USDA Forest Service Protocols for Delineation of Economic Impact Analysis Areas

METI Corp/Economic Insights of Colorado, LLC

Table of Contents

Introduction

The USDA-Forest Service conducts economic impact analyses in response to issues raised by the public at all levels of planning and at all levels of the agency. A critical step in each analysis is determining the geographic area that provides functional economic integrity. In the past, the agency has often relied upon Component Economic Areas (CEAs) developed the Bureau of Economic Analysis to provide that base. However, these areas have an urban focus, whereas many impact analyses conducted by the Forest Service address economic issues in rural areas. This is especially true in the West. Forest Service economists have attempted to define smaller, more responsive economic areas by using "gut feel" or "best judgment" to delineate the boundaries. With recent reductions of economic expertise in the agency, the need for more rigorous, well-defined protocols that define economic analysis areas has emerged. This document provides detailed protocols and examples to provide Forest Service analysts with objective guidance for delineating geographic areas appropriate for economic impact analysis required by law, regulation, agency direction, or public interest.

.

There are three components to designing a successful economic impact analysis: issues, tools, and analysis area delineation. All three should be aligned for the most effective analysis. Each is introduced below.

The theoretical basis for defining economic areas is founded on labor and trade relationships. "Functional economic areas" (FEAs) have a legacy of being labor-based, while central place theory (CPT) offers a more holistic concept of trade. Industrial clusters or agglomeration theory provides a different view of economic areas that is defined more narrowly and by a variety of external economies of scale. See "**Economic Area Delineation: Identifying Areas for Economic Impact Analysis in the USDA-Forest Service**" for details. Because each theory explains economic relationships with a different focus, each one also suggests a different geographic area. This distinction is particularly evident when comparing labor-based (FEA) and trade-based (CPT) concepts. While industrial clusters have geographic boundaries, they center on the intensity and complexity of trade flows within an area rather than the extent of the area. Because labor is a strong component of most industrial clusters, labor market concepts (FEA) offer a credible means for identifying the analysis area. Ultimately, analysts should focus on either FEA or CPT concepts for area delineation.

Input-output (I-O) models are the preferred analysis tool for most economic impact analysis done in the Forest Service. IMPLAN® is the data/software tool primarily used by the agency, having its origin in the Forest Service. I-O models describe the linkages between elements of a regional economy and predict effects based on these linkages. Relationships between business production, household income, and household spending – captured in "induced effects" – is an important part of each I-O model. These labor and income flows align strongly with the FEA concept. Relationships among industries as they trade goods and services with each other – captured in “indirect effects” – is another important part of each model. These trade flows align strongly with the CPT concept. Model results are very dependent upon analysis area delineation. Therefore, an analysis of labor and income should be matched with an area defined by labor market (FEA) concepts and an analysis of production inputs should be matched with an area defined by trade flow (CPT) concepts.

All analyses start with particular issues or questions to be addressed. Most economic impact issues facing Forest Service managers can be divided into the same two categories noted above: labor or income based, and trade based. Labor and income based issues are by far the most common. These should be addressed using labor flow based (FEA) analysis areas. When trade flow issues are raised, trade flow (CPT) analysis areas should be used by the analyst.

Protocols in this document begin with the classification of economic impact issues – Step 1, then proceed to the delineation of a corresponding analysis area – Step 2 or 3.

Step 1 – Issue Identification

An economic impact analysis area is determined by the classification of economic issues. The classification provides a divide that fundamentally defines the focus of analysis. The primary question is:

> Are the issues fundamentally concerned with labor and income, or are they concerned with business interactions?

If labor and income dominate, then an analysis area based on labor markets and commuting patterns drives the delineation. If business interactions dominate, then an analysis area based on the flow of goods and services (commodities) drives the delineation.

If neither issue category dominates, then both must be addressed for the project or program being analyzed. In these cases, the analyst should develop one analysis area for each basic issue category. If the analyst determines that the geographic areas are substantially alike, then a single area may be used for the entire impact analysis. If the resulting analysis areas are not substantially alike, two separate analyses should be conducted, each using their respective geographic areas.

If the issues are general in nature, such as “consider the local economic impacts of the alternatives,” use an analysis area based on labor markets and commuting patterns.

The above approach to analysis area definition is not resource dependent. A change in production for any resource – regardless of whether it is timber, minerals, grazing, special uses, or recreation – may affect labor markets and/or business interactions. While one resource, such as recreation, may be traditionally aligned with labor market issues, it would be unwise to permanently exclude the potential for local concerns about business interactions.

The classification of economic issues and topics generally follow the outline below:

Labor and income flows (labor markets)

- Jobs
    - *Number*
    - *Occupational types*
    - *Seasonality*
    - *Full-time/part-time*
- Income
    - *Per job (“livable wages”)*
    - *Community wealth*
- Commuting
    - *Distance &/or time*
    - *Bedroom communities*

- Housing
    - *Affordability*
    - *Availability*
- Labor force
    - *Unemployment rate*
    - *Available skills*
    - *Training programs for new skills*

Business interactions (commodity markets)

- Supporting industries (supply chains)
- Economic development
    - *New/additional economic “drivers”*
    - *Value-added or “forward linkage” industries*
    - *Plugging economic “leaks”*
- Business retention

The best time to clarify economic impact issues is during the NEPA scoping process. Context within written and oral comments is often key to determining the intended meaning of somewhat vague or generally stated economic issues. Classification of the issues will be easier and subsequent analyses will be more effective when comments are clearly understood.

Clarification of economic issues may also require discussions or correspondence with community leaders, state officials, and other interested parties, especially when their comments are unclear. The purpose of these discussions is to clarify and isolate the relevant issues so that subsequent analyses are focused. There are occasions where community leaders may be hesitant or unable to narrow the scope of their issues. The analyst must be open to whatever issue(s) the community expresses, yet diligent in seeking clarification. Distinguishing among the topics listed above is critical for determining the analysis area and subsequent impact analysis. Because economic development comments may be vague, it is important that local and/or state development professionals are part of the dialog in narrowing relevant issues.

Economic impact effects are classified three ways: direct, indirect, and induced. Induced effects are those impacts resulting from the local spending of household income. Traditionally, the income originates from economic “drivers” or engines in the local economy. However, this income can originate from any income source outside the study area, including government transfer payments (e.g. social security, Medicare, welfare) and personal investment income (e.g. retirement accounts, pensions). Induced effects are strongly connected with labor markets, and thus align with labor-based issues. Indirect effects are those impacts resulting from local spending by businesses to acquire inputs (goods and services, commodities) into their production process. Wood fiber provided to sawmills and pulpmills, forage provided to cattle ranching, and pipelines provided to oil and gas production are all examples of critical inputs into production processes. Indirect effects are determined by the ability of an area to provide goods and services needed for local production processes, and thus align with commodity trade flows.

Once the issues have been identified, analysis area delineation can proceed. For labor and income issues, follow the labor market protocol in Step 2. For business interaction issues, follow the trade flow protocol in Step 3.

Step 2 - Labor Market Protocol

The purpose of this protocol is to delineate analysis areas for issues that are classified primarily as labor-based (employment and income).

Start with a proposed analysis area of one or more counties where project- or program-related business transactions are likely to occur. NFS land ownership is not necessarily a reliable guide when considering the location of business transactions. Follow the procedure outlined in Table 1 to generate a "Labor Shed Analysis" report.

Table 1. Procedures to generate a "Labor Shed Analysis" report using LED OnTheMap.

Step	**Screen Window**	**Tabs**	**Analysis Tab Details**	**Actions**
1	Browser Window			Go to http://lehdmap3.did.census.gov/themap3/
2	Opening Window			In "Place Name" enter the name of a county or state of interest. Do not enter "county" or "state" after the name.
3	Map Window	Search		Select one of the states or counties from the left-hand list. Center & size the map by dragging with the mouse & using the zoom tool
4		Map Key		No action, information only.
5		Layers		Check the desired boxes.
6		Analysis	Data Settings	Within "**Live or Work**", select "**Workplace Area**"; Within "**Years**", select the most recent; Within "**Job Type**", select "**All Jobs**", Accept remaining defaults; Click NEXT
7		Analysis	Study Area Selection	Click on "**Layer**", select "**Counties**" from pull-down menu, click "**Points**" button. On the map, click once inside each county of interest. Once "Area Shape" outline appears, verify selection. If incorrect, click in "Clear Selection" button and repeat steps. When finished, click NEXT.
8		Analysis	Advanced Area Selection	Click NEXT.
9		Analysis	Map Overlay/ Report	Enter "Report Title" as desired. Select "**Labor Shed Analysis**". Click "GO!"
10		Results Tab		Verify that map results appear reasonable. If they are not, repeat steps 3-9 as needed. View Report in desired form by clicking on format link. Select Excel format for saving results; select PDF format for quick viewing & printing.
11				Determine analysis area by using criteria that follow this table.

Examine the share column of "Job Counts in Counties Where Workers Live" portion of "Labor Shed Analysis" report. Use the following criteria to determine the best area for conducting economic impact analyses.

General circumstances

1. The larger the cumulative share of jobs, the more comprehensive the impact assessment will be. Using the "Labor Shed Analysis Report", start with the first county listed and add counties in the order given until the cumulative share of job count is at least 60% of total, subject to the following:
   a. Counties that add at least 25% to the share of local jobs should always be included.
   b. Counties that add less than 25% may be included in the area, but require further examination before the determination is made. Run a "Commute Shed Analysis" report for each of these counties. A "Commute Shed Analysis" shows where workers are employed who live in the selection area. A "Labor Shed Analysis" shows where workers live who are employed in the selection area. See Table 2 below for details. If at least 25% of the resident workers are employed within the proposed analysis area, add the county in the delineation. If it does not meet this test, exclude the county from the proposed analysis area.
2. If a county selected by the analyst is not listed in the "Labor Shed Analysis" report, or listed with a very small share of total jobs, consider the following:
   a. A very small, rural county may be strongly connected to the area but have few workers and consequently a very small share of total job counts. Verify this by running a "Commute Shed Analysis" report. If at least 25% of the resident workers are employed within their own county or other counties selected by the analyst for the proposed analysis area, retain the county in the delineation. If the county does not meet this test, remove the county from the proposed analysis area.

Table 2. Procedures to generate a "Commute Shed Analysis" report using LED OnTheMap.

Step	**Screen Window**	**Tabs**	**Analysis Tab Details**	**Actions**
1-5				Same as shown in Table 1
6		Analysis	Data Settings	Within "**Live or Work**", select "**Home/Residential Area**"; Within "**Years**", select the most recent; Within "**Job Type**", select "**All Jobs**", Accept remaining defaults; Click NEXT
7		Analysis	Study Area Selection	To clear any previous counties, click in "**Clear Selection**" button. Click on "**Layer**", select "**Counties**" from pull-down menu, click "**Points**" button. On the map, click once inside each county of interest. Once "**Area Shape**" outline appears, verify selection. If incorrect, click in "**Clear**

				Selection" button and repeat steps. When finished, click NEXT.
8		Analysis	Advanced Area Selection	Click NEXT.
9		Analysis	Map Overlay/Report	Enter "Report Title" as desired. Select "**Commute Shed Analysis**". Click "GO!"
10		Results Tab		Verify that map results appear reasonable. If they are not, repeat steps 3-9 as needed. View Report in desired form by clicking on format link. Select Excel format for saving results; select PDF format for quick viewing & printing.
11				Determine analysis area by using criteria that follow this table.

3. Do not include urban counties in the analysis areas. See the discussion under "Urban National Forests" for more details regarding identification of urban or metropolitan areas. Metro counties should not be included when the issue is focused on labor markets between more rural or non-metropolitan counties. Including highly populated metro counties generally masks economic impact consequences desired when analyzing smaller rural counties.

See the Rochester RD and Jackson RD examples for basic applications of this protocol.

Urban National Forests

Delineating analysis areas for urban national forests can be especially difficult. Most urban national forests include lands and management actions within OMB-defined "metropolitan areas". Because the U.S. Census Bureau does not identify urban areas or urban clusters at the county level, OMB-defined "metropolitan areas" must be used as an urban approximation. See http://www.census.gov/population/www/metroareas/metrodef.html for a complete list of areas and their county components in the US. Census designations of "urban"/"rural" are determined using criteria distinct from OMB designations of "metro"/"non-metro". Thus OMB metropolitan areas will often have both "urban" and "rural" counties within their delineation. If business transactions are expected in one of these counties, use the following guidelines.

Rural counties within metropolitan areas – In these settings, forest -related business transactions often occur in rural counties that are dominated by commuting patterns linked to urban counties. They are typically classified as "outlying" counties within the metropolitan area. The 60 percent threshold for a labor market cannot be met without including substantial urban – or "central" -- counties. Local government and community leaders in these areas often see forest-related economic effects as important contributors to their county. Consequently, leaders raise labor and income issues in their attempts to encourage local businesses and generate local tax revenues. Under these circumstances, the analysis area should be limited to the rural county or counties of concern. They represent a portion of the larger labor market defined by the metropolitan area. To maintain the integrity of OMB-defined labor market areas, do not mix these counties in the same analysis area with counties outside the metropolitan area.

