acres of the map units is the total credits for the project. See *Section 2.2.2: Mitigation and Proximity Ratios* for additional information on determining mitigation ratios.

The credit baseline habitat function is based on the pre-existing local-scale habitat function and the typical site-scale habitat function for the relevant region and habitat type to account for the avoided risk of potential threats that would degrade habitat function if the project was not implemented. In addition, using the typical site-scale habitat function instead of pre-existing site-scale habitat function rewards Credit Developers who have demonstrated stewardship and enables credits to be generated by credit projects that will maintain and protect currently high quality habitat. See *Section 2.2.1: Habitat Quantification Tool* for description of scales. Credit baseline habitat function is calculated by multiplying

- Local-scale, pre-project habitat function as determined by the HQT, and
- Site-scale, regional standard habitat function as defined in Table 11.

The credit site-scale, regional habitat functions shown in Table 11 are used for the WAFWA Zone and seasonal habitat type associated to each map unit. These site-scale regional standard habitat functions are based on median habitat function values, and these values and spatial delineations will be reevaluated in the future as additional site-scale data on existing conditions and more effective methods of delineating habitat throughout the State of Nevada become available.[10]

Table 11: Site-scale regional standard habitat functions

		WAFWA Management Zones		
		MZ III	MZ IV	MZ V
SEASONAL HABITAT TYPES	Breeding	30%	30%	20%
	Late Brood-Rearing	20%	30%	20%
	Winter	65%	60%	60%

The winter regional standard habitat function values in Table 12 are expected to be adjusted in 2015. The current values are expected to be higher than appropriate because the winter scoring curves currently in the HQT and which were used to inform these baseline values do not entirely incorporate snow depth. The values in this table and the HQT will be adjusted at the same time in order to avoid impacting the relative value of winter habitat quantified before and after this change.

An example credit baseline habitat function calculation is illustrated in Table 12 for a map unit with high pre-project local-scale habitat function and a 20% site-scale regional standard habitat function.

Table 12: Example credit baseline habitat function calculation

Local-scale Pre-Project Habitat Function	**Site-scale Regional Standard Habitat Function**	**Credit Baseline Habitat Function**
80%	20%	16%

Additional Credit Baseline Habitat Function Considerations

Credit projects on public lands, or sites currently or previously participating in a federal funding program, or currently generating credits under other *ecosystem service* program or market, may require an adjusted credit baseline habitat function as defined by the following sections.

2.3.5 DEVELOPING CREDITS ON PUBLIC LANDS AND OTHER DESIGNATIONS

The Credit System allows for credits to be generated on public lands (e.g. BLM, Forest Service, State of Nevada trust lands etc.) or other lands already under permanent conservation restrictions (e.g. existing conservation easements) for mitigation purposes if the proposed credit project would add additional benefit above and beyond what would be achieved under the existing land designation or planned and funded conservation actions. Credit projects on public land are able to meet additionality requirements of the Credit System if the Credit Developer can demonstrate that verifiable benefit using the HQT can be attained by the credit project.

---

[10] The site-scale regional standard habitat function values below are based on BLM's Assessment, Inventory, and Monitoring (AIM) data and adjusted for identified bias in the data set for the use as regional standard within baseline calculations in the Credit System.

In order to generate credits on public lands, the Credit Producer must have authorization from the relevant public land management agency, under which the public land manager maintains management authority over the land.

2.3.6 PARTNERING WITH FEDERAL PROGRAMS ON PRIVATE LANDS

The Credit System allows for credits to be generated on private lands currently or previously participating in a federal funding program (e.g., U.S. Department of Agriculture (USDA) Farm Bill conservation programs). Guidance for determining the number of potential credits on sites that are currently or have previously participated in a federal funding program is provided below. There are two discrete time periods when payments may be partnered with federal funds including 1) when a current federal contract is still in effect, and 2) after a previous federal contract has expired.

Where conservation values have already been permanently protected or restored under other federal programs benefitting the greater sage-grouse, the Credit Developer can only receive credit for conservation values if enrollment of the credit site in the Credit System would create additional conservation benefit above and beyond the terms of the original agreement.

During an Existing Federal Contract

Within an existing federal contract, a Credit Developer can receive credits for additional habitat benefit generated. The allocation of credits on affected acreage will be proportionate to the non-federal contribution to the conservation benefit for sage-grouse. For example, acreage capable of producing ten credits, but with a fifty percent (50%) federal contribution, will be allocated five credits. This rule only applies to the portion of the benefit on a particular credit site that can be attributed to federal funds. The rest of the benefit is fully creditable.

Following a Federal Contract

A Credit Developer may receive full credit for long-term or permanent contract extension, management or protection agreements following expiration of a federally-funded contract. These long-term contract extensions and permanent conservation agreements could be entered into contemporaneously with execution of the underlying contract or thereafter, but these provisions (and Credit System credits) would not take effect until after the expiration of the underlying contract.

2.3.7 STACKING CREDIT TYPES

Although the Credit System currently only supports the generation and sale of one type of credit (e.g. greater sage-grouse credits), the Credit System allows for multiple credit types to be generated from spatially overlapping areas. However, the amount of each type of credit generated must be based on additional habitat function maintained compared to the habitat function maintained for other credit types. If a site under the Credit System is currently or has previously generated and sold credits under a different ecosystem service program or market (i.e. carbon, water quality, etc.), then restrictions related to partnering with federal funds during existing or following previous federal contracts apply.

In the future, the Credit System may expand to support the generation and sale of credits for other species and resources (e.g. mule deer) in addition to greater sage-grouse. Similar to restrictions on generating credits within a federally-funded contract or on public lands, Credit Developers would be able to generate and sell credits for different species and resources if they demonstrate additionality of specific conservation and management practices. A Credit Developer would not be eligible to sell multiple habitat credits from a single management practice. However, additional and unique management practices undertaken for a particular species would be eligible to generate additional credits. In order to demonstrate additionality for different species and resources, the Credit System will need to quantify and track habitat benefits for each species or resource. HQTs will need to be developed to provide habitat function scores for multiple species on a single project site. The species that receives the highest pre-project score will be the focus of the initial project design. Then, any additional and unique management actions built into that project design in order to generate function for other species or resources will be considered additional, and can be sold as separate credits under the Credit System.

2.3.8 INTEGRATION WITH CCA/CCAAS

Credit Developers enrolled in Candidate Conservation Agreements (CCAs) or Candidate Conservation Agreement with Assurances (CCAAs) can enroll in the Credit System and generate credits if the benefits generated are additional to the minimum conservation measures required by the CCA or CCAA. Credit projects previously enrolled in a CCA or CCAA must work with the Administrator to determine an appropriate site-scale credit baseline, such as pre-project conditions, considering the existing CCA or CCAA. This site-scale credit baseline adjustment should consider the increased additionality and durability resulting from securing conservation benefits through a long-term or permanent credit project that goes beyond the duration of the CCA or CCAA.

2.4 CREDIT DURABILITY PROVISIONS

This section describes credit project durability provisions to ensure credit projects are producing expected outcomes for their entire duration. Durability provisions include legal, financial and Credit System management mechanisms. Credit Developers are the primary audience of this section.

2.4.1 CREDIT SITE PROTECTION

All participating credit projects are required to complete and sign a Participant Contract and accompanying Management Plan that assigns responsibility for meeting monitoring, reporting and verification requirements of each project to the Credit Developer for the duration of the project. Additional information on credit project duration is provided in *Section 2.4.2: Credit Project Duration*. The Participant Contract is the legal agreement between one or more Credit Developers and the Administrator that defines obligations of the Credit Developers and secured financial assurances, binds a participating credit site to a Management Plan, and lays out the relevant terms and conditions for the development of credits under the Credit System. This includes habitat function performance standard, financial assurances for long-term management and intentional reversals, and other provisions related to the signatories.

Additional site protection measures, such as easements or public land use designations on private and public lands respectively, can reduce the probability of competing land uses invaliding the credits generated on the credit site. Reserve account contributions for individual projects reflect these considerations – the probability of competing land uses, the level of risk of the specific site protection mechanism secured, and the unique terms secured for each credit project. The level of risk then determines the reserve account contribution amount required of each project, which creates an incentive to increase land protection and select sites less likely to be affected by other uses. The increased contribution amount also helps ensure the Reserve Account is capable of covering invalidated credits regardless of the site protection measures in place. See *Section 2.4.3: Reserve Account Contribution* for more information on the competing land use factor including how the probability of a reversal from competing land uses is determined.

2.4.2 CREDIT PROJECT DURATION

Credit project duration is the length of time that the Credit System recognizes a project. Credit project duration is the length of time that a Credit Developer has committed to enhancing and maintaining habitat function as stated in credit project's Participant Contract and Management Plan. The duration of credit projects can be either limited term or in perpetuity, and limited term credit projects can be renewed within the Credit System after the credit project duration expires.

. The minimum credit project duration is 10 years and the maximum project duration is in perpetuity. Project duration is defined in 5 year increments. Thus, project duration can be 10, 15, 20, 25 years, and so on, up to and including in perpetuity. The rationale behind the 10 year minimum is based on scientific opinion that rapidly changing habitat function can be detrimental to populations. Longer-term credit projects are preferable and credits from long-term projects are anticipated to attract greater market demand, as Credit Buyers are required to match credit project duration to the expected duration of the debit project, which includes the time required to allow species to begin to use the site after the debit project. See below for matching of duration discussion.

Credit Developers define project duration in the Participant Contracts and Management Plans submitted to the Administrator. Upon expiration of the duration of the credit project, the Credit Developer can elect to renew the project under the Credit System. Renewal entails developing a new Management Plan, using the current HQT and the Credit System Manual policy and technical requirements that are approved at the time of renewal to assess the habitat function and amount of credit generated by the site. Renewal also requires a qualified, third-party verification. See *Section 2.4.5: Credit Site Verification* for additional information on credit site verification. If the project is not renewed, the Credit System no longer recognizes credits after the end of the project duration.

2.4.3 RESERVE ACCOUNT CONTRIBUTION

A percentage of credits generated by a credit projects are transferred into the reserve account at the time that credits are transferred to a Credit Buyer's account. Credits in the reserve account may be used to temporarily cover credits invalidated from intentional and unintentional reversals in order to ensure there are always more credits than debits in the Credit System. The percentage of credits that a credit project contributes to the reserve account is determined by the probability of the credits on that site becoming invalidated unintentionally, which creates an incentive for the Credit Developer to reduce the risks that could invalidate those credits. The use of the reserve account and financial assurances is defined in *Section 2.1.7: Reserve Account Management and Use of Financial Assurances*.

The reserve account checklists determine the unique contribution amount for each credit project, taking the sum of the numeric values assigned to each of the factors defined below. As described in greater detail below and illustrated in Equation 3, the total reserve account contribution percentage consists of a standard base contribution and additional contributions related to the probability of adverse impacts from wildfire and competing land uses. As shown in Equation 4, the total reserve account contribution percentage is multiplied by the total number of credits transferred to a Credit Buyer's account to determine the total reserve account contribution amount for each credit transfer. The credit site must have sufficient credits available to fulfill the amount transferred to the Credit Buyer's account and the reserve account contribution.

Equation 3: Total reserve account contribution percentage equation

$$\begin{aligned}\textit{Total Reserve Account Contribution Percentage} \\ &= \text{Standard } \textit{Base Contribution Percentage} \\ &+ \textit{Probability of Adverse Impacts from Wildfire Percentage} \\ &+ \textit{Probability of Competing Land Uses Percentage}\end{aligned}$$

Equation 4: Total reserve account contribution percentage equation

$$\begin{aligned}\textit{Total Reserve Account Contribution Amount} \\ &= \textit{Credits Transferred to Credit Buyer} \\ &* \textit{Reserve Account Contribution Percentage}\end{aligned}$$

Base Contribution

The base reserve account contribution for all credit projects is 4% of the credits generated on-site that are transferred to a Credit Buyer's account. The base contribution is required due to the inherent uncertainty in the measurement and estimation of the long-term benefits of credit projects due to force majeure events, climate change, and other circumstances.

Probability of Adverse Impacts from Wildfire

In addition to the base reserve account contribution, a portion of each transfer of credits to a Credit Buyer's account is transferred into the reserve account to be available to temporarily cover credits invalided by wildfire, the predominant force majeure event anticipated to affect greater sage-grouse habitat in the State of Nevada. For each transfer of credits that occurs, a contribution for wildfire is determined by the credit site's:

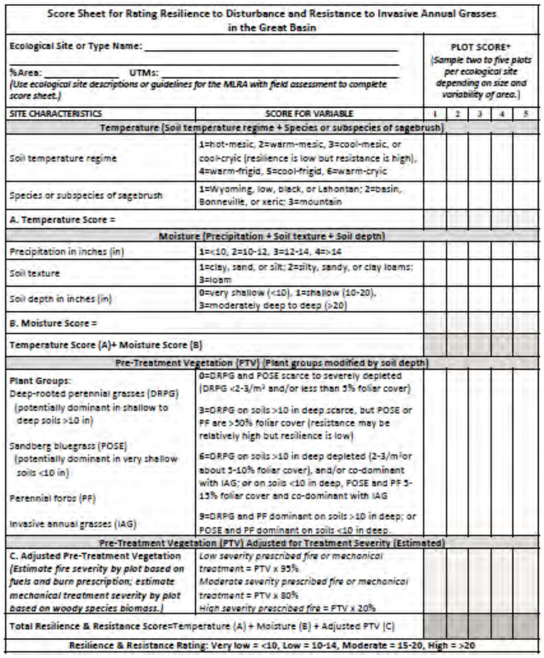
1) Resistance to invasive annual grasses and resilience following wildfire
2) Ability to control wildfire

The Ability to Control Wildfire factor is currently not required because the score card is not currently available developed and adopted by SEC. The score card is expected to be developed in 2015 and included in a future version of the Manual. The description of the factor is included below as a place holder for the expected inclusion of this factor once the scorecard is available.

Resistance & Resilience

Using concepts of resistance and resilience to determine the reserve account contribution encourages credit sites to be located in areas that are less likely to be negatively affected by fire and more likely to recover from disturbances and helps to ensure that the reserve account is capable of covering credits invalidated based on natural disturbances from wildfire.[11]

The resistance to invasive annual grasses and resilience following wildfire is determined using the Miller et al. 2014 (Score Sheet for Rating Resilience to Disturbance, Resistance to Annual Invasive Grasses, and the Suitability of an Ecological Site or Type for Treatment) field guide and score sheet illustrated in Figure 16.[12] Variables defined in the score card produce a field assessment with scoring based on soil temperature, moisture indicators, and vegetation. Credit projects often include more than one ecological site type, and scores are determined for each ecological site type or grouping of similar ecological sites within the credit project area. The score for each ecological site type within the credit project area has a range of 0 – 26, with a score of <10 = Very Low; 10 -14 = low; 15 – 20 = Moderate; and >20 = High. A weighted score, based on the proportion of the area within each ecological site type is calculated for the credit project area. Table 13 provides the reserve account contribution percentage based on the weighted score for the credit project site.



Score Sheet for Rating Resilience to Disturbance and Resistance to Invasive Annual Grasses in the Great Basin						
Ecological Site or Type Name: ______ **%Area:** ______ **UTMs:** ______ *(Use ecological site descriptions or guidelines for the MLRA with field assessment to complete score sheet.)*		**PLOT SCORE*** *(Sample two to five plots per ecological site depending on size and variability of area.)*				
SITE CHARACTERISTICS	SCORE FOR VARIABLE	1	2	3	4	5
Temperature (Soil temperature regime + Species or subspecies of sagebrush)						
Soil temperature regime	1=hot-mesic, 2=warm-mesic, 3=cool-mesic, or cool-cryic (resilience is low but resistance is high), 4=warm-frigid, 5=cool-frigid, 6=warm-cryic					
Species or subspecies of sagebrush	1=Wyoming, low, black, or Lahontan; 2=basin, Bonneville, or xeric; 3=mountain					
A. Temperature Score =						
Moisture (Precipitation + Soil texture + Soil depth)						
Precipitation in inches (in)	1=<10, 2=10-12, 3=12-14, 4=>14					
Soil texture	1=clay, sand, or silt; 2=silty, sandy, or clay loams; 3=loam					
Soil depth in inches (in)	0=very shallow (<10), 1=shallow (10-20), 3=moderately deep to deep (>20)					
B. Moisture Score =						
Temperature Score (A)+ Moisture Score (B)						
Pre-Treatment Vegetation (PTV) (Plant groups modified by soil depth)						
Plant Groups: Deep-rooted perennial grasses (DRPG) (potentially dominant in shallow to deep soils >10 in) Sandberg bluegrass (POSE) (potentially dominant in very shallow soils <10 in) Perennial forbs (PF) Invasive annual grasses (IAG)	0=DRPG and POSE scarce to severely depleted (DRPG <2-3/m² and/or less than 5% foliar cover) 3=DRPG on soils >10 in deep scarce, but POSE or PF are >50% foliar cover (resistance may be relatively high but resilience is low) 6=DRPG on soils >10 in deep depleted (2-3/m² or about 5-10% foliar cover), and/or co-dominant with IAG; or on soils <10 in deep, POSE and PF 5-15% foliar cover and co-dominant with IAG 9=DRPG and PF dominant on soils >10 in deep; or POSE and PF dominant on soils <10 in deep.					
Pre-Treatment Vegetation (PTV) Adjusted for Treatment Severity (Estimated)						
C. Adjusted Pre-Treatment Vegetation ***(Estimate fire severity by plot based on fuels and burn prescription; estimate mechanical treatment severity by plot based on woody species biomass.)***	*Low severity prescribed fire or mechanical treatment = PTV x 95%* *Moderate severity prescribed fire or mechanical treatment = PTV x 80%* *High severity prescribed fire = PTV x 20%*					
Total Resilience & Resistance Score=Temperature (A) + Moisture (B) + Adjusted PTV (C)						
Resilience & Resistance Rating: Very low = <10, Low = 10-14, Moderate = 15-20, High = >20						

Figure 16: Miller et al. 2014 score sheet

Table 13: Resistance and Resilience reserve account categories and contribution percentages

Score sheet Score	Contribution Percentage
>20	0%
15-20	1%
10-14	2%
<10	4%

Ability to Control

Factoring the ability to control wildfire to into the overall reserve account contribution for credit projects encourages sites to be placed where natural and human-created features improve the ability to control a wildfire, including existing and new (e.g. developed as part of the credit project) human-created pre-suppression features (e.g. green strips). Any human-created feature that impacts the reserve account contribution must be maintained throughout the term of the project, and described in the site's Management Plan.

The ability to control wildfire is determined using the area and site-level assessment checklist developed by the Sagebrush Ecosystem Program with contributions from other State of Nevada and Federal agency staff.[13] The assessment evaluates common risk factors (i.e. fuels, topography, ease of access, and distance from initial attack fire-fighting resources) that hinder or improve the ability of firefighting resources to control a wildfire under typical summer weather conditions for the project site. The assessment includes evaluation of the effectiveness of existing fire suppression features on the landscape, as well as the effectiveness of fire suppression features implemented as part of the credit project. Table 14 provides the reserve account contribution percentage based on the assessment score for the credit project site.

Table 14: Ability to Control reserve account categories and contribution percentages

Assessment Category	Contribution Percentage
High	*TBD*
Moderate	*TBD*
Low	*TBD*

Probability of Competing Land Uses

In addition to the base reserve account contribution, a portion of each transfer of credits to a Credit Buyer's account is contributed into the reserve account to be available to temporarily cover credits invalided by competing land uses. The Credit System determines the probability of competing land uses based on credit site ownership, the application of land protection mechanisms on the credit site and other characteristics of the credit project.

Different land protection mechanisms are available on privately- and publicly-owned land, and other unique characteristics of privately- and publicly-owned land influence the probability of completing land uses invaliding credit sites. Table 15 and Table 16 identify different credit site characteristics related to the probability of completing land uses invalidating credits for private- and publicly-owned lands, respectively. Note that each credit site must meet minimum site eligibility requirements, including proof of no imminent threat of direct or indirect disturbance to the credit site. See the *Section 2.3.3: Credit Site Eligibility* for additional information.

Important credit site characteristics related to the probability of competing land uses are expected to arise that do not justify a different contribution percentage than defined by the tables below. In these cases, the Credit Developer and Administrator will address issues as they arise on a case-by-case basis. Further, federal agencies are currently working on guidance related to durability on public lands - Table 16 is expected to be updated once this guidance becomes available.

---

[13] As of December 4, 2014, the assessment checklist is currently under development by the SEP.

Table 15: Competing Land Uses reserve account categories and contribution percentages for credits on privately-owned land

Minimum Competing Land Use Related Requirements	**Contribution Percentage**
Participant Contract and Conservation Easement and Ownership of Subsurface Rights	0%
Participant Contract and Conservation Easement	1%
Participant Contract and Ownership of Subsurface Rights	3%
Participant Contract	4%

Table 16: Competing Land Uses reserve account categories and contribution percentages for credits on publicly-owned land

Minimum Competing Land Use Related Requirements*	**Contribution Percentage**
Participant Contract and Public Land Authorization and Located within BLM Priority Habitat Management Area and Other Authorizations on the Site Prohibited*	0%
Participant Contract and Public Land Authorization and (Located within BLM Priority Habitat Management Area or (Located within BLM General Habitat Management Area and No Existing Authorizations on the Site under Other Ownership**))	2%
Participant Contract and Public Land Authorization	4%

*Other authorizations may be prohibited due to the Credit Developers authorization (e.g. Easement) and protection described in the associated NEPA decision or special land use designations (e.g. Area of Critical of Environmental Concern (ACEC)).

**Existing authorizations include mining claims, oil and gas leases, and grazing leases. Note that other authorizations (e.g. grazing lease) owned by the Credit Developers comply with this requirement since the Credit Developer has control of the other authorizations effect on the credit site achieving the performance standard.

Credit Developers must provide evidence that minimum competing land use related requirements have been fulfilled. For example, public land authorizations and relevant existing authorizations owned by the Credit Developer must be attachments to the Management Plan.

2.4.4 CREDIT RELEASE

The Credit System uses credit release schedules to manage risk and uncertainty by releasing credits only when specific performance standards are met. Credit releases occur when a new milestone of performance standards, in terms of habitat function, is achieved on the credit site that warrants an increase in the amount of credit generated on that project site. Credit releases require third-party verification, defined in *Section 2.4.5: Credit Site Verification*. Specific performance standards are defined in each credit project's Management Plan, and each credit project will have a unique credit release schedule based on those performance standards. A credit release schedule is different than credit payment schedules described in *Section 2.4.6 Financial Assurances*.

If a credit project is unable to achieve performance standards defined in the credit project's Management Plan in order to release credits, the Credit Developer will work with the Administrator to adjust the performance standards and release schedule. A decline in habitat function outside of the tolerances defined in *Section 2.4.5: Credit Site Verification* after credits are released will require the credit site to be remedied, or the credit site's financial assurances may be used to replace the invalidated credits. See *Section 2.4.6: Financial Assurances* for additional information on financial assurances.

Stewardship Management Actions

For credit projects based on stewardship management actions, credit release occurs when a habitat function performance standard defined in the credit project's Management Plan is achieved. Credit projects based on stewardship management actions cannot include performance standards defined by management actions, but rather only performance standards defined by habitat function. Credit projects that primarily maintain pre-project habitat function are likely to have a single credit release. If a credit project based on stewardship management actions includes multiple credit releases, the portion of credits released at each milestone must be less than or equal to the percent increase in habitat function relative to the total increase in habitat function expected to be achieved by the project. A credit release schedule associated with specific performance standards in the credit project's Management Plan can include multiple credit release intervals; however each release must require at least a 5% increase in site-scale habitat function. Credits are released at the point when a third-party verifies an achieved performance standard. Credits released are valid for the full duration of the project's life, provided that the Credit Developer continues to meet that performance standard as confirmed by third-party verification and self-monitoring reports. Verification requirements are defined in *Section 2.4.5: Credit Site Verification*.

Restoration Management Actions

For credit projects containing restoration management actions and habitat quality is anticipated to significantly improve over the life of the project, credit releases occur when a performance standard defined in the project's Management Plan is achieved. Credit projects containing restoration management actions can include performance standards defined by management actions and habitat function, as described in the bullets below. Credits are released at the point that a third-party verifies an achieved performance standard. A credit release schedule associated to a performance standard in the credit project's Management Plan can include multiple credit release intervals; however each credit release defined by habitat function must require at least a 5% increase in site scale habitat function. Credit release does not necessarily follow the same schedule as the payment structure for Credit Developers described in *Section 2.4.6 Financial Assurances*.

- Up to, but no more than the first **one third** of credits may be released upon implementation of management actions defined in the project's Management Plan. Credits released based on fulfilling management action criteria are limited to **one third** of the total credits that the project is ultimately anticipated to generate and the portion must be agreed to by the Administrator. For example, a credit project site with the potential to generate 600 credits, only 200 credits, may be released upon implementation of specified management actions.
- The remaining **two thirds** or more of credits are released over additional credit release intervals upon verification that the habitat quality is meeting the performance standards. The portion of credits released at each milestone must be less than or equal to the percent increase in habitat function relative to the total increase in habitat function expected to be achieved by the project.

Table 17 below illustrates an example credit release scheduled with one third of credits released based on management actions, and the remaining two thirds released in two additional credit releases. Upon verifying conditions to release all credits anticipated by the credit project, all credits are expected to be maintained for the full duration of the project's life, according to the performance standards defined in the Management Plan and confirmed in verification and self-monitoring reports.

Table 17: Example Credit Release Schedule for a Restoration Project

Performance criteria achieved	Credits Released
Milestone 1: Management Actions - Restore riparian area - 1/3 of performance assurances secured	**33%** of Total Anticipated Credits
Milestone 2: Habitat Function Performance - 66% of expected HQT score for the project - 2/3 of performance assurances secured	**66%** of Total Anticipated Credits
Milestone 3: Habitat Function Performance - 100% of expected HQT score for the project - All performance assurances secured	**100%** of Total Anticipated Credits

The Credit System ensures net benefit for greater sage-grouse and limits overall program risk by limiting management action-based credit releases to up to one third of the anticipated credits and using a combination of additional mechanisms, including mitigation ratios, the reserve account, and financial assurances. Should a restoration project fail to generate the credits indicated in the credit site's Management Plan, this combination of mechanisms covers any shortfalls in credits.

Although restoration projects may carry some risk of not achieving projected outcomes, it is important for the long-term viability of the species that habitat is restored to improved functionality, and therefore important that Credit Developers are incentivized to undertake these types of projects. A credit release upon implementation of management actions, along with the credit baseline function for restoration projects defined in *Section 2.3.4: Calculating Credit Baseline Habitat Function*, helps to enable restoration activities to be more economically viable.

2.4.5 CREDIT SITE VERIFICATION

All credit projects require verification prior to the release of any portion of the anticipated credits generated from projects, and throughout the duration of each credit project. See *Section 2.4.4: Credit Release* for additional information on credit release requirements and schedules.

The purpose of verification for credit projects is to provide confidence to all participants, including the Administrator, that credit calculations represent a true and accurate account of on-the-ground implementation actions and habitat function, as defined in each project's Management Plan. In addition, ongoing verification and monitoring ensures that projects are maintained over time and support the expected habitat quality commensurate with the amount of credits generated. Ongoing verification also confirms whether activities on adjacent project sites have occurred that compromise the ability of enrolled credit sites to generate credits according to their Management Plan. The required frequency and process for verification, and Verifier selection is described below.

Verification of the HQT functional acre calculations and other criteria defined in the Management Plan is required prior to a credit release and periodically throughout the duration of the project. These verifications are conducted using the HQT and review of the Management Plan by third-party Verifiers who are trained and certified by the Administrator. Credit Developers are also required to conduct and report on annual self-monitoring, as defined in each Management Plan.

Credit Verification Schedule

The verification schedule for a credit project is based on the credit release schedule defined in each Management Plan, and incorporates the following requirements:

1. Before first credit release (Verifier)
2. Before additional credit releases (Verifier)
3. At least every 5th year (Verifier)

4. Periodic spot checks and audits (Administrator or relevant public land management agency)
5. Annual self-monitoring (Credit Developer)

Before first credit release

Third-party verification is required and the Administrator reviews the verification report as a necessary component of the documentation before the first credit release is approved.