Urban counties within metropolitan areas – In these settings, forest -related business transactions typically occur in very urban counties that are dominated by commuting patterns to and from other parts of the large urban area. These counties are typically classified as "central" to the metropolitan area. The 60 percent threshold for a labor market typically cannot be met without including other "central" counties. Typically, forest-related business transactions are so small compared with the metro area economy, that labor and income issues are not relevant. However, if the national forest project or plan offers substantial changes to the lifestyle or business environment in a particular county, local government and community leaders may see forest-related economic effects as important. In these circumstances, the analysis area should be limited to the county or counties of concern. They represent a portion of the larger labor market defined by the metropolitan area. Do not mix metropolitan area counties in the same analysis area with counties outside the metropolitan area.

Other special circumstances

Occasionally, the 60% threshold cannot be obtained without violating the non-metro criterion. This is often true for resort areas where local housing costs exceed the financial means of many workers. In these situations, commuting distances may be significant, drawing workers from urban counties. A metro county should only be included when at least 25% of that county's resident workers commute to the proposed analysis area. See White River NF East example.

Occasionally, one county will participate in two distinct labor markets. Topography and transportation routes will isolate each part of the county resulting in two distinct commuting patterns. Because counties are used as building blocks for analysis area delineation, they cannot be split. Include a county if at least 25% of the resident workers in a given county are employed in the proposed analysis area. See White River NF West example.

When delineating two or more analysis areas that adjoin, repeat the procedures shown above for "General circumstances" to decide which counties should be included in each area. See White River NF East & West examples.

Occasionally, a count will fall just short of the 25% criterion for inclusion. See Garfield County in the White River NF West example. Similarly, an entire analysis area may fall short of the 60% threshold. In these circumstances, consultation with state and/or local labor market officials is advised. State labor market officials are typically located in the state department, agency, and staff that has responsibilities for collecting covered employment and wages data. Following consultation, the analyst may determine that the area best suited for labor market analysis will not meet the criteria provided above. See the McCall RD example.

Using a labor market IMPLAN model

IMPLAN models based on labor market areas may not be well suited for analyzing the consequences of trade flows. Although labor markets are generally used to identify functional economic areas, professional expertise should be sought before using a labor-flow based IMPLAN model for addressing trade flows. A regional economist should be consulted.

Labor market protocol examples

1. Rochester RD, Green Mountain NF

   The Sugarbush Ski Area has proposed modifications that are expected to increase skier visits. Additional workers will be needed to support the increase in skier volume. What analysis area should the analyst use to evaluate the economic impacts of the proposed action?

   The proposed action is located in Washington County, VT. Washington County also has communities that are likely to capture associated worker spending. A “Labor Shed Analysis” report is prepared and shown in Figure A. Workers living in Washington County constitute 58% of the work force. This falls short of the 60% threshold given in the criteria. Should Chittenden County be included in the analysis area? A “Commute Shed Analysis” report is prepared and shown as the second table in Figure A. Only 4% of the Chittenden County work force is employed in Washington County, and thus Chittenden County should not be included. Next on the Washington County report is Orange County. A “Commute Shed Analysis” report is prepared for Orange County and shown as the third table in Figure A. Over 32% of the Orange County work force is employed in Washington County, thus meeting the 25% criterion for inclusion in the labor market area. The final analysis area should include both Washington and Orange Counties. These two counties account for over 67% of all workers employed in Washington County.

Figure A. Labor Market Reports for the Rochester RD, Green Mountain NF (2006)

Washington County, VT		
	Count	**Share**
Jobs Total	34,165	100.0%
Job counts in Counties Where Workers Live		
	Count	**Share**
Washington Co., Vermont	19,822	58.0%
Chittenden Co., Vermont	3,683	10.8%
Orange Co., Vermont	3,271	9.6%
Caledonia Co., Vermont	1,201	3.5%
Lamoille Co., Vermont	1,007	2.9%
Rutland Co., Vermont	939	2.7%

2. Jackson RD, Bridger-Teton NF

   An endangered bird species nests in habitat found along the Gross Ventre River. The District proposes to expand the nesting habitat, potentially increasing bird numbers. It is expected that birders will now flock to Jackson and nearby towns to observe the nesting behavior. An economic impact analysis is needed in response to tourism issues raised during NEPA scoping. What counties should be included in the analysis area?

   The proposed action is located in Teton County, WY. A "Labor Shed Analysis" report is prepared and shown in Figure B. Workers living in Teton County, WY fall short of the 60% threshold given in the criteria. Teton County, ID looks like a good candidate for inclusion, but does not meet the 25% criterion based on the Teton County, WY report. A "Commute Shed Analysis" report for the Idaho county is prepared and also shown in Figure B. Over half of Teton County, ID workers are employed in Teton County, WY, easily meeting the 25% criterion for inclusion in the labor market area. The final analysis area should include Teton County from both Wyoming and Idaho, and exceeds the 60% threshold.

Figure B. Labor Market Reports for the Jackson RD, Bridger-Teton NF (2006)

Lincoln Co., Wyoming	15	0.3%
All Other Locations	62	1.4%

Sources: US Census Bureau, LED Origin-Destination Data Base (2nd Quarter 2002, 2003 and 2004)

3. McCall RD, Payette NF

A pest infestation on the McCall District has run its course. To remove hazard trees, capture the value of dead timber, and restore watershed conditions, a substantial amount of timber removal and reforestation work must be done. During scoping, some businesses expressed concern that the size of this project will adversely affect their businesses during two summers of project activity. An economic impact analysis is conducted to assess likely effects on local jobs and income. What counties should be included in the analysis area?

The proposed action is located in Valley County, ID. Processing of the timber is expected to occur in Valley County as well. A “Labor Shed Analysis” report is prepared and shown in Figure C. Workers living in Valley County alone do not meet the 60% threshold given in the criteria. Ada County looks like a potential candidate for inclusion, but does not meet the 25% criterion based on the Valley County report. A “Commute Shed Analysis” report for Ada County is prepared and shown in Figure C. A very small share of Ada County workers is employed in Valley County – so small that it is included in “All other locations”. In addition, Ada County is dominated by Boise and therefore is considered urban. (This information is obtained from other sources, such as first-hand knowledge of the area or reviewing information at http://www.census.gov/population/www/metroareas/metrodef.html) Even if Ada County met the 25% criterion, it should not be included. Adams County is the next candidate. A “Commute Shed Analysis” report for Adams County is prepared and shown in Figure C. Adams County just meets the 25% criterion (25.2%), and should be included in the area. With the inclusion of Adams County, the analysis area only accounts for 53.6% of employment – still short of the 60% threshold. Canyon County is next on the list for consideration. A “Commute Shed Analysis” report for Canyon County is prepared and shown in Figure C. Like Ada County, a very small share of Canyon County workers is employed in Valley County – so small that it is included in “All other locations”. And like Ada County, Canyon County is dominated by Nampa and the Boise metropolitan area. Even if Canyon County met the 25% criterion, it should not be included. Although not shown in the abbreviated report below for Valley County, all remaining counties either provide a very small share of workers to the area or are located in counties that are quite distant and not contiguous to the area. Even though the Valley-Adams County area falls short of the 60% threshold, the analyst believes it is the best analysis area for the project. This is confirmed by discussions with the state labor market agency.

White River NF East

Vail Associates, Inc has submitted ski area modification plans to the White River NF for both Vail and Breckenridge ski areas. A small amount of additional employment will be required for each area once the modifications are in place and operational. Opponents of the plans argue that additional employees will make current labor force issues worse, increasing the demand for limited housing, and adding to greenhouse gases as more workers commute to both areas. As part of the NEPA documentation, an economic impact analysis is needed. What counties should be included in the analysis area?

The analyst is unsure whether to analyze impacts for Summit County (home of Breckenridge) and Eagle County (home of Vail) separately or combined. A “Labor Shed Analysis” report is prepared for Summit County first, and shown in Figure D. Workers living in Summit County alone are substantially short of the 60% threshold given in the criteria. Jefferson County looks like a potential candidate for inclusion, but does not meet the 25% criterion based on the Summit County report. The analyst already knows that Jefferson County is part of the Denver metro area, and therefore excludes the county. Lake County is next on the report. A “Commute Shed Analysis” report for Lake County is prepared and shown in Figure D. Lake County just misses the 25% criterion, but is so close that the analyst reserves judgment. Denver County is next, but the analyst already knows that Denver is very urban and should not be included in the analysis area. Eagle County is considered next. Since Eagle County has become a candidate for inclusion with Summit County, the analyst now realizes that a combined analysis area of at least Summit and Eagle must be used. By reviewing the “Commute Shed Analysis” report for Lake County, it becomes clear that Lake County should be included in the analysis area.

At this point, the analyst decides to reconfigure the “Labor Shed Analysis” report and run it for a combined Eagle-Lake-Summit area. The result is shown in Figure D. Residents in this 3-county area account for nearly 52% of total employment. A quick scan of the report reveals that all subsequent counties are part of the Denver-Aurora metro area, and therefore should not be included, except Garfield. A “Commute Shed Analysis” report is prepared for Garfield County, and reveals that it does not meet the 25% criterion for inclusion (report is shown in Figure E). After some consultation with local and state officials, the analyst settles on the Eagle-Lake-Summit analysis area.

4. White River NF West

   The Aspen District is experiencing increased recreation pressure during the summer season. In response, the Forest has decided to propose substantial facility expansions and improvements. At the same time, the Colorado Department of Transportation (CDOT) has announced plans to improve Highway 82, the only major route into Aspen. Some organizations are concerned that all the improvements will persuade even more visitors to the county, making daily commutes by workers into Aspen even worse, while others are concerned that the construction will provide an impediment to critical summer tourist seasons. Both are concerned with the economic consequences of tourism. As part of a cumulative effects analysis, an evaluation of economic impacts will be included in the Forest's NEPA document. What analysis area should be used?

   Pitkin County is the location of both Forest and CDOT proposed actions. A "Labor Shed Analysis" report is prepared for Pitkin County first, and shown in Figure E. Workers living in Pitkin County alone fall short of the 60% threshold given in the criteria. Garfield County just misses the 25% criterion, but is so close that the analyst reserves judgment. A "Commute Shed Analysis" report for Garfield County is prepared and shown in Figure E. Only 15% of the Garfield work force is employed in Pitkin County. Eagle County is the next county listed in the Pitkin County report. A "Commute Shed Analysis" report for Eagle County is prepared and shown in Figure E. Only 14% of the Eagle work force is employed in Pitkin County. The analyst realizes that the southwestern tip of Eagle County includes the towns of El Jebel and Balsalt, two communities that are geographically separated from the population center of Eagle County. Based on this information, the analyst excludes Eagle County, and decides to include Garfield County. Consultation with local and state officials confirms that the final analysis area should include both Pitkin and Garfield Counties.

Step 3 – Trade Flow Protocol

The purpose of this protocol is to delineate analysis areas that respond primarily to one or more input commodities of interest. Input commodities are also known as goods and services needed for a production process.

Start with a proposed analysis area of one or more counties where project- or program-related production inputs are needed (destination counties). NFS land ownership is not a reliable guide for identifying these counties.

Trade flow areas should encompass the most important inputs required by the subject industry. Commodity issues may specify the inputs of greatest interest. If issues do not specify a particular commodity, use the top ten commodity inputs identified in Tables 3 and 4. These commodities are ranked based on their share of each dollar (coefficient) spent in the production process. Table 5 offers supplemental information on the role of commodities, total value added, and labor in total production for selected resource-related industries. Tables 3, 4, and 5 are derived from a 2006 IMPLAN model for the U.S.

Some inputs may suggest one trade area, while other inputs may suggest a different one -- or none at all. If more than one input is specified in public comments or if several inputs shares are of similar magnitude in the tables, multiple commodities may be used to identify a comprehensive or mixed trade flow area. Because commodities may have very different market areas that could render a comprehensive or mixed trade flow area as ineffective or misleading, seek professional expertise before proceeding. A regional economist should be consulted.

Source: Minnesota IMPLAN Group, Inc, 2006 US Model.

Follow the procedure outlined in Tables 6 and 7 to generate a trade flow report for the input commodities of interest.

Table 6. Procedures to Generate a Trade Flow Report Directly from Local Data Sources.

Step	Actions
1	Inquire from an industry representative or other knowledgeable source the states/counties where inputs of interest are obtained for their production processes. Firm names need not be revealed. Origin states should only include those adjacent to your state of interest.
2	Map the counties
3	Evaluate results using the criteria listed below.

Table 7. Procedures to Generate a Trade Flow Report from IMPLAN Trade Flow Data.

Step	Actions
1	Obtain a trade flow database file (.mdb) for the state of interest and TradeFlow_Report_Builder.mdb from the WO-PAG website. The files may be placed anywhere on your computer hard drive, but placing both in the same folder will expedite the process. The report builder works for 2006 data only.
2	Open TradeFlow_Report_Builder.mdb. Follow Steps 1 through 5 to create and export a report.
3	Step 1 – Click on the button “Select State Tradeflow Database”. Once the window opens, locate the state trade flow database of interest, highlight it, then click on “Open”. The state database has now been linked to the report builder.
4	Step 2 – In the first column, select the same state as the database that was linked in Step 1. In all other columns, select one or more items as needed. Hold the “Control” button to select multiple counties, state, or commodities.
5	Steps 3 & 4 – Click on the button “Create Reports”. A window appears allowing the user to append the results of this report to any previous reports that have been created. This feature is helpful when multiple counties or commodities are selected in separate reports, but the user wishes to see all results in a single report. Once the reports have been created, click on the button “Open Detailed Report” or the button “Open Summary Report” to view results. The summary report combines multiple commodity values by origin county.
6	Step 5 – To save the reports, click on the button “Export Reports to Excel”. The reports are exported in a single file to the same folder that holds the Report Builder. Change the name of the exported file to avoid replacement by future exported files from Report Builder.
7	If desired, report can be imported into mapping software, e.g. ArcView. See mapping software for details.
8	Evaluate results using the criteria listed below.