Before additional credit releases

Third-party verification is required to confirm that conditions meet the performance standard specified in the credit release schedule in a project's Management Plan before a release of additional credits.

At least every 5th year

At least every fifth year, a third-party verification is conducted and all documentation (i.e. current conditions data, HQT outputs, and final credit calculations) is reviewed by the Administrator to evaluate the project based on performance standards included in the Management Plan. When verification is conducted to either support an increase in credit amount or for a periodic spot check and audit, the verification required every five years is reset. Thus, if project verification is completed in year 3 to support a new credit release, then the next verification is not required until year 8.

Periodic spot checks and audits

The Administrator or relevant public land management agency for credit projects on public lands conduct random audits of approximately 5-10% of credit sites in any particular year.

Self-monitoring

Credit Developers are expected to conduct self-monitoring annually to ensure that the site is meeting defined performance standards and to report results to the Administrator.

Credit Variability & Verification Results

Credit variability is variation in habitat function on a site as measured by the HQT at two different points in time. Even on relatively stable sites, variability is likely to result due to variation in climatic conditions and other natural events that influence habitat function. Credit variability is also likely to occur due to sampling error that is inherent to any measurement method. Based on these considerations, the Credit System allows for limited variability in habitat function as a mechanism to insulate Credit Developers from being subject to penalties for minor fluctuations in habitat quality.

Upon each credit release, third-party verification must substantiate that the site meets or exceeds the habitat function defined in the credit release schedule of the project's Management Plan. Subsequent verifications may be no more than an appropriate site-specific percentage below the site-scale habitat function performance standard as determined using the HQT. The appropriate percentage, or credit variability tolerance, must be approved by the Administrator and documented in the Management Plan prior to the first credit release. Credit project verifications within the credit variability tolerance are considered as meeting performance standards defined in the Management Plan, and therefore do not require a reduction in credits, or trigger the use of Financial Assurances for the site.

If verification shows that a credit site is performing below the credit variability tolerance and is therefore not meeting performance standards, the Credit Developer must work with the Administrator to determine a remedial action plan. Credit projects outside of the credit variability tolerance may be subject to the Credit System's processes related to credit reversals. See *Section 2.1.7: Reserve Account Management and Use of Financial Assurances* for more information on how credit reversals are addressed.

Verifier Selection

Contracting and payment for verification of credit projects is handled by the Administrator. The Credit Developer does not directly hire a Verifier. The Administrator receives a verification fee and a signed verification contract to allow access to the site from the Credit Developer. The Administrator selects from the pool of certified Verifiers, and notifies the Credit Developer before the Verifier conducts a site visit. Verifications conducted as periodic spot checks and audits are funded by the Administrator.

2.4.6 FINANCIAL ASSURANCES

The Credit System requires that Credit Developers establish appropriate financial assurances for each credit project site in order to sell credits. Financial assurances are fiscal mechanisms that are used to ensure the durability of credits generated throughout the full duration of a credit project. Financial assurances are defined in each Credit Developer's Participant Contract and documented in an accompanying Management Plan, and can consist of contract terms, such as financial penalties for intentional reversals and specific payment terms, and financial instruments, such as long-term stewardship funds and contract surety bonds. Financial assurances must ensure that funds are available:

1) For the implementation and long-term management of each credit project, including remedial actions in the event of unintentional reversals, and
2) To promptly replace credits that have been sold but become invalidated due to intentional reversals.

The Administrator and Credit Developer will define a financial assurance package that is acceptable to both the Administrator and Credit Developer. The specific financial assurances package can be a combination of one or various mechanisms (e.g., long-term stewardship funds, contract payment terms, contract surety bonds and contract penalties) that ensure sufficient funds are available to meet the above needs. Financial instruments must be held either by the Administrator or a qualified third party institution that is approved by the Administrator.

The following overarching principles and basic minimum requirements guide the development of financial assurance packages:

- Minimize financial transaction costs and maximize payments to Credit Developers for actions that improve habitat;
- Appropriately allocate risk to Credit Developers and not solely to the Administrator;
- Preferably use mechanisms that do not require the Administrator to engage in costly litigation with Credit Developers to secure funds for credit replacement;
- Include provisions that hold to the principal that projects will not receive any future payments for projects that are not producing credits, even in the case of force majeure if a credit project has been deemed inappropriate to remediate;
- Design financial instruments to cover long-term management of credit project sites and replacement of credit reversals, considering:
  - Management and maintenance activities defined in Management Plan
  - Monitoring and verification defined in Management Plan
  - Appropriate fund management and rate of return
  - Relevant inflation rates
  - Credit market price trends

Financial Assurances for Long-term Credit Site Management, Monitoring, and Unintentional Reversals

Financial assurances are required for the long-term management and monitoring of all credit projects. Financial assurances established for long-term management and monitoring must be designed to meet the following requirements:

- Cover all anticipated costs expected to perform maintenance and monitoring of the project as defined in the Management Plan for the duration of the contract;
- Ensure contingency funds are available to address periodic project-related costs that are likely to occur; and

- Ensure an ongoing financial incentive that is greater than the anticipated cost to maintain and monitor the project.

Financial instruments may be secured to ensure long-term credit site management, monitoring, and remedial actions in the event of unintentional reversals. If used, the type of financial instrument required is dependent on the duration of the credit project. Permanent credit projects require a long-term financial instrument for which the principal amount is managed in perpetuity. Term credit projects require a financial instrument that is managed such that no funds remain at the end of the credit project.

Financial instruments established for long-term management and monitoring must use an initial deposit amount that factors in annual payments intended for the Credit Developer and accounts for inflation, as well as expected financial returns from appropriately investing funds for long-term management and monitoring. Annual payments may be structured to provide variable annual amounts when additional costs are expected in specific years or on years when third-party verification is performed and the credit site is shown to perform at, or above, expected performance. Variable payments must be structured such that the financial instrument is sufficient to make all defined payments for the full duration of the project. The Administrator must agree that the initial deposit amount for each credit project will cover the necessary annual payments using a predictive financial model that accounts for inflation and interest rates.

Financial instruments established for long-term management and monitoring must be accompanied by contract terms that ensure funds intended for the Credit Developer are available to the Administrator in the case of an unintentional reversal, so that all remaining funds for long-term management and monitoring can be used to remediate the credit site or to purchase credits from a different site, as defined in *Section 2.1.7: Reserve Account Management and Use of Financial Assurances*. These payment terms align the incentives of the Credit Developer and the Administrator by sharing the financial risk for ongoing performance.

In situations where credit projects do not require long-term management and monitoring funds, or a large upfront payment is made to the Credit Developer, such as for restoration projects, other financial instruments, such as a contract surety bond, may be used to ensure sufficient funds are available to the Administrator in the case of unintentional reversals.

Financial Assurances for Intentional Reversals

Financial assurances must be established to ensure the Administrator has access to funds at the level required to replace credits sold but that have become invalidated due to intentional reversals. Financial assurances established for intentional reversals must be designed to meet the following requirements:

- Cover the monetary costs of acquiring new credits to replace all invalidated credits; and
- Ensure that the additional effort incurred by the Administrator to secure new credits is fully funded.

Financial assurances that can fulfill the intentional reversals requirement include contract terms, such as financial penalties, and financial instruments, such as contract surety bonds. Contract terms must define that if performance standards on a credit project site are not met, the financial assurances used to fulfill the intentional reversal requirement as well as remaining funds in that project's financial assurances for long-term management and monitoring are available to the Administrator. See *Section 2.1.7: Reserve Account Management and Use of Financial Assurances* for additional information on how the Administrator will use the reserve account and financial assurances in the case of intentional reversals.

2.5 CREDIT OBLIGATION PROVISIONS & CREDIT INVESTMENT STRATEGIES

This section describes credit obligation provisions for debit projects to ensure credit obligations offset the direct and indirect impacts of debit projects. Credit obligation provisions include debit project duration and verification requirements. In addition, this section describes investment strategies that debit projects and other Credit Buyers can be used to acquire credits, depending on the goal of the acquisition. Credit Buyers are the primary audience of this section.

2.5.1 DEBIT SERVICE AREA

The Credit System service area is the mapped geographic region where credits are required to offset debits that occur when disturbances are proven unavoidable, and minimization does not provide for complete direct or indirect impact avoidance.[14] Debits on public lands within the service area will be tracked and reported by the Credit System. The service area designation has important implications for the viability of the Credit System transactions and for the ability of the System to generate a net benefit for greater sage-grouse habitat from the impacts from anthropogenic disturbances.

The current SGMA is the Credit System service area, and the 2014 SGMA map is provided in Figure 17 as an example. The boundaries of this management area are based on the range of the species in the State of Nevada and are aligned with State of Nevada development project review requirements. Anthropogenic disturbances to habitat on BLM, USFS, State of Nevada, and local government lands within the service area require consultation with the SETT and the appropriate government agency, as defined in the 2014 Nevada Greater Sage-Grouse Conservation Plan.

Figure 17: Greater sage-grouse service area

While the Service Area broadly defines the domain of the Credit System, the Mitigation Ratios establish incentivizes to offset debits using credits generated in close proximity to debit sites. *Section 2.2.2: Mitigation and Proximity Ratios* describes how the WAFWA Management Zones and the NDOW PMUs, depicted in the Figure 12 and Figure 13**Error! Reference source not found.** respectively, are incorporated into the proximity ratio. In addition, three Management Categories are also incorporated into the Mitigation Ratios to encourage the generation of credits and discourage debits in Core and Priority Management Areas, which are estimated to have high space-use by greater sage-grouse. Credits and debits will be tracked in the Credit System Registry and reported by the Administrator by WAFWA Zones and PMUs.

2.5.2 DEBIT PROJECT TYPES

Proposed anthropogenic disturbances to habitat on BLM, USFS, State of Nevada and local government lands within the SGMA require consultation with the SETT and the appropriate government agency, as defined in the 2014 Nevada Greater Sage-Grouse Conservation Plan. Anthropogenic disturbances are considered debit projects when they are proven to be unavoidable, and when minimization does not

---

[14] US Fish and Wildlife Service. Greater Sage-Grouse Range-Wide Mitigation Framework Version 1.0. September 3, 2014. Page 6.

provide for complete direct or indirect impact avoidance[15]. A debit project may be a new anthropogenic disturbance, an expansion in the operation of an existing anthropogenic disturbance, or an extension in duration of an existing anthropogenic disturbance.

As defined in the 2014 Nevada Greater Sage-Grouse Conservation Plan, an anthropogenic disturbance is defined as any human-caused activity or action or human-created physical structures that may have adverse impacts on greater sage-grouse or their habitat. Anthropogenic disturbance project categories include:

- Mineral development and exploration and its associated infrastructure;
- Renewable and nonrenewable energy production, transmission, and distribution and its associated infrastructure;
- Paved and unpaved roads and highways;
- Cell phone towers;
- Landfills;
- Pipelines;
- Residential and commercial subdivisions;
- Activities undertaken pursuant to special use permits and right-of-way grants; and
- Other infrastructure development.

Livestock operations and agricultural activities and infrastructure related to ranch and farm businesses (e.g. water troughs, fences, etc.) are not included in this definition of debit project types. Section 7.5 and Appendix A of the 2014 Nevada Greater Sage-Grouse Conservation Plan address how to minimize impacts to greater sage-grouse and their habitat from these activities.

2.5.3 MITIGATION HIERARCHY AND PERMIT REQUIREMENTS

The Credit System is intended to be used in the context of state and federal policies that require the full mitigation hierarchy sequence (e.g. avoidance, minimization, compensatory mitigation). Credits are used to offset debits that occur when disturbances are proven unavoidable, and minimization does not provide for complete direct or indirect impact avoidance.[16] Debit projects permitted through federal and state agencies will use the Credit System to purchase credits that fulfill their compensatory mitigation obligations prior to development of the debit project.[17]

2014 Nevada Greater Sage-Grouse Conservation Plan

The State of Nevada's overriding policy for all management actions within the Sage-grouse Management Area is to "avoid, minimize, and mitigate" impacts to sage-grouse habitat.

Credit Buyers can acquire verified credits directly from Credit Developers, including Aggregators, or the Administrator who may carry an inventory of Credits to facilitate offset transactions. Credits cannot be acquired from Credit Developers or the Administrator until credits are released by the Administrator, which requires verification that habitat function is meeting the defined performance criteria for the credit project. Credit Buyers may use alternative investment mechanisms to acquire credits, such as reverse auctions that leverage competitive bidding processes to procure the greatest amount of credits for a set

---

[15] US Fish and Wildlife Service. Greater Sage-Grouse Range-Wide Mitigation Framework Version 1.0. September 3, 2014. Page 6.

[16] US Fish and Wildlife Service. Greater Sage-Grouse Range-Wide Mitigation Framework Version 1.0. September 3, 2014. Page 6.

[17] As of December 4, 2014, debit projects permitted through federal agencies are not required to use the Credit System to fulfill their compensatory mitigation obligations. However, the Credit System is expected to be included in the BLM/USFS Land Use Plans for the Northeastern California-Nevada Sub Region as the tool for defining and fulfilling compensatory mitigation requirements for anthropogenic disturbances to greater sage-grouse habitat on BLM and USFS lands in the State of Nevada.

amount of funding. The Credit Buyer pays the full cost of acquiring credits including all necessary administrative fees.

Those Credit Buyers who purchase credits to fulfill regulatory requirements for compensatory mitigation are responsible for meeting all requirements of the relevant permitting process through the State of Nevada, BLM, or other government agencies. Credit Buyers must provide documentation of the permit stipulations and debit project design documents to the Administrator to ensure proper identification of the total amount of credits needed to offset the debit project, and the total duration of the debit project. This allows the Administrator to 1) ensure that the debit project is appropriately offset with a credit project and 2) transparently track and report on all credit transactions and programmatic net benefit generated. See *Section 2.2: Habitat Quantification and Credit and Debit Calculation* for additional information on calculating credit obligations and *Section 2.5.4: Debit Project Duration* for additional information on project duration provisions.

2.5.4 DEBIT PROJECT DURATION

Debit project duration is the length of time that the project is anticipated to impact habitat function or in perpetuity. For impacts that are anticipated to return to pre-project habitat function, an additional set period of time beyond the length of time that the project is anticipated to impact habitat function is required to allow the species to begin to use the site. The stated duration in the permit or lease for each anthropogenic disturbance plus an additional 10 years will be used as a starting point for establishing the debit project duration for impacts with limited term impacts..

Like credit projects, the duration of debit projects can be either limited term or in perpetuity. Debit projects that are not expected to return to pre-project habitat function have an in perpetuity project duration. *Rehabilitation* necessary to return a debit site to pre-project habitat function will be defined in the permit or lease for the anthropogenic disturbance in order for the Administrator to agree to the debit project duration.

Debit projects may include areas within the project boundary that are expected to return to pre-project habitat function and other areas that are not expected to return to pre-project habitat function. Further, debit may include areas that are impacted for longer durations than others. For example, habitat indirectly impacted by a debit project is likely to return to pre-project habitat function with minimal rehabilitation such as removal of roads and structures. However, habitat directly impacted by a debit project such as an open-pit mine are not expected to return to pre-project habitat function. Therefore, debit projects may generate debits with different project durations, including different term periods and a mix of term and in perpetuity.

For term debits, third-party verification is required to demonstrate that the habitat impacted by the debits has returned to pre-project habitat function. See *Section 2.5.6: Debit Site Verification* additional information on verification requirements. If verification demonstrates that a term debit project has not yet been fully rehabilitated, the Administrator will require additional credits sufficient to cover the residual impact be purchased for an additional term.

Matching the Duration of Credits and Debits

The Credit System requires the duration of a contracted credit project to be equal to, or greater than, the duration of the debit project it is offsetting. The Administrator ensures that credit project durations are sufficient to meet or exceed the duration of the debit project they are offsetting through *static offsets* or *dynamic offsets*.

- **Static Offsets –** A debit project is offset by a credit project that is fixed in a single geographic location with the Participant Contract, Management Plan and associated site protection mechanisms in place for the contracted duration of the debit project.

- **Dynamic Offsets –** A debit project is offset by a series of limited term credit projects such that the location of the credit projects can shift across a defined geographic space (i.e. a set of rolling term projects funded for the full duration of the debit project). Dynamic offsets are defined as a series of strategically located, limited term-based agreements that, when sequentially aggregated, meet or exceed the duration of the impact.

Requirements for Dynamic Offsets

A Credit Developer, Aggregator or the Administrator may develop a dynamic offset arrangement that commits to meet the credit requirements for a debit project using a series of limited term credit projects. The series of limited term credit projects under a dynamic offset arrangement must cover the credit obligation of the debit project for each year of the debit project. For example, if the credit obligation of a debit project is 1,000 credits into perpetuity, then the limited term credit projects must provide 1,000 credits for each year into perpetuity. The limited term credit projects cannot provide 3,000 credits for the first 30 years and 0 credits for the next 60 years.

In addition, each limited term credit project under a dynamic offset arrangement must have duration of at least 30 years because the debit project is permanent and rapidly changing habitat function (credit sites) can be detrimental to populations.

The financial assurances associated with a dynamic offset credit project are similar to those required for static offset projects but include additional requirements to ensure durability and require that finances are in place to secure new limited term contracts for the full length of the impact. Additionally, the Administrator must be able to ensure compliance and accountability through tracking and reporting, enforcement for credit reversals, and direct management of financial instruments. See *Section 2.1.7: Reserve Account and Use of Financial Assurances* for more information.

The potential benefits of dynamic offset projects include increased participation and a greater number of total credit projects and credits available for sale due to Credit Developer preferences for term contracts. Term projects also enable the ability to shift the location of high quality habitat in response to population dynamics and potential effects of climate change.

2.5.5 CALCULATING DEBIT BASELINE HABITAT FUNCTION

Debit baseline habitat function is the starting point from which functional acre loss is measured. Functional acre loss is then multiplied by a mitigation ratio to determine the debits generated for each map unit within a debit project. See *Section 2.2.2: Mitigation and Proximity Ratios* for additional information on determining mitigation ratios. Functional acre loss represents the functional acre change from debit baseline functional acres that results from implementing a project. Functional acre loss is equal to the difference between the post-project functional acres and the pre-project functional acres.

Debit baseline habitat function is the pre-project habitat function of each map unit within the debit site, and is calculated by multiplying

- Local-scale, pre-project habitat function as determined by the HQT, and
- Site-scale, pre-project habitat function as determined by the HQT.

See *Section 2.2.1: Habitat Quantification Tool* for description of scales.

An example debit baseline habitat function is illustrated in Table 18 for a map unit with high local-scale and moderate site-scale pre-project habitat function.

Table 18: Example debit baseline calculation

Local-scale Pre-Project Habitat Function	Site-scale Pre-Project Habitat Function	Debit Baseline Habitat Function

80%	40%	32%

Pre-project habitat functional-acres calculated must be verified by a third-party Verifier before any development on the site can begin. See *Section 2.5.6: Debit Site Verification* for additional information on verification requirements.

Recent Wildfire

Vegetation characteristics required to calculate site-scale habitat function by the HQT are unlikely to reflect the future habitat function on the site if wildfire has impacted a debit site recently. If wildfire has impacted a debit site within the last 10 years, site-scale habitat function is calculated using the greater of the following for the portion of the project area impacted by wildfire to calculate debit baseline:

1) Site-scale pre-project habitat function as determined by the HQT.
2) Site-scale regional standard habitat function as defined in Table 11 plus 10%.

Inaccessible Areas

For some debit projects, the Credit Buyer will not be able to calculate the site-scale pre-project habitat function for a portion of the area indirectly impacted by the debit project. For example, the debit project may indirectly impact a private party for which the Credit Buyer is not able to secure access to in order to collect field data necessary to calculate site-scale habitat function using the HQT. In these situations, the Habitat Suitability Index (HSI) score, as measured by the HQT as part of the local-scale habitat function calculation, is used as a proxy for the site-scale habitat function for the inaccessible areas. The HSI is spatially explicit and easily available for any site within SGMA.

2.5.6 DEBIT SITE VERIFICATION

All debit projects require verification prior to beginning the development of the debit project and throughout the entire duration of each debit project. The purpose of verification for debit projects is to provide confidence to all participants, including the Administrator, that debit calculations represent a true and accurate account of on-the-ground habitat function, as defined in each debit project's regulatory permit. Ongoing verification and monitoring ensures that debit projects are implemented and impacts cease as defined in the project's permit. The required frequency and process for verification, as well as the process for verification selection, is described below.

Verification of debit projects is an independent, expert check on the HQT calculations and other project design documentation. Verifications are conducted using the HQT by third-party Verifiers trained and certified by the Administrator. Verification includes a review of changes to the site over the previous 10 years to ensure that the site was not been recently degraded intentionally to reduce the credit obligation

Biological Monitoring

Biological monitoring is an essential element of the Credit System, and is a separate but complementary process to verification. Biological monitoring is executed through the Credit System's adaptive management process as described in *Section 3.3: Managing the Credit System*. While verification confirms on-site performance in relation to a Management Plan and HQT score, biological monitoring means observing, recording and assessing the quantity and quality of all credit-producing activities, as well as the biological response of greater sage-grouse and critical habitats across the Credit System service area. The goals of biological monitoring under the Credit System are to:

- Assess the status and trend of greater sage-grouse populations
- Assess the net contribution of conservation management outcomes to greater sage-grouse habitat and population goals at a variety of spatial scales
- Assess the effectiveness of management actions in regard to achieving expected habitat outcomes
- Collect and incorporate new information for adaptive management
- Detect and address changed or unforeseen circumstances (e.g. shifts in species distribution)

of the current permit application.

Debit Verification Schedule

Debits under the Credit System are verified at four distinct points in time:

1. Before debit project begins (Verifier)
2. During the project implementation period (Verifier)
3. When debits end or decrease (Verifier)
4. Periodic spot checks and audits (Administrator or relevant public land management agency)

Before debit project begins

Third-party verification of the pre-project condition of greater sage-grouse habitat on debit sites is required before development of debit projects can begin.

During project implementation period

Third-party verification is necessary to verify site conditions after a debit project has been implemented to confirm that the appropriate amount of debit is being attributed to the debit project. Verification during this period is aligned with project design documentation and permit and regulatory requirements.

When term debits end or reduce

Third party verification is necessary at the end of a term debit to confirm that the term debit site is no longer impacting habitat function. If, at the end of the debit project's duration, the site has not been rehabilitated to recover habitat function and allow for species use, the Credit Buyer will be required to purchase additional credits for an additional term. If third-party verification demonstrates a reduction in the impact and amount of credits needed as an offset, the Credit Buyer may sell and transfer surplus credits to another Credit Buyer's account to fulfill their credit obligation in accordance to Credit System requirements defined in *Step D5.2: Sell and Transfer Credits in Section 3*.

Periodic spot checks and audits

The Administrator or relevant public land management agency conducts random audits of approximately 10% of debit sites in any particular year.

Verifier Selection

Contracting and payment for verification of debit projects is handled by the Administrator. The Credit Buyer does not directly hire a Verifier. The Administrator receives a verification fee and a signed verification contract to allow access to the site from the Credit Buyer. The Administrator selects from the pool of certified Verifiers, and notifies the Credit Buyer before the Verifier conducts a site visit. Verifications conducted as periodic spot checks and audits are funded by the Administrator.

2.5.7 CREDIT INVESTMENT STRATEGIES

Credit Buyers have the flexibility to acquire credits in whatever way best meets their credit investment goals, within the bounds and requirements of the Credit System. Credit Buyers can create financial agreements and contracts to secure desired credits with Credit Developers, including Aggregators, completely independent of Administrator oversight. However, financial agreements must provide for financial assurances to be appropriately accessible to the Administrator in the case of reversals, and must include provisions for all administrative fees and contract terms required by the Credit System. Further, all credits and debits generated under the Credit System must be quantified, verified and managed according to Credit System requirements, giving appropriate access and authorities to the Administrator and other designated parties.

Different mechanisms can be used to acquire credits, depending on the goal of the acquisition. The goal of acquisitions ranges from acquiring credits for future sales to acquiring credits for a specific debit project.

Table 19 describes a few of these potential investment approaches, but is not intended to be an exhaustive list.

Table 19: Potential investment strategies

Investment Strategy	Description	Benefits	Typical Uses
Reverse Auction or Requests for Proposal	Bids are solicited for credits or projects that meet defined criteria; Credit Developers submit applications specifying price to deliver a defined quantity of credits	Efficient mechanism to procure the most habitat benefit (credits) for a set amount of funding	▪ Investing set pools of funding ▪ Fulfill credit obligations
Direct Credit Purchase	Credit Buyers purchase verified credits directly from the Credit System Registry	Limits risk for Credit Buyer –credits already verified	▪ High impact investing ▪ Fulfill credit obligations
Select from Potential Project List	Select project from a list of eligible projects that have not yet been implemented that are expected to meet Credit Buyer criteria; Credit Developers estimate expected number of credits	Credit Buyers have quantified information to inform project selection	▪ Conservation funding programs ▪ Fulfill future credit obligations

SECTION 3: CREDIT SYSTEM OPERATIONS

This section defines the Nevada Conservation Credit System (Credit System) Operations, along with associated tools, forms, and templates used to quantify, track, transfer, and report on habitat credit generated through the Credit System. The Credit System Operations are described in the three sections described in Table 20:

Table 20: Overview of the Credit System Operations Sections

Section Name	Primary Audience	Description
Section 3.1: Generating Credits	Credit Developers	Steps for estimating and verifying quantified credits from an individual credit site, including fulfilling ongoing verification requirements. These steps are primarily implemented by Credit Developers and thus are labeled **D1 through D5**.
Section 3.2: Acquiring Credits	Credit Buyers	Steps to obtain credits and use them to meet mitigation requirements and report on accomplishments. These steps are primarily implemented by Credit Buyers and thus are labeled **B1 through B3**.
Section 3.3: Managing the Credit System	Credit System Administrator	Steps to systematically evaluate new information, report results, and improve Credit System operations. These steps are primarily implemented by Administrators and thus are labeled **A1 through A6**.

The following legend is used throughout this section to indicate process steps:

- "**D**" indicates steps taken to develop credits
- "**B**" indicates steps taken to buy credits
- "**A**" indicates steps taken to administer and manage the Credit System over time

SECTION 3.1: GENERATING CREDITS

QUESTIONS ANSWERED

- How does a Credit Developer estimate expected credits from planned management actions?
- How are monitoring and verification results used to determine the amount of credit issued?
- How does a Credit Developer and the Credit System Administrator resolve issues and questions, and agree to final credit estimates and release schedules?

This section describes the process of turning management actions into verified credits. It begins by selecting a site and determining eligibility to generate credits, estimating credits from projected actions, and verifying that on-the-ground conditions are consistent with the submitted credit estimates. Credits are then issued, tracked and transferred between Credit Developer and Credit Buyer accounts. After transfer, the Credit Developer is responsible for meeting the monitoring, reporting and verification requirements of each project for the life of the project (described in *Step D3*). Figure 18 and Table 21 provide an overview of the steps of credit generation and the different participants engaged at each step.

Figure 18: Credit Generation Overview

Effective credit projects result in improved habitat and environmental conditions. Effectiveness depends both on implementing a quality project design and ensuring the project site is maintained to produce the expected environmental outcomes. Steps D1 and D2 define the process for estimating the number of credits generated from implementing the credit project. Step D3 defines the process to verify that actual on-the-ground conditions support the expected credits over time. Steps D4 and D5 describe how credits are issued, tracked and transferred.

Table 21: Overview of Roles, Tools & Products to Estimate, Verify, Issue and Track Credits from Projects

Process Step	Credit Developer[18]	Administrator	Buyer	Relevant Tools, Forms & Templates	Completed Products
D1. Select & Validate Site	■	■	□	▪ Validation Checklist	▪ List of Credit Opportunities ▪ Notice of Validation

■ Indicates a necessary or active role
□ Indicates potential participation or a support role

D1 SELECT & VALIDATE PROJECT SITE

Figure 19: Select & Validate Project Site

In this step, the Credit Developer identifies a project site that is likely to produce credits and the Administrator validates that the site is eligible to produce credits through the Credit System.