Examine the originating states and counties in the trade flow report. Use the following criteria to guide identification of the best area for conducting economic impact analyses.

General circumstances

1. Limit trade flow areas to originating counties where dollar volume of the input commodity is significant. In most cases, a minimum of at least $10,000 ($0.01 in millions) should be required. In rare cases, $10,000 may be too insignificant and, therefore, the minimum should be raised. See the Nez Perce County example for Sawmill products (commodity 112) and the Montrose County example for Logs & Stumpage (commodities 14 & 15).
2. The trade flow issue is typically raised by parties with a particular geographical interest. Therefore, limit the trade flow area to counties within this geography. For broader acceptance and understanding, a trade flow area within this geography should be contiguous. The contiguous area must include originating counties and destination counties, plus a minimum of unaffected counties. In situations where any part of a state is regarded as economically or politically relevant to the issue, the trade flow area may include counties geographically separated from the destination counties. The separate areas may be in the same state as or in different states from the destination counties. Where originating counties are widely scattered within a state or across several states, a trade flow area may be too diluted to offer useful impact information for that commodity. See the Shoshone County example for Conveyor & Construction Equipment (commodities 259 & 292) and the Moffat County example for Hay (commodity 10).
3. Do not include metropolitan area counties when the issue is focused on linkages between non-metro counties. Metro counties should be excluded from the trade flow area if substantial inputs are obtained from non-metro counties of interest. Including metro counties generally mask economic impact consequences in smaller rural counties.

Using a trade flow IMPLAN model

IMPLAN models based on trade flow areas for particular input commodities should only be used for analyzing the consequences of those particular input commodities. There is no assurance that such models would be suitable for addressing other economic impact issues, unless the model area was purposefully designed to address those issues. For example, models designed to address commodity trade flow issues may not provide appropriate induced effects expected from local labor and income flows. In a second example, models designed to address indirect effects related to one input commodity may not provide appropriate indirect effects related to a second commodity that was not considered in the initial analysis area. If a second input commodity is being examined, then a different analysis area designed for that input should be delineated. Models based on market areas for more than one commodity should be reviewed by a regional economist for their applicability.

Trade flow protocol examples

1. Nez Perce County, ID

   Lewiston, ID is a center for pulp production in the Northwest. There is local concern that one pulpmill is on the verge of closing. It is known that the mill makes significant purchases of fiber from area sawmills. The Forest Service is considering management changes that will reduce timber supplies tyically purchased by the pulpmill. This action may further threaten the viability of the mill. During scoping, an issue is raised regarding the impact on area sawmills – even those that rely heavily on private timber – if the pulpmill closes in response to the reduced fiber from NFS lands. What counties should be included in the analysis?

   Based on Table 3, the public is rightly concerned about the linkages between sawmills and pulp mills. Sawmill output is the second largest commodity input into the pulp mill production process. The analyst seeks information on local sawmill input sources, but pulp mill and industry officials decline to comment. By following the protocol using IMPLAN trade flow data, the likely origins of Commodity 112 whose destination is Nez Perce County, Idaho can be identified. Results from the trade flow report builder may be entered into mapping software. The example is shown in Table 8 and Figure F. Based on this information, it would be reasonable to limit the analysis area to Nez Perce County. An argument could be made for including Latah County as well, but the shipments are only about 1% as large as those from Nez Perce County. No other counties provide large enough shipments to merit inclusion in the analysis area.

2. Shoshone County, ID

The Lucky Friday silver mine near Mullan, ID has submitted a special use permit request to use NFS land for auxillary operations. These operations will allow the mine to expand production. During scoping, the local economic development council submitted comments stating that mine expansion would provide excellent development opportunities throughout all of northern Idaho, especially for conveyor and construction equipment manufacturers. It is well known that several firms in Kootenai County currently provide critical conveyor and construction equipment to the mine. The Forest Service agrees to analyze the potential impacts. How large an analysis area should be used?

Based on Table 3, conveyor equipment (Commodity 259) and construction equipment (Commodity 292) are the third and sixth largest inputs into silver mine production processes, accounting for eight percent of total production costs. Mine managers were asked to reveal sources of these inputs, but they declined comment. By following the protocol using IMPLAN trade flow data, the likely origins of Commodities 259 and 292 whose destination is Shoshone County, Idaho can be identified. Results from the trade flow report builder may be entered into mapping software. The example is shown in Table 9 and Figure G. While Kootenai County is indeed a large supplier of this commodity, large supplies also come from counties across Washington, Oregon, southern Idaho, and Montana. There are no other counties in northern Idaho that currently provide substantial supplies. Unless the Forest Service analyst, in collaboration with the local economic development council, intended to create new sectors in other parts of northern Idaho to explore development potential, the analysis area should be limited to simply Shoshone and Kootenai Counties. This area best responds to concerns about northern Idaho.

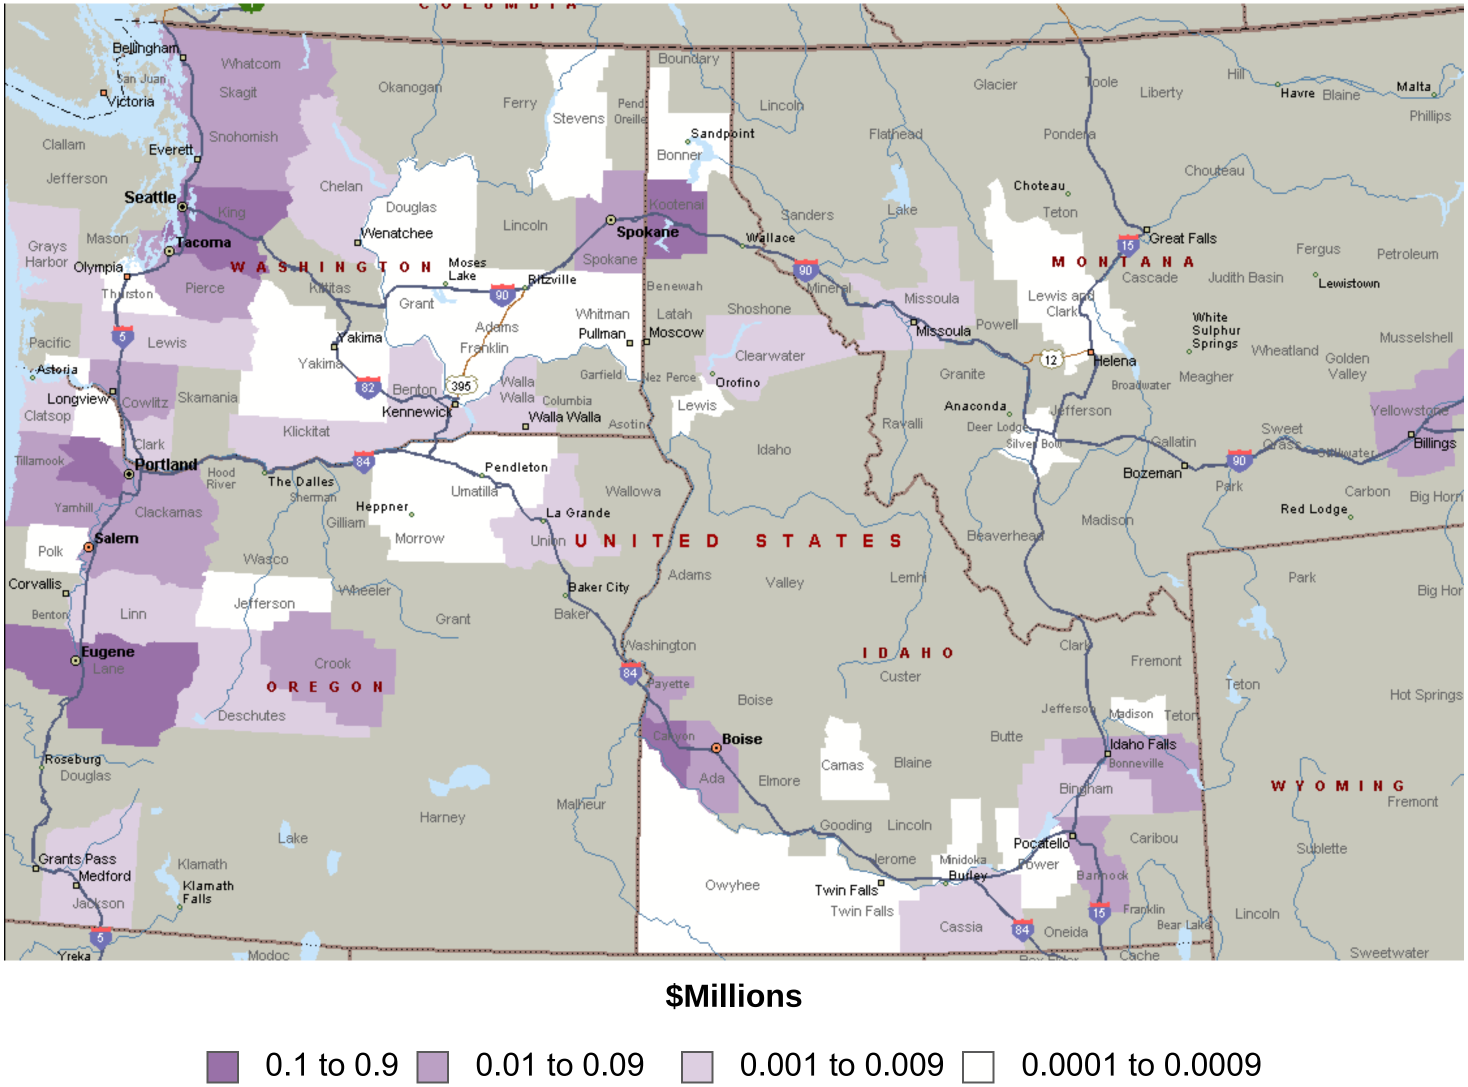
Figure G. Estimated Value and Location of Conveyor & Construction Equipment Commodity (Commodities 259 & 292) Shipments to Shoshone County, ID (2006)



3. Moffat County, CO

In response to severe drought and degraded watershed conditions, a reduction of authorized grazing on the western reaches of the Routt National Forest is being proposed. It is anticipated that the reduction may be in effect for three years to allow full recovery of watershed conditions. Reduced grazing is expected to increase the demand for additional hay for permittee herds. As part of an economic impact analysis, what counties should be included in the analysis area to capture the effects of additional hay purchases?

Based on Table 3, “All Other Crop Farming” – primarily hay (Commodity 10) – is the second largest input into cattle ranching, accounting for nearly 16 percent of total production costs. The local county extension agent was asked where Moffat County ranchers typically buy hay. The agent’s answer was that hay came from many places both in and out of state, but particular counties were unknown. By following the protocol using IMPLAN trade flow data, the likely origins of Commodity 10 whose destination is Moffat County, Colorado can be identified. Results from the trade flow report builder may be entered into mapping software. The example is shown in Table 10 and Figure H. Other than Weld County, hay is likely to come from eleven counties in Utah, eleven counties in New Mexico, and nineteen counties in Colorado. After consultation with the county extension agent, the analyst decides to limit the analysis to Moffat, Routt, and Jackson Counties. The analyst uses the mapped trade flow information in a narrative to explain likely origins of hay imports to the local area.

Table 10. Estimated Value and Location of Hay and Other Crop Commodity (Commodity 10) Shipments to Moffat County CO (2006) (Abbreviated)

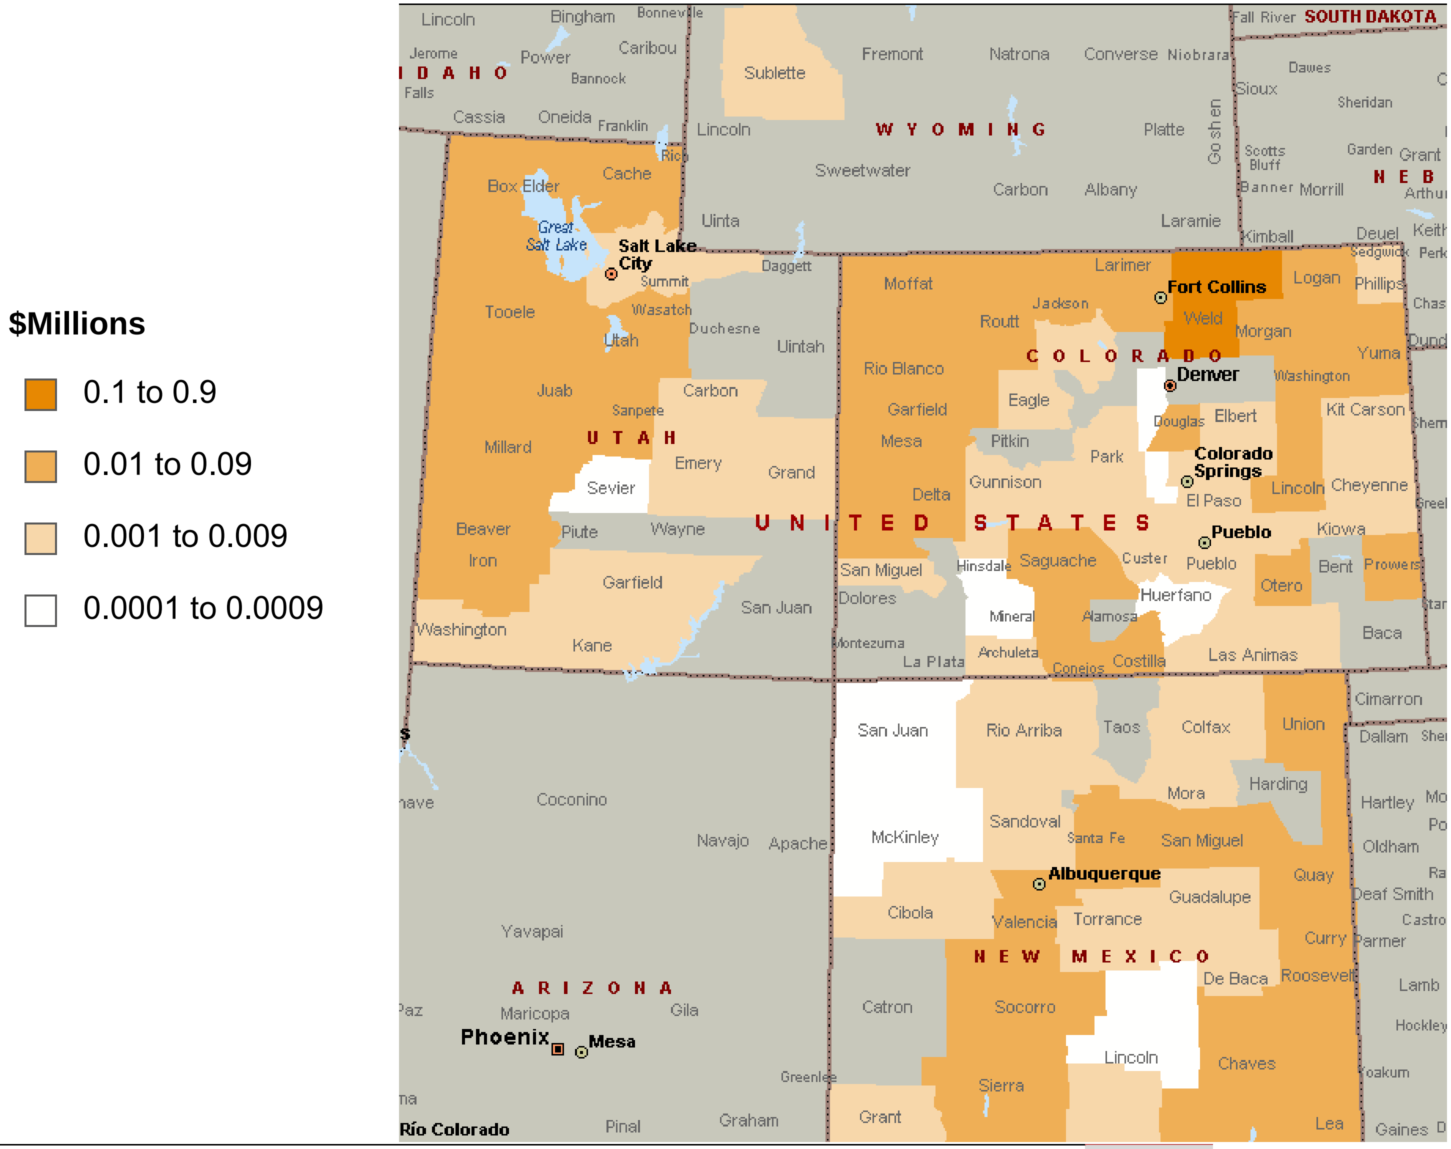
Figure H. Estimated Value and Location of Hay and Other Crop Commodity (Commodity 10) Shipments to Moffat County, CO (2006)



4. Montrose County, CO

The state legislature is concerned about a shrinking forest products industry, and asks the Forest Service if it can provide an independent estimate of economic contributions provided by the last large sawmill in the state located in Montrose County. All sources of timber – Federal, state, and private – must be accounted for in the estimate. The analysis must be completed within a few hours so that a response can be provided at meetings with legislators the following day. What counties should be included in the analysis area to best account for log deliveries to the mill?

Based on Table 3, "Logging" (Commodity 14) and "Timber" (Commodity 15) are the two largest inputs into sawmills, accounting for nearly 42 percent of total production costs. Logging accounts for log deliveries from independent and contract loggers, while "Timber" (or stumpage) is provided directly from the timber owners, such as the Forest Service. The analyst decides to model for both commodities, since together they account for all timber input to the mill. Mill managers cannot be reached in time to provide detailed input. By following the protocol using IMPLAN trade flow data, the likely origins of Commodities 14 and 15 – Logging and Stumpage – whose destination is Montrose County, Colorado can be identified. Results from the trade flow report builder may be entered into mapping software. The example is shown in Table 11 and Figure I. Boulder, Mesa, Montrose, and Rio Blanco Counties are the largest suppliers, but twelve other counties provide $10,000 or more of product to the Montrose County. After examining the trade flows, the analyst decides to include all counties in western Colorado, and exclude the urban counties along Colorado's Front Range.

Non Technical Summary
Local communities are in conflict over the general directions and specific actions of public lands policy. This project will provide scholarly research, extension, and educational programs that will improve the knowledge base upon which public land management decisions are made. Consistent economic models will be developed for various western states so that

Goals / Objectives
1. Continue to develop and refine economic models and methodologies in Western States to analyze public land issues. 2. Assess the social impacts of public land policies on selected communities and households in western states. 3. Identify the constraints to policy alternatives mandated under existing and proposed federal legislation and policy. 4. Continue to support the Policy Analysis Center for Western Public Lands through memberhsip on the Technical Committee and Project Teams, as requested.

Project Methods
Models developed in Idaho, Oregon, Colorado, and New Mexico will be used as the basis for those to be developed in the other states. Additional funding will be pursued to expand the case studies to additional counties, as specified in the original Fund for Rural America project. Regional models will be constructed and tested in the case study areas in Wyoming. Legal and policy constraints facing western communities, resource users, and others will be identified through a review of existing legislation and federal policies. A paper summarizing this effort will be prepared during the first year of the project. The Policy Analysis Center for Western Public Lands is organized around a Technical Committee that oversees project-specific Project Teams. The Center was created under the aegis of W-192, and the work of W-192 continues to be essential to the long-term research underpinnings of the Center. Project teams will assist Cooperative Extension personnel in educating the public about how public lands affect rural communities. Specified audiences will be supplied with readily accessible educational materials outlining how communities function with respect to public lands. The computer-based economic models will be combined with a set of educational aids to develop an educational package for use throughout the West. In addition to traditional bulletins, workbooks, and workshops, informational databases will be created as interactive learning tools for community members, policy makers, land managers, and others. These allow audiences to examine scenarios from other communities concerning potential ecological, economic, and social impacts of proposed public land management policies. Much of this material will be made available through the PACWPL website (http://www.agecon.nmsu.edu/center/Index.htm), white papers, and other output from the Center.

Progress 10/01/01 to 09/30/06

Outputs
OUTPUTS: Ranch-level models reflecting the impacts of limited access to federal grazing were completed (as proposed for the Fund for Rural America project due the summer fo 2002). In addition, two reports were prepared by the PACWPL technical committee. The first dealt with the pinyon-juniper pine as a potential energy source. The second dealt with the potential listing of the sage grouse as an endangered species. A proposal has been written for submission to the BLM and FS Joint Fire Science Program. A large multi-disciplinary project addressing fire danger in the Great Basin is underway. Another proposal dealing with ranch-level analysis, regional analysis, environmental values, and social impacts of fire and control alternatives on cheatgrass and juniper infested rangelands is also in preparation. The Policy Analysis Center for Western Public Lands (PACWPL) (Objective 4 of W-192) released a report on the sage grouse and how that population might be maintained. In addition, there have been numerous ranch and regional policy models developed (i.e., input-output, computable general equilibrium (CGE), and various linear programming models. The New Mexico component of the ranch value study underway in several states has been submitted to JARE (in for 2nd review). Arizona is planning on conducting a ranch values study also similar to those done in New Mexico and Idaho. A number of regionally funded projects (through the Fire Science Program involving USDA and USDI) are underway. The existing GAMS ranch-level model is being enhanced for this additional work. The A to Z Retained Ownership program has now been operating for 13 years in Idaho. This program has benefitted ranchers who have participated by garnering additional profits. Economic impact analyses related to federal

livestock grazing have been completed for Park County, Wyoming. The Bighorn National Forest plan was revised with the help of Taylor (Wyoming). Analyses of economic impact of livestock grazing, oil and natural gas development and production, and recreation on the economy of the surrounding region were completed for two Resource Management Areas in Wyoming (Casper and Kemmerer). PILT (Payment in Leu of Taxes) fact sheets were developed for each county in Wyoming. In Oregon, work has begun on beef cattle management to improve riparian areas and ranch economics. Additional work has been completed regarding the evaluation of social and economic impacts of public land policy. An evaluation of the control of Cheatgrass in the sagebrush biome has also been initiated. Work in the area of risk management ("www.rightrisk.org) has been understaken in Arizona. Finally, the relationship between recent state predator control efforts on federal lands and the Alaska National Interest Lands Conservation Act (ANILCA) and National Environmental Policy Act has been examined. Several procedural oversights have been identified. PARTICIPANTS: See W-192 report in NIMSS TARGET AUDIENCES: See W-192 report in NIMSS PROJECT MODIFICATIONS: Nothing significant to report during this reporting period.

Impacts

The first scientific analysis of the sage grouse population and potential ways to stop its decline was produced and made available to decision-makers. Impacts of proposed changed in public land policy have been estimated for a number of states in the west using various models. Hedonic models of ranch sales have been developed showing the values intrinsic to ranching as opposed to those associated with ranch livestock production. Impacts of proposed changes in public land policy have been estimated for a number of states in the west using several different modeling approaches. Hedonic pricing models of ranch sales in Idaho and New Mexico continue to show that the price of the ranch is tied to values intrinsic to ranching rather than those associated with actual livestock production. Ranch-level models were developed and used for a variety of purposes including (a) animal distribution practices, (b) profit maximizing treatments of western juniper using stochastic cattle prices and rainfall patterns, and (c) used in the revision of three National Forest plans in northeastern Oregon in order to best meet ecological, economic, and social needs of the region and country. Results of the White Pine and Eureka (Nevada) county studies have been used by the BLM and county governments in their Resource Planning process, particularly in relation to water allocation issues. An examination of the predator control processes consistent with the Alaska National Interest Lands Conservation Act and the National Environmental Policy Act will allow federal land managers in Alaska to avoid legal challenges. The multi-period GAMS LP model developed as part of this project continues to be used for policy analysis by several western states, particularly with respect to livestock distribution on rangland. The conclusion of the ranch value research in New Mexico has been that both deeded and public land acreage addes to ranchland value irrespective the livestock grazing capcity and income earning potential of the land. Empirical evidence does not support the traditional cost capitalization model. The analysis of intensive management has provided federal land managers with a clearer understanding of their duties and responsibilities and provided state managers with a better understanding of the laws that constrain their federal counterparts. Results of study for Elko County Commissioners have also been accepted as input by U.S. Forest Service in their development of an EIS. In addition an additional study to estimate the county-wide economic impacts of rangeland fires in Elko County is being conducted. In addition a study has been commissioner to investigate potential economic impacts of changes to Elko and Eureka counties from proposed changes in the 1872 Mining Law. Work on the economic impact of various development alternatives in Wyoming have facilitated a rational development process for the inherent conflicts between public lands and the emerging gas and oil development.

Progress 01/01/05 to 12/31/05

Outputs

Budget data was collected from cattle producers in Park County. This information was used to develop a multi-period linear programming model of Federal grazing dependent cattle operations in Park County. The framework for this linear programming model was developed through the W-192 Regional Research Project. Results from the linear programming model indicate that net ranch income declines by 9.4 percent with a 10 percent reduction in Federal grazing, 24.8 percent with a 25 percent reduction in Federal grazing, 54.9 percent with a 50 percent reduction in Federal grazing and 91.9 percent with a 100 percent reduction in Federal grazing. As a second part of this project a modified IMPLAN model of Park County was used to estimate the community impact of Federal grazing in the county. The results from this model indicated that depending on assumptions Federal grazing supported between 70 and 344 jobs and $1.7 and $8.4 million in labor earnings in Park County. The project also found that agricultural land accounts for 30 percent of elk winter range, 40 percent of antelope winter range, 76 percent of whitetail deer yearlong range, and 49 percent of mule deer range. Finally, the project found that replacing 35 acres of agricultural land with one average size household generates more county revenues, but also considerably more county expenditures. For every dollar of tax revenue generated an average of $2.35 of expenditures was incurred by the county.

Impacts

This information has been used to increase community awareness regarding the economic importance of Federal livestock grazing in Park County. The report is currently being used as an input for the Shoshone National Forest planning process. It is also anticipated that it will be included in the forthcoming Worland and Cody Resource Management Areas planning efforts. Also, as a result of this effort a request for a similar project has been received from Hot Springs County. In addition based on the results of this project, the economic analysis for the Bighorn National Forest Plan was expanded to include a more complete evaluation of the economic importance of livestock grazing on the forest.

About the Authors

L. Allen Torell is a professor in the Department of Agricultural Economics and Agricultural Business at New Mexico State University.

John A. Tanaka is an associate professor in the Department of Agricultural and Resource Economics at Oregon State University.

Neil Rimbey is a professor in the Department of Agricultural Economics and Rural Sociology at the University of Idaho.