D1.1 INDICATE INITIAL INTEREST & INITIATE COMMUNICATION

This first step for the Credit Developer is to become aware of the opportunity to participate in the Credit System. The Credit Developer is introduced to the Credit System through outreach, communication materials or word of mouth, and learns about the potential benefits of participating. The Credit Developer or the Credit Developer's representative makes contact with the Administrator by email or phone to provide basic information, such as name, area of interest, and contact information. The Administrator provides a list of Technical Support Providers in the project area to assist with project design, credit quantification, and project implementation.

---

[18] Any reference to steps undertaken by Credit Developers may actually be implemented by Technical Support Providers or aggregators.

D1.2 SELECT PROJECT SITE

The Credit Developer should consider potential conservation opportunities, the likelihood that a project will deliver significant sage-grouse habitat benefits, and the potential costs and challenges to implement the project. Technical Support Providers or Aggregators can help provide advice to Credit Developers on these considerations.

D1.3 SUBMIT PROJECT VALIDATION CHECKLIST

The Credit Developer completes an eligibility screen, addressing a site's ability to generate credits, and its potential alignment with identified Credit Buyers and funding programs. This step is typically supported by a knowledgeable Technical Support Provider or Aggregator who helps the Credit Developer complete a Validation Checklist. This checklist records the proposed management actions, timeline, and location of a proposed project site. It also confirms certain minimum eligibility criteria, such as basic information related to ownership, site history, and land protection.

Product ■ Completed Validation Checklist

D1.4 VALIDATE & IDENTIFY CONSERVATION OPPORTUNITY

The Administrator reviews the Validation Checklist. If all validation criteria are met, the Administrator coordinates approval from any additional validation leads, such as relevant regulatory agencies, and issues a Notice of Validation to the Credit Developer. The Notice of Validation is a statement that the project is eligible to generate credits if all information provided is accurate and complete. It is not a confirmation of the quantity of credits to be issued. All information and documentation provided in the Validation Checklist is reviewed in greater depth during verification (Step D3).

If validation criteria are not met, the Administrator provides reasons why the project may not be eligible to participate in the Credit System.

The Administrator maintains a list of projects seeking funding for implementation while respecting confidentiality rules outlined by the Credit System and described in *Section 2: Policy and Technical Elements*. The Administrator may include the credit project on its list of credit projects seeking funding on the List of Credit Opportunities, if so desired by the Credit Developer.

Product ■ Notice of Validation

Product ■ List of Credit Opportunities

D2 CALCULATE CREDIT & IMPLEMENT PROJECT

Figure 20: Calculate Credit & Implement Project

Typically, a Technical Support Provider or Aggregator assists the Credit Developer in designing the credit project and estimating the expected credit amount using the HQT. Credit calculation must be done by a person well-versed in the HQT. The Credit Developer has the option to check the design calculations with the Administrator to gain confidence that the initial estimate of credits is accurate. Typically, practical opportunities and constraints that arise during implementation cause actual conditions to differ from design plans. Thus, final calculations must be revised to reflect actual post-project conditions.

Alternatively, the Credit Developer may wait to calculate habitat function until the project is complete, and then perform all calculations using post-project conditions. If this is the desired course of action, care must be taken to thoroughly document pre-project conditions using the HQT. Project proponents are advised to consult with the Administrator before initiating credit project implementation.

D2.1 CALCULATE PRE-PROJECT CONDITIONS

The Credit Developer follows the process defined in the HQT to define the credit project boundaries and calculate the pre-project conditions. Although baseline habitat function for credit projects is based on the site scale, regional standard baseline, calculating pre-project condition is necessary for the Credit Developer to confidently estimate and Administrator to agree to post-project habitat function performance standards. The Credit Developer or Technical Support Provider fills in the pre-project data results from the field inventory, completes any necessary calculations using the HQT, and provides the completed field datasheets to the Administrator.

Product ■ Pre-project HQT Results with Associated Forms

D2.2 DEFINE & SUBMIT PROJECT DESIGN INFORMATION

The Credit Developer completes a pre-project draft Management Plan that defines credit project boundaries and anticipated post-project conditions, based on initial HQT estimates. The Credit Developer can elect to include multiple credit project design scenarios in the pre-project draft Management Plan to estimate and compare the amount of credit generated from different design options. The pre-project draft Management Plan is submitted to the Administrator for pre-approval, prior to the implementation of management practices. These steps are described in further detail below.

Delineate Project Boundaries & Estimate Projected Credits

The Credit Developer follows the process defined in the HQT to define the credit project boundaries and estimate expected post-action conditions[19]. Guidance for selecting the appropriate duration of a credit project is included in the *Section 2.4.2: Credit Project Duration*. Project boundaries, planned management actions, including ongoing maintenance and monitoring, project duration, and expected post-project conditions for the site are documented in the pre-project draft Management Plan.

Product ■ Pre-project Draft Management Plan

Submit Pre-project Draft Management Plan to Administrator for Pre-Approval

The Credit Developer submits the pre-project draft Management Plan to the Administrator for pre-approval before initiating project implementation to gain assurance that the credit calculations are correct given the design assumptions used. The pre-project draft Management Plan may contain multiple project design scenarios, with associated credit calculations. If appropriate and requested by the Credit Developer or a potential Credit Buyer, regulatory entities may also be involved in this pre-approval check to confirm the credit project meets any special requirements necessary for regulatory approval. This optional step provides the Credit Developer with an indication of the amount of credits expected from the project if the conservation measures are implemented as designed.

Product ■ Pre-project Draft Management Plan

Secure Project Implementation Funding (If Applicable)

The Credit Developer secures any necessary funding to implement the project, as needed. For restoration projects, the Administrator may require proof of financial assurances for the construction period. The full

---

[19] Note that pre-project and post-project boundaries must be exactly the same to develop an accurate comparison between pre- and post-project conditions. Map units, as defined in the HQT, may change between pre- and post-project calculations.

set of financial assurances is not required until step D2.3 when all materials are submitted to the Administrator to signal readiness for verification.

Product ■ Proof of Construction Period Financial Assurances (if applicable)

D2.3 IMPLEMENT PROJECT, REFINE CALCULATIONS & SUBMIT

Implement Project

The Credit Developer, Technical Support Providers or Aggregator implements the project with the understanding that final credit amounts will be determined using post-project conditions. The ability to adjust calculations based on site design enables the Credit Developer to identify additional opportunities to make improvements during project implementation and enables practical adjustments that may be necessary due to unforeseen site constraints.

Confirm or Refine Credit Calculations

The Credit Developer either confirms that the project was completed consistent with the submitted pre-project draft Management Plan, or includes a new project design scenario that accurately reflects post-project conditions. If post-project conditions differ from design expectations, or if pre-project calculations were not completed, the Credit Developer uses the HQT to calculate the number of credits generated using post- project conditions.

Product ■ Revised draft Management Plan

Refine Management Plan & Credit Release Schedule

The Credit Developer further refines the draft Management Plan to define the specific management actions and expected outcomes for the site including ongoing maintenance and monitoring requirements. The Credit Developer also includes a credit release schedule in the Management Plan, defining the amount of credits released based on the implementation of management actions and achievement of the desired habitat conditions as indicated by the HQTs.

Product ■ Management Plan

Secure Financial Assurances

The Credit Developer must secure necessary financial assurances. See *Section 2.4.6: Financial Assurances* for guidance. Financial assurances ensure that funds are available to cover credit shortfalls and support long-term management of individual project sites, as specified in the Management Plan.

Product ■ Management Plan with proof of secured financial assurances

Submit Post-Project Calculations & Documentation

The Credit Developer submits the final credit estimate and all required documentation to the Administrator for verification reflective of post-project conditions. Once the Administrator verifies the credit estimates and other documentation, the Management Plan is finalized and the Credit Developer and Administrator sign a Participant Contract.

Product ■ Signed Participant Contract
Product ■ Final Management Plan

Establish Verification Contract

The Credit Developer completes a contract with the Administrator for verification services. A sample contract is available in Appendix B: Tools, Forms & Templates.

Product ■ Completed Verification Contract

D3 VERIFY CONDITIONS

Figure 21: Verify Conditions

All projects require verification. Verification is an independent, expert check on the credit estimates provided by the Credit Developer, Technical Support Providers, or Aggregator. The purpose of verification is to provide confidence to all Credit System participants that credit calculations represent a faithful, true and fair account of impacts and benefits – free of material misstatement and conforming to accounting and credit generation standards. Ongoing verification ensures the project is maintained over time and supports the expected level of credit reflected in calculations. The required frequency of verification is defined in *Section 2.4.5: Credit Site Verification*.

Initial project verification is completed for the credit project before credits are issued, and periodically over the life of the project as defined in *Section 2.4.5: Credit Site Verification*. Self-Monitoring Reports must be completed in non-verification years to confirm that conditions are maintained according to the specifications in the Management Plan.

D3.1 SELECT VERIFIER

Upon receiving complete documentation and a finalized contract for verification services from the Credit Developer, the Administrator assigns an accredited third-party Verifier to perform a full verification.

Verifiers must be accredited by the Administrator before they are eligible to conduct verification activities. The independence of verification is important. Verifiers acting on behalf of the Administrator must work in a credible, independent, nondiscriminatory and transparent manner, complying with applicable state and federal laws. Verifiers must demonstrate their ability to professionally assess a specific type of credit without conflicts of interest. This includes disclosing any pre-existing relationships between the Credit Developer or Credit Buyer and the Verifier. Verifiers must provide a Conflict of Interest Form to the Administrator before verification can proceed.

Becoming an Accredited Verifier

The Credit System Administrator will accredit Verifiers to review credit projects. Verifiers will act as subcontractors to the Credit System Administrator. Verifiers bear no liability for project implementation or project performance. Interested Verifiers must complete the following steps:

- Attend a Verification Training Session
- Keep the Credit System Administrator informed of any changes affecting the accreditation (e.g. potential conflicts of interest)
- Participate in refresher courses held by the Credit System Administrator at least biannually

Product ■ Completed Conflict of Interest Form

D3.2 PERFORM ONGOING PROJECT MAINTENANCE AND MONITORING

The Credit Developer is responsible for monitoring and maintaining project conditions throughout the life of the project to ensure that on-the-ground conditions reflect the information provided in the verified credit estimate and Management Plan. Depending on the implemented conservation practices, project conditions may appropriately degrade throughout the year. Before project monitoring is finalized, the Credit Developer maintains the project as necessary to ensure that actual, on-the-ground conditions support the credits calculated in Step D2 and documented in the Management Plan. In years when an on-site verification is not required, the Credit Developer submits a Self-Monitoring Report to the

Administrator in accordance with the requirements defined in *Section 2.4.5: Credit Site Verification* and the specifics in the Management Plan.

Product ■ Self-Monitoring Report (non-verification years)

D3.3 PROJECT VERIFICATION

The Verifier confirms that:

- The Credit System Manual was followed completely and accurately.
- Appropriate documentation is in place (e.g. land protection or management agreements).
- The amount of credit issued for a project is appropriate given actual, on-the-ground conditions as verified through the HQT methods.
- For sites with future credit releases scheduled, management actions have been implemented and the desired performance criteria have been achieved as indicated by the HQT.

The Verifier performs a review of all relevant forms and documentation, and schedules a site visit with the Credit Developer[20]. The Verification Report is completed with information gathered during the site visit using the HQT User Guide. An example Verification Report and the HQT User Guide are available through the Administrator.

Credit calculations must be found to be free of material misstatements and meet the performance criteria defined in the Management Plan. If performance criteria are not met, the Verifier discusses the issues with the Credit Developer and Administrator. The Credit Developer and Administrator determine if corrective actions are necessary and appropriate, and the Administrator defines the appropriate amount of credit to be awarded given site conditions. If appropriate corrective actions or amount of credit cannot be agreed to by the Credit Developer and Administrator, then the Oversight Committee will facilitate the dispute resolution process.

Submit Project Verification Report

Once successful verification is complete, the Verifier submits their Verification Report to the Administrator. The Verification Report contains a summary of verification activities, an opinion on the credit estimates, and a log of activities and findings.

Product ■ Verification Report

D4 REGISTER PROJECT & ISSUE CREDITS

Figure 22: Register & Issue Credits

Registration ensures that credits from a specific project are real and traceable throughout the entire life of the project. All verified and certified credits generated through the Credit System must be registered. Supporting information related to each credit include vintage (year issued), HQT and Manual version used, duration of the credit, and owner of the credit.

---

[20] Verifiers follow a defined Verification Protocol that is the focus of the Verifier certification training conduct by the Credit System Administrator.

D4.1 CREATE A CREDIT SYSTEM REGISTRY ACCOUNT

The Credit Developer sets up an account on the Credit System Registry. Once a Credit Developer establishes a user account, any number of projects can be registered under the same user account. The Administrator provides detailed guidance on using the Credit System Registry.

Product ■ Credit System Registry Account

D4.2 REGISTER PROJECT

The Credit Developer can register a project as soon as a project is validated (Step D1), and a project must be registered before credits can be released or transferred to Credit Buyers. Registering a project does not indicate a release of credits into the project account on the Credit System Registry (see step D4.3 below). The Credit Developer begins a new project on the Credit System Registry and uploads all required documentation, as specified by the Administrator.

The Administrator reviews all documentation before the project is registered. If errors are found or additional documentation is needed, the Administrator contacts the Credit Developer to request the needed information.

Product ■ Registered Project

D4.3 RELEASE CREDITS

The Credit Developer requests issuance after verification is complete and all required documentation is submitted to the Administrator. The Administrator confirms all documentation is complete, the amount of credits registered is correct, and issues the credits to the Credit Developer's registry account.

Product ■ Issued Credits

D5 TRACK & TRANSFER CREDITS

Figure 23: Track & Transfer Credits

Credits issued on the Credit System Registry are assigned unique serial numbers so that they can be tracked over time. Once issued, credits can be sold and transferred between Credit System Registry accounts. The sale, transfer and ownership of each credit are tracked by the Credit System Registry. The terms of payments and sales are completed external to any of the Credit System Registry or processes. All Credit System Registry activities, including credit transfers, are monitored by the Administrator.

D5.1 ALLOCATE CREDITS TO RESERVE ACCOUNTS

Reserve account allocation requirements are defined in *Section 2.4.3: Reserve Account Contribution* and identified for the specific project in Step D2.3. The Administrator allocates the appropriate amount of credits to the reserve account upon transfer to a Credit Buyer. Credits allocated to the reserve account are never available for sale.

Product ■ Notice of Transfer From

D5.2 SELL AND TRANSFER CREDITS

Credit Developers and Credit Buyers connect via the Credit System Registry. The price, terms and conditions are all set by the Credit Developers and Credit Buyers, and are completed external to any of the Credit System Registry or Administrator processes with the exception of provisions provided in the Participant Contract. Once an agreement to transfer credits is reached, the Credit Developer submits a Notice of Transfer Form to the Administrator, who transfers credits between accounts and assesses appropriate transaction fees.

All listed credits can be transferred between accounts until they expire and are no longer available to be transferred to another Credit Buyer. Thus, a Credit Buyer may resell and retransfer credits that have not expired and are no longer used to fulfill credit obligations to another Credit Buyer. Once credits expire, the Credit System Registry moves them into an expired credit account that can be reported on but not accessed for transfer.

The portion of credits from each transaction that are dedicated to the reserve account are transferred directly to the reserve account, which can be accessed by the Administrator in the future for authorized uses, such as to cover invalidated credits from a credit reversal.

Product ■ Notice of Transfer

D5.3 REPORT OF ACCOMPLISHMENTS (OPTIONAL)

The Administrator generates reports that summarize the amount of credit generated from each registered project and the total amount of credit generated from all registered projects. Supporting information related to each credit can also be produced, including vintage (year issued), HQT version, and duration of the credit. Reports can also be generated that show transfers of credits and expired credits.

Product ■ Accomplishments Report (optional)

SECTION 3.2: ACQUIRING CREDITS

QUESTIONS ANSWERED

- How does a Credit Buyer use credits to demonstrate mitigation requirements have been met?
- How does a Credit Buyer use credits to report on the accomplishments of their investments?

Figure 24: Credit Acquisition Overview

This section describes the process to acquire credits. Credit Buyers include entities mitigating for impacts to fulfill regulatory requirements, and entities seeking to improve the environment. The Credit System enables private and public Credit Buyers to efficiently invest with confidence, knowing that quantified environmental benefits are consistently defined, transparent and traceable. Credit Buyers can increase efficiency by relying on the programmatic structure to guide project design and verify that completed projects deliver expected environmental benefits. This increases accountability with Credit Developers and allows for greater coordination with other Credit Buyers to fund large-scale projects. Further, credits provide Credit Buyers with quantitative information to evaluate and report on the environmental value generated from their investments. Figure 24 and Table 22 provide an overview of the steps of credit acquisition and the different participants that may be engaged at each step.

Table 22: Overview of Roles, Tools & Products to Purchase, Track and Report Credits

■ Indicates a necessary or active role
□ Indicates potential participation or a support role

B1 INDICATE INTEREST

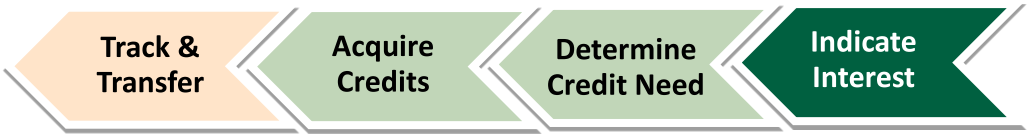

Figure 25: Indicate Interest

The Credit Buyer defines their investment goal and selects an appropriate strategy for acquiring credits.

B1.1 INDICATE INITIAL INTEREST & INITIATE COMMUNICATION

This first step for the Credit Buyer is to become aware of the opportunity or requirement to participate in the Credit System. The Credit Buyer is introduced to the Credit System through outreach materials or word of mouth, and learns about the potential benefits of participating. The Credit Buyer or the Credit Buyer's representative contacts the Administrator to provide basic information, such as name, area of interest and contact information. General information for how credits can be used to meet regulatory requirements is provided in *Section 2.1: Program Governance* with specific requirements in permits and regulatory instruments. The Administrator provides a list of Technical Support Providers in the project area who can assist with developing an investment strategy, if this assistance is desired. The Administrator compiles a list of identified Credit Developers and Credit Buyers.

Product ■ List of Identified Credit Developers & Credit Buyers

B2 DETERMINE CREDIT NEED

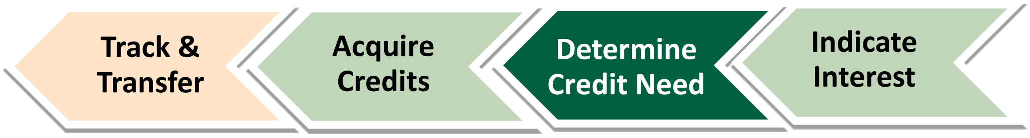

Figure 26: Determine Credit Need

Credit Buyers determine the geographic region, duration and amount of credit needed to best meet their regulatory requirements or investment goals.

B2.1 DETERMINE APPLICABLE GEOGRAPHY & PROJECT CHARACTERISTICS

The Credit Buyer identifies the specific geographic region from which to purchase Credits, in accordance with their investment goal. *Section 2.3.1: Credit Service Area* defines the applicable geographic scope of the Credit System and *Section 2.2.2: Mitigation and Proximity Ratios* defines the proximity ratio applied to debits and determined by the proximity between the debit site and offsetting credit site. Credit Buyers may also choose to focus investment within a specific geographic area to achieve unique investment goals.

The Buyer must also consider the duration or term to purchase credits. Projects produce credits for specific durations of time, including some projects which produce credits perpetually. *Section 2.5.4: Debit Project Duration* defines specific parameters for project duration.

The Buyer may also be interested in other characteristics that would focus investment on specific project types or Credit Developers. For instance, the Credit Buyer may want to only invest in projects that produce new habitat on working lands from small farms and ranches.

Product ■ Determination of Credit or Project Specifications

B2.2 DETERMINE CREDIT AMOUNT (REGULATORY OFFSET CREDIT BUYERS ONLY)

Each Credit Buyer defines their needed or desired amount of credit. If the Credit Buyer is not in a regulatory context, skip ahead to Step B3.

The remainder of this step defines the process to determine the amount of debit resulting from anthropogenic disturbances and the associated credit obligation to offset these impacts in a regulatory context. Development activities must be avoided and minimized through the SETT Consultation process, using best available and practicable technology and practice. Full compliance with all relevant laws and rules is required before credits can be used to satisfy the remaining regulatory requirements from unavoidable impacts.

Debits are quantified and verified units of functional acre loss using the HQT, and adjusted based on a mitigation ratio defined in *Section 2.2.2: Mitigation and Proximity Ratios*. The number of credits that must be acquired to offset the debits generated is the number of debits calculated adjusted by the proximity ratio defined in *Section 2.2.2: Mitigation and Proximity Ratios*. The process to calculate and verify debits is the same as the process to quantify credits except that verification occurs prior to project implementation. The following sections are a summary of that process. See Step D2 for additional information on calculating credits from a credit site.

Define & Submit Baseline Assessment

Credit Buyers first define the project boundary using guidance in the HQT. For debits, baseline is defined as the condition of the site prior to any new or expansion of an existing anthropogenic disturbance. Debit sites require a field assessment to determine pre-project conditions. The Credit Buyer conducts an assessment of the project area and applies the applicable HQT to calculate the baseline site functionality. Field and data collection forms are used to run the HQT and generate a habitat function score. The project baseline information, photo point documentation and HQT scores are submitted to the Administrator. As described later in this step, third party verification commissioned by the Administrator of debit baseline habitat function scores is required before the anthropogenic disturbance can be implemented. Since there are specific permissible windows for collecting official habitat function scores, commissioning an approved third-party Verifier to conduct the field assessment and gaining pre-approval from the Administrator to use those scores as the verified scores may be preferred by the Credit Developer to avoid a delay in the permitting process.

The Administrator reviews the baseline information and confirms all calculations are complete and consistent with relevant regulatory guidance, and allows the project to proceed.

Product ■ Complete Baseline Assessment

Determine Credit Obligation

A Credit Buyer's credit obligation is based on the difference between baseline functional acres and anticipated post-project functional acres, adjusted by mitigation and proximity ratio as defined in *Section 2.2: Habitat Quantification and Credit and Debit Calculation*. The estimated post-project habitat function is produced using the baseline functional acre assessment and development design documents defining the area, scope and activities to be completed as part of the development actions. The data sets are entered in the HQT, which produce the functional acre loss, debits and the credit obligation, and are submitted to the Administrator.

Product ■ Estimated Credit Obligation & Project Design Form

Acquire Agency Approval (If Necessary)

Consult with development permitting agencies for specific permit requirements to determine if agency approval is needed to use credits for regulatory offsets.

Establish Verification Contract

The Credit Buyer completes a contract with the Administrator for verification services. A sample contract is available in Appendix B: Tools, Forms & Templates.

Product ■ Complete Verification Contract

Verify Baseline

Verification of debits, like credits, is an independent review of all projects by third parties. Once final versions of all required documents are submitted to the Administrator, the Administrator reviews documentation to ensure completeness and assigns an accredited third-party Verifier to perform a full verification. Verification of debit baseline functional acres occurs before the anthropogenic disturbance has been implemented.

Once successful verification is complete, the Verifier submits the Verification Report to the Administrator. The Verification Report contains a summary of verification activities, an opinion on the debit estimates and a log of activities and findings.

Product ■ Verification Report

Post-Project Verification (If Necessary)

Consult *Section 2.5.6: Debit Site Verification* and specific permit requirements to determine if post-project verification is required to ensure that the amount of debit is not greater than what was estimated during project design.

B3 ACQUIRE CREDITS

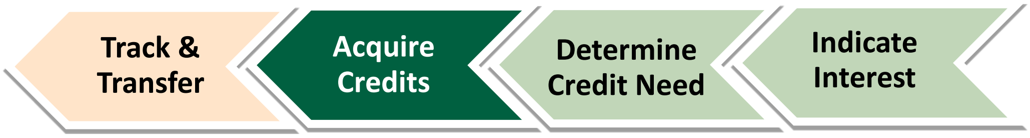

Figure 27: Acquire Credits

B3.1 SUBMIT PROJECT INFORMATION

To acquire and track credits, the Credit Buyer contacts the Administrator to provide information about the debit and credit obligation in order to acquire needed credits. All information provided to the Administrator is subject to the confidentiality provisions described in *Section 2.1.7: Participant Confidentiality*.

B3.2 PURCHASE CREDITS

Credit Developers and Credit Buyers connect via the Credit System Registry, and come to agreement on credit quantities, price, timing of funding, and other terms. The terms of payments and sales are completed between Credit Developers and Credit Buyers, external to any of the Credit System Registry or Administrator processes. Once an agreement is complete, the Credit Buyer or Credit Developer submits a Notice of Transfer to the Administrator.

Product ■ Notice of Transfer

B4 TRACK & TRANSFER CREDITS

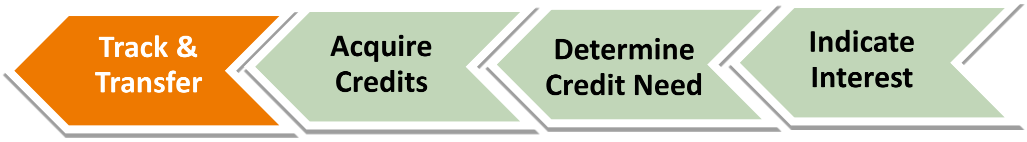

Figure 28: Track & Transfer Credits

Credits and debits are assigned unique serial numbers that identify the source of each credit or debit, the HQT and version used to estimate credits and debits, and the current owner. All registered projects are tracked by the Administrator, and information is subject to confidentiality provisions defined in *Section 2.1.7: Participant Confidentiality*. The terms of payments and sales are completed external to any of the Credit System Registry or Administrator processes.

B4.1 TRANSFER CREDITS

Upon receiving a Notice of Transfer, the Administrator transfers credits between accounts. Credits used to fulfill credit obligations are not available for resale. All remaining credits may be held by the Credit Buyer or resold. Even after transfer, the Credit Developer is responsible for meeting the monitoring, reporting and verification requirements of each project for the life of the project (described in *Section Step D3 in Section 3*).

B4.2 REPORT ON ACCOMPLISHMENTS (OPTIONAL)

The Administrator can generate reports for Credit Buyers that show transfers of credits and expired credits.

Product ■ Annual Accomplishments Reports

SECTION 3.3: ADAPTIVELY MANAGING THE CREDIT SYSTEM

QUESTIONS ANSWERED

- How is the Credit System managed to improve accuracy and efficiency without causing market uncertainty?
- What information is reported to ensure transparency and increase accountability?
- How are research and monitoring findings synthesized and used to improve the Credit System?
- How are Credit System improvement recommendations developed and used to inform annual Credit System improvement decisions?

The Credit System Management System is defined as a formal, structured programmatic adaptive management approach to dealing with uncertainty in natural resources management, using the experience of management and the results of research as an ongoing feedback loop for continuous improvement. This section describes the transparent and inclusive management process used for the Credit System. The Credit System Management System requires an ongoing flow of information from 1) research and monitoring activities conducted by scientists, 2) the practical experiences of Credit Developers and Credit Buyers, and 3) changing context from stakeholders to inform Credit System improvements. A systematic and transparent decision making process ensures that improvements to the Credit System do not cause uncertainty for participants. Figure 29 and Table 23 provide an overview of the Credit System Management System steps and the different participants that may be engaged at each step[21].