Tim Darden is a research associate in the University Center for Economic Development in the Department of Applied Economics and Statistics at University of Nevada, Reno.

Larry Van Tassell is professor and head of the Department of Agricultural Economics and Rural Sociology at the University of Idaho.

Aaron Harp is director of the Policy Analysis Center for Western Public Lands.

The authors would like to thank E. Tom Bartlett, Colorado State University; William Champney, University of Nevada, Reno; Wendy Favinger, USDI Bureau of Land Management, Billings, MT; Roy Allen, USDI Bureau of Land Management, Cheyenne, WY; and John Martin, USDI Bureau of Land Management, Boise, ID for their valuable comments and criticisms.

The mission of the Policy Analysis Center for Western Public Lands is to help rural communities, policy makers, resource managers and users, and others understand, analyze and engage effectively in the public land policy process. The Center will provide relevant, science-based information and analysis of ongoing and proposed public land management policies.

Table of Contents

1. Introduction

The greater sage-grouse (*Centrocercus urophasianus*) is widely discussed as a candidate for listing under the Endangered Species Act (ESA). Biologists, conservation groups and government organizations have documented sage-grouse population declines and the apparent reasons for these declines, and have made recommendations for how to recover the species (see, for example, American Lands Alliance 2002, Connelly et al. 2000, USDI-BLM 2000 and 2001). Most states have convened local sage-grouse working groups to develop sage-grouse recovery plans built on collaboration across agencies and communities (see Nevada Sage-Grouse Project 2001, USDI-BLM 2001). Suggested conservation actions include educational programs about the species, mapping of sage-grouse habitat and distributions, research to evaluate how to manage and improve sage-grouse habitat, and habitat-restoration programs to recover the species and maintain habitat quality (Connelly et al. 2000, USDI-BLM 2001). Some proposed actions include significant changes to livestock grazing, and many biologists and environmentalists believe livestock grazing is the single greatest threat to sage-grouse (Clifford 2002).

A Memorandum of Understanding (MOU) between the Western Association of Fish and Wildlife Agencies (WAFWA), the U.S. Department of Agriculture, Forest Service (USFS), the U.S. Department of the Interior, Bureau of Land Management (BLM), and the USDI Fish and Wildlife Service (FWS) was signed in 2000. This MOU provided for the establishment of a team of representatives from the federal agencies and four states (Nevada, Idaho, Montana and Wyoming) to coordinate state and federal efforts to conserve sagebrush and sage-grouse. Specifically, the states and agencies agreed to consider, among other things, the WAFWA Guidelines to Manage Sage-Grouse Populations (Connelly et. al. 2000) in designing recovery plans for sage-grouse. These guidelines call for recovery plans that use local working groups to identify and solve regional problems related to the grouse. Local differences in conditions that affect sage-grouse populations may occur and Connelly et al. (2000) suggests these local differences should be considered in conservation plans.

Most management actions in completed state and regional sage-grouse plans are general and could apply in varying degrees to almost any area of the sagebrush ecosystem. This generality makes an assessment of potential impacts stemming from management changes impossible until local and specific courses of action are defined. One possible exception is livestock grazing.

Relatively healthy populations of sage-grouse occur in habitats grazed by domestic livestock, and grazing management in these areas results in habitat characteristics that support sage-grouse populations. However, low density or declining sage-grouse populations also occur in some areas characterized by a depleted herbaceous understory that may be the result of past or present grazing practices. Changes in grazing management may be necessary to increase sage-grouse populations, but experimental data are lacking to guide management decisions.

The political discussion surrounding livestock grazing and sage-grouse recovery is intense (see Clifford 2002). In many western states, the BLM lists the sage-grouse as a "sensitive species," and USFS defines it as a "management indicator species." This obligates these agencies to account for the needs of sage-grouse populations in their planning and management decisions. Management of public lands for the needs of livestock and sage-grouse will, at a minimum, require changes in land-use policies and goals. These changes are likely to occur even if an Endangered Species Act listing is postponed.

An example of these changes is a recent appeal by the National Wildlife Federation of a USFS environmental assessment (EA) on the Big Sheep grazing allotments in the Beaverhead-Deerlodge National Forest in Montana (National Wildlife Federation 2001). The appeal was based on two essential points. First, the appellants asserted that the USFS had failed to monitor sage-grouse populations over time on the grazing allotments in question. Second, the agency concluded that continuation of current grazing programs and maintenance of upland range improvements would have no significant impact on sage-grouse, even though the agency had virtually no population information for sage-grouse. The appellants argued that, because sage-grouse population data was lacking, this decision violated federal law. They requested that a "sage-grouse" alternative be added and the EA process be repeated with this alternative considered. The proposed alternative did not include elimination of grazing. It contained two main objectives (National Wildlife Federation 2001, p. 16):

> 1."...fully implement the *Guidelines to Manage Sage-Grouse Populations* (Connelly et al. 2000) by adopting range utilization standards that provide optimal breeding habitat and protect summer and winter habitats. Such an alternative would have forage utilization standards of around 25% (well

> below current levels), would avoid the construction of new water developments, and would assess whether elk winter range utilization was negating the effects of livestock utilization standards."
>
> 2."...reduce or eliminate the existing upland water developments and fences."

Sage-grouse is a management indicator species for the USFS and this appeal constitutes an example of how that management status will confront land agencies with demands to modify grazing use to meet the habitat needs of sage-grouse. Modifications to forage utilization, existing and potential range improvements and changes in grazing seasons in the name of sage-grouse are within the realm of likely policy changes.

Sage-grouse habitat needs for breeding, nesting and brooding coincide with the periods when cattle are grazing on public lands (Connelly et al. 2000). Thus, the habitat needs of the grouse will likely constitute a benchmark against which management policies will be judged under both the threat of and the event of an ESA listing. If sage-grouse habitat does not meet this benchmark, it is our conclusion that reductions in grazing on public lands (such as the 25% forage utilization limit mentioned in the USFS appeal discussed above) is as likely to occur as any other management change.

Given the continuing controversy and efforts to list the sage-grouse under the ESA, the Policy Analysis Center for Western Public Lands (PACWPL) was asked to evaluate policy alternatives and the implications of an ESA listing for both the sage-grouse and for affected human communities. This paper provides an analysis of potential ranch-level impacts from altered livestock grazing uses on public lands.

1.1. Impact Alternatives Considered

During the spring, sage-grouse chicks need herbaceous cover for protection. Forbs are particularly critical to their diet during this period (Connelly et al. 2000). While the condition of spring habitat is critical for the survival of sage-grouse chicks, this spring period is also critical for forage and livestock production. In this paper, we estimate the value of BLM spring forage for livestock production. We also estimate the economic consequences of eliminating spring grazing and reducing grazing capacity on BLM lands so as to improve and maintain habitat for sage-grouse. The projected economic consequences of two policy changes (i.e. eliminating spring grazing and reducing federal land allotments) would be applicable for numerous other endangered species and land-use issues where similar policy changes have been suggested. The answer is generic in its application.

Economic options available to many ranchers are to use deeded lands and meadows more intensively as grazing alternatives to public lands. Unfortunately, these same acreages are often prime habitat for sage-grouse, and adjusting seasons of use and stocking levels on deeded rangelands and meadows could be counterproductive. We make no judgment about whether the adjusted grazing strategies determined to be economically optimal with altered public land grazing policies would actually benefit sage-grouse. Our purpose is to provide an estimate of the economic value of public land forage potentially lost to representative ranches in each of three study states: Idaho, Nevada and Oregon.

2. Literature Review

2.1. Removal of Spring Grazing

On western ranches, the typical harvest pattern for forages and raised feeds, and level of dependence on western rangelands, varies by season. In northern climates where rangelands are grazed seasonally during the spring, summer and fall, a typical seasonal grazing use pattern may include feeding hay in November or December and continuing until March, April or early May when livestock are moved to BLM and state trust lands. During the summer, livestock may be moved to USFS permits or remain on BLM and state trust lands. As hay harvest is completed and temperatures cool in the fall, cattle are moved back to the ranch headquarters, grazing deeded lands and hay aftermath until the cycle starts again.

Rangelands traditionally provide a substantial amount of forage during selected seasons for many western ranches. If a ranching operation is permitted for yearlong grazing on public lands, as is typical in New Mexico and Arizona, a decrease in allowed federal grazing would likely reduce production in the same proportion as the decrease in available public AUMs. If the ranch is dependent seasonally on federal forage, a reduction in federal AUMs may create forage imbalances and produce a greater reduction in grazing capacity than just the loss of the federal AUMs.

The federal government has recognized the varying seasonal importance of federal grazing in many parts of the West. The 1986 Grazing Fee Review and Evaluation report (USDA/USDI 1986, p. 3) states:

> In numerous local areas in the West, the operating size of many livestock operations often is affected by the amount of federal range available during seasons of feed shortage on privately owned lands. Such critical periods may occur in the fall prior to hay feeding, in the summer when forage on private lands is low in nutritive value compared to forage on public ranges at higher elevations, and in the spring when private lands are needed to produce next winter's feed.

The impacts of eliminating or reducing spring grazing will depend on ranch resources and the substitute forage alternatives that are economically available. Obviously, the winter feeding period could be extended if spring grazing was eliminated, but this would increase feed costs. In many cases it would mean spring hay feeding would have to move from meadows to other areas so irrigation water could be applied.

Leased private lands might be available in the spring if public land grazing capacity were reduced, but in many cases additional grazing forage could only be leased by shipping livestock a substantial distance and with a substantial increase in feed costs. Marginal hay land could be converted to pasture and grazed, and grazing use of deeded rangelands and existing improved pastures could be adjusted by season where possible. However, in most cases there is little flexibility to implement seasonal changes in grazing use, and herd size reductions may be the only alternative, at least in the short run.

Some research on the economics of reduced or eliminated federal land grazing is available. Greer (1994) found that the reliance of southeastern Oregon ranchers on public lands can appear insignificant when calculated on an acreage or AUM basis, but, when calculated on a seasonal dependency basis, federal grazing is quite important. Taylor et al. (1992) found that, in Colorado, federal forage meets only 25% of annual forage requirements; yet, over 50% of summer season forage is obtained from federal lands.

Cook et al. (1980) found that changes in spring use had a greater impact on livestock sales per AUM for Colorado ranchers than did AUM changes in any other season. Van Tassell and Richardson (1998) also found that spring and summer forage obtained from public lands was critical to the operation of federally based ranches in Wyoming. Similarly, Torell et al. (1981) found the same situation for public land ranches in northern Nevada. Optimal production strategies and ranch income were not exceptionally sensitive to increases in the grazing fee, but production and net returns changed substantially when federal AUMs were removed from any season, particularly the spring season.

If an altered land-use policy means that grazing will not be allowed during the spring period, but the number of public land AUMs allowed for grazing is not correspondingly reduced, it is possible that eliminating spring grazing and shortening the allowed grazing period on public lands would increase optimal herd sizes. Torell et al. (1981) estimated this would be the situation for northeastern Nevada ranchers when spring grazing was eliminated. Given the cost/price definition of the analysis, the profit-maximizing strategy was to make up lost public land AUMs during the spring period by feeding more hay and to substitute other forages where possible. Net returns were reduced, but it was most profitable to use BLM AUMs previously grazed during the spring in other seasons and to expand herd size. For other ranches with few low-cost alternative sources of forage, optimal herd size could decrease with the elimination of spring grazing.

2.2. Allotment Reductions

Linear programming (LP) and ranch budgeting procedures have been used to estimate the seasonal value of public land forage (Bartlett 1983, Gee 1983, Hahn et al. 1989) and to estimate economic impacts from changes in federal land policies (Bartlett et al. 1979, Gee 1981, Perryman and Olson 1975, Rowe and Bartlett 2001, Torell et al. 1981, Van Tassell and Richardson 1998). All of these earlier LP models were single-year models that considered production under some defined average cost/price situation. Typical or representative ranches were defined from available cost-and-return studies in the various study areas. These studies found reductions in income and net ranch returns were not proportional to reductions in federal forage. The rigidity of seasonal forage availability meant the optimal use of other forages and resources were impacted when federal AUMs were removed. Other forages were reallocated to offset part of lost federal forage (Gee 1981, Van Tassell and Richardson 1998).

Gee (1981) and Hahn et al. (1989) used LP to estimate forage value on BLM and USFS lands. Forage values in 1981 were estimated to be $10.86/AUM for BLM and $11.58/AUM for USFS (Gee 1981). Hahn et al. (1989) updated Gee's work and reported forage values for each of nine USFS regions and as a national average. Values ranged from $9.22/AUM in Region 3 (New Mexico and

Arizona) to $15.11/AUM in Region 5 (California). Van Tassell and Richardson (1998) reported much higher values for BLM and USFS AUMs. For the Wyoming ranches studies, complete elimination of the BLM permit was estimated to decrease annual net cash income by an average of $55/BLM AUM removed. Eliminating the USFS permit decreased annual net returns by a similar amount, $52/AUM. At the other extreme, because some western ranchers are not necessarily in the business to make a profit and spend more than they justifiably should to produce livestock, Rowe and Bartlett (2001) found that eliminating federal grazing permits in Colorado would actually benefit some ranchers by forcing them to reduce the size of their money-losing livestock enterprise. Economic changes from allotment adjustments varied widely, ranging from a loss of $40/AUM to a gain of $27/AUM when herd reductions were the assumed adjustment strategy.

3. Methods and Procedures

We define the economic situation, typical resource base, production rates and practices for western ranches in three areas in the West: Owyhee County, Idaho; Northeastern Nevada; and Lake County, Oregon. Representative ranches in these areas were selected because livestock cost-and-return estimates and policy impact models had been developed for these areas. Additionally, ranches in these areas provide sage-grouse habitat and are dominated by the sagebrush rangeland type.

Data from cost-and-return studies were used to build multi-period linear programming (LP) models to evaluate how optimal (profit-maximizing) production strategies would change as permitted grazing use on public land changes. The specific ranches considered included medium-sized (300 cows) ranches in the Jordan Valley area of Owyhee County, Idaho; large ranches (720 cows) in northeastern Nevada; and large ranches (500 cows) in Lake County, Oregon.

The economic analysis was completed in four steps. First, ranch-level data defining typical production practices, production rates and production costs were gathered from group interviews with area ranchers (Darden et al. 2001, Rimbey et al. 1998, Oregon cost-and-return studies have not yet been published). Second, a multi-period linear programming model was developed to depict the production processes of each representative ranch. Published cost-and-return studies that provided baseline cost data were for either the 1997 or 1998 production years. All prices were adjusted to real 1997 levels.

An initial baseline optimization was estimated for each model ranch. This was followed by additional optimizations that evaluated profit-maximizing production strategies under different policy scenarios. The estimated impact of changes in land-use policies is then the difference in optimal herd size, forage use and economic returns as compared to the baseline.

The projected economic consequences of two policy changes, elimination of spring grazing on BLM land and BLM allotment reductions, are evaluated. For eliminating spring grazing, we considered the removal of the first month of grazing. Spring grazing dates considered varied between the representative ranches because typical turn-out dates are different for each ranching area and ranch model, but in all cases the defined spring period would correspond to a period of critical concern for sage-grouse. During these spring months, sage-grouse use sagebrush habitats for breeding, feeding, roosting, nesting and rearing young. Available sagebrush, herbaceous cover and insects are considered to be critical for sage-grouse chick survival during the spring period (Connelly et al. 2000).

Allotment reductions considered included a 50% reduction, 75% reduction and total elimination of available BLM AUMs. The actual reduction level that might be necessary to improve sage-grouse habitat on a particular allotment, and alternative management options that could be used to minimize the disruption of grazing uses, will be site specific and variable. Further, reduction levels considered in the analysis may not be adequate because of the inter-dispersed nature of land tenure on many western ranches. State trust lands are often small, scattered parcels located with the BLM allotment, and private lands are also scattered within allotment boundaries. The Jordan Valley, Idaho model, for example, was defined to have state trust lands in addition to BLM lands, but the exact location of these lands was not defined. Elimination of spring grazing or reductions in federal land grazing may mean elimination or reductions on these other lands as well.

Each representative ranch has different amounts and types of resources defined to be available for grazing, and different options for replacing public land forage. Substitute forages and strategies considered to be available as BLM allotment grazing capacity was reduced included leasing outside private forage, converting native meadow hay land to irrigated pasture, extending the hay feeding period, and reducing the size of the cow herd. These alternative forage sources were considered to be available during selected seasons for both the base run and for additional policy impact runs. Converting hay land to pasture was not considered an option in the Oregon model because of the improved meadow and meadow hay produced.

We considered two alternative analyses for the elimination of spring grazing on BLM land. The first scenario was restrictive but may be most realistic in many cases because of limited opportunities to develop forage substitutes. This scenario considers only the options of feeding hay or reducing herd size. The second scenario allowed leasing outside private AUMs, converting hay land to pasture, moving the season of use of all deeded land to the spring, extending the winter feeding period, and reducing herd size.

We considered reductions to the BLM allotment to be phased in over five years in equal increments. The first 1/5 of the reduction was considered to occur during the second year. Results reported for optimal number of BLM AUMs used started with the sixth year when the full reduction had been implemented.

3.1. Linear Programming Model Description

The policy impact models used in this analysis were developed in five states and are structured for western livestock ranches that rely on both deeded and public lands for grazing capacity. A limited number of crop-raising alternatives are included in the models, but only as these crops provide forage, crop residue and feed for livestock production.

The net present value (NPV) of discounted net annual returns (profits or gross margin) is maximized over a T-year planning horizon subject to linear constraints that define resource limitations and resource transfers between years. Seasonal forage supply and demand is explicitly considered.

Figure 1 illustrates the general structure of the constraint set for the LP models during a given year t. Equations are discussed from top to bottom in the figure. A ranch has available a given set of cropland and rangeland for harvest and grazing. Each type of land is restricted at a level at or below some available upper limit, and that is the first block of equations in the model. Also considered in this block is recognition that certain forages will be restricted in use to only selected seasons, because of regulation, physical availability or production limitations.

The next block of equations is included to

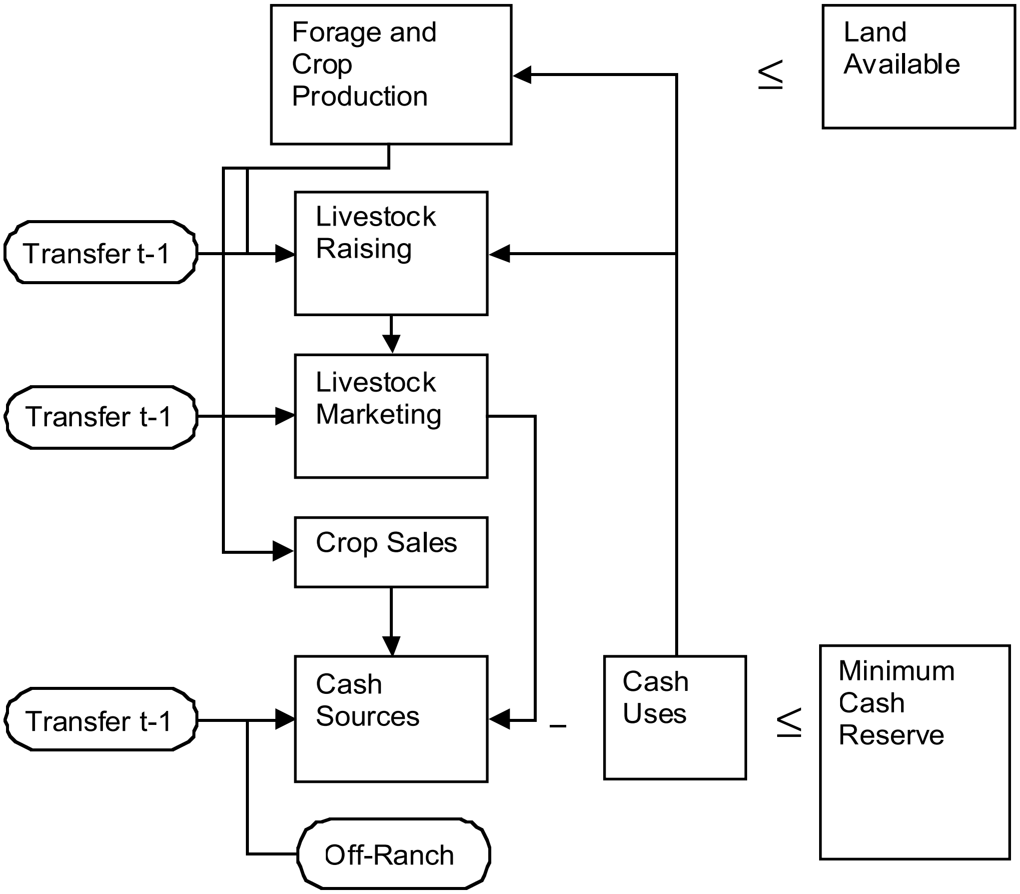

Figure 1. LP model constraint structure.

transfer forage and crop production to livestock-raising activities and crop-selling activities. Within the livestock-raising block are equations that define the required ratio between different animal classes. Some examples: bulls must be included based on a specified bull-to-cow ratio and the specified calf crop defines the number of young animals available for sale and herd replacement.

Seasonal forage requirements for each animal class are calculated based on defined animal unit equivalencies (Table 1) and the length of each grazing season. Equations are also included that transfer brood animals from the previous year. Typical animal death loss and the relative number of different animal classes are considered at the time of the transfer. The livestock-marketing block includes equations that transfer between livestock-raising and livestock-selling activities. Yearling animals are carried over from year t-1 to year t; this is another inter-year linkage in the model.

Table 1. Animal unit equivalencies used to calculate seasonal forage requirements [from Vallentine (1990)].

Animal Class	Animal Unit Equivalency (AUE)
Brood cows	1.00
Bulls	1.25
Horses	1.25
Weaned calves	0.50
Yearlings	0.75

The next equations define the cash flow constraint. Crop and livestock sales generate income and are a source of cash. Livestock-, crop- and forage-raising activities use cash. The cash constraint requires that a cash reserve be maintained so as to cover variable production expenses, fixed ranch expenses, family living expenses, loan obligations and an annual cash residual. Excess cash at year t-1 can be transferred to year t, and in fact it is implicitly assumed that any excess cash from a "good" year will be transferred to cover expenses and cash shortfalls in future years. Other sources of cash include off-ranch income and annual borrowing. Any funds borrowed must be repaid during the next year. Borrowing is not allowed during the last year and all debt obligations must be paid in full by the end of the T-year planning horizon. While numerous equations are included to define the production and economic processes of the representative ranch, forage resources and available cash ultimately determined the level of production possibilities.

Torell et al. (2001) and numerous other studies reviewed in that paper highlight that western ranchers do not have profit maximization as the primary goal; rather, they ranch for the way of life and the desirable attributes of rural living. As noted by Van Tassell and Richardson (1998), western public land ranchers will, for the most part, continue to ranch until forced to do something else. How, then, do we justify using profit maximization as our model objective? First, the utility-maximization model that ranchers subscribe to is impossible to measure and quantify. Individual ranchers and ranch families have differing levels of commitment to the ranching lifestyle and decreasing annual ranch income through altered land-use policies can be expected to dampen enthusiasm for ranching to varying degrees. It will not be possible to predict how many ranchers a particular land-use policy will force out of business (Torell et al. 2001).

The profit-maximizing objective provides a measurable criterion against which to judge policy changes. It is tempered by considering only investment alternatives related to ranching and livestock production, and by including cash flow restrictions. The LP model determines the optimal production strategy with the current policy prescription and how optimal production changes with a new policy. The implicit assumption is that ranch families will continue to consider only the limited investment opportunities associated with the ranch property; they prefer more money to less; and will continue to ranch until cash flow restrictions can no longer be met and they are forced from the business.

3.2. Representative Ranches

Table 2 summarizes forage resources, typical production rates and costs, and forage harvesting alternatives defined for each of the representative ranches. The grazing seasons and the seasons when alternative forages were considered to be available for grazing are defined in Table 3. Grazing seasons were defined based on typical turn-out dates, potentially adjusted turn-out dates and livestock marketing dates. Notice that the cost per unit of harvesting both federal and private forage (Table 2) includes both fee and non-fee grazing costs (e.g. herding cattle, checking cattle, improvement maintenance) as estimated by Van Tassell et al. (1997) and Van Tassell and Richardson (1998). The cost of leasing private rangeland in Nevada was considered to be exceptionally high ($30/AUM) because little private forage is available for lease in the state and this activity would require high non-fee costs because of the distance to available private leases.

Table 4 presents the assumed productivity of rangeland and pasture resources for each of the

Table 2. Characteristics and resources of the representative ranches.

		Number of Units			Objective Function Cost ($/unit)		
	Units	Idaho	Nevada	Oregon	Idaho	Nevada	Oregon
Land resources owned							
Alfalfa hayland	Acres			90			400.00
Native meadow hayland	Acres[a]	325	800	290	50.00	50.00	97.00
Convert meadowland to pasture	Acres[a]	325	800		13.75	12.50	
Deeded rangeland	AUMs	240	115	600	3.25	3.25	3.25
Land resources leased or purchased[b]							
State trust land	AUMs	144			10.64		
BLM	AUMs	2,098	4,148	2,400	7.19	7.19	7.19
USFS	AUMs			2,560			9.46
Private leased land	AUMs	500	500	500	13.25	30.00	13.25
Purchase alfalfa hay	Tons		Unlimited		100.00	85.00	120.00
Purchase meadow hay	Tons		Unlimited		NA	70.00	85.00
Sell alfalfa hay	Tons		All available				100.00
Sell meadow hay	Tons		All available		55.00	55.00	65.00

Bulls	Head	19	36	29			
Horses	Head	6	12	10			
Miscellaneous income/expenses							
Fixed ranch expenses	$				24,430	33,361	25,432
Family living allowance	$				24,000	24,000	24,000
Off-ranch annual income	$				30,000	10,000	10,000
Required minimum cash reserve	$				500	500	500
Efficiency measures[d]							
Calf Crop (Calves born as % of Jan. 1 cow inventory)	%	88	85	90			
Calf death loss	%	4	3	4			
Cow death loss	%	2	2	2			
Bull death loss	%	1	1/2	1			
Steer calf sale weight	lb	440	475	525			
Heifer calf sale weight	lb	390	435	450			
Heifer yearling sale weight	lb	800	750	850			
Cull cow sale weight	lb	950	950	1,100			
Cull bull sale weight	lb	1,800	1,450	2,000			

[a]/Converting hayland to grazable pasture is not generally practiced but is a possible source of forage if public land AUMs are removed. This conversion would use some of the available hayland and thus would reduce the land available for crop production. The cost of the conversion was estimated by Van Tassel and Richardson (1998).