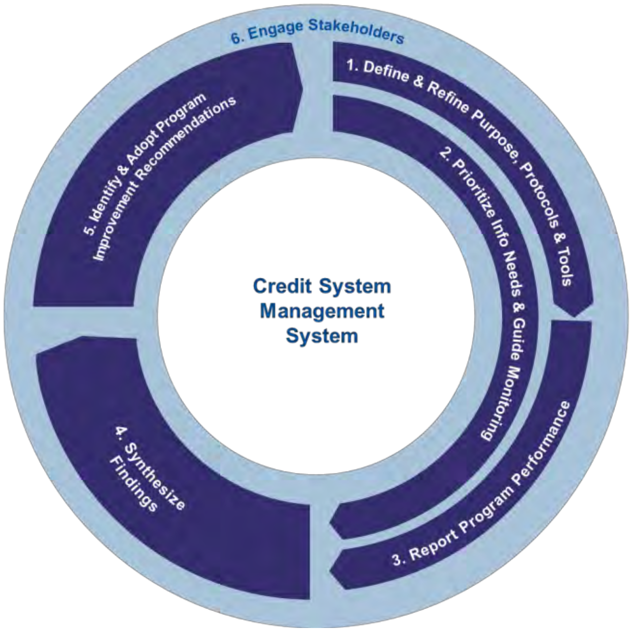

Figure 29: Overview of Credit System Improvement Management System Steps

---

[21] This management process has been adapted from The Conservation Measures Partnership's Open Standards for the Practice of Conservation, which can be found at www.conservationmeasures.org. Significant changes were made to adapt the Open Standards to 1) a market context where individual projects are selected and implemented by individual market participants and 2) be a formally governed process that balances the needs for improvements with the needs to limit market uncertainty for all participants.

The Administrator performs the day-to-day functions to manage the Credit System. The Administrator is accountable to an Oversight Committee, which approves all changes to the Credit System Manual and HQT. The composition of the Oversight Committee and the relationship between the Oversight Committee, Administrator and Credit System participants are defined in *Section 2.1.1: Governance Roles*.

A1 UPDATE PROTOCOL & TOOLS

Figure 30: Update Manual & Tools

This Credit System Manual and associated tools, templates and forms provide guidance for the Credit System to consistently track and report benefits and impacts. Updating the Credit System Manual, tools, templates, and forms is necessary to ensure practical experience and new scientific information result in increased efficiency and effectiveness. This step describes the process for the Credit System to review and update guidance documents, policies and tools.

A1.1 UPDATE CREDIT SYSTEM IMPROVEMENTS LIST

Credit System participants, the Administrator and other stakeholders may make suggestions to improve the Credit System at any time throughout the year by submitting a recommendation through the Credit System website. The Administrator adds recommendations received to the compiled Credit System Improvements List. The Administrator may also add improvement recommendations to the list reflecting personal experience or non-formal input from stakeholders. The Credit System Improvements List ensures that suggestions are not overlooked during the annual Credit System adjustment process.

Product ■ Credit System Improvements List

Review & Sort Improvement Suggestions

The Administrator reviews the Credit System Improvements List throughout the year and identifies relevant thematic changes that are categorized according to the following definitions:

- **Category 1** improvements consist of minor administrative adjustments or clarifications to communication or guidance materials that does not change the intent, form or operations. Category 1 improvements may be executed by the Administrator at any time; however the Oversight Committee and public must be informed of these changes as they occur.
- **Category 2** improvements are substantive changes to technical tools, protocols or guidance. Category 2 adjustments require input and approval from the Oversight Committee before they are implemented. The process for Oversight Committee review and adoption is defined in Step A5: Identify & Adopt Credit System Improvement Recommendations. When in doubt, the Administrator assigns the recommendation to Category 2. Upon review by the Oversight Committee, these suggestions may be re-categorized as needed.
- **Category 3** improvements necessitate adjustments to related policies if adopted. Category 3 adjustments are reviewed and approved or rejected by the Oversight Committee with consultation from the appropriate agency staff. These improvements may require agency approval, and thus follow the appropriate policy change process as defined by relevant state and federal agencies.

It is at the discretion of the Administrator, with guidance from the Oversight Committee, to prioritize funding to implement the most important improvements which can be successfully completed using available resources. The Administrator provides a prioritized Credit System Improvements List to the Oversight Committee, which includes Category 1 improvements implemented so that they can be reviewed and confirmed by the Oversight Committee. The Oversight Committee decides which improvement recommendations are to be implemented, at the periodic meetings described in Step A5:

Identify & Adopt Credit System Improvement Recommendations. For improvements that require additional time or resources to implement, the Administrator develops a brief implementation plan that is approved by the Oversight Committee.

Product ■ Updated Credit System Improvements List

A1.2 UPDATE EXISTING HQT, FORMS AND TEMPLATES

The Administrator may implement Category 1 improvements throughout the year. The Administrator implements all additional approved Category 2 and 3 improvements within a timeline approved by the Oversight Committee. The date at which updates go into effect should be clearly defined by the Oversight Committee with the expectation that changes which may affect the amount of credit generated from a project are not applied to previously registered projects.

Product ■ Updated Documents, Guidance & Tools

A1.3 INTEGRATE NEW AND ALTERNATIVE QUANTIFICATION TOOLS

The Credit System Manual is built to easily integrate new credit types (e.g. mule deer) and new or alternative HQTs. Once a new credit type and a new or alternative quantification tool is identified as needed, the Administrator convenes a technical committee to assess the proposed method and provide recommendations for improvement or adoption. Quantification tools require several field tests to determine accuracy, repeatability, sensitivity and ease of use. Once improvement recommendations are addressed, the Administrator presents the proposed new or alternative quantification tool, with supporting materials that define the use of any new credit types, to the Oversight Committee for review and approval (as described in Step A5: Identify & Adopt Credit System Improvement Recommendations).

Product ■ New Quantification Tools

Recommended Research and Monitoring Contract Terms

Research and monitoring contracts should reflect the need for clear, timely and consistently presented- findings so that findings can be easily used to address identified needs. Specific contract requirements can increase the likelihood that funded research and monitoring projects produce directly useful findings by:

- Identifying specific questions for investigators to address through specific projects.
- Requesting a one-to-two page summary of findings that directly relates findings to identified questions and related items on the List of Areas for Investigation.
- Requiring that reports be submitted in a timely manner so findings may be considered in the development of the Synthesis of Findings Report (Step A4).
- Requesting interim updates for long-duration projects, in order for these projects to provide insights with potential to influence current decisions and future expectations.
- Holding final payments until a draft report has been reviewed by an appropriate group of participants and review comments have been satisfactorily addressed.

A2 PRIORITIZE INFORMATION NEEDS & GUIDE MONITORING

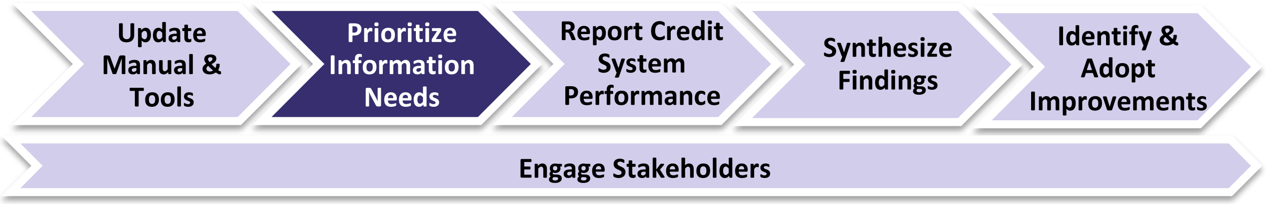

Figure 31: Prioritize Information Needs & Guide Monitoring

Monitoring and research are necessary to check that the habitat benefits projected by the HQT result in the projected improvements for the habitat attributes of concern. The Credit System may collaborate with monitoring initiatives led by other active programs in the region or initiate its own research with approval from the Oversight Committee.

A2.1 DEVELOP & ADJUST LIST OF AREAS FOR INVESTIGATION

The Administrator takes input from the Science Committee and other technical experts and maintains the List of Research Needs. The List of Research Needs catalogs and prioritizes research and monitoring needs identified by participants as being important to improve HQT, better understand the effectiveness of management actions and impact of anthropogenic disturbances, and follow the status and trend of habitat attributes of concern.

The Credit System may be able to collaborate with other monitoring programs to monitor status and trend of habitat conditions and greater sage-grouse populations, but is likely to take a more active role in directing monitoring intended to calibrate HQTs and improve their accuracy. The HQT estimates the amount of credit expected from credit projects based on technical assumptions. These assumptions are tested by technical experts and practitioners conducting monitoring and research to address items on the List of Research Needs. Scientists review results and improve HQT and associated field methods accordingly.

Product ■ List of Research Needs

A2.2 PROVIDE INPUT TO RESEARCH & MONITORING FUNDING PROCESSES

The Administrator coordinates with participants, regulators, technical support, grant funders and stakeholders to identify and secure funding for priority needs identified on the List Research Needs. Research and monitoring may be conducted through direct contracts with the Credit System funded through transaction fees or conducted through partnerships with existing monitoring programs, or any other parties.

Product ■ Research & Monitoring Contracts and Results

A3 REPORT CREDIT SYSTEM PERFORMANCE

Figure 32: Report Credit System Performance

Routine reporting of accomplishments is essential to ensure transparency and drive accountability. The annual Credit System Performance Report (Performance Report) reports all credits tracked by the Credit System and informs interested parties of recent changes to the Credit System. The Performance Report highlights successes and challenges from the past year, both regionally and for each specific geographic area of interest. This is the highest profile product produced by the Credit System and is targeted to an informed public audience.

Recommended Performance Report Content

The use of a standard report template both increases efficiency and enhances understanding by providing information in a consistent format. The Performance Report addresses:

- Overall credit and debit results from the past year and over the life of the Credit System, including progress towards goals
- Credits and debits within specific geographic areas of interest
- Summary of recent and expected near-term changes

A3.1 COMPILE CONTENT & PUBLISH PERFORMANCE REPORT

The Administrator uses tracking outputs, such as the number of credits created during the year, to generate the quantitative information for the Performance Report, which includes a ledger of all credits and debits generated cumulatively and each year to demonstrate net benefit for greater sage-grouse. Credits are summed across geographic locations and for each specific area of interest. Additionally, information related to non-habitat accomplishments may also be highlighted, such as administrative improvements. The Performance Report is posted online and submitted to any relevant regulatory agencies.

The Administrator updates the content from the previous year's Performance Report and develops a narrative summary of overall accomplishments, and projected improvements to the Credit System over the past year. The Performance Report is annually approved by the Oversight Committee. It is then posted to the Credit System website within an appropriate timeframe and available to all interested stakeholders.

Product ■ Annual Credit System Performance Report

A4 SYNTHESIZE FINDINGS

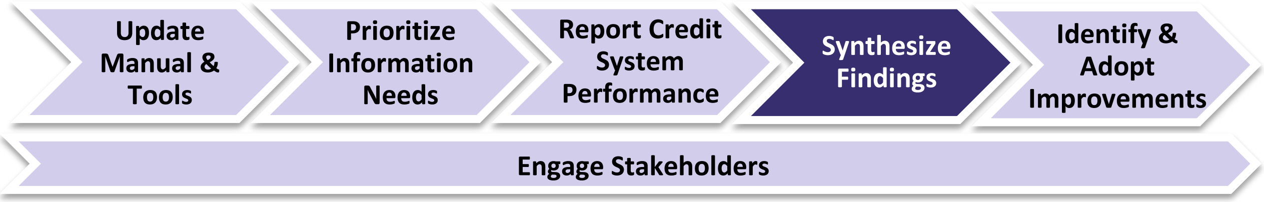

Figure 33: Synthesize Findings

Synthesizing findings into information that is directly related to the operations of the Credit System is essential to inform management decisions. The Synthesis of Findings Report bridges the gaps between the Oversight Committee, Credit System participants, engaged scientists, and agency staff, by synthesizing learning from experience implementing the Credit System and from new monitoring and research findings. It is not intended to be a comprehensive review of all literature and available information. Providing highly-nuanced recommendations with extensive discussion does not meet the primary audience's needs. Rather, findings are presented in clear statements. Supporting information should be targeted, providing the most relevant information necessary to understand the issues in context of the Credit System.

The Synthesis of Findings report is developed by the Administrator annually. A more formal review of the Credit System and committee structure is recommended to occur at least every fifth year.

A4.1 COMPILE FINDINGS & DEVELOP SYNTHESIS OF FINDINGS REPORT

The Administrator requests input from participants and relevant stakeholders, including posting an invitation for input to the Credit System website. Findings may address needs related to improving 1) the accuracy of credit estimation and verification methods, 2) the effectiveness of different management actions, and 3) the efficiency of Credit System operations. The Administrator decides how to catalogue and organize input received and develops a brief report to present to the Oversight Committee.

Product ■ Synthesis of Findings Report

A5 IDENTIFY & ADOPT CREDIT SYSTEM IMPROVEMENT RECOMMENDATIONS

Figure 34: Identify & Adopt Credit System Improvement Recommendations

Creating and transparently adopting clear recommendations to improve the Credit System is the most critical step in the annual Credit System management process. The predictability and transparency of the adjustment process enables Credit Developers, Credit Buyers and other stakeholders to adjust practices and expectations without causing market uncertainty or disruptions that result in participants becoming resistant to changes.

A5.1 PROPOSE CREDIT SYSTEM IMPROVEMENT RECOMMENDATIONS

The process for maintaining and prioritizing the Credit System Improvements List is described in Step A1: Update Credit System Improvements List. The Credit System Improvement List and the Synthesis of Findings Report are the most critical inputs for the Administrator to consider when identifying Credit System Improvement Recommendations.

Develop Credit System Improvement Recommendations

The Administrator reviews the Credit System Improvements List and identifies priority improvements to recommend to the Oversight Committee for implementation. The Administrator will engage the Science Committee in the development and prioritization of the Improvements List. The Administrator describes the following for each recommended improvement:

- Clear statement of need for change and expected improvements to efficiency or effectiveness resulting from implementing the change.
- Description of what specific portions of documents, forms, guidance, or the HQT will be changed, potentially including red-line versions of recommended changes.
- Identification of any potential complications or impacts the change may have to stakeholders or to the Credit System.
- For changes that require contract resources or greater than one-month to implement, a brief implementation plan with associated budget.

Recommendations are grouped by the Categories described in Step A1.1. Note, all Category 1 improvements implemented by the Administrator during the year are documented and may be reviewed by the Oversight Committee to confirm that changes are acceptable.

Product ■ Draft Credit System Improvement Recommendations

Develop Final Recommendations

The Credit System Improvement Recommendations are sent to the Oversight Committee for review in advance of the next Oversight Committee meeting. The Oversight Committee members discuss recommendations of interest or concern with the Administrator and consult stakeholders as necessary.

Product ■ Final Credit System Improvement Recommendations

A5.2 ADOPT CREDIT SYSTEM IMPROVEMENTS

The Oversight Committee meets, discusses and considers adopting Credit System Improvement Recommendations at least annually. For policy decisions and those directly related to regulatory or funding requirements, the decision may be to bring a proposal before relevant agency management or other decision making authorities.

The Oversight Committee designates an individual to compile a Record of Decisions. A Record of Decisions defines the agreed-to changes, the rationale, the party responsible for implementing the changes, and the date when changes go into effect for any new projects or operational practices. Changes do not alter the amount of credit available from previously registered projects for the duration of the project, and should not require changes to existing project management plans or credit obligations. Any recommendations not acted upon are addressed by providing a brief rationale and an indication of whether the recommendation may be considered at a later date or if the recommendation has been rejected and should not be brought back in the future.

Product ■ Record of Decisions

A5.3 OVERSEE CREDIT SYSTEM OPERATIONS

Annually, the Oversight Committee conducts or designates an independent entity to conduct a third-party audit of Credit System operations, including a detailed review of a portion of individual credit and debit sites. The audit confirms that procedures are being consistently followed, all documentation is present and complete, and all Credit System management products are developed and maintained. An Audit Report describes the audit procedures, findings and any proposed areas where corrective actions should be considered. The Audit Report is made available to the Oversight Committee and discussed at a subsequent Oversight Committee meeting. The final Audit Report, less information identified as confidential, is posted to the Credit System website.

Product ■ Audit Report

A5.4 RESOLVE OUTSTANDING DISPUTES

As defined in the dispute resolution process defined in Step D3, the Oversight Committee or a subcommittee of the Oversight Committee resolves disputes between Credit System participants that cannot be resolve independently or in consultation with the Administrator. If the dispute is in reference to regulatory requirements, the regulatory agency has the final decision-making authority.

A6 ENGAGE STAKEHOLDERS

Figure 35: Engage Stakeholders

Consistent stakeholder engagement is necessary to ensure the Credit System operates efficiently, increases understanding, and drives accountability. Stakeholder engagement occurs throughout the year using the reports and products defined in Steps A1-A5, as well as through email and in-person engagements.

A6.1 MAINTAIN CREDIT SYSTEM WEBSITE

The Administrator maintains the Credit System website as the central location for all publicly available information not deemed confidential. This includes all tools, guidance and reference materials related to the Credit System. The website also informs interested stakeholders of upcoming events and meetings, and provides the opportunity for stakeholders to provide Credit System improvement recommendations (as described in A1).

Product ■ Updated Credit System Website

A6.2 DISTRIBUTE UPDATE EMAILS

The Administrator maintains an ongoing list of interested stakeholders and their email contact information. The Administrator disseminates a periodic email update to interested stakeholders to provide information about Credit System progress. Email updates also notify stakeholders when reports are expected to be available for public review, and about upcoming opportunities for in-person engagement.

Product ■ Email Communications

A6.3 PRESENT AT COMMUNITY FORUMS

The Administrator and other participants may make presentations at community events and meetings upon request and as resources are available. This is critical to ensure local groups understand the basic functions and role of the Credit System and understand how they may be able to participate.

Product ■ Community Presentations

A6.4 CONDUCT TRAININGS

The Administrator or experienced Technical Support Providers periodically conducts trainings to teach potential Credit System participants how to efficiently use the Credit System, including guidance on using tools and forms. These trainings are generally open to all interested parties. Verifier certification trainings are conducted as needed with an expectation of at least annually.

Product ■ Hosted Trainings

A6.5 CONVENE ANNUAL STAKEHOLDER MEETING

The Administrator annually convenes meeting open to all stakeholders. This meeting is an opportunity to highlight accomplishments and identify areas for improvement with participants and interested stakeholders. The meeting is held after the annual Performance Report is posted to the Credit System website for review, and before final Program Improvement Recommendations are considered by the Oversight Committee (as described in Step A5).

At this annual meeting, stakeholder input should be structured such that input directly related to identified areas of operational improvement and areas for investigation are recorded in context of the specific need. Stakeholders also should have the opportunity to identify new needs and concerns for consideration. Input may be added to the Credit System Improvements List or List of Research Needs.

Stakeholder input that does not directly relate to these ongoing lists of needs is summarized and the notes posted to the Credit System website.

Product ■ Stakeholder Meeting & Summary of Input Received

APPENDIX A: GLOSSARY

Additionality: Habitat functionality improvements that represent an overall increase in, or avoided reduction of, habitat functionality, relative to the habitat functionality that would occur in absence of the Credit System.

Administrator: An organization or entity responsible for managing the day-to-day operations of the Credit System, including facilitating and overseeing all credit generation and transaction activities.

Aggregator: A person or institution that works with multiple landowners to implement credit projects, secure performance assurances, and register and sell credits. An Aggregator facilitates financial transactions between the Credit Buyers and Credit Developers, and may charge a fee for the service, but is not directly involved in the chain of ownership of credits.

Baseline: The starting point for calculating the functional acres generated by a credit or debit, which is the difference between baseline and post-project functional acres. Baseline does not necessarily mean pre-project condition.

Candidate Conservation Agreement (CCA): A formal agreement between the USFWS and one or more Federal or non-Federal parties to address the conservation needs of proposed or candidate species, or species likely to become candidates for listing under the Endangered Species Act, in which participants voluntarily commit to implementing specific actions that will remove or reduce the threats to these species, so that listing is no longer necessary.[22]

Candidate Conservation Agreement with Assurances (CCAA): A formal agreement between the USFWS or NMFS and one or more non-Federal parties who voluntarily agree to manage their lands or waters to remove threats to candidate or proposed species and in exchange receive assurances that their conservation efforts will not result in future regulatory obligations in excess of those they agreed to at the time they entered into the Agreement.[23]

Competing Land Uses: Land uses that reduce the functionality of habitat and invalidate the credits being generated on a site.

Compensatory Mitigation: The stewardship or restoration of habitat to compensate for unavoidable adverse impacts to the habitat elsewhere.[24]

Condition: Condition is the relative ability of a site to support and maintain its complexity and capacity for self-organization with respect to species composition, physicochemical characteristics and functional processes.

Conservation Action: Actions to conserve habitat and do not generate credits.

Conflict of Interest: A situation in which, because of activities or relationships with or perceived to be with other persons or organizations, a person or firm is unable or potentially unable to render an impartial verification opinion of Credit Developer's estimated credits.

Credit: A quantifiable unit of a greater sage-grouse habitat conservation value which serves as the currency in the Credit System. A credit is a measure of the difference between credit baseline functional acres (see Functional Acre definition) and post-project functional acres multiplied by a mitigation ratio. Credits are consistently quantified and traded, and secured by contract requirements, a project-specific Management Plan and financial assurances.

---

[22] USFWS DRAFT GRSG Mitigation Framework Glossary

[23] USFWS DRAFT GRSG Mitigation Framework Glossary

[24] USFWS DRAFT GRSG Mitigation Framework Glossary revised

Credit Buyer: An entity that purchases credits for a range of reasons including general conservation purposes or mitigating the adverse effects of a debit project.

Credit Developer: Landowners or managers who produce and sell credits in the Credit System.

Credit Obligation: Quantity of credits that must be acquired to offset debits generated by a debit project. Credit obligation is the number of debits calculated using the HQT and debit mitigation ratio adjusted by the proximity ratio, determined by the proximity between the debit site and offsetting credit site.

Credit Project: Management actions and administrative requirements including a Participant Contract and Management Plan that create a credit.

Credit Release: An award of credits made available for transfer by the Administrator to a Credit Developer upon meeting specified management and performance criteria.

Credit Site Eligibility: A set of requirements that a credit project site must meet in order to be able to participate in the Credit System.

Agreement: A signed agreement between the Administrator and other public agencies that authorizing the use of Credit System credits for mitigation purposes within the State of Nevada, or between the Administrator and other parties to use Credit System tools and procedures.

Credit System Operations: A set of rules that defines the universal processes through which credits and debits are generated, tracked, and traded within the Credit System.

Credit Variability: Fluctuations in the generation of credits and debits on a project site that are created due to factors that are outside the control of the participants, such as environmental conditions and climatic effects.

Debit: A quantifiable unit of loss to greater sage-grouse habitat conservation value from an impact. A debit is a measure of the difference between debit baseline functional acres (see Functional Acre definition) and post-project functional acres multiplied by a mitigation ratio (but not yet multiplied by proximity factor), and are based on the same methods and HQT used to calculate credits.

Debit Project: An anthropogenic disturbance that creates a debit.

Direct Impact: The effects that are caused by, or will ultimately result from, the direct footprint of a debit project.

Durability: Credit projects that demonstrate defined habitat functionality performance prior to credit release through the end of the project's duration.

Dynamic Offsets: When a stream of term credits are used to cover a debit, such that the mitigation is functionally the same duration as the debit but shifts on the landscape.

Ecosystem Services: The benefits people obtain from nature. These include provisioning services such as food, water, timber, and fiber; regulating services that affect climate, floods, disease, wastes, and water quality; cultural services that provide recreational, aesthetic, and spiritual benefits; and supporting services such as soil formation, photosynthesis, and nutrient cycling.

Financial Assurances: Mechanism to ensure that funds are available to replace credits invalidated by intentional causes, and to ensure funds are available for long-term management and monitoring of individual project sites.

Force majeure: Event or circumstance beyond the control of Participants under which they are not liable. This includes Acts of God, including fire, flood, earthquake, storm, hurricane or other natural disasters.

Functional Acre: The single unit of value that expresses the assessment of quantity (acreage) and quality (function) of habitat or projected habitat through the quantification of a range-wide scale, landscape-scale, local-scale and site-scale attributes defined in the *HQT Scientific Methods Document*.

Habitat Conservation Plan (HCP): A conservation plan that specifies the anticipated effects of a proposed activity on the taking (see "*Incidental take*") of federally-listed species and how those impacts will be minimized and mitigated. The HCP is submitted with an incidental take permit application to the USFWS or NMFS. Incidental take permits are available to private landowners, State and local governments, Tribal governments and other non-Federal landowners through section 10 of the Endangered Species Act.[25]

Habitat Function: The ability or value of a measured patch of land to meet the needs of greater sage-grouse.

Habitat Suitability Index (HSI): A continuous map surface developed by Nevada's Sagebrush Ecosystem Program that contains the probability of use by sage-grouse per pixel across Nevada. This surface is represented by probability values that range across a continuous spectrum of 0.0 to 1.0.

Habitat Quantification Tool: A set of metrics (i.e. measurements and methods), applied at multiple spatial scales, to evaluate current conditions and changes in conditions indicative of habitat quality, baseline, and mitigation ratios to determine the amount of total credit or credit obligation debit resulting from credit and debit projects. The attributes measured and methods used to measure those attributes are defined in the *HQT Scientific Methods Document*.

Incidental Take: take of listed species that results from, but is not the purpose of, carrying out an otherwise lawful activity. Incidental take may be authorized through section 7 or 10 of the Endangered Species Act.[26]

Indirect Impact: Effects that are caused by or will ultimately result from a debit project. Indirect impacts could occur at some point in the future or outside of the direct footprint of the debit project site.

Landscape Scale (2nd order): 2nd order selection is described by the home range of a sage-grouse population or subpopulation, and attributes are measured to delineate the best areas for conservation and identify where credit projects should be targeted and disturbances should be avoided.

Local Scale (3rd order): 3rd order selection is based on sage-grouse use of, and movement between, seasonal habitats within their home range according to their life cycle needs, and attributes are measured to consider the availability of suitable habitat and the effects of anthropogenic disturbances.

Management Actions: Stewardship and restoration of a site in order to generate credits.

Management Plan: Plan that defines specific restoration and management actions over the life of a credit project, including ongoing maintenance and monitoring requirements. Plan includes existing project site information, such as a site map and information on current management practices, and anticipated project start and end dates, and any management limitations.

Management Process: A formal, structured programmatic adaptive management approach to dealing with uncertainty in natural resources management, using the experience of management and the results of research as an ongoing feedback loop for continuous improvement.

Map unit: Sub-divisions of the project area based on unique vegetation communities and vegetation structure.

---

[25] USFWS DRAFT GRSG Mitigation Framework Glossary

[26] USFWS DRAFT GRSG Mitigation Framework Glossary

Mitigation: Stewardship or restoration of habitat to compensate for unavoidable adverse impacts from a debit project and verified through the Credit System. Credit projects are mitigation for debit projects.

Monitoring: The process to observe and record current environmental conditions, changes in environmental conditions and effects of management actions over space and time.

Offset: *See Mitigation*.

Oversight Committee: Formal, representative stakeholder group, which is responsible for overseeing the operations of the Credit System and making Credit System management decisions. The Sagebrush Ecosystem Council serves as the Oversight Committee.

Participant: General term for all entities participating in the Credit System, with the exception of the Administrator and the Oversight Committee. Participants include: Credit Developers, Credit Buyers, Technical Support Providers, Aggregators, and Verifiers.

Participant Contract: Legal agreement between one or more Credit Developers and the Administrator that defines obligations of the Credit Developers and secured financial assurances, binds a participating credit site to a Management Plan, and lays out the relevant terms and conditions for the development of credits under the Credit System.

Participant Confidentiality: Processes to ensure sufficient information is available to monitor compliance, ensure progress toward environmental goals, and inform a robust Credit System management process, while not revealing identifying information of participants.

Performance Standards: Management actions and habitat function described in a credit project's Management Plan that defined credit project expectations including requirements for credit releases.

Project Duration: The period of time that the Credit System recognizes a credit or debit before requiring that the project be renewed using current HQT and protocols.

Range-wide Scale (1st order): 1st order selection is described by the geographic range of the sage-grouse population in Nevada.

Rehabilitate: Return habitat function of a debit site to pre-project or better condition.

Remedial Action Plan: Any corrective measure which the Administrator or a Credit Developer is required to take to correct an adverse impact to a participating credit site as a result of a failure to achieve the performance criteria outlined the site's Management Plan.

Remediate: Correction of an adverse impact to a credit site.

Reserve Account: A pool of credits, funded by a percentage of the credits transferred in each transaction, that are used to cover shortfalls when credits that have been generated and sold are invalidated due to contract breach, a force majeure, or other circumstances. The Reserve Account helps to ensure that there is always a net positive amount of habitat tracked under the Credit System.

Restoration: The reestablishment of ecologically important habitat or other ecosystem resource characteristics and function(s) at a site where they have ceased to exist, or where they exist in a substantially degraded state, and that renders a positive biological response by the species or habitat.

Reversal: Credit project that does not persist for the full, required, duration due to natural or man-made causes.[27]

---

[27] USFWS DRAFT GRSG Mitigation Framework Glossary revised

Safe Harbor Agreement (SHA): Formal agreement between the USFWS or NMFS and one or more non-Federal landowners in which landowners voluntarily manage land for listed species for an agreed amount of time providing a net conservation benefit to the species at the end of the time period and, in return, receive assurances from the Federal agency that no additional future regulatory restrictions will be imposed.[28]

Science Committee: The group of species and ecology experts appointed by the Sagebrush Ecosystem Council and are responsible for analyzing the best-available species and ecological science and making adaptive management recommendations.

Service Area: The geographic area within which habitat credit trading occurs, as defined by the current SGMA; the geographic area within which impacts to covered species' habitat can be offset at a particular habitat offset site as designated in an agreement or program.[29]

Site Scale (4th order): 4th order selection is based on sage-grouse selection for vegetation structure and composition that provide for their daily needs, including forage and cover.

Split Estate: Surface rights and subsurface rights (such as the rights to develop minerals) for a piece of land are owned by different parties.[30]

Stacking Payments and Credits: The creation of different credit types or payments on the same project site. Stacking credits allows Credit Developer to market multiple ecological values, and also allows payments from federal programs to be paired with payments from private sector mitigation markets for different services on the same land.

Static offset: Mitigation achieved for a debit project by the use of single credit project produced for the duration of the relevant debit project.

Stewardship: Maintenance of high quality habitat currently used by or in close proximity to habitat used by greater sage-grouse, or manipulation of existing habitat to increase specific habitat functionality. Examples range from placing a conservation easement on existing high quality habitat and committing to maintaining that high quality for the full duration of the credit project to improvement of habitat quality, as measured through functional HQT scores, through a prescribed grazing plan on existing rangeland.

Technical Support Provider: Entities with technical expertise in conservation planning and project design, who understand how to use the Credit System tools and forms. May be hired by Credit Developers to help design credit projects, use the HQT to estimate credits, and submit all required materials to the Administrator. There is no formal process to designate or certify a Technical Support Providers as qualified.

Transfer: The transfer of credits between account, such as between the account of a Credit Developer and Credit Buyer, or a Credit Developer and the reserve account. After transfer of credits between the accounts of a Credit Developer and a Credit Buyer, the Credit Developer is responsible for meeting the monitoring, reporting and verification requirements of each project for the life of the project (described in Step D3 in Section 3).

Verification: An independent, expert check on the HQT calculations and other specifications of the Credit System. The purpose of verification is to provide confidence to all participants, including the

---

[28] USFWS DRAFT GRSG Mitigation Framework Glossary

[29] USFWS DRAFT GRSG Mitigation Framework Glossary

[30] USFWS DRAFT GRSG Mitigation Framework Glossary

Administrator, that credit and debit calculations represent a faithful, true and fair account of conditions on-the-ground.

Verifier: A person that conducts site visits to assess the accuracy of credit and debit calculations. Verifiers must be trained and certified by the Administrator and must meet qualifications established by the Oversight Committee.

THIS PAGE INTENTIONALLY LEFT BLANK

APPENDIX B: TOOLS, FORMS & TEMPLATES

The following tools, forms and templates with associated instructions are referenced in the Credit System Manual and help to support ongoing operations of the Nevada Conservation Credit System (Credit System). The Tools, Forms & Templates Table describes these products, including the officially approved version that should be used in association with the current version of the Credit System Manual.

- **Tool**: A document, spreadsheet, or website used by Credit Developers, Credit Buyers or the Administrator to carry out a particular operational step in the Credit System Manual. For example, the Habitat Quantification Tool (HQT) is used to determine credit and debit from project sites. Tools are maintained by the Administrator.
- **Form**: A document with pre-defined fields that participants fill out and submit to the Administrator. For example, the Validation Checklist provides a set of fields that Credit Developers fill out to provide basic information to the Administrator about a proposed credit project.
- **Template**: A document with defined content outline and formats that a Credit System participant uses to efficiently populate with unique information. For example, the Administrator uses the previous year's Annual Performance Report to update information and create the next year's Annual Performance Report.

The Tools, Forms & Templates Table uses the following fields to define each product.

- **Name & Version**: Name of the document and the currently approved version for use by participants in the Credit System.
- **Type:** Specifies whether the document is a tool, form, or template as described above.
- **Description**: A brief description of the purpose of each document.
- **Related Step(s)**: Related steps where the document is referenced in the *Section 3: Credit System Operations*.
- **Responsible Party**: Specifies which party is responsible for using a tool, filling out a form, or creating a product from a template.

[The tools, forms and templates in the following table will be built out over the coming months including specific supporting guidance. The only exception is the Habitat Quantification Tool, which a draft has been released along with the Manual.]

#	name & Version	Type	Description	Related Step(s)	Responsible Party
1	**VALIDATION CHECKLIST** (VERSION - TBD)	Form	Basic information to provide an initial screen of a credit project's eligibility to participate in the Credit System.	D1.3	Credit Developer
2	**LIST OF CREDIT OPPORTUNITIES** (VERSION – TBD)	Template	List of credit projects seeking funding and Credit Buyers interested in purchasing credits.	D1.4, B1.1	Administrator
3	**HABITAT QUANTIFICATION TOOL (HQT)** (VERSION – TBD)	Tool	A set of metrics (i.e. measurements and methods), applied at multiple spatial scales, to evaluate vegetation, anthropogenic, and environmental conditions related to habitat quality and quantity.	D2, B2.2	Credit Developer, Buyer

#	name & Version	Type	Description	Related Step(s)	Responsible Party
4	**CREDIT ESTIMATE FORM** (VERSION – TBD)	Form	Records and documents the results of HQT outputs including: ▪ Pre-project site condition. ▪ Credits projected to be achieved on site under the proposed restoration or management plan. ▪ Description of conservation threats.	D2.2, D2.3	Credit Developer
5	**MANAGEMENT PLAN** (VERSION – TBD)	Template	Template that guides a Credit Developer to define specific restoration and management actions over the life of a credit project, including ongoing maintenance and monitoring requirements. ▪ Existing project site information, such as a site map and information on current management practices. ▪ Management plan information, including proposed management or restoration practices, anticipated start and end dates, and any management limitations.	D2.3	Credit Developer
6	**VERIFICATION CONTRACT** (VERSION – TBD)	Form	A Credit Developer or Buyer signs a contract with the Administrator for third-party verification of a credit or debit site.	D3.1, B2.2	Credit Developer, Buyer
7	**CONFLICT OF INTEREST FORM** (VERSION – TBD)	Form	Submitted by a Verifier to the Administrator about any pre-existing conflicts of interest for verification.	D3.1, B2.2	Verifier
8	**VERIFICATION REPORT** VERSION – TBD)	Template	Report submitted by a Verifier after site verification attesting to his or her opinion on whether a Credit Developer's Credit Estimate Report matches on-the-ground conditions, or a Buyer's baseline measurement.	D3.3, B2.2	Verifier
9	**SELF-MONITORING REPORT** (VERSION – TBD)	Template	Report submitted by Credit Developers in non-verification years demonstrating that specifications of the Management Plan have been fulfilled.	D3.3, B2.2	Credit Developer
10	**CREDIT OBLIGATION FORM** (VERSION – TBD)	Form	Form submitted to the Administrator outlining to total credit obligation of a mitigation buyer, including the total debit multiplied by the appropriate mitigation ratio.	B2.2	Buyer
11	**VERIFICATION PROTOCOL** (VERSION – TBD)	Tool	The step-by step description of the verification process for Verifiers to use as guidance.	D3.3, B2.2	Administrator
12	**NOTICE OF CREDIT TRANSFER** (VERSION – TBD)	Form	Notice from the Credit Developer or Buyer to direct the Administrator to transfer credits between accounts.	D5.1, D5.2, B3.2	Credit Developer, Buyer

#	name & Version	Type	Description	Related Step(s)	Responsible Party
13	**ACCOMPLISHMENT REPORTS** (VERSION – TBD)	Template	Reports provided by the Administrator to Credit Developers and Credit Buyers outlining project accomplishments.	D5.3, B4.2	Administrator
14	**CREDIT SYSTEM IMPROVEMENTS LIST** (VERSION – TBD)	Template	Suggestions for improving the Credit System collected throughout the year and maintained by the Administrator.	A1.1	Administrator
15	**LIST OF RESEARCH NEEDS** (VERSION – TBD)	Template	Catalogs and prioritizes research and monitoring needs identified by participants.	A2.1	Administrator
16	**CREDIT SYSTEM PERFORMANCE REPORT** (VERSION – TBD)	Template	The Administrator generates quantitative information to show Credit System accomplishments with respect to overall goals.	A3.1	Administrator
17	**SYNTHESIS OF FINDINGS REPORT** (VERSION – TBD)	Template	Synthesizes learning from experience implementing the Credit System and from new monitoring and research findings	A4.1	Administrator
18	**CREDIT SYSTEM IMPROVEMENT RECOMMENDATIONS MEMO** (VERSION – TBD)	Template	Recommendations of priority Credit System improvements for approval by the Oversight Committee	A5.1	Administrator
19	**RECORD OF DECISIONS** (VERSION – TBD)	Template	Defines the agreed-to changes, rationale, the party responsible for implementing changes, and the date changes go into effect.	A5.2	Administrator
20	**AUDIT REPORT** (VERSION – TBD)	Template	Independent audit of the Credit System operations by the Oversight Committee or third-party.	A5.3	Oversight Committee

SIERRA FRONT-NORTHWESTERN GREAT BASIN AREA	**NORTHEASTERN GREAT BASIN AREA**	**Mojave-Southern Great Basin Area**
STANDARD 1. SOILS: Soil processes will be appropriate to soil types, climate and land form. As indicated by: - Surface litter is appropriate to the potential of the site; - Soil crusting formations in shrub interspaces, and soil compaction are minimal or not in evidence, allowing for appropriate infiltration of water; - Hydrologic cycle, nutrient cycle and energy flow are adequate for the vegetative communities; - Plant communities are diverse and vigorous, and there is evidence of recruitment; and - Basal and canopy cover (vegetative) is appropriate for site potential.	**STANDARD 1. UPLAND SITES:** Upland soils exhibit infiltration and permeability rates that are appropriate to soil type, climate and land form. As indicated by: Indicators are canopy and ground cover, including litter, live vegetation and rock, appropriate to the potential of the site.	**STANDARD 1. SOILS:** Watershed soils and stream banks should have adequate stability to resist accelerated erosion, maintain soil productivity, and sustain the hydrologic cycle. Soil indicators: - Ground cover (vegetation, litter, rock, bare ground); - Surfaces (e.g., biological crusts, pavement); and - Compaction/infiltration. Riparian soil indicators: - Stream bank stability. All of the above indicators are appropriate to the potential of the ecological site.
GUIDELINES 4. After a range fire or other natural catastrophic event, vegetation should be returned to the native species as rapidly as possible, to afford forage and habitat for native animals. If a nurse crop is needed to **protect the land from erosion**, all native nurse crops should be used first. 5. Treated areas will be rested from livestock grazing for two growing seasons or until seedlings are established or the vegetative response has achieved objective levels. Wild horse and burros removed from Herd Management Areas will be restored after rehabilitation objectives have been met. 6. Alternative solutions (e.g., reseeding, funding, labor, equipment use or rental) to facilitate fire rehabilitation may	**GUIDELINES** 1.1 Livestock grazing management and wild horse and burro population levels are appropriate when in combination with other multiple uses they maintain or promote upland vegetation and other organisms and provide for infiltration and permeability rates, soil moisture storage, and soil stability appropriate to the ecological site within management units. 1.2 When livestock grazing management and wild horse and burro herd management alone are not likely to restore areas of low infiltration or permeability, land management treatments should be designed and implemented where appropriate. 1.3 Livestock grazing management and wild horse and burro herd management are	**GUIDELINES** 1.1 Upland management practices should maintain or promote adequate vegetative ground cover to achieve the standard. 1.2 Riparian-wetland management practices should maintain or promote sufficient residual vegetation to maintain, improve, or restore functions such as stream flow energy dissipation, sediment capture, groundwater recharge, and streambank stability. 1.3 When proper grazing practices alone are not likely to restore areas, land management practices may be designed and implemented where appropriate. 1.4 Rangeland management practices should address improvement beyond this standard, significant progress toward achieving standards, time necessary for recovery, and time

be included in cooperative agreements involving qualified groups and individuals who want to participate. 7. Appropriate livestock grazing treatments will be implemented to control the frequency, duration, and level of grazing use. Where livestock grazing is authorized, grazing systems will provide within any one grazing year one or more of the following treatments: a. Rest or deferment from livestock grazing on a specified area as appropriate to meet Standards. b. Systematic rotation of deferred use and/or rest from livestock grazing among two or more units. c. Continuous, season-long use where it has been demonstrated to be consistent with achieving identified Standards. Once season long use is determined to be unacceptable, an alternative system will be developed and implemented before termination of season long use, prior to the next grazing season. d. Excluding further livestock grazing within the affected use area through appropriate techniques when utilization objectives are reached. 11. Encourage the use of prescribed and natural fires, meeting prescription objectives, for the restoration and maintenance of healthy rangelands. 12. Departure from traditional grazing management practices may be authorized by BLM to	adequate when significant progress is being made toward this standard. See Appendix C (a) for additional guidelines for vegetation management.	necessary for predicting trends.

achieve Standards on a case by case experimental basis for rangeland restoration and rehabilitation. 13. The best available science and technology will be utilized in monitoring and assessing the condition of rangelands from the pasture to the BLM District level. 18. Implement aggressive action to reduce the invasion of exotic plant species into native plant communities. Control the spread of noxious weeds through various methods such as, grazing management, fire management and other vegetative management practices. 20. The utilization, monitoring and evaluation process will be used as a tool to promote healthy rangelands and achieve Standards.		
STANDARD 2. RIPARIAN/WETLANDS: Riparian/Wetland systems are in properly functioning condition. As indicated by: - Sinuosity, width/depth ratio and gradient are adequate to dissipate streamflow without excessive erosion or deposition; - Riparian vegetation is adequate to dissipate high flow energy and protect banks from excessive erosion; and - Plant species diversity is appropriate to riparian-wetland systems.	**STANDARD 2. RIPARIAN AND WETLAND SITES:** Riparian and wetland areas exhibit a properly functioning condition and achieve state water quality criteria. As indicated by: Stream side riparian areas are functioning properly when adequate vegetation, large woody debris, or rock is present to dissipate stream energy associated with high water flows. Elements indicating proper functioning condition such as avoiding accelerating erosion, capturing sediment, and providing for groundwater recharge and release are determined by the following measurements as appropriate to the site characteristics: Width/Depth ratio; Channel roughness; Sinuosity of stream	**STANDARD 2. ECOSYSTEM COMPONENTS:** Watersheds should possess the necessary ecological components to achieve state water quality criteria, maintain ecological processes, and sustain appropriate uses. Riparian and wetlands vegetation should have structural and species diversity characteristic of the stage of stream channel succession in order to provide forage and cover, capture sediment, and capture, retain, and safely release water (watershed function). **Upland Indicators:** - Canopy and ground cover, including litter, live vegetation, biological crust, and rock appropriate to the potential of the ecological site. - Ecological processes are adequate for the vegetative communities. **Riparian Indicators:**

	channel; Bank stability; Vegetative cover (amount, spacing, life form); and Other cover (large woody debris, rock). Natural springs, seeps, and marsh areas are functioning properly when adequate vegetation is present to facilitate water retention, filtering, and release as indicated by plant species and cover appropriate to the site characteristics.	- Stream side riparian areas are functioning properly when adequate vegetation, large woody debris, or rock is present to dissipate stream energy associated with high water flows. - Elements indicating proper functioning condition such as avoiding accelerating erosion, capturing sediment, and providing for groundwater recharge and release are determined by the following measurements as appropriate to the site characteristics: - Width/Depth ratio; - Channel roughness; - Sinuosity of stream channel; - Bank stability; - Vegetative cover (amount, spacing, life form); and - Other cover (large woody debris, rock). - Natural springs, seeps, and marsh areas are functioning properly when adequate vegetation is present to facilitate water retention, filtering, and release as indicated by plant species and cover appropriate to the site characteristics. The above indicators shall be applied to the potential of the ecological site.
GUIDELINES 3. Management practices within allotments will maintain or promote stream channel morphology, appropriate soil organisms; adequate amounts of ground cover to support infiltration, maintain soil moisture storage, and stabilize soils; and the hydrologic cycle, nutrient cycle and energy flow. 9. Salt and/or supplements will be placed at least ¼ mile from live waters (springs/streams) and outside of associated riparian areas, permanent livestock	**GUIDELINES** 2.1 Livestock grazing management and wild horse and burro population levels will maintain or promote sufficient vegetation cover, large woody debris, or rock to achieve proper functioning condition in riparian and wetland areas. Supporting the processes of energy dissipation, sediment capture, groundwater recharge, and stream bank stability will thus promote stream channel morphology (e.g., width/depth ratio, channel roughness, and sinuosity) appropriate to climate, landform,	**GUIDELINES:** 2.1 Management practices should maintain or promote appropriate stream channel morphology and structure consistent with the watershed. 2.2 Watershed management practices should maintain, restore or enhance water quality and flow rate to support desired ecological conditions. 2.3 Management practices should maintain or promote the physical and biological conditions necessary for achieving surface characteristics and

watering facilities, wet or dry meadows, and aspen stands. Also salt should not be placed in known historic properties. 10. Night bedding of sheep will be located at least ¼ mile from live waters, streams, springs, seeps, associated riparian areas, wet or dry meadows, and aspen stands. 16. The development of springs and seeps or other projects affecting water and associated resources shall be designed to maintain the associated riparian area and assure the attainment of Standards. 19. Riparian structural developments (i.e., gabions, dams, etc.) designed to achieve improvement in riparian and wetland conditions shall only be implemented in conjunction with changes in existing grazing management practices, where grazing is a significant factor contributing to a riparian condition needing such attention. Where grazing is not a significant factor causing a riparian condition needing attention, structural developments designed to achieve improvement in riparian and wetland conditions may be implemented independent of changes in existing grazing management practices.	gradient, and erosional history. 2.2 Where livestock grazing management and wild horse and burro herd management are not likely to restore riparian and wetland sites, land management treatments should be designed and implemented where appropriate to the site. 2.3 Livestock grazing management and wild horse and burro herd management will maintain, restore or enhance water quality and ensure the attainment of water quality that meets or exceeds state standards. 2.4 Livestock grazing management and wild horse and burro herd management are adequate when significant progress is being made toward this standard. See Appendix c(a) for additional guidelines for vegetation management	desired natural plant community. 2.4 Grazing management practices will consider both economic and physical environment, and will address all multiple uses including, but not limited to, (i) recreation, (ii) minerals, (iii) cultural resources and values, and (iv) designated wilderness and wilderness study areas. 2.5 New livestock facilities will be located away from riparian and wetland areas if they conflict with achieving or maintaining riparian and wetland functions. Existing facilities will be used in a way that does not conflict with achieving or maintaining riparian and wetland functions, or they will be relocated or modified when necessary to mitigate adverse impacts on riparian and wetland functions. The location, relocation, design and use of livestock facilities will consider economic feasibility and benefits to be gained for management of lands outside the riparian area along with the effects on riparian functions. 2.6 Subject to all valid existing rights, the design of spring and seep developments shall include provisions to protect ecological functions and processes. 2.7 When proper grazing practices alone are not likely to restore areas of low infiltration or permeability, land management practices may be designed and implemented where appropriate. Grazing on designated ephemeral rangeland watersheds should be allowed only if (i) reliable estimates of production have been made, (ii) an identified level of annual growth or residue to remain on site at the end of the grazing season has been established, and (iii) adverse effects on perennial species

		and ecosystem processes are avoided. 2.8 Rangeland management practices should address improvement beyond these standards, significant progress toward achieving standards, time necessary for recovery, and time necessary for predicting trends.
STANDARD 4. PLANT AND ANIMAL HABITAT: Populations and communities of native plant species and habitats for native animal species are healthy, productive and diverse. As indicated by: - Good representation of life forms and numbers of species; - Good diversity of height, size, and distribution of plants; - Number of wood stalks, seed stalks, and seed production adequate for stand maintenance; and - Vegetative mosaic, vegetative corridors for wildlife, and minimal habitat fragmentation. **STANDARD 5. SPECIAL STATUS SPECIES HABITAT:** Habitat conditions meet the life cycle requirements of special status species. As indicated by: - Habitat areas are large enough to support viable populations of special status species; - Special status plant and animal numbers and ages appear to ensure stable populations; - Good diversity of height, size,	**STANDARD 3. HABITAT:** Habitats exhibit a healthy, productive, and diverse population of native and/or desirable plant species, appropriate to the site characteristics, to provide suitable feed, water, cover and living space for animal species and maintain ecological processes. Habitat conditions meet the life cycle requirements of threatened and endangered species. As indicated by: Vegetation composition (relative abundance of species); Vegetation structure (life forms, cover, heights, or age classes) Vegetation distribution (patchiness, corridors); Vegetation productivity; Vegetation nutritional value.	**STANDARD 3. HABITAT AND BIOTA:** Habitats and watersheds should sustain a level of biodiversity appropriate for the area and conducive to appropriate uses. Habitats of special status species should be able to sustain viable populations of those species. Habitat Indicators: - Vegetation composition (relative abundance of species); - Vegetation structure (life forms, cover, height, and age classes); - Vegetation distribution (patchiness, corridors); - Vegetation productivity; and - Vegetation nutritional value. **Wildlife Indicators:** - Escape terrain; - Relative abundance; - Composition; - Distribution; - Nutritional value; and - Edge-patch snags. The above indicators shall be applied to the potential of the ecological site.

and distribution of plants; - Number of wood stalks, seed stalks, and seed production adequate for stand maintenance; and - Vegetative mosaic, vegetative corridors for wildlife, and minimal habitat fragmentation.		
GUIDELINES 4. After a range fire or other natural catastrophic event, vegetation should be returned to the native species as rapidly as possible, to **afford forage and habitat for native animals**. If a nurse crop is needed to protect the land from erosion, all native nurse crops should be used first. 8. Conservation of Federal threatened or endangered, proposed, species of concern (formally Category One and Two) and other special status species is promoted by the restoration and maintenance of their habitats. 14. Recognizing State Water Law requirements, wildlife and wild horses/burros within their Herd Management Areas will have access to surface water they customarily use. 15. Design of water facilities will incorporate features to ensure safe access and escape for small animals and birds. 17. Grazing management practices shall be planned and implemented to allow for habitat requirements of wildlife and wild horses and burros within Herd Management Areas. 21. Implement grazing management practices that sustain	**GUIDELINES** 3.1 Livestock grazing management and wild horse and burro population levels will promote the conservation, restoration and maintenance of habitat for threatened and endangered species, and other special status species as may be appropriate. 3.2 Livestock grazing intensity, frequency, season of use and distribution and wild horse and burro population levels should provide for growth and reproduction of those plant species needed to reach long-term land use plan objectives. Measurements of ecological condition and trend/utilization will be in accordance with techniques identified in the Nevada Rangeland Monitoring Handbook. 3.3 Livestock grazing management and wild horse and burro management should be planned and implemented to allow for integrated use by domestic livestock, wildlife, and wild horses and burros consistent with land use plan objectives. 3.4 Where livestock grazing management and wild horse and burro herd management alone are not likely to achieve habitat objectives, land treatments may	**GUIDELINES** 3.1 Mosaics of plant and animal communities that foster diverse and productive ecosystems should be maintained or achieved. 3.2 Management practices should emphasize native species except when others would serve better for attaining desired communities. 3.3 Intensity, frequency, season of use and distribution of grazing use should provide for growth, reproduction, and when environmental conditions permit, seedling establishment of those plant species needed to reach long-term land use plan objectives. Measurements of ecological condition, trend, and utilization will be in accordance with techniques identified in the Nevada Rangeland Handbook. 3.4 Grazing management practices should be planned and implemented to provide for integrated use by domestic livestock and wildlife, as well as wild horses and burros inside Herd Management Areas (HMAs). 3.5 Management practices will promote the conservation, restoration and maintenance of habitat for special status species. 3.6 Livestock grazing practices will be designed to protect fragile ecosystems of limited distribution and size that support unique

biological diversity across the landscape. 22. To prevent transmission of disease between domestic and bighorn sheep, adopt and implement the "Guidelines for Domestic Sheep Management in Bighorn Sheep Habitats" contained in Mountain Sheep Ecosystem Management Strategy in the 11 Western States and Alaska.	be designed and implemented as appropriate. 3.5 When native plant species adapted to the site are available in sufficient quantities, and it is economically and biologically feasible to establish or increase them to meet management objectives, they will be emphasized over non-native species. 3.6 Livestock grazing management and wild horse and burro herd management are adequate when significant progress is being made toward this Standard. See Appendix C (a) for additional guidelines for vegetation management.	sensitive/endemic species or communities. Where these practices are not successful, grazing will be excluded from these areas. 3.7 Where grazing practices alone are not likely to achieve habitat objectives, land management practices may be designed and implemented as appropriate. 3.8 Vegetation manipulation treatments may be implemented to improve native plant communities, consistent with appropriate land use plans, in areas where identified standards cannot be achieved through proper grazing management practices alone. Fire is the preferred vegetation manipulation practice on B. (1) The combined aerial parts of plants and cannot be achieved through proper grazing management practices alone. Fire is the preferred vegetation manipulation practice on areas historically adapted to fire; treatment of native vegetation with herbicides or through mechanical means will be used only when other management techniques are not effective. 3.9 Rangeland management practices should address improvement beyond this standard, significant progress toward achieving standards, time necessary for recovery, and time necessary for predicting trends.
STANDARD 3. WATER QUALITY: Water quality criteria in Nevada or California State Law shall be achieved or maintained. As indicated by:	**ORIGINALLY IN STANDARD 2 ABOVE:** Chemical, physical and biological water constituents are not exceeding the state water quality standards	**ORIGINALLY IN STANDARD 2 ABOVE:** **Water Quality Indicators:** - Chemical, physical and biological constituents do not exceed the state water quality standards. The above indicators shall be applied

- Chemical constituents do not exceed the water quality Standards; - Physical constituents do not exceed the water quality Standards; - Biological constituents do not exceed the water quality Standards; and - The water quality of all water bodies, including ground water located on or influenced by BLM lands will meet or exceed the applicable Nevada or California water quality Standards. Water quality Standards for surface and ground waters include the designated beneficial uses, numeric criteria, narrative criteria, and antidegradation requirements set forth under State law, and as found in Section 303(c) of the Clean Water Act. **GUIDELINES** 1. Waters must be free from high temperature, biocides, organisms pathogenic to human beings, toxic, corrosive or other deleterious substances attributable to domestic or industrial waste or other controllable sources at levels or combinations to interfere with any beneficial use of the water. Compliance with the provisions of this subsection may be determined in accordance with methods of testing prescribed by the State. If used as an Indicator, survival of test organisms must not be significantly less in test water than in control water. 2. Grazing management practices should be planned and		to the potential of the ecological site.

implemented to meet water quality provisions in either California State water law or Nevada Administrative Code Section 445A.120-121 as applicable.		
NO SIMILAR STANDARD **GUIDELINE** 23. Rangeland management plans will consider listings of known historic properties and new eligible properties as they become known.	**STANDARD 4. CULTURAL RESOURCES**: Land use plans will recognize cultural resources within the context of multiple use. **GUIDELINES:** 4.1 Rangeland management plans will consider listings of known sites that are National Historic Register eligible or considered to be of cultural significance and new eligible sites as they become known. 4.2 Wild horse and burro herd management will be designed to avoid or mitigate damage to significant cultural resources	**NO SIMILAR STANDARD**
NO SIMILAR STANDARD	**STANDARD 5. HEALTHY WILD HORSE AND BURRO POPULATIONS**: Wild horses and burros exhibit characteristics of a healthy, productive, and diverse population. Age structure and sex ratios are appropriate to maintain the long term viability of the population as a distinct group. Herd management areas are able to provide suitable feed, water, cover and living space for wild horses and burros and maintain historic patterns of habitat use. As indicated by:	**NO SIMILAR STANDARD**

	Healthy rangelands that provide sufficient quantities and quality of forage and water to sustain the appropriate management level on a year long basis within a herd management area. Wild horses and/or burros managed on a year-long basis for a condition class greater than or equal to five to allow them normal chances for survival in the winter (See glossary for equine body conditioning definitions). Highly adoptable wild horses and burros that are readily available from herd management areas. Wild horse and burro herds that exhibit appropriate age structure and sex ratio for short and long term genetic and reproductive health **GUIDELINES:** 5.1 Implement the objectives outlined in the Wild Free-Roaming Horses and Burros Tactical Plan for Nevada (May 1999). 5.2 Manage for wild horses and/or burros in herd management areas based on the capability of the HMA to provide suitable feed, water, cover and living space for all multiple uses. 5.3 Set appropriate Management Levels based on the most limiting habitat factor (eg. available water, suitable forage, living space and cover) in the context of multiple use. 5.4 Manage herd management area populations to preserve and enhance physical and biological characteristics that are of	

	historical significance to the herd. 5.5 Manage wild horse and burro herds for short and long term increases and to enhance adoptability by ensuring that wild horses and burros displaying desirable traits are preserved in the herd thus providing a reproductive base to increase highly adoptable horses and burros for future demands. 5.6 Identify and preserve historic traits and characteristics within the herd which have proven to be highly desirable by the adoption public to increase the long term availability of animals bearing these features. 5.7 Wild horse and burro selective removal criteria are modified on a per herd basis to correct deficiencies in population age and sex ratios which threaten short and long term genetic diversity and reproductive health.	