[b]/In addition to the $1.35/AUM grazing fee that has been paid for public land grazing in recent years, grazing costs shown above include estimates of non-fee grazing costs (e.g. herding, checking, moving). These estimates were made by Van Tassell and Richardson (1998) using rancher producer panel data and grazing cost data reported by Van Tassell et al. (1997).

[c]/Animal numbers reported are from the published cost-and-return publications for each state. Optimal animal numbers in the LP model will vary by year as beef prices vary. Animal costs exclude the cost of feed stuffs and non-fee grazing costs which are separate activities in the LP model. Animal costs include expenses for other classes of animals like bulls and horses as well.

[d]/Other production parameters used to develop the LP models are defined in the cost-and-return series publications.

Pasture native hayland	AUMs/acre	5.5	5.0	

representative ranches. These rates were defined in the cost-and-return publications for each state.

3.3. Linear Programming Analysis

Optimal production and economic returns for the representative ranches was simulated over a 40-year planning horizon with 100 different iterations (beef price situations). The ranch starts the process in year 1 with an inventory of breeding animals (Table 2). From this point, during years 2 through 40, the model is free to adjust herd size (purchase or sell) to profit-maximizing levels subject to forage and cash limitations. Forage and pasture resources can be grazed or not grazed depending on its potential contribution to profit. An exception to this was state trust land in Idaho. Because the Idaho Department of Lands requires fees be paid whether the land is grazed or not, the restriction was included that state land AUMs had to be used.

3.3.1. Output Prices

Annual ranch income and optimal production strategies are greatly influenced by crop and livestock prices. To minimize the effect of beef prices on the results of the policy assessment, a Monte Carlo analysis was used (Hillier and Leiberman 1986). Real (constant 1997) livestock prices were stochastic exogenous variables in the LP analysis. Monthly average livestock prices were used from markets in each of the three study states for the period January 1, 1980 to August 24, 2000 (Unpublished data supplied by David Weaber, Cattle-Fax, Inc., Centennial, Colo., Sept. 8, 2000) to estimate a time series price-forecasting model. The beef price model considers and estimates an approximate 12-year cycle of beef prices. It considers the relative price spread between different classes of livestock and the interdependence of beef prices for different animal classes at any point in time.

The starting point of the beef price cycle was randomly assigned for each iteration. Running the model with numerous alternative beef price scenarios and reporting averages and standard deviations across all iterations minimizes the effect of beef prices in the policy impact assessment.

The cost of purchasing bulls was not reported in the Cattle-Fax data. Data from the Tucumcari, N.M. bull sale was used to estimate that the sale price of bulls (constant 1997) is about twice that of bred cow prices.[1]

Hay prices were not varied by iteration because a long-term data series was not available to estimate annual price variability and relationships. The assumed real purchase and sale price of hay (Table 2) was considered to be the same during each year of the analysis. Another limitation was that annual fluctuations in forage production were not considered. While the importance of variability in annual forage production and the need to adjust stocking rates downward when production is low is widely recognized (Vallentine 1990), it is rarely considered in economic studies because of data limitations. We followed the standard analysis procedure of assuming an average annual level of forage production from each alternative forage source.

Initial debt obligations were not considered as an expense category in the analysis. This is because cost-and-return data used to define typical production practices, production rates, and costs and returns of the representative ranches do not include information about "typical" debt obligations of area ranchers. This personal data is generally not available and is known to vary widely from ranch to ranch. Gentner and Tanaka (2002) reported relatively low average debt loads for different classifications of public land ranchers responding to a West-wide survey.

The amount of off-ranch income and wealth available to ranch families is also variable. Recent studies have found new ranch buyers are not the traditional ranch family that depends exclusively on the ranch for disposable income (Gentner and Tanaka 2002, Torell et al. 2001). People with wealth or great outside income are purchasing many western ranches. As an overall weighted average, Gentner and Tanaka (2002) found large, full-time ranchers to have about $10,000 in annual off-ranch, retirement, and/or investment income. Small, part-time ranchers had $47,000 in off-ranch and other income, and depended on the ranch for less than 20% of annual disposable income. By comparison, full-time ranchers depended on the ranch for about 80% of disposable income (Gentner and Tanaka 2002).

While debt loads, wealth and off-ranch income are highly variable between ranches, the commitment of western ranchers to remain on the ranch remains constant (Gentner and Tanaka 2002, Torell et al. 2001). Given this commitment and the variability in financial resources across ranches, we followed two modeling procedures. First, we did not include investment opportunities like land development or the stock market. The LP model maximizes net discounted returns given the economic opportunity of raising cows or selling hay. Second, we assumed that the representative ranch would have at their disposal average levels of off-ranch income near that found by Gentner and Tanaka (2002). We assumed the 333 AUY ranch in Jordan Valley, had $30,000 in off-ranch income and the larger Nevada and Oregon models had $10,000 in off-ranch income. We assumed no initial wealth other than the initial inventory value of breeding animals and the ranch capital investment. For the base run and impact assessment, there were no debt obligations against the cow herd or the land. Given the known variability in debt across ranches, we then conducted a sensitivity analysis to investigate how the base run and policy impacts would change with increasing debt obligations and/or reduced levels of off-ranch income. We computed the average annual debt payment that could be sustained before and after the land-use policy change. The cash flow constraints of the LP model are of key importance for this assessment in that they require all variable, fixed and family living expenses to be covered each year, given calculated

---

[1] The regression equation estimated was Bull Price = 154 + 2.0549_Bred Cow Price, R^2 = 73%. [Annual average prices 1975 – 2001].

annual ranch returns and alternative assumptions about off-ranch income.

Annual borrowing was allowed (10% annual interest rate) with the full amount repaid the following year. The model allows repeated borrowing from year to year across a 40-year planning horizon, but debt must be repaid at the end of that period. Incurring an annual land payment or intermediate loan payment is equivalent to having an additional fixed expense obligation. If fixed expense obligations are too high, the cash flow constraint cannot be met and an "infeasible solution" is obtained. This is how the sensitivity analysis was conducted. The assumed level of off-ranch income was repeatedly reduced and even made negative (implying a borrowing situation) to investigate how decreasing levels of off-ranch income and increasing levels of debt added to the frequency by which annual cash flow requirements would become limiting. This was done for both the base run and the policy impact runs.

The sensitivity analysis presents a best-case situation because the model assumes that all excess funds in good years are saved to meet future cash shortfalls. With this definition the ranch family does not squander money during the good years; they live within the $24,000 family living allowance. Other fixed obligations of the ranch including depreciation and replacement of vehicles, equipment and improvements; electricity; telephone; and insurance are also subtracted as an annual fixed expense (Table 2).

4. Results

4.1. BLM Grazing Reductions

4.1.1. Jordan Valley, Idaho Model

Table 5 presents the average and standard deviation [computed over 100 beef price situations (iterations) and 40 years] of key production, and economic and resource variables estimated to be optimal (profit-maximizing) for the Jordan Valley, Idaho model under different levels of BLM AUM availability. For the current situation, given the defined seasonal forage resources of the representative ranch, approximately 22% of BLM AUMs would optimally go unused each year because cash and forage resources in other seasons are more limiting. An average 345 AUY would be maintained on the ranch. Annual net cash income[1] was estimated to be $8,856 with a great deal of variability (standard deviation of $21,820). Given an assumed annual input of $30,000 from off-ranch sources, this means the ranch was subsidized by off-ranch employment by about $21,000/year. Approximately 35% of the time net annual income (including ranch and off-ranch sources) would be negative, requiring transfer of savings from previous years or borrowing to meet cash flow requirements. These periods of negative income occurred in low beef price years or when herd expansion was economically optimal.

With off-ranch income and assumed frugal behavior and saving, the Jordan Valley model was always able to find a feasible solution, i.e., cash flow requirements could always be met. Only a minimal amount of annual borrowing was required with current allowed uses of federal forage.

As BLM grazing was sequentially reduced, net annual ranch returns decreased. The reduction in net ranch income per BLM AUM removed ranged from $2.41/AUM with a 50% BLM reduction to $3.44/AUM when BLM grazing was precluded. Average annual net cash income decreased from $8,856/year under the current situation to $1,631/year with a 100% BLM grazing reduction. This is the average residual amount that remains as a return on total ranch investment once all variable costs, loan costs, fixed costs and family living expenses have been paid.

Because the representative ranch did not depend on BLM land for 100% of annual grazing capacity, the optimal reduction in herd size was far less in percentage terms than the percent reduction in BLM forage. A 50% BLM reduction, for example, reduced optimal average herd size by 19% and a 100% BLM reduction reduced optimal average herd size by 42% (Table 5). This reduction is very near the average 39% that the representative ranch depended on BLM for annual grazing capacity under the current allotment allocation.

In addition to herd size reductions, other optimal adjustments to reduced BLM AUMs included conversion of hay land to pasture. Over 100 acres of hay land would optimally be used as pasture if the total BLM allotment were removed (Table 5). At an assumed cost of $13.25/AUM, private leased forage would only be the least-cost forage substitute when beef prices were relatively high and minimum number of private leased AUMs would optimally be used.

4.1.1.1. Sensitivity Analysis

It was assumed that the representative Jordan Valley model ranch had at its disposal an annual $30,000 in off-ranch income. The utmost level of

---

[1] /Net cash income was defined to be gross crop and livestock sales + off-ranch income – variable production expenses – annual loan costs – fixed ranch expenses - family living expenses. It is the residual return to the investment in land and cattle, and to risk.

frugality was assumed with all excess funds in the good years saved to meet shortfalls in future years. With this frugal savings plan, a minimal level of annual borrowing was required.

Figure 2 shows how the likelihood of going broke (i.e. incurring an infeasible solution) increased with decreasing amounts of off-ranch income and for alternative reductions in available BLM AUMs. As shown, access to about $25,000 in outside annual income is crucial. With the current allocation of BLM AUMs, the Jordan Valley ranch would be unable to meet cash flow requirements in 5 out of 100 iterations (beef price situations) when off-ranch income was reduced to the $25,000 level. These infeasible solutions occurred when relatively low beef prices were realized in the early years of the analysis.

As off-ranch income was reduced to $20,000/year and below, cash flow restrictions became limiting in all cases. The $15,000 range in off-ranch income (from $30,000 to $15,000) between being able to always meet annual ranch and family expenses and the 100% probability of going broke is extremely narrow. There is no ability to service

[a]/Number in parenthesis is the standard deviation measured over the 100 iterations and 40 years.

[b]/The assumption was made that the reduction in allowed grazing capacity would be incrementally phased in over 5 years. Thus, the computed average is for years 6 through 40 after the reduction is fully implemented.

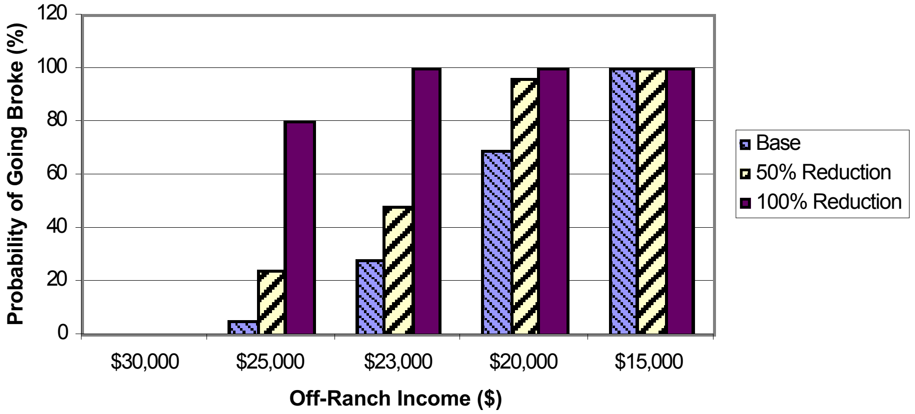

Figure 2. Probability of not being able to meet cash flow requirements with alternative levels of off-ranch income and with BLM allotment reductions, Jordan Valley, Idaho model.

long-term or intermediate debt from net ranch income for this 300-AUY ranch. This representative ranch must be subsidized by off-ranch income or accumulated wealth if the assumed fixed costs and family living allowance is to be paid each year.

The percentage of time that the representative ranch went broke increased as increasing levels of BLM forage was removed. Removal of the BLM permit would cause an 80% probability of going broke when off-ranch income was reduced from $30,000, to $25,000 (Fig. 2).

As shown by Gentner and Tanaka (2002), many public land ranchers have annual off-ranch income and wealth far in excess of what was assumed here. Others have less. Whether ranchers will remain in business as federal AUMs are removed will depend on their willingness to incur reduced ranch income, and their commitment to the ranching lifestyle. The cash flow restriction does not limit production opportunities for ranchers subsidizing the ranch enterprise with large amounts of off-ranch income and wealth, but it was a limiting factor for the defined representative ranch.

4.1.2. Northeastern Nevada Model

Table 6 presents results for the Northeastern Nevada model under different levels of BLM AUM availability. About 7% of available BLM AUMs would optimally go unused with the current AUM allocation. An average 728 AUY would be produced on the ranch. Annual net cash income was estimated to be $30,794 ($42.30/AUY) with the current BLM allotment. Given an assumed annual input of $10,000 from off-ranch sources, this means the representative northeastern Nevada ranch returned an average net annual profit from livestock and crop production of about $20,800/year (i.e., return to investment and risk). Approximately 25% of the time, net annual income would be negative.