NE NEVADA APPENDIX

Other RACs do not have this!

VEGETATION GUIDELINES

The Nevada Northeastern Great Basin Resource Advisory Council (RAC), as chartered by the Department of the Interior, has developed Guidelines for Vegetation Management on about 16.2 million acres of public lands administered by the Bureau of Land Management within the designated geographic area of the Northeastern Great Basin within the State of Nevada.

These Vegetation Management Guidelines are intended to serve as a supplement to the Standards and Guidelines for Rangeland Health which were adopted in 1997 and later expanded to include Wild Horse and Burro Standards and Guidelines in 2000. These recommended Standards and Guidelines reflect the stated goal of improving rangeland health in the Northeastern Great Basin.

NON-INDIGENOUS ANNUAL GRASSLANDS
DEFINITIONS:

Cheatgrass/Annual Grass Monoculture: Areas dominated by cheatgrass or other non-indigenous annual grass species that have crossed a threshold and lost the ability to recover naturally due to lack of perennial species.

Cheatgrass/Annual Grass Dominant: Recently burned areas having native perennial species present with potential for natural recovery with appropriate management of non-indigenous annual grasses.

Cheatgrass/Annual Grass Infested: Shrub dominated communities with a limited understory of native perennial species, but a significant amount of annual grasses, exhibiting a high potential to be converted to non-indigenous annual grass dominated ranges.

Desired Conditions: Communities will exhibit or be progressing toward a healthy, productive, diverse population of native and or desirable plant species, and functioning disturbance processes appropriate to the site characteristics.

Guidelines Common to All:

1) Encourage research and field trials in all non-indigenous annual grass ranges to determine effectiveness of control on recovery and rehabilitation efforts in perennial plant communities.
2) Non-indigenous annual grass monoculture and dominated ranges must follow a successional process from annual/perennial grass mix to a shrub/grass community. Large scale seeding of shrubs should be discouraged, and small scale (islands), of intensively managed shrub seedings/transplants encouraged.

Guidelines for Cheatgrass/Annual Monoculture:

1) Break up the monoculture through the use of chemical, biological, and/or mechanical means to stop the spread of the effected area especially in areas that border critical habitat. Use native and non-native desirable species known to be fire tolerant and resistant during the late summer fire season.
2) Use the best available information to determine the most effective processes to break up the monoculture, reduce the cheatgrass seed bank, and restore native plant communities.

Guidelines for Cheatgrass Dominant and Cheatgrass infested ranges:

1) Encourage innovative approaches to control cheatgrass, such as, strategically controlled grazing and the use of prescribed fire to favor production of perennial species.
2) Seed areas with perennial grass species to reduce the dominance of cheatgrass.

Strategies:

1) Management practices to maintain healthy ecological sites should include: prescribed fire, prescribed natural fire, mechanical manipulations, specialized prescription herbivory, chemical treatments, re-seeding, or combinations of treatments.

2) Special emphasis must be placed on management activities where public safety at wildland-urban interfaces is jeopardized.

SALT DESERT SHRUBLANDS

DEFINITION: Plant communities dominated by members of the Chenopodiaceae family including: shadscale, four-wing saltbush, black and Bailey greasewoods, spiny hopsage, and white sage; with an understory including ricegrass, squirreltail, saltgrass, and other saline tolerant species.
Desired Conditions: Communities will exhibit or be progressing toward a healthy, productive, diverse population of native and or desirable plant species, and functioning disturbance processes appropriate to the site characteristics.

Guidelines:

1) Grazing should generally be limited to very early season or dormant season rather than year round. If very early season grazing is permitted or prescribed to control cheatgrass early in the spring, grazing should be terminated early enough to allow perennial plant species to set seed.
2) After disturbance such as fire, insect infestation, and periods of less than desirable grazing management, considers resting communities for an appropriate amount of time relative to moisture conditions.
3) All management and revegetation strategies must consider current site conditions and associated thresholds (i.e., current status in state-and-transition model appropriate for the site). In addition, factors such as ecological site, presence of undesirable species (e.g., invasive or noxious species), adjacent plant communities, current use or management status, and position in the watershed must be considered prior treatment application.
4) Encourage research and field trials in salt desert shrub communities to determine the best effective methods of restoration.

Strategies:

1) Management practices to maintain healthy ecological sites should include: prescribed fire, prescribed natural fire, mechanical manipulations, specialized prescription herbivory, chemical treatments, re-seeding, or combinations of treatments.
2) Special emphasis must be placed on management activities where public safety at wildland-urban interfaces is jeopardized.

SAGEBRUSH/BUNCHGRASS RANGELANDS

DEFINITIONS: Plant communities dominated by one or more members of the Artemisia genus including Wyoming big sagebrush, low sagebrush, basin sagebrush, black sagebrush, Lahontan sagebrush, and mountain sagebrush. Herbaceous understory is dominated by perennial grasses but includes a component of annual and perennial forbs. Other shrubs may also be present.
Desired Conditions: Communities will exhibit or be progressing toward a healthy, productive, diverse population of native and or desirable plant species, and functioning disturbance processes appropriate to the site characteristics.

Guidelines:

1) Create and maintain a diversity of sagebrush age and cover classes on the landscape through the use of prescribed fire, prescribed natural fire, mechanical, biological, and/or chemical means to provide a variety of habitats and productivity conditions.
2) Vegetation treatments should be of appropriate size to meet land management objectives. Where possible, inclusions of intact sagebrush should be left scattered within the treated area or in relatively close proximity to provide a seed source for recruitment. Distribution of residual plants will determine in part, the time period required for the successional process to proceed toward sagebrush recolonization.
3) All treatments must consider current site conditions and associated thresholds (i.e., current status in state-and-transition model appropriate for the site). In addition, factors such as ecological site, presence of undesirable species (e.g., invasive or noxious species), adjacent plant communities, current use or management status, and position in the watershed must be considered prior to treatment application.
4) Where initial condition has a depleted herbaceous understory, vegetation treatment should include seeding with desirable species suited or adapted to site conditions. Seeding methods and dates should be appropriate to the plant materials and site conditions.
5) Where a mosaic of age and cover classes already exists, maintain landscape diversity through fuels management and periodic disturbance. Recognize the system is dynamic, and suitability of the plant

community for any given specie or group of species will change over time. Maintenance of diverse habitat conditions will provide a continuous suite of seasonal habitats over time.
6) Where pinyon pine and/or juniper trees have encroached into sagebrush communities, use best management practices to remove trees and re-establish understory species.

Strategies:

1) Management practices to maintain healthy ecological sites should include: prescribed fire, prescribed natural fire, mechanical manipulations, specialized prescription herbivory, chemical treatments, re-seeding, or combinations of treatments.
2) Special emphasis must be placed on management activities where public safety at wildland-urban interfaces is jeopardized.

NOXIOUS WEEDS

DEFINITIONS:
Noxious weed monoculture: Areas that have lost the ability to recover naturally due to lack of native perennial species.
Noxious weed dominant: Areas having native perennial species present with potential for natural recovery if noxious weeds are controlled.
Noxious weed infested: Plant communities with a limited understory of perennial species and a high potential to be converted to noxious weed dominant.

Desired Conditions: Communities will exhibit or be progressing toward a healthy, productive, diverse population of native and or desirable plant species, and functioning disturbance processes appropriate to the site characteristics.

Guidelines Common to All:

1) Encourage research and field trials in all noxious weed rangelands to determine effectiveness of noxious weed control in the recovery process of restoring perennial plant communities.
2) Noxious weed monoculture and noxious weed dominant ranges must follow a successional process from grass/grass mix to a shrub community. Use best management practices to return site to best approximation of site potential.

Guidelines for Noxious Weed Monoculture:

1) Break up monoculture using an Integrated Weed Management approach that combines chemical, biological, and/or mechanical means to reduce spread of affected area, especially in areas that border critical habitat or other sensitive sites. Treatment regime should be based on ecology and phenology of the noxious species.
2) Use best available information to determine the most effective process to break up continuity and rehabilitate native plant communities, recognizing that beneficial, introduced species may provide excellent interim benefits.

Guidelines for Noxious Weed Dominant and Infested Rangelands:

1) Encourage practices to eliminate new noxious species entry and limit current infestations to existing levels.
2) Utilize an Integrated Weed Management approach, that consists of chemical, biological, and/or mechanical means to control noxious species.
3) Encourage innovative approaches to control noxious species, such as strategically controlled grazing and use of prescribed and prescribed natural fire to favor production of native perennial species.
4) Seed areas with perennial species to reduce dominance of noxious species.

PINYON-JUNIPER WOODLANDS

Definition: Plant communities dominated by one or both species of Utah juniper and/or single leaf pinyon pine. Pinyon pine generally dominates at higher and juniper at lower elevations. Herbaceous understory is dominated by perennial grasses but includes a component of annual and perennial forbs. Shrubs may also be present. In the past, woodlands were generally restricted to sites with very low fire frequency such as rocky ridges and steep slopes with little soil development.

Desired Conditions: Woodland communities will exhibit or be progressing toward a healthy, productive, diverse population of native and or desirable plant species, and functioning disturbance processes appropriate to the site characteristics. Healthy, sustainable pinyon and juniper woodlands will be maintained on appropriate soil types as identified by Natural Resource Conservation Service soil surveys within appropriate Major Land Resource Areas (MLRAs).

Guidelines:

1) Woodlands will exhibit a combination of successional stages based on differing pinyon and juniper species composition, age structure, and understory composition appropriate to site characteristics on a watershed, or portion of a watershed.

2) Woodlands will be separated from other ecological sites by an ecotone interface zone, rather than a well-defined edge. Woodlands should not encroach outside of soil sites correlated with woodland communities.

3) Woodland stand structure should not, under normal conditions support catastrophic, stand replacing fires. Community species composition and proportionalities should follow Natural Resource Conservation guidelines appropriate to the site.

4) All management and revegetation strategies must consider current site conditions and associated thresholds (i.e., current status in state-and-transition model appropriate for the site). In addition, factors such as ecological site, presence of undesirable species (e.g., invasive or noxious species), adjacent plant communities, current use or management status, and position in the watershed must be considered prior treatment application.

Strategies:

1) Management practices to maintain healthy woodlands should include: prescribed fire, prescribed natural fire, mechanical manipulations, specialized prescription herbivory, chemical treatments, or combinations of treatments.

2) Special emphasis must be placed on management activities where public safety at wildland-urban interfaces is jeopardized.

REHABILITATION AND REVEGETATION STRATEGIES

Re-vegetation includes natural recovery as well as direct management actions.

General Guidelines for Rehabilitation and Revegetation:

1) On burned areas, allow natural regeneration when it is determined that populations of native perennial grasses, forbs, and shrubs are sufficient to re-vegetate the site.

2) Where appropriate, rest rehabilitated and naturally regenerating areas to allow recovery and establishment of perennial plant species based upon objectives and ecological site potential.

3) Determine to what extent re-vegetation success may be site specific and may depend on soil moisture, rainfall, elevation, soil type, slope, aspect, previous vegetative community (ie. native vegetation or cheatgrass prior to a fire), type of seeding, aerial vs. drill seeding etc., seed mixtures, and post seeding management.

4) Use native plant species for rehabilitation except where native species are not available in sufficient quantities; native plant species cannot maintain or achieve the standard; or non-native plant species provide for enhanced protection of native habitats or soil resources.

5) To the extent possible, obtain seeds that are: 1) source identified; or commercial varieties; and meet agency standards.

Note: In emergency situations and with agency approval, seeds may be obtained with lower standards to meet rehabilitation requirements.

6) Establish protocols for pre- and post rehabilitation/restoration monitoring to assist in future evaluation methods. Assemble a team to evaluate multi-district historical data on restoration/rehabilitation projects.

Strategies:

1) On burned areas greater than 1,000 acres, limit sagebrush seeding to no more than 10-20% of the burned area, distributed over no less than 5 locations within the burned area.
2) Enhance sagebrush and other shrub species germination and establishment by utilizing available and appropriate water conservation strategies (e.g., snow fence, surface imprinting, and mulching.
3) On older, large burned areas where previous sagebrush establishment efforts were unsuccessful, interseed sagebrush on areas where perennial grasses have established. Limit seeding to no more than 20% of the area, distributed over no less than 5 locations within the area.
4) Rehabilitation of perennial, introduced grass seedings (e.g., crested wheatgrass) should include grazing treatments at appropriate levels to reduce abundance and competition potential. Reductions can be followed by interseeding with sagebrush as well as native grasses and forbs. Encourage early season grazing and removal to promote seed production and increase native species.
5) Rehabilitation of decadent sagebrush communities should be promoted by using appropriate tools to reduce sagebrush, followed by direct seeding operations. Scale should be appropriate to management objectives.
6) Rehabilitation of pinyon-juniper encroached sagebrush communities should be promoted using appropriate tools to reduce trees, followed by direct seeding operations. Scale should be appropriate to management objectives.

MINED-LAND REVEGETATION GUIDELINES FOR THE NEVADA DIVISION OF ENVIRONMENTAL PROTECTION, THE BUREAU OF LAND MANAGEMENT AND THE U.S.D.A. FOREST SERVICE

Reclaimed Desired Plant Communities for Mining Operation Disturbances

Reclamation goals for mining disturbances are 1) stabilize the site, and 2) establish a productive community based on the applicable land use plan and designated post-mining land uses. To meet these goals, a Reclaimed Desired Plant Community (RDPC) should be selected for use on the disturbed mine sites. A RDPC is defined as: A perennial plant community established on a disturbed site which contributes to stability through management and land treatment, and which produces that type and amount of vegetation necessary to meet or exceed both the land use and activity plan objective established for the site.

Several RDPCs may be selected based on site-specific revegetation goals and variable site characteristics for the mining disturbances. When selecting RDPCs, major alterations in reconstructed soils and the subsequent effect of this on the site's capability to establish and sustain the desired vegetation must be considered. A RDPC must have a reasonable chance for success when making the selection.

The plant community for the RDPC should be diverse, and when appropriate for the site should include grasses, forbs, shrubs and/or trees. The RDPC shall be comprised of species native to the area, or introduced species where the need is documented for inclusion to achieve the approved post-mining land use. The RDPC must meet the requirements of applicable State and Federal seed, poisonous and noxious plants, and introduced species laws or regulations. All RDPCs must be approved by the agencies. Plants for RDPCs may be selected using one or more of the following methods:

1. Select existing vegetation types around the mine site to represent the varied RDPCs.
2. Use test plots, demonstration areas, or areas concurrently reclaimed within the mine site or within similar representative areas from adjacent mines to serve as the RDPCs as long as they meet the reclamation goal.
3. For areas where existing vegetative types adjacent to the mine area are severely disturbed or where test plots or demonstration areas are not reasonable alternatives, RDPCs may be selected using appropriate ecological or range site descriptions or other technical sources.

Guidelines for Successful Revegetation

The revegetation release criteria for reclaimed mine sites will be to achieve as close to 100 percent of the perennial plant cover of selected comparison areas as possible. The comparison or reference areas will be selected from representative plant communities adjacent to the mine site, test plots or demonstration areas or, as appropriate, representative ecological or range site descriptions. As approved by the agencies, the selected plant communities or reference areas must have a reasonable chance for success on the mine site. Each plan-of-operations shall identify the site-specific release criteria in the reclamation plan or permit. The agencies may also require specific release standards for individual plant species or vegetative types (grasses, forbs, shrubs, trees). Cover would be estimated using a method as described in Sampling

Vegetation Attributes, Interagency Technical Reference, 1996, BLM/RS/ST-96/002+1730 or other acceptable technical methods.

Good Friday Afternoon to Joan, Joe, Quincy and Brent!!

I wanted to share with you our Attachment A from the Federal Family Meeting notes. This Attachment summarizes the action items that we need to follow up on from our meeting. The notes, themselves, are not ready to be distributed as Sarah is still reviewing and commenting on the 29 pages of them….they should be ready in a week or two.

Please do not distribute Attachment A any further than your desks at this point. They may change or be modified as a result of the Rocky Mountain Meeting next week….but I wanted you all to think about what we have left to do on this list. The Solicitors and the WO have many of the tasks to follow up on.

Quincy…..your name comes up a lot as well!!

I am not sure if we are going to distribute this list at the Rocky Mtn. FFM, or just use it as points of discussion….haven't heard yet.

I won't be on the PL Tuesday call for the next two weeks – and neither will David. I am sure he will have someone else from EMPSi open up the meetings and take notes – so plan on having the calls. Next week we will be in Denver at the Rocky Mtn. FFM, and the next week in Washington to do a roll-up of the roll-up meetings. I think that is where the rubber is going to meet the road.

If anything REALLY interesting comes up…..I will send you all out an e-mail and let you know.

Carry on with all the great things you are accomplishing. Have a great week-end!

Lauren

I added our current verbiage to the table in red for a quick comparison. The only one I am opposed to is the conifer encroachment and I think we need to discuss the 12 inch precip. with the fire folks-IF we have an option not to adopt the language.

Joe-thoughts?

Attachment A-GRSG GBR Fed Family Mtg PDX_2014_08_19-21_Reviewed_Distribute_ADK.docx
80K

ATTACHMENT A:
GREATER SAGE-GROUSE GREAT BASIN FEDERAL FAMILY MEETING - SUMMARY OF OUTCOMES AND ACTION ITEMS

Applicable Sub-regions?	Topic or Resource Program	Outcome and Action	Who?	NV/CA
All	Land Tenure / Retention	The following land retention policy text should be included into the ADPP for land retention and related management actions should be adjusted as appropriate: "Lands classified as priority habitat and general habitat (or habitat classification appropriate for the sub-region) for Greater Sage-Grouse will be retained in federal management unless: (1) the agency can demonstrate that disposal of the lands will provide a net conservation benefit to the Greater Sage-Grouse or (2) the agency can demonstrate that the disposal of the lands will have no direct or indirect adverse impact on conservation of the Greater Sage-Grouse."	PMs to incorporate as written into ADPP	Action G-LR-LT 1: Retain public ownership of PPMA and PGMA in compliance with existing acts regarding land disposal. Consider exceptions when: -Disposal and acquisitions of public lands would allow for more contiguous federal ownership patterns within GRSG habitat, or where a land tenure adjustment would result in a net gain in amount or quality of GRSG habitat.
All	Vegetation Management/ Prescribed Fire	Incorporate the following language regarding when fire would be used as a vegetation treatment tool for areas with <12” precip. • Avoid using prescribed fire in Greater Sage-Grouse habitat unless evaluation of site-specific conditions demonstrate that there would be a net benefit for sage-grouse. If prescribed fire is used in Greater Sage-Grouse habitat, include an analysis in the NEPA document that indicates how Greater Sage-Grouse goals and objectives will be addressed and met by its use, why alternative techniques were not selected, and a risk assessment to address how potential threats to Greater Sage-Grouse habitat would be minimized. • If prescribed fire is to be used at the implementation level,	Lauren to consolidate language PMs to incorporate	**We do not mention < 12 inch precip. zones** Action G-WFM-HFM 5: If prescribed fire is to be used at the implementation level, at a minimum, the burn plan will indicate how Conservation Objective Team objectives would be addressed and met and why alternative techniques were not selected. Action G-WFM-HFM 6: Prior to using prescribed fire, conduct a fire risk assessment to ensure that

ATTACHMENT A:
GREATER SAGE-GROUSE GREAT BASIN FEDERAL FAMILY MEETING - SUMMARY OF OUTCOMES AND ACTION ITEMS

Applicable Sub-regions?	Topic or Resource Program	Outcome and Action	Who?	NV/CA
		at a minimum, the burn plan will indicate how Conservation Objective Team/land use plan objectives would be addressed and met and why alternative techniques were not selected. • Avoid prescribed fire as a vegetation or fuels treatment in Wyoming big sagebrush or other xeric sagebrush species, or in areas with a potential for post-fire exotic annual dominance. However, after other treatment opportunities have been explored and as site-specific variables allow, prescribed fire could be used in these areas to meet specific fuels objectives that would maintain, improve, or restore Greater Sage-Grouse habitat in PPMAs (e.g., creation of fuel breaks that would disrupt the fuel continuity across the landscape in stands where annual invasive grasses are a minor component in the understory, burning slash piles from conifer reduction treatments, used as a component with other treatment methods to combat annual grasses and restore native plant communities). • Allow no treatments in known winter range unless the treatments are designed to strategically reduce wildfire risk around and/or in the winter range and would protect, maintain, increase, or enhance winter range habitat quality.	into ADPP	GRSG goals and objectives are met.
All	Disturbance	All ADPPs should refer to the "disturbance cap" instead of disturbance threshold.	PMs to incorporate into ADPPs	ADPP

ATTACHMENT A:
GREATER SAGE-GROUSE GREAT BASIN FEDERAL FAMILY MEETING - SUMMARY OF OUTCOMES AND ACTION ITEMS

Applicable Sub-regions?	Topic or Resource Program	Outcome and Action	Who?	NV/CA
All	Conifers/Veg Management?	Incorporate the following common goal for conifer removal: "Remove conifers encroaching into sagebrush habitats. Prioritize treatments closest to occupied sage-grouse habitats and near occupied leks, and where juniper encroachment is phase 1 or phase 2. Use of site-specific analysis and tools like VDTT and the FIAT report will help refine the location for specific priority areas to be treated."	PMs to incorporate as written into ADPPs	**This should reflect Table 2-6 as well. I'd prefer to leave it as currently written and not change language.** Action G-VEG-WD 2: Where pinyon and/or juniper trees are encroaching in sagebrush plant communities, design treatments in PPMA and PGMA to focus on enhancing, reestablishing, or maintaining habitat components (e.g., cover, security, and food) in order to achieve GRSG habitat objectives identified in Table 2-6. Focus treatment design on addressing the most limiting habitat component and to decrease conifer encroachment, and increase cover of sagebrush and understory to improve habitat for GRSG and minimize avian predator perches and predation opportunities on GRSG. Action G-VEG-WD 3: On public lands, manage pinyon and/or juniper stands in encroached sagebrush vegetation communities to meet GRSG habitat objectives (Table 2-6). Prioritize Phase I and early Phase II pinyon and/or juniper stands in areas with a sagebrush component and select treatment methods that maintain sagebrush and shrub cover and composition. Only treat habitats in late Phase II or Phase III condition to create movement corridors, connect habitats, or reduce the

				potential for catastrophic fire. RDF G-VEG-WD 1: Prioritize removal of Phase I and early Phase II standing and encroaching trees within: 3.2 miles (5 kilometers) of leks Out of line of site within 1.86 miles (3 kilometers) of leks
All	Fire	Ensure ADPPs discuss the current authority for temporary closures as a travel management tool to reduce fire ignition risk. "In PPMA and PGMA, temporary closures will be considered in accordance with 43 CFR subpart 8364 (Closures and Restrictions); 43 CFR subpart 8351 (Designated National Area); 43 CFR subpart 6302 (Use of Wilderness Areas, Prohibited Acts, and Penalties); 43 CFR subpart 8341 (Conditions of Use). Temporary closure or restriction orders under these authorities are enacted at the discretion of the authorized officer to resolve management conflicts and protect persons, property, and public lands and resources. Where an authorized officer determines that off-highway vehicles are causing or will cause considerable adverse effects upon soil, vegetation, wildlife, wildlife habitat, cultural resources, historical resources, threatened or endangered species, wilderness suitability, other authorized uses, or other resources, the affected areas shall be immediately closed to the type(s) of vehicle causing the adverse	PMs to verify this is discussed in Chapter 2.	ADPP **Exact verbiage already included**

ATTACHMENT A:
GREATER SAGE-GROUSE GREAT BASIN FEDERAL FAMILY MEETING - SUMMARY OF OUTCOMES AND ACTION ITEMS

Applicable Sub-regions?	Topic or Resource Program	Outcome and Action	Who?	NV/CA
		effect until the adverse effects are eliminated and measures implemented to prevent recurrence. (43 CFR 8341.2) A closure or restriction order should be considered only after other management strategies and alternatives have been explored. The duration of temporary closure or restriction orders should be limited to 24 months or less; however, certain situations may require longer closures and/or iterative temporary closures. This may include closure of routes or areas."		
All	Fluid Minerals	Exemptions related to fluid minerals - All ADPPs will consider NPT Guidance	PMS	ADPP
All	Consistency	Mitigation team will review buffer sizes between ADPPs to validate the science and provide recommendations for consistent buffers.	Frank/Science Team (USGS)	9/8/14
All	Consistency	Disturbance and Monitoring Sub-team to continue work on disturbance framework striving for a simple formula.	Frank / Vicki / Gordon	9/8/14
All	Consistency	Develop a template for priority management/habitat to PAC crosswalk. This would include a map showing an overlay of priority habitat/management and general habitat/management with the PACs.	Kathy and Matt	9/22/14
All	Clarity	Define loose language (e.g., "if technically and economic feasible…" what is technical feasibility?)	Ed	

ATTACHMENT A:
GREATER SAGE-GROUSE GREAT BASIN FEDERAL FAMILY MEETING - SUMMARY OF OUTCOMES AND ACTION ITEMS

Applicable Sub-regions?	Topic or Resource Program	Outcome and Action	Who?	NV/CA
All	Consistency	Grazing management and monitoring is not consistent across plans. • Review rangeland health science (e.g. Connelly vs. Coates). Is it appropriate to cite this current science or reference best available science to allow for flexibility to adjust as we learn more? • Ensure grazing programs have an objective statement about maintaining or improving sagebrush habitat in order to provide an intent for standards and monitoring.	SOL	ASAP
All	Fluids? RDFs? Energy Development?	Develop a table summarizing existing conditions for development and for RFDs for Great Basin by population.	Matt, Frank, BLM PMs	9/8/14
All	Fluid minerals	Consider incorporating the language from the Lander plan that addresses the approach of prioritizing fluid mineral development outside PACs.	Matt to provide language to SOL for review. PMs incorporate	ADPP

ATTACHMENT A:
GREATER SAGE-GROUSE GREAT BASIN FEDERAL FAMILY MEETING - SUMMARY OF OUTCOMES AND ACTION ITEMS

Applicable Sub-regions?	Topic or Resource Program	Outcome and Action	Who?	NV/CA
			into ADPPs.	
Oregon	ROW and mining	Review general habitat for infrastructure and mining management direction in population #31	Jerry and Joan	8/21/14
All	Habitat maps	BLM State offices should work with USFWS, the Solicitor's Office, and internally when/if they get new maps from their respective State counterparts that identify new or redefined boundaries for GRSG habitat.	BLM State Offices (PMs?) and SOL	On-going
Utah	Restoration	ADPP should include the following language regarding restoration: "Restoration needs to occur in areas where birds are able and likely to re-settle or the ratio of restoration must necessarily increase. One option could be restoration of habitat adjacent to existing populations."	Quincy add to ADPP	ADPP
Utah	ROWs / Corridors	Coordinate with USFWS, the Solicitor's Office, and internally regarding designation of new energy corridors.	Quincy and SOL	ADPP
Utah	Habitat maps	State of Utah has identified new areas that they are labeling as PACs. These new areas were not identified in the DEIS as non-habitat. Need to determine whether BLM can include these areas of non-habitat within newly identified Utah PACs into priority management (red areas on map within PACs).	SOL	ASAP

GREATER SAGE-GROUSE GREAT BASIN FEDERAL FAMILY MEETING - SUMMARY OF OUTCOMES AND ACTION ITEMS

Applicable Sub-regions?	Topic or Resource Program	Outcome and Action	Who?	When?
All	Land Tenure / Retention	The following land retention policy text should be included into the ADPP for land retention and related management actions should be adjusted as appropriate: "Lands classified as priority habitat and general habitat (or habitat classification appropriate for the sub-region) for Greater Sage-Grouse will be retained in federal management unless: (1) the agency can demonstrate that disposal of the lands will provide a net conservation benefit to the Greater Sage-Grouse or (2) the agency can demonstrate that the disposal of the lands will have no direct or indirect adverse impact on conservation of the Greater Sage-Grouse."	PMs to incorporate as written into ADPP	ADPP
All	Vegetation Management/ Prescribed Fire	Incorporate the following language regarding when fire would be used as a vegetation treatment tool for areas with <12" precip. • Avoid using prescribed fire in Greater Sage-Grouse habitat unless evaluation of site-specific conditions demonstrate that there would be a net benefit for sage-grouse. If prescribed fire is used in Greater Sage-Grouse habitat, include an analysis in the NEPA document that indicates how Greater Sage-Grouse goals and objectives will be addressed and met by its use, why alternative techniques were not selected, and a risk assessment to address how potential threats to Greater Sage-Grouse habitat would be minimized. • If prescribed fire is to be used at the implementation level, at a minimum, the burn plan will indicate how Conservation Objective Team/land use plan objectives would be addressed and met and why alternative techniques were not selected. • Avoid prescribed fire as a vegetation or fuels treatment in Wyoming big sagebrush or other xeric sagebrush species, or in areas with a potential for post-fire exotic annual dominance. However, after other treatment opportunities have been explored and as site-specific variables allow, prescribed fire could be used in these areas to meet specific fuels objectives that would maintain, improve, or restore Greater Sage-Grouse habitat in	Lauren to consolidate language PMs to incorporate into ADPP	ADPP

Tague, Melvin (Joe) <jtague@blm.gov>

"Old Growth" Pinyon/Juniper Language

4 messages

Quincy Bahr <qfbahr@blm.gov> Mon, Jul 21, 2014 at 10:25 AM
To: Melvin Tague <jtague@blm.gov>, Brent Ralston <bralston@blm.gov>, Joan Suther <jsuther@blm.gov>

All,

With all the focus on p/j encroachment, the Utah FWS has asked that we include a management action that limits reduction of "old growth" p/j. Then they asked us to provide a definition of such. The FS in Utah has included something general, like removing persistent stands of trees over 100 years old should be avoided, but my IDT really isn't warm to that kind of language. At this point, we've worded our management action to focus on removing "encroaching" p/j to restore sagebrush habitat, going with the concept that so-called "stable stands" of p/j that are ecologically in an area not conducive to sagebrush won't fit that management approach, dodging the "retain" p/j concept altogether.

Do any of you have other language limiting p/j treatment in p/j ecological areas that you'd be willing to share?

Quincy Bahr

Quincy,

Here is our management action and language for old growth. I've also attached an email with the reference.

VEG-8: Utilize conifer (juniper) removal treatments to reduce the extent of conifer encroachment areas. Refrain from using prescribed fire and conducting removal projects in old-growth juniper stands. Old-growth juniper trees are characterized by rounded tops and spreading canopies, often containing dead limbs and/or spike tops, large branches near the base of the tree, as well as furrowed, fibrous bark, and are typically host to arboreal lichens. Leader growth in the upper quarter of the tree is usually less than one inch. These trees are generally distributed on rock outcrop or rubble land soils, or other soils with coarse fragments in the soil-surface and/or slopes over 12-25%, where juniper vegetation type is the climax plant community (IDFG 2000; Miller et al 2005; USDI and USGS 2007).

All,

We did not mention "old growth" P/J in or Proposed Plan. We have the following action:

Action G-VEG-WD 3: On public lands, Manage pinyon- and/or juniper stands in encroached sagebrush vegetation communities to meet GRSG habitat objectives (Table 2-6). Prioritize Phase I and early Phase II pinyon and/or juniper stands condition in areas with a sagebrush component and select treatment methods that maintain sagebrush and shrub cover and composition. Only treat habitats in late Phase II or Phase III condition to create movement corridors, connect habitats, or reduce the potential for catastrophic fire.

The update State of Nevada alternative does have an action with "old growth" as follows:

TMA-7.3: Prioritize areas for treatment of Phase III Pinyon and/or-Juniper encroachment in strategic areas to break up continuous, hazardous fuel beds. Treat areas that have the greatest opportunity for recovery to SGMAS based on ecological site potential. Old growth trees should be protected on woodland sites.

Since this is a sage-grouse plan and not a woodland management, I don't see the need to mention it. If it was an issue on a site, it should be addressed at the implementation level.

Joe

Subject: "Old Growth" Pinyon/Juniper Language

All,

With all the focus on p/j encroachment, the Utah FWS has asked that we include a management action that limits reduction of "old growth" p/j. Then they asked us to provide a definition of such. The FS in Utah has included something general, like removing persistent stands of trees over 100 years old should be avoided, but my IDT really isn't warm to that kind of language. At this point, we've worded our management action to focus on removing "encroaching" p/j to restore sagebrush habitat, going with the concept that so-called "stable stands" of p/j that are ecologically in an area not conducive to sagebrush won't fit that management approach, dodging the "retain" p/j concept altogether.

Do any of you have other language limiting p/j treatment in p/j ecological areas that you'd be willing to share?

Quincy Bahr

Hi all - here is our language:

Retain all culturally significant and important wildlife trees that originated prior to 1850 (old trees) and all old growth stands of juniper within 4 miles of occupied or pending leks. See OSU Technical Bulletin 152, or its successor, for the key characteristics of old trees. Old growth stands are those where the dominant trees in the stand meet the key characteristics for old trees.

We also reference Miller's paper, as Brent does.

>
> VEG-8: Utilize conifer (juniper) removal treatments to reduce the extent of conifer encroachment areas. Refrain from using prescribed fire and conducting removal projects in old-growth juniper stands. Old-growth juniper trees are characterized by rounded tops and spreading canopies, often containing dead limbs and/or spike tops, large branches near the base of the tree, as well as furrowed, fibrous bark, and are typically host to arboreal lichens. Leader growth in the upper quarter of the tree is usually less than one inch. These trees are generally distributed on rock outcrop or rubble land soils, or other soils with coarse fragments in the soil-surface and/or slopes over 12-25%, where juniper vegetation type is the climax plant community (IDFG 2000; Miller et al 2005; USDI and USGS 2007).

I like it, we could call it old growth avoidance if you all like it better. Thanks, Glen

On Tue, Apr 22, 2014 at 2:21 PM, Lepak, Dominika <dlepak@blm.gov> wrote:
Glen - if this looks good to you, I will send it on to Meredith and Brent. I don't know if "treatment avoidance" is the right term, but I'm not coming up with anything else. Thanks!

For purposes of treatment avoidance, old-growth juniper is defined by location on the landscape and tree growth form.

Growth Form: Old-growth juniper trees are characterized by rounded tops and spreading canopies, often containing dead limbs and/or spike tops, large branches near the base of the tree, as well as furrowed, fibrous bark, and are host to arboreal lichens. Leader growth in the upper quarter of the tree is usually less than one inch.

Landscape Distribution: Generally Rock Outcrop or Rubble Land soils, or other soils with coarse fragments in the soil-surface and/or slopes over 12-15%, where juniper vegetation type is the climax plant community.

Split Estate Language

3 messages

Lauren Mermejo <lmermejo@blm.gov> Tue, Sep 16, 2014 at 10:36 AM
To: Quincy Bahr <qfbahr@blm.gov>, Brent Ralston <bralston@blm.gov>, Joan Suther <jsuther@blm.gov>, Melvin Tague <joe_m_tague@blm.gov>
Cc: Johanna Munson <jmunson@blm.gov>

Hi You All-
Could you all please send your fluid mineral language for how you are addressing split estate (what stipulations are being applied) to Sarah Shattuck and Aaron Moody ASAP - like within the next hour or two?
Thanks....once again we are looking for a consistent approach to this issue due to the legal applicability.

Bahr, Quincy <qfbahr@blm.gov> Tue, Sep 16, 2014 at 11:05 AM
To: Sarah Shattuck <Sarah.Shattuck@sol.doi.gov>, Aaron Moody <aaron.moody@sol.doi.gov>
Cc: Brent Ralston <bralston@blm.gov>, Joan Suther <jsuther@blm.gov>, Melvin Tague <joe_m_tague@blm.gov>, Johanna Munson <jmunson@blm.gov>, Lauren Mermejo <lmermejo@blm.gov>

We were planning to apply every stipulation applicable to areas where BLM has both mineral and surface estate to areas where the BLM has just the mineral estate, to the degree that the site-specific circumstances allow. We did not specify different stipulations.

We apply the NTT language, with an adjustment based on the RDF exceptions:
"Where the federal government owns the mineral estate in PPMAs, and the surface is in non-federal ownership, apply the conservation measures applied on public lands.

"Where the federal government owns the surface, and the mineral estate is in non-federal ownership in PPMAs, the RDFs identified in Appendix J would be applied to surface developments, unless at least one of the following can be demonstrated in the NEPA analyses associated with the specific project:
- A specific design feature is documented to not be applicable to the site-specific conditions of the project/activity;
- A proposed design feature or BMP is determined to provide equal or better protection for GRSG or its habitat;
- Analyses conclude that following a specific feature will provide no more protection to GRSG or its habitat than not following it, for the specific project being proposed."

Hope this helps.

To: Lauren Mermejo <lmermejo@blm.gov>

Here you go:

Mineral Split Estate Actions

Goal G-MSE 1: Manage federal split estate (private surface/federal minerals; federal surface/private minerals) to provide for the conservation, maintenance, and enhancement of PPMA and PGMA.

Objective G-MSE 1: For federal mineral estate, minimize surface disturbance in PPMA and PGMA to the maximum extent permissible under existing authorities.

Objective G-MSE 2: For federal surface estate, minimize surface disturbance in PPMA and PGMA to the maximum extent permissible under existing authorities consistent with use rights to the private mineral estate.

Action G-MSE 1: Where the BLM administers the mineral estate in GRSG habitat and the surface is in nonfederal ownership, apply the appropriate conservation measures and RDFs that are applied on public lands in coordination with the SETT, NDOW and CDFW.

Action G-MSE 2: Where the federal government owns the surface and the mineral estate is in nonfederal ownership in PPMA and PGMA, apply appropriate surface use stipulations and RDFs to surface development in coordination with the SETT, NDOW and CDFW..

I haven't finished rolling in the NV language into the Utah Proposed Plan, but we plan to incorporate the concepts. I say concepts, because Utah does not have separate sage-grouse goals and objective for each separate resource/use. As such, we will not have wild horse goals that deal specifically with sage-grouse, but we will include all the concepts raised by the NV language as management actions, some of which may be rather general management direction to bring in the NV objectives.

Here you go for NV-CA.

Wild Horse and Burros

Goal G-WHB 1: Manage active herd management areas (HMAs) and wild horse and burro territories (WHBTs) in PPMA and PGMA habitats to achieve GRSG habitat objectives (Table 2-6). Use all available and future approved management tools to actively manage wild horses and burros within HMAs and WHBTs.

Objective G-WHB 1: Evaluate existing Appropriate Management Levels (AMLs) within HMAs and WHBTs within PPMA and PGMA and make appropriate adjustments to AML to achieve and maintain seasonal GRSG habitats (Table 2-6).

Objective G-WHB 2: Manage wild horse and burro population levels in PPMA and PGMA at the lower limit of the established AML ranges to maintain or enhance GRSG habitat.

Objective G-WHB 3: Prioritize gathers and population growth suppression techniques in HMAs, and WHBTs in PPMA and PGMA, unless removals are necessary in other areas to address higher priority environmental issues, including herd health impacts. Place higher priority on Herd Areas occupied by wild horses and burros in PPMA and PGMA, areas as these areas are to be managed for zero wild horses and burros. Additional prioritization would be given for HMAs and WHBTs that are near AML or where a reduction would serve the most beneficial purpose.

Action G-WHB 1: In PPMA and PGMA, assess and adjust AMLs through the NEPA process within HMAs and WHBTs that are at least partially degraded due to wild horses or burros (as identified in grazing land health assessments) if current AML is not being exceeded . Monitor HMAs or WHBTs annually to assess attainment of habitat objectives and to help determine future management decisions. Unless already meeting the lowest level of the established AML range, adjust AMLs to a level consistent with maintaining GRSG habitat objectives (Table 2-6).

Action G-WHB 2: Ensure that Herd Management Area Plans (HMAP) and WHBT plans are developed and/or amended to consider GRSG habitat objectives (Table 2-6) within PPMA and PGMA.

Action G-WHB 3: Continue to use interdisciplinary team specialists to cooperatively conduct land health, proper functioning condition, and habitat objective assessments.

Action G-WHB 4: When WHB populations exceed the upper limit of the established AML range, conduct gathers in combination with the use of population growth suppression techniques to obtain the lowest level of the AML range. This would enable AML to be maintained for longer periods and reduce the frequency of gathers and associated cost and effort.

Action G-WHB 5: Consider removals or exclusion of WHB during or immediately following emergency situations (such as fire, floods, and drought) where HMAs and WHBT overlap with PPMA and PGMA to enhance recovery time and restoration efforts.

Action G-WHB 6: Provide new water locations to ensure dispersal or avoidance of sites heavily impacted by wild horses (Feist 1971; Pellegrini 1971; Ganskopp and Vavra 1986; Naiman et al. 1992) in compliance with Nevada state Water Law and subject to valid existing rights.
Action G-WHB 7: Coordinate with professionals from other federal and state agencies, researchers at universities, and others to utilize and evaluate new management tools (e.g., population growth suppression, inventory techniques, and telemetry) for implementing the WHB program.

> Amy,
>
> As luck would have it, I had to be out of the room on the phone when Glen gave this presentation today. Unfortunately this one attached here is corrupted somehow – much of it does not display. Any chance Joe could send it again to me and to Ren? (I think he would be interested to see this as well).

Greater Sage-Grouse Planning Strategy

Update on Fire and Invasive Annual Grass Assessment

National Policy Team

June ??, 2014

FOREST SERVICE
DEPARTMENT OF AGRICULTURE

NATIONAL SYSTEM OF PUBLIC LANDS
U.S. DEPARTMENT OF THE INTERIOR
BUREAU OF LAND MANAGEMENT

Background

- Large-scale loss of sagebrush from wildfires and the conversion of sagebrush ecosystem to annual grasses or woodland expansion are contributing to the decline of Greater Sage-grouse.

- BLM, FS and F&WS agreed that a need existed for a strategic assessment of these threats to assist in prioritization of limited funds to maintain or restore habitat.

- Assessment process has evolved from the draft EIS's protocol to one that incorporates:
  - Resistance to invasive annual grasses
  - Resiliency after disturbance (wildfires).

Scientific Basis

- Resistance and Resilience Concepts developed by the WAFWA Fire and Invasive Team Led by Ken Mayer

- Forest Service General Technical Report
  Using Resistance and Resilience Concepts to Reduce Impacts of Invasive Annual Grasses and Altered Fire Regimes on the Sagebrush Ecosystem and Greater Sage-Grouse – A Strategic Multi-scale Approach-Chambers et al. (in press)

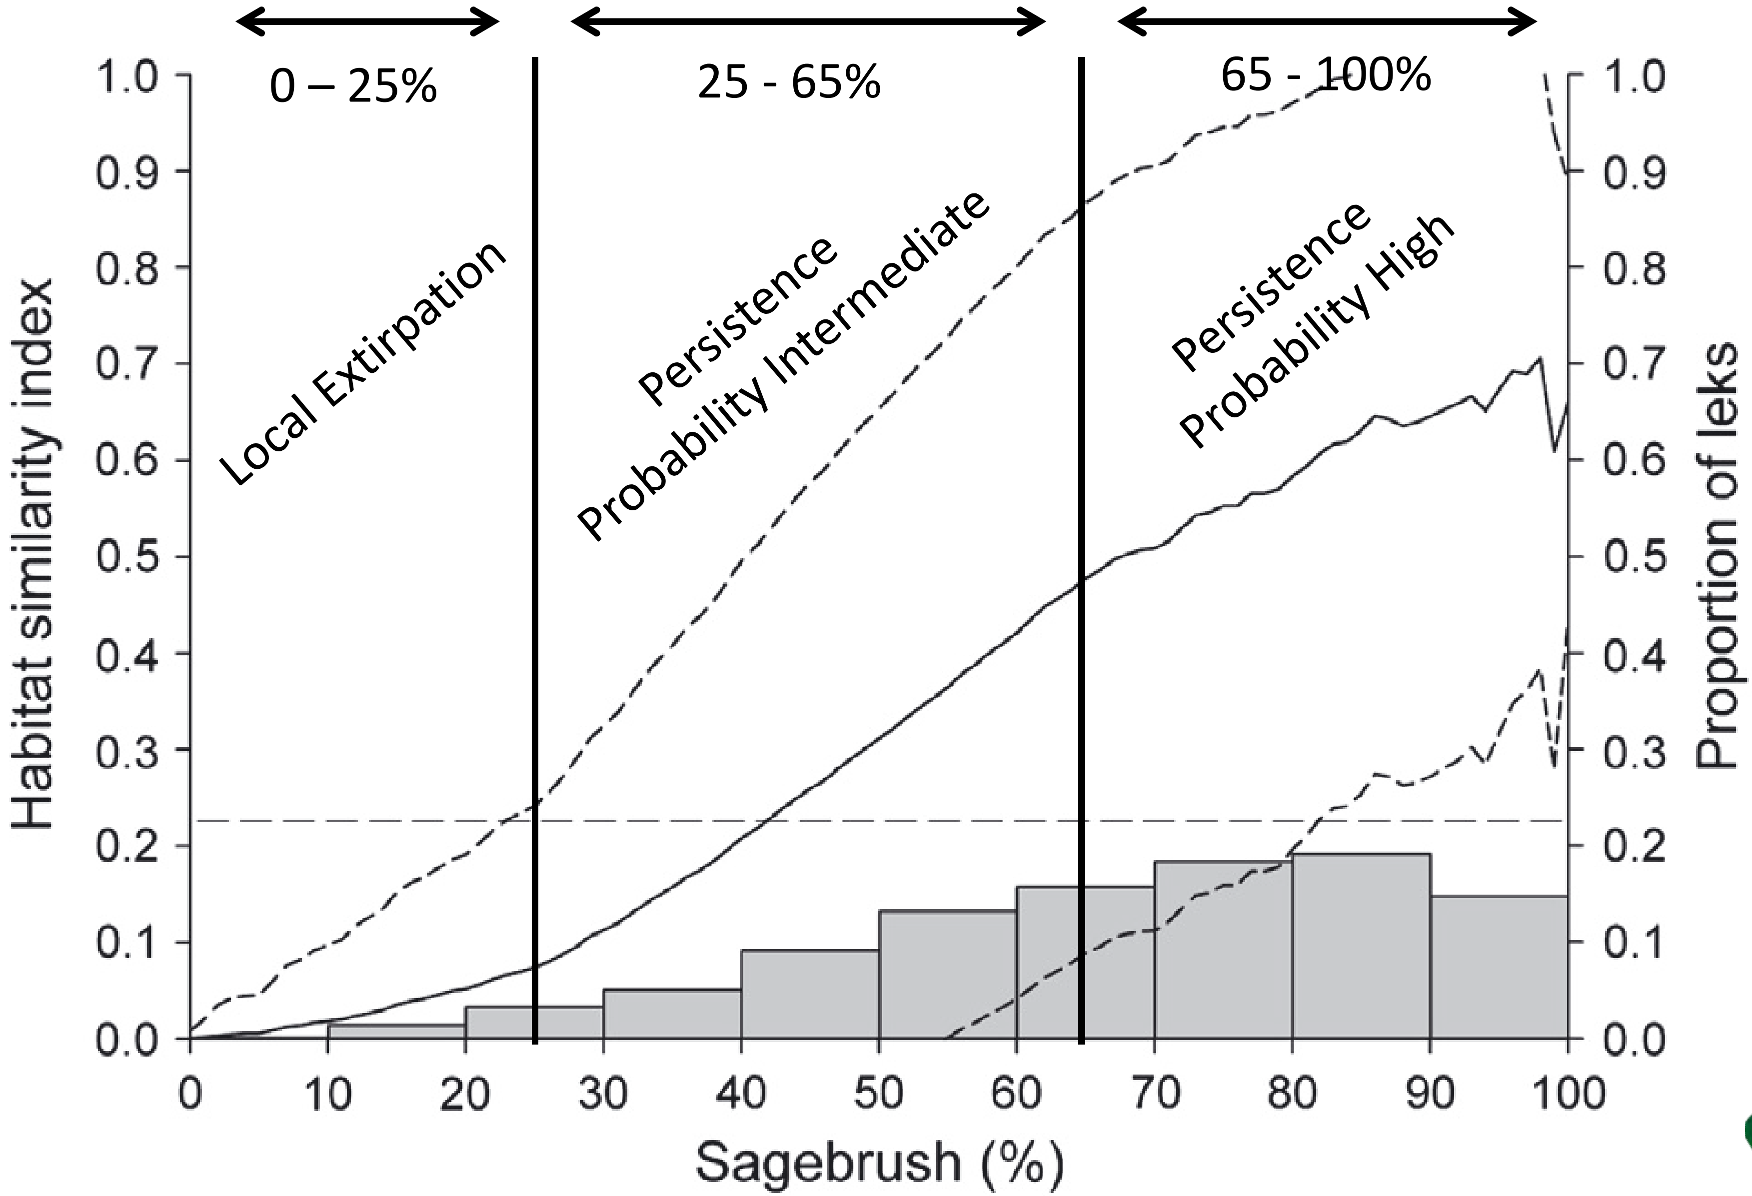
ENVIRONMENTAL GRADIENTS

Warm-Dry ⟷ **Cold-Moist**

→

Resistance to Invasive Annual Grasses and Resilience after Wildfire Increases

SAGEBRUSH LANDSCAPE COVER & SAGE-GROUSE



(modified from Knick et al. 2013)

SAGE-GROUSE HABITAT MATRIX

Proportion of Landscape Dominated by Sagebrush

Resilience to Disturbance & Resistance to Invasive Annual Grasses

	Low **< 25% Sagebrush Landscape Cover**	***Medium*** **26-65% Sagebrush-Landscape Cover**	***High*** **> 66% Sagebrush-Landscape Cover**
High	Sagebrush lacking - Natural recovery likely Low annual invasive risk	Sagebrush limiting - Natural recovery likely Low annual invasive risk	Sagebrush sufficient - Natural recovery likely Low annual invasive risk
Moderate	Sagebrush lacking - Natural recovery possible Invasive risk is site dependent	Sagebrush limiting - Natural recovery possible Invasive risk is site dependent	Sagebrush sufficient - Natural recovery possible Invasive risk is site dependent
Low	Sagebrush lacking - Natural recovery unlikely High annual invasive risk	Sagebrush limiting - Natural recovery unlikely High annual invasive risk	Sagebrush sufficient - Natural recovery unlikely High annual invasive risk

Fire and Invasive Annual Grass Assessment

Objective

- Develop a standardized agency assessment protocol that incorporates Resistance and Resilience concepts into Greater Sage-Grouse Land Use Plan Amendments

Organization

Team Leader

- Mike Pellant (mpellant@blm.gov)

Development Team

- Purpose: Develop assessment protocol using the Resilience & Resistance Matrix
- Included 5 members of the WAFWA Team
- Members from the BLM/FS/FWS/NRCS/USGS

Review Team

- Provided the first level of review and input on assessment protocol
- Provided additional expertise to Development Team

Assessment Protocol

Two-Step Process

- Step 1- Identify high priority (Important) areas for Greater Sage-grouse based on Priority Areas for Conservation (PACs) and management strategies to address threats

- Step 2- Develop interagency/partner implementation plans to maintain or restore priority habitats (process included in FEIS)

STEP 1A

High Density Populations at Highest Risk from Wildfire and Invasive Annual Grasses

PACs in Management Zones III, IV, and V. were evaluated on the basis of high density (75 percent) Breeding Bird Density, sagebrush landscape cover, and soil temperature and moisture regimes (resistance and resilience) to identify initial PACs that are a priority for assessments

High Density Sage-Grouse Habitats at Risk from Conifer Expansion

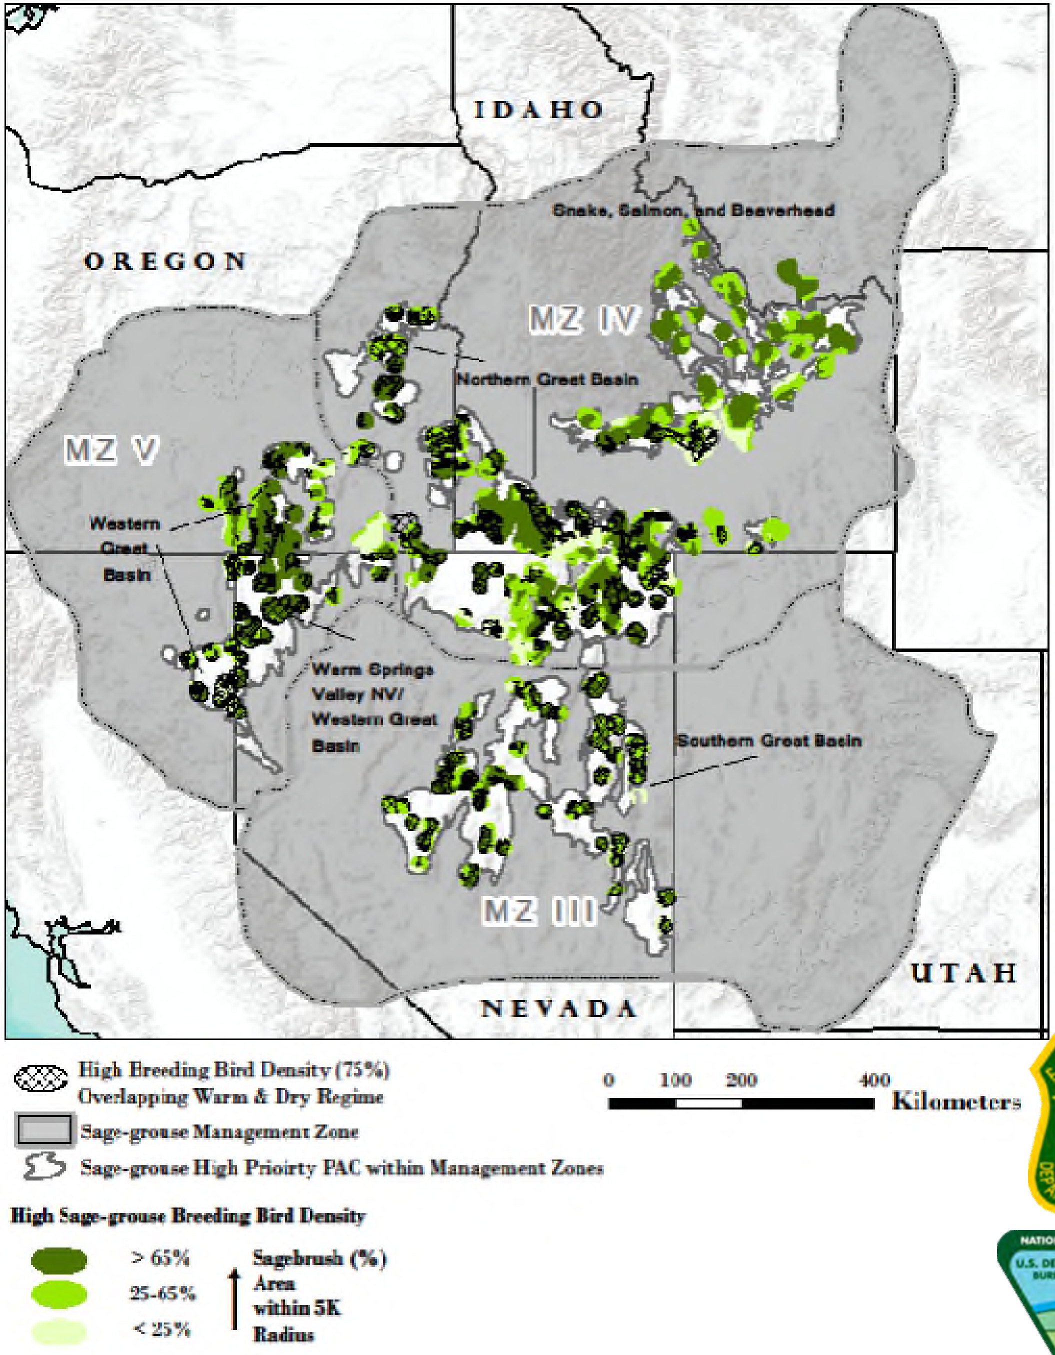
PACs, sagebrush landscape cover, and the 75 percent BBD data were also used in conjunction with the conifer expansion data (Mainer et al. 2013) to provide an initial stratification to determine assessment priority in PACs where conifer removal would benefit important sagebrush habitats.

Priority PACs for Fire/Invasive Assessments

1. Northern Great Basin
2. Southern Great basin
3. Snake, Salmon, and Beaverhead
4. Warm Springs Valley, NV/Western Great Basin
5. Western Great Basin

Focal habitats for assessments are 75% BBD intersected with areas within PAC with > 25% sagebrush landscape cover

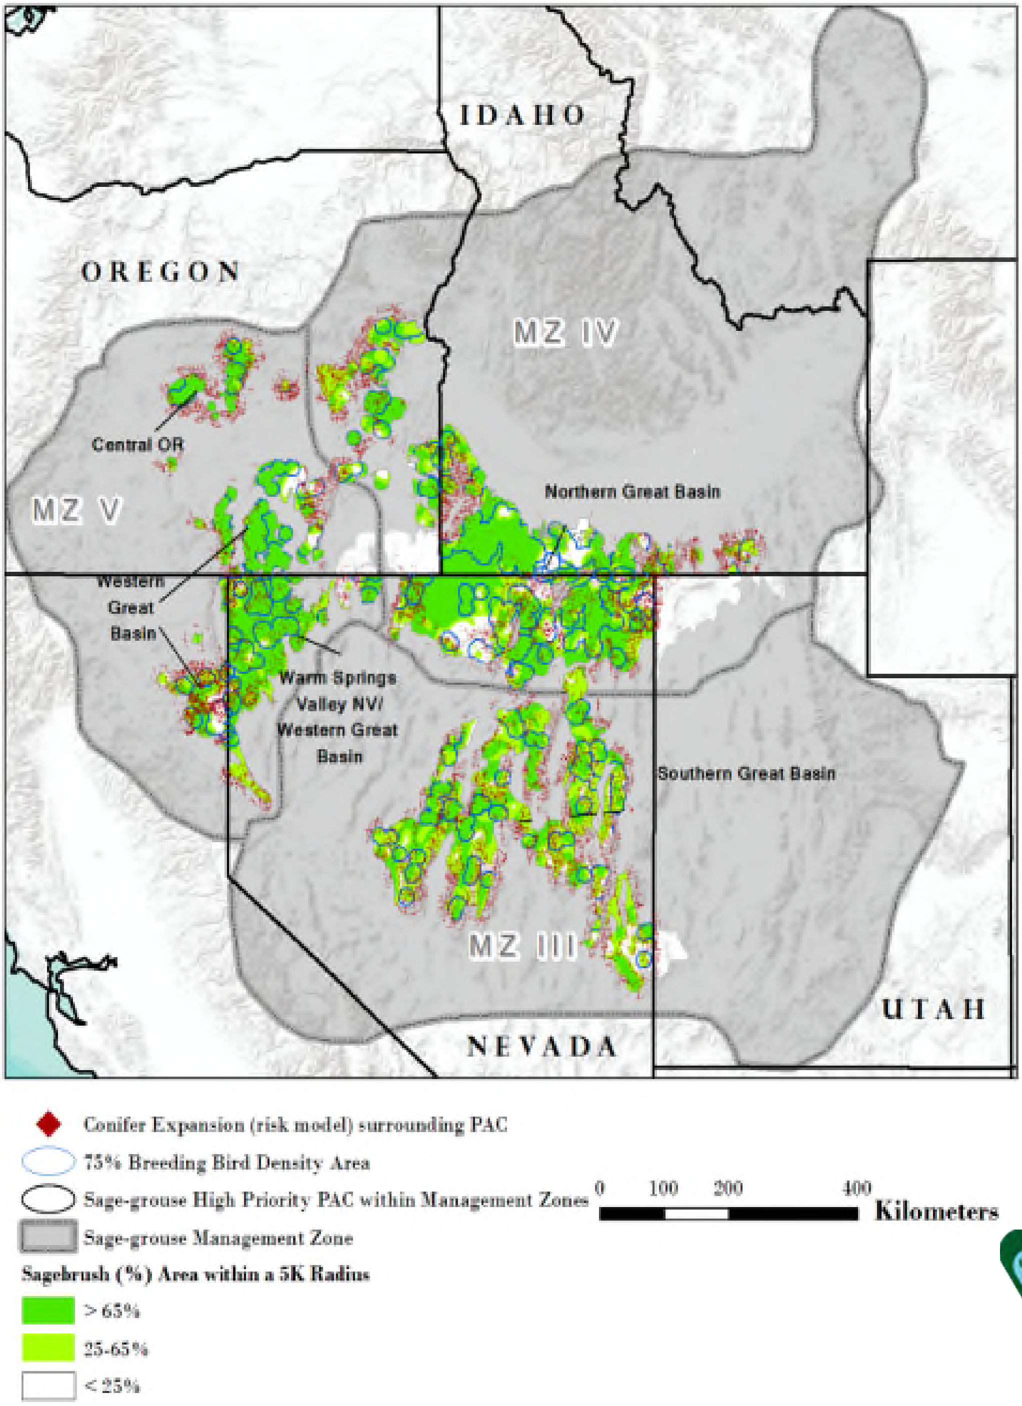
Cross-hatched areas are emphasis areas for treatments in or near focal habitats (low resistance and resilience)



Priority PACs for Conifer Expansion

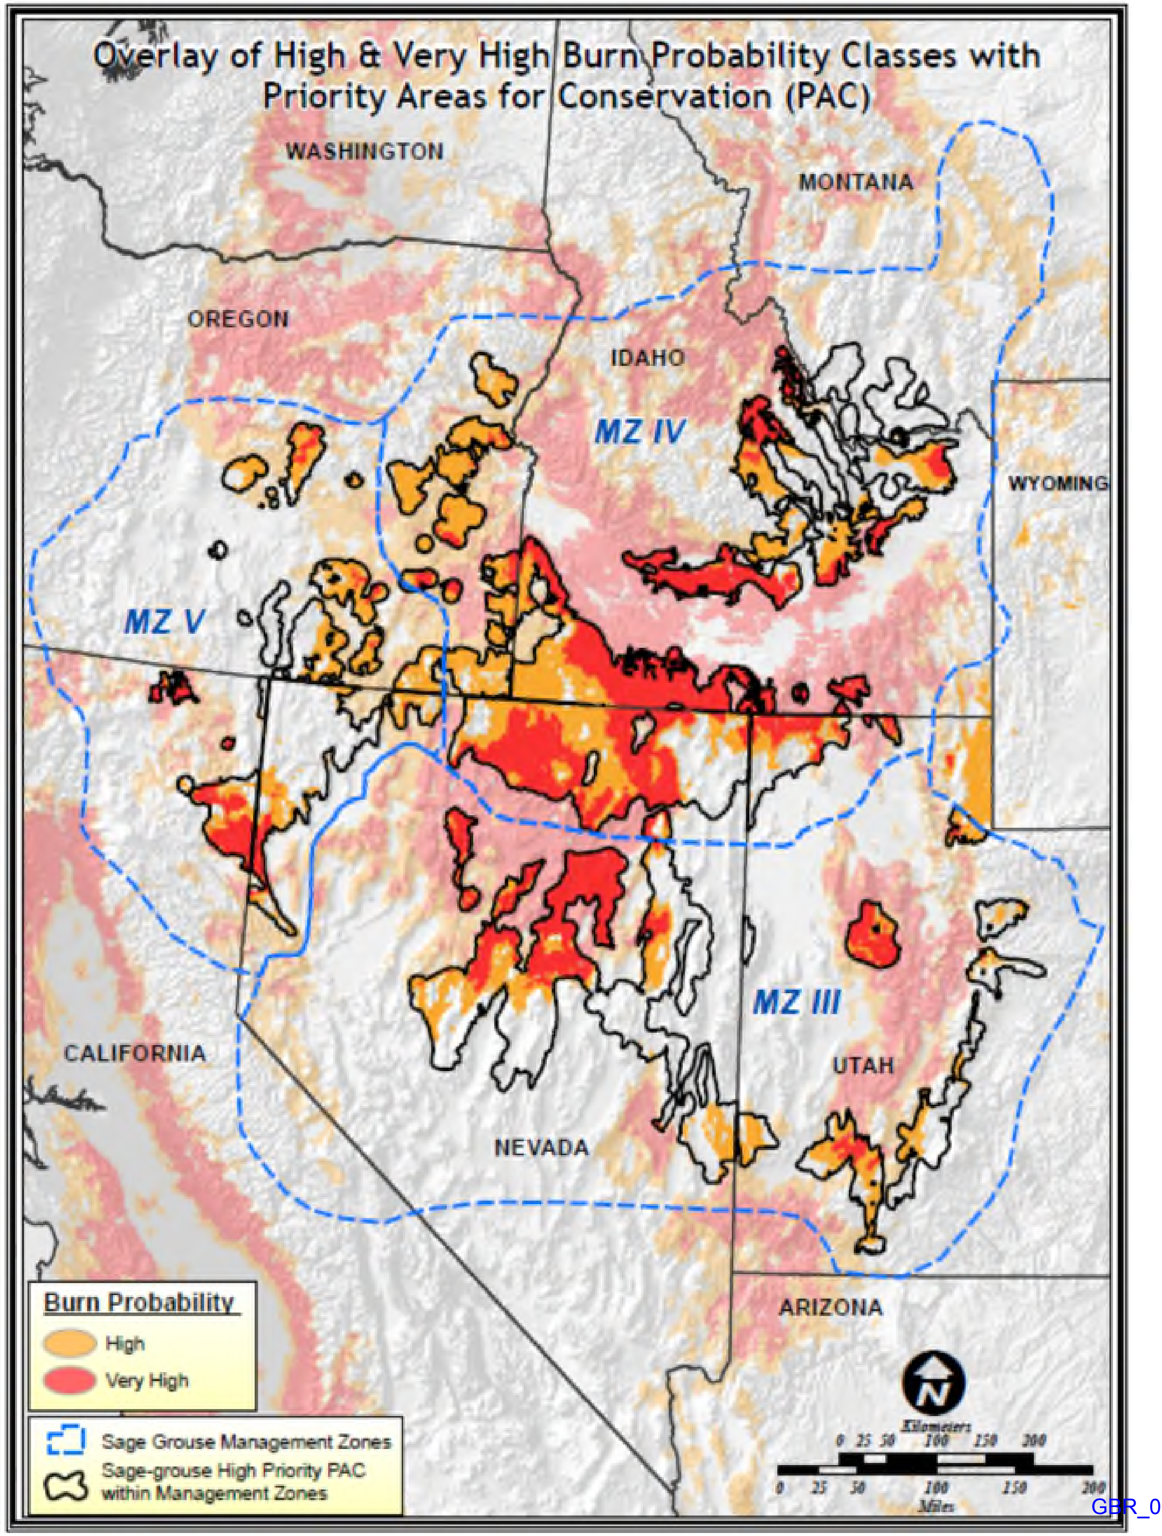
1. Northern Great Basin
2. Southern Great Basin
3. Warm Springs Valley, NV/Western Great Basin
4. Western Great Basin
5. Central Oregon

Focal habitats for assessments are areas within PAC with > 25% sagebrush landscape cover intersected with modeled conifer expansion



Wildfire Probability (Burn probability)

Very high and high probability of burning displayed in Great Basin PACs in Management Zones III, IV, and V.



Results of Step 1B
Identify Management Strategies

Based on Tables 3 and 4 contained in Chambers et. al. (in press)

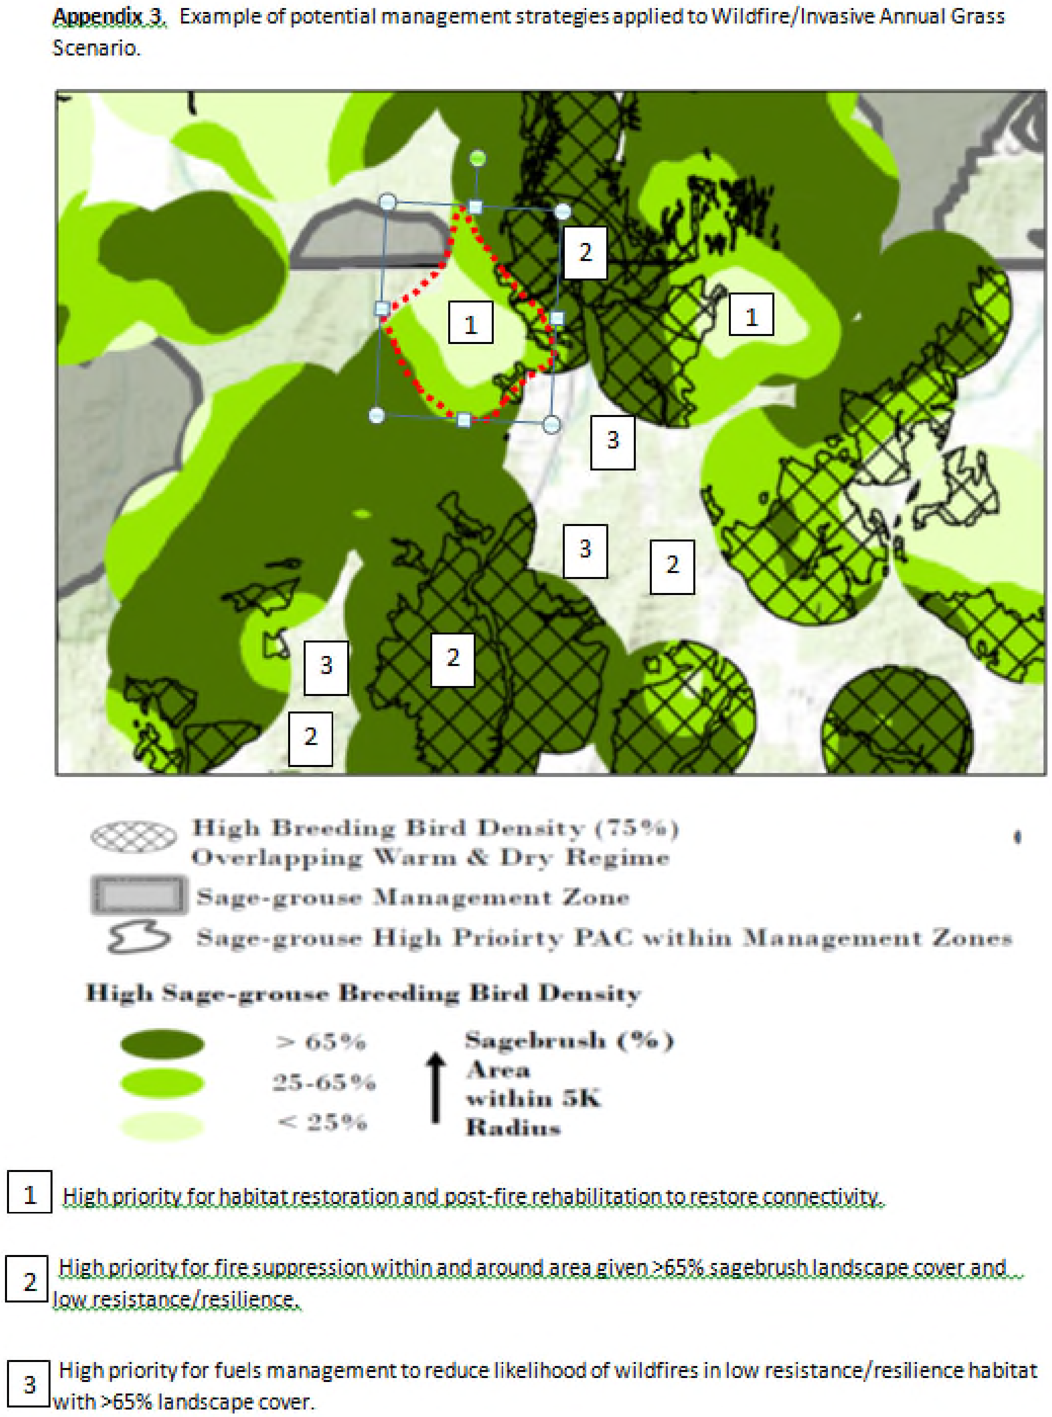
Management Strategies

- Proactive
  - Fuels Management
  - Habitat Recovery/Restoration
- Reactive
  - Fire Operations
  - Post-Fire Rehabilitation

Management Strategies

Example of Step-down management strategies

Red outlined area represent a location where connectivity could be restored.



Appendix 3. Example of potential management strategies applied to Wildfire/Invasive Annual Grass Scenario.

▨ High Breeding Bird Density (75%) Overlapping Warm & Dry Regime

▭ Sage-grouse Management Zone

Sage-grouse High Prioirty PAC within Management Zones

High Sage-grouse Breeding Bird Density

🟩	> 65%	↑ Sagebrush (%) Area within 5K Radius
🟩	25-65%	
🟩	< 25%	

1 High priority for habitat restoration and post-fire rehabilitation to restore connectivity.

2 High priority for fire suppression within and around area given >65% sagebrush landscape cover and low resistance/resilience.

3 High priority for fuels management to reduce likelihood of wildfires in low resistance/resilience habitat with >65% landscape cover.

Step 2

- Incorporate local data and GIS layers to conduct FIAT assessments
- Complete local assessments on Priority PACs (focal habitats)
- Interagency/Intra-state Teams
- Identify implementation projects

Next Steps

- Issuance of Final Fire and Invasive Annual Grass Assessment Report (FIAT)
- Publication of “Resistance and Resilience Concepts” in Forest Service General Technical Report (GTR)
- Incorporate FIAT report and GTR in FEIS, Propose Plan and Record of Decision
- BLM Issuance of Instruction Memorandum- complete assessments on priority PACs by 12/15/2014
- Based on Pilot Test(s), need to identify a ‘training cadre’ to assist local teams in completing assessments

Ted: Here is the revised table which includes the percentages, and pulling out grazing and recreation from the other program areas.

On closer inspection, it shows that in 5 program areas Oregon has indicated there are identical (or almost identical) acreage (and percentages) for existing authorizations and RFDs. This could mean that either they are expecting absolutely no new development in these program areas, or that they are estimating the impacts to double. I have inquiries out now to clear this up. Similarly, Utah's numbers for fluid minerals seem out of whack – perhaps this is real, but it deserves some attention. As you can see, many of the data are still missing.

By way of this email, I am including Joe on this conversation in the hope that he could recirculate this table to 1) fill in any missing data, 2) address those issues mentioned above.

All,

Here is the final Table 2 we put together.

Joan – Please look at the Oregon information and answer Ron's questions as the number of existing and proposed were the same.

Quincy – Ron also had a question on your fluid minerals.

I am also including Table 1 for your info.

Joe

Hi Joe - I talked with Ron to explain our minerals related numbers. Essentially we don't anticipate higher levels of development, and did not conduct RFD scenarios for this plan amendment - therefore little to no change. However, there has been a modicum of interest in fluid minerals, but no applications or pre-app mtgs, so difficult to gauge.

Unless I'm mistaken, the "ROW" category refers to small ROWs (e.g., a road to someone's house) and permits, while the "ROW & Corridors" refers to large, utility-scale corridors and major pipelines.

Joe – is this correct?

Cc: Joan Suther <jsuther@blm.gov>, Brent Ralston <bralston@blm.gov>

Is the table supposed to show acres of actual disturbance, or acres where we don't have discretion? I heard both in Portland, so for fluid minerals, we presented total acres as following:

- acres leased (796,261 leased in PPMA and PGMA), where there are valid existing rights, but not anticipated development;
- acres that are leased AND held by production (207,680 leased in PPMA and PGMA) where the potential for a lease going away is less than just a plain old lease;
- acres that have actually been disturbed from O&G developments (32,793, only 9,358 of which are in PPMA)

The 4,242 acres of potential is tied specifically to acres of disturbance that are anticipated from future development, not future leases. As such, in order for current and future to be similar, the current number should be 9,358 acres, with 0.807% in the percentage column.

Similarly, for mineral materials, we provided acreages of both areas under a saleable permit (VER) AND the area of actual disturbance, thusly:

- acres where there is a valid permit granted, creating a valid existing right (24,173), not differentiated by type of saleable mineral (free-use, commercial, etc.)
- acres that have actually been disturbed by a backhoe, as mapped using aerial photography (705)

The percentage presented in the table (.013%) is based on the disturbed area, so the acreage should likely also be based on the actual disturbance in the acres column (705 acres).

It appears we need clarification in this table whether we are talking actual disturbance acreage, acres where the BLM/FS don't have a lot of discretion (i.e., where there's current VERs), or acres where there is potential (it was originally talked about, but doesn't appear to have been carried into any tables). Such clarification will be necessary to make sure the numbers are truely comparable and summarizable.

Hi Ron - here are a couple of assumptions made by our geologist as he calculated acres of mining claims:

1. Each claim was given a value of 160 acres; while it could encompass as little as 5 or less acres.
2. If any part of a claim could have been in PPH or PGH, the entire claim was counted in.

I believe this grossly overestimates the actual acreage of claims on sage-grouse habitat, by 4 or 5 times. I would recommend using approximately 20,000 ac currently authorized. We simply do not have the mining claims data available in a very spatially explicit format - unfortunate for this process.

Please contact me with any questions. J.

	Important			Open		
	PGMA	Open [NV-3]	Open [OR-1]	Open	Open	Varies [UT-1]

Footnotes:

[NV-1] Use of solar and wind to power existing facilities OK if no impacts to GRSG or habitat is documented.

[NV-2] No new utility corridors allowed; some wide corridors reduced to maximum width of 3500 feet.

[NV-3] All disturbances to GRSG habitat must follow State of Nevada avoid-minimize-mitigate procedures to attain no net unmitigated loss of habitat.

[UT-1] PGMA is for BLM-UT is managed according to the existing LUP allocations (O&G- open, CSU, NSO, closed; ROWs: open, avoidance, exclusion, mineral materials and non-energy leasables: open, closed; other allocations: etc.). In addition to whatever the existing LUP includes, there is an added requirement for no net unmitigated loss of GRSG habitat that would be applied to both PPMA and PGMA.

[UT-2] Several new ROW corridors were identified in the ADPP as a mean to focus future development from collocating with any existing line on the landscape to be located in areas where they would do less damage to GRSG. Additionally, the decision in the ADPP for ROW corridors is to avoid GRSG habitat entirely, if possible, but if that is not feasible, to locate in the corridors and apply a variety of other stipulations to minimize impacts, including mitigation.

[UT-3] Per NPT, closed unless adjacent to existing operations, where it could be allowed with mitigation and within the disturbance cap. Utah went further and wouldn't allow expansion within 1 mile of lek, and would require mitigation to be completed before the project is initiated, as well as other stipulations such as to eliminate impacts from noise and tall structures.

[OR-1] Open except where closed in existing plans

[ID-SW MT-1] Southwest Montana BLM areas have already completed travel management planning and identified designated roads and trails.

Here is a copy of the letter that Nevada is sending out today, if you want to use it.

Stephanie gave the OK…we are good to go.

Dear Cooperating Agency:

Thank you for your continued interest in the *Nevada and Northeastern California Greater Sage-Grouse Land Use Plan Amendment*. As you are aware, the Bureau of Land Management (BLM) is in the midst of an unprecedented land use planning effort. The BLM is preparing 15 Environmental Impact Statements and amending or revising 68 land use plans for the conservation of the Greater Sage-Grouse. We anticipate completing the planning process this summer. As a cooperating agency, the Bureau of Land Management will be providing you an administrative draft of the *Nevada and Northeastern California Greater Sage-Grouse Land Use Plan Amendment* (ADPP) during the week of April 29 for a two week review. Please provide comments, per your responsibility under our Memorandum of Understanding, within two weeks of receipt.

Sincerely,

John F. Ruhs
Acting State Director

Subject: Fwd: Rights-of-Way Data Layers for NOC Roll-Up

---------- Forwarded message ----------
From: **Lauren Mermejo** <lmermejo@blm.gov>
Date: Wed, May 21, 2014 at 3:15 PM
Subject: Rights-of-Way Data Layers for NOC Roll-Up
To: Quincy Bahr <qfbahr@blm.gov>, "Suther, Joan" <jsuther@blm.gov>, "Melvin (Joe) Tague" <jtague@blm.gov>, Brent Ralston <bralston@blm.gov>
Cc: Matthew Magaletti <mmagalet@blm.gov>

Hi All – Please coordinate with your GIS folks on the clarification items below……..

There were a few questions from Oregon on how to map a number of the ROW data layers to send to the NOC – and to ensure that we are doing it consistently for the "Roll-Up".

As a reminder, there are four data layers pertaining to ROWs going forward for the roll-up. These are:

1. Designated Corridors – displayed as "Open" as per WO guidance

2. Wind - PPMA displayed as Exclusion; PGMA displayed as either Exclusion or Avoidance as per WO guidance

3. Solar - PPMA displayed as Exclusion; PGMA displayed as either Exclusion or Avoidance as per WO guidance

4. ROW (the data layer for High Voltage Transmission Lines and Major Pipeline) – displayed as all Avoidance for PPMA and PGMA as per WO guidance

So….Based off of the guidance that the Designated Corridor layer would show as 'open' to ROWs:

1. When mapping the Wind and Solar data layers as exclusion in PPMA, and/or exclusion or avoidance in PGMA – should the Designated Corridor layer of "open" be shown on those exclusion maps?

> Response: NO – the data layers for Wind and Solar are exclusion and/or avoidance, no matter what the Designated Corridor map shows. We would NOT

> provide a ROW grant for wind or solar in PPMA under any circumstances under an exclusion, and probably never even under an avoidance in PGMA. The designated corridors have nothing to do with the wind and solar allocations.

2. When mapping the high voltage transmission or major pipeline ROWs data layer for submission to the NOC – all PPMA and PGMA would be displayed as avoidance (in accordance with the WO guidance). Should the Designated Corridors be eliminated from that data layer because they are “open”?

> Response: YES – in effect, you are showing that high voltage transmission or major pipeline ROWs are avoidance areas in PPMA and PGMA, but could be considered more readily in the open designated corridors. Remember that this is the ONLY real “ROW” layer that we are sending forward….we are not forwarding the “general ROWs” layer in the WO guidance.

If you have any questions, please give me a call. Thanks…and thanks to Oregon for bringing up these questions. We need to get it right the first time, cuz we won’t have time to redo!!