As BLM AUMs were reduced by 50%, 75% and 100%, a nearly constant reduction in net returns per AUM was estimated, $5.77/AUM, $6.03/AUM and $6.16/AUM, respectively (Table 6). Annual net cash income decreased from $30,794/year under the current situation to $5,259/year (83% reduction) with a 100% BLM grazing reduction. This means the ranch would move from a positive average profit of $20,800/year to an average loss of $4,741/year with removal of the BLM permit. Annual net cash income was estimated to be positive because of the assumed off-ranch income. With a 100% BLM reduction, 44% of the time, annual net cash income would be negative. In addition to herd size reductions, other optimal adjustments to reduced BLM AUMs included conversion of hay land to pasture (Table 6). Private leased land was not profitable to graze at the assumed $30/AUM cost for the Nevada model (Table 2).

4.1.2.1. Sensitivity Analysis

A negative level of off-ranch income is equivalent to including an annual loan payment or cash outlay. Sensitivity analysis indicates the representative Northeastern Nevada model, given the current allocation of BLM grazing capacity, could incur an additional $10,000 fixed annual

[b]/The assumption was made that the reduction in allowed grazing capacity would be incrementally phased in over 5 years. Thus, the computed average is for years 6 through 40 after the reduction is fully implemented.

payment and still cover production expenses, fixed costs and the family living allowance. With this $10,000 annual payment, the model would fail to meet cash flow requirements only 2% of the time (Fig. 3). This payment could service an approximate $100,000, 30-year loan to purchase the ranch, or a revolving $35,000 5-year loan (assuming a 9% interest rate). The likelihood of going broke quickly increases as additional $5,000 increments of annual loan obligation are added. Further, the ability of the representative Northeastern Nevada ranch to incur added debt is quickly removed as BLM AUMs are removed (Fig. 3). The average optimal size of the ranch moves from 728 AUY with the current BLM allotment allocation to 389 AUY when the permit was removed (Table 6), and this reduced ranch size is no longer able to generate the income needed to cover loan payments.

4.1.3. Lake County, Oregon Model

Table 7 presents results for the Lake County, Oregon model under different levels of BLM AUM availability. All available BLM AUMs would be used each year with the current allotment allocation and resource combination. About 2% of available USFS AUMs would optimally go unused in the baseline situation. An average of 723 AUY would optimally be produced on the ranch. Over half (57%) of the grazing capacity of the ranch would come from BLM and USFS grazing allotments.

Annual average net cash income was estimated to be $50,059/year ($69.24/AUY) with current BLM and USFS allotments. Approximately 16% of the time, net annual income would be negative.

The economic impact of sequentially reducing the availability of BLM AUMs ranged from about $10/BLM AUM removed for 50% and 75% BLM allotment reductions to $11.77/AUM with total elimination of BLM grazing. Annual net cash income was reduced to $21,808/year (56% reduction) with a 100% BLM reduction (Table 7).

With a 100% reduction in BLM grazing, the optimal use of USFS AUMs would be reduced by about 11%. Some of the BLM AUMs were replaced by leasing increasing amounts of private forage (Table 7), but the primary way the profit-maximizing model adjusted to AUM reductions was to reduce herd size. The average number of livestock produced was reduced from 723 AUY with the current allotment allocation to 485 AUY (33% reduction) with elimination of the BLM permit (Table 7). The representative Lake County, Oregon model is defined to have substantial hay land resources and optimally switches to hay selling when the size of the BLM allotment is reduced.

4.1.3.1. Sensitivity Analysis

With the current BLM and USFS allotment allocation, the representative Lake County, Oregon model could sustain a $40,000 annual debt payment (Fig. 4). Similar to the other two ranch models, removing BLM AUMs reduced the optimal scale (herd size) and profitability of the ranch. The ability to service debt was increasingly reduced with increasing reductions in BLM grazing capacity.

4.2. Eliminating Spring Grazing

4.2.1. Jordan Valley, Idaho Model

The representative Jordan Valley Ranch under current policy turns out on BLM and state lands on April 15. Table 8 presents the optimal seasonal grazing use when the turn-out date is moved to May 15. In this analysis, the only possible or allowed grazing alternative was to extend winter feeding through the April 15 – May 15 period. Herd size

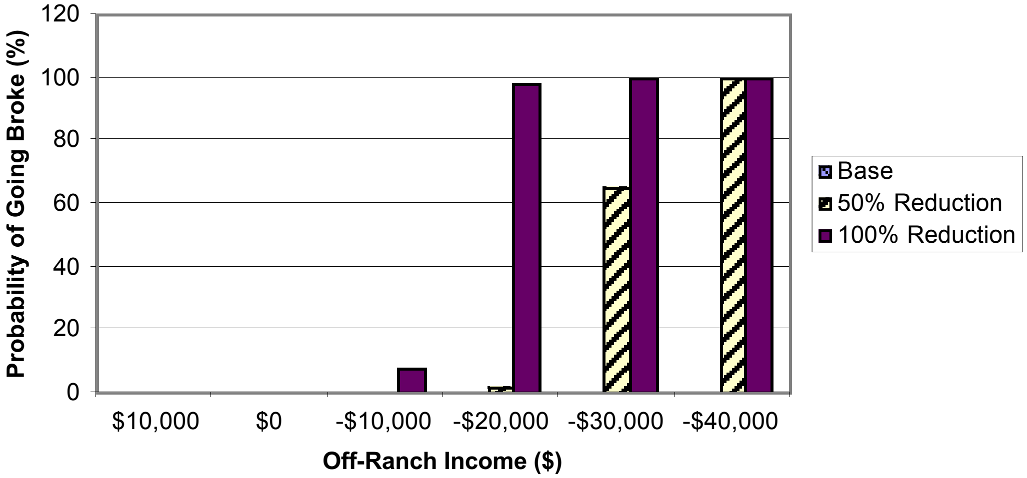

Figure 4. Probability of not being able to meet cash flow requirements with alternative levels of annual debt payment and with BLM allotment reductions, Lake County, Oregon model.

could also be altered if that was most profitable.

With these two available options, the profit-maximizing adjustment would be to reduce average herd size from 345 AUY to 274 AUY. An estimated 75 tons (182 AUMs) of hay would be required to replace the loss of AUMs of grazing capacity previously harvested from BLM land (Table 8). With the reduced herd size, 18 tons of additional hay would be sold.

The average 248 AUMs previously grazed during the April 15 – May 15 on BLM land was not removed from potential grazing; only the season of use was restricted in the analysis, but, eliminating spring grazing reduced optimal average BLM AUM use to 972 AUMs. This was a 683 AUM reduction relative to the base run. Spring grazing now limits annual production, and AUMs supplied in other seasons are not economically useful; thus, elimination of spring grazing became economically equivalent to an allotment reduction.

Average net economic returns decreased by $5,994 with the elimination of spring grazing (Table 8). When divided by the 248 AUMs previously grazed on BLM land during the spring period (Table

8), the loss in net returns is $24.17/AUM removed.

The economic impact of removing spring grazing will depend on what alternative forages are considered to be available. Thus, as a second analysis, spring grazing on BLM land was removed, but in this case it was assumed the ranch could freely adjust the seasonal use of all deeded AUMs. Hay land could be converted to pasture and grazed in the spring, and private leased land could be leased during the spring. With these forage alternatives (table not shown), the economic impact of removing spring grazing on BLM land was much less ($5.34/AUM removed from spring grazing). The optimal adjustment would be to graze nearly all deeded AUMs in the spring and lease a small amount of private AUMs. Optimal herd size would be reduced to 311 AUY. Optimal BLM AUM use would decrease to 1,342 AUMs.

The flexibility to have alternative forage sources is likely not possible for many of the Jordan Valley ranches, but the analysis clearly shows the potential to minimize the economic impact of removing spring grazing if other grazing resources can be substituted.

4.2.2. Northeastern Nevada Model

The representative Northeastern Nevada ranch under current policy turns out on BLM land on April 8. Table 9 presents the optimal seasonal grazing adjustments when the turn-out date is moved to May 8. In this analysis, the only possible or allowed grazing alternative was to extend winter feeding through the April 8 – May 8 period. Herd size could also be altered.

With elimination of BLM spring grazing, hay sales would be reduced from 221 tons to 120 tons.

An estimated 222 tons (538 AUMs) of hay would be required to replace the loss of AUMs of grazing capacity previously harvested from BLM land during the spring (Table 9). Average herd size would also be reduced from 728 AUY to 589 AUY.

Eliminating spring grazing reduced optimal average BLM AUM use to 2,187 AUMs. This was a 1,684 AUM reduction (44% reduction) from the base run. A major shift in the seasonal use of forage would optimally occur. BLM AUMs supplied in other seasons could not economically be used because of the forage shortages in the spring.

Net economic returns decreased by $17,171 with elimination of spring grazing (Table 9). When divided by the 665 AUMs previously grazed on BLM land during the spring period, the loss in net returns was $25.82/AUM removed from spring grazing. If more seasonal flexibility of other forages was assumed, the estimated loss would still be relatively high, $18.76/BLM AUM removed in the spring. In this second analysis, additional hay land would optimally be converted to pasture and deeded AUMs would be allocated for spring grazing (table not shown). Hay feeding would not increase. Similar to the Jordan Valley, Idaho model, grazing alternatives are cheaper then hay feeding if those alternatives exist.

4.2.3. Lake County, Oregon

The representative Lake County, Oregon ranch under current policy turns out relatively early on BLM land (March 1). Table 10 presents the optimal adjustments when this turn-out date is moved to April 1. Alternative sources of spring forage considered only the feeding of hay. Herd size could be altered if that would be more profitable. With these two allowed adjustments, the optimal strategy would be to extend the winter hay feeding period by a month. The 285 BLM AUMS removed during March would optimally be used later in the grazing

Table 9. Optimal adjustments to elimination of spring grazing on BLM land, Northeast Nevada model.

[1]/Number in parenthesis is the standard deviation computed over the 100 iterations and 40 years.

season, allowing herd size to increase by 19 head.

This result of using the BLM forage during a later season and increasing herd size is different from the results for the Nevada and Idaho models, but similar to the findings of Torell et al. (1981). The Oregon model is defined to have substantial hay resources, yet the assumed production cost of the hay ($/ton) is nearly equivalent to the sale price (Table 2). By comparison, the profit margin is defined to be $22/ton for the Idaho and Nevada models. Further, developing marginal hay meadows for grazing was not considered to be a viable option for the Oregon model whereas these activities were included for the Idaho and Nevada models. For the Oregon model, limited alternatives for hay land were included and the opportunity cost of feeding the hay to cows was relatively low. This likely explains the difference in the optimal adjustment strategy when spring BLM AUMs were removed.

The economic consequences of eliminating spring BLM grazing was to reduce net income by $8.17/BLM AUM removed from grazing during March. The total loss of net income for the ranch was $5,607.

If an expanded number of leased private AUMs are allowed to be grazed during the March period (table not shown), the economic consequences of removing spring grazing on BLM is minimal. Under the current situation, the ranch optimally leases an average of 250 AUMs of private leased forage. Most of that is leased May 1 to October 1 (Table 10). If the ranch has the flexibility to alter when those private AUMs are leased, the cost-minimizing adjustment would obviously be to move them to March and graze BLM later in the summer. By doing this, the model suffered no economic losses from the season-of-use adjustment. Economic returns and herd size remained unchanged; just the seasonal use pattern of forage was changed.

5. Summary and Conclusions

Public land is an important seasonal source of forage for western ranches. Thus, eliminating BLM grazing to improve habitat for sage-grouse would

have a significant impact on the economic viability of affected ranches. This is especially true during the spring period. Early spring grazing is valuable because few alternative forage sources are available at that time. In most cases, the only feasible forage alternative would be to feed hay.

Rowe and Bartlett (2001, p. 64) concluded that once hay was needed to compensate for public forage losses, reducing herd size would be the most cost-effective adjustment. Our results generally support this conclusion. Making alterative grazing resources available during the spring always minimized losses relative to feeding hay or reducing herd size. If complete flexibility of other deeded forages were assumed, the economic loss of restricting the early use of BLM lands was minimal; seasonal use of alternative forages would be rearranged with little if any economic consequence.

The economic value of the BLM forage during the spring period was found to be 5 to 10 times the value in other seasons later in the year for both the Idaho and Nevada models. In this case, the elimination of spring grazing was equivalent to a grazing reduction because the BLM forage would not be used at a later date for profit maximization. This was not the case for the Oregon model with the major difference being the assumed hay resources. The Lake County, Oregon model was defined to have substantial hay land resources that made feeding hay a feasible alternative for the spring period. BLM AUMs would optimally be used in a later season allowing an increase in the average optimal herd size.

The economic impacts from reducing BLM grazing in any season were found to vary widely depending on several key factors. First, individual ranches will be able to substitute alternative forages to varying degrees as federal AUMs are eliminated. Substituting forages minimizes economic losses relative to the option of feeding hay and reducing cow herd size. Those ranches with restricted seasons of forage availability will have less ability to substitute alternative forages if BLM grazing is removed.

Annual average economic losses from removing AUMs ranged from about $3/AUM for the Jordan Valley, Idaho model, $6/AUM for the Northeastern Nevada model, to about $10/AUM for the Lake County, Oregon model. This is a wide range in annual value, but other similar studies in the literature report even a wider value range (Hahn et al. 1989). The contributory value of the federal grazing permits for livestock production varies widely depending on the seasonal complement of forage and pasture resources ranches have, and the level of dependency on federal lands.

Seasonal forage limitations, the degree to which public land forages meet seasonal forage demands, and the availability of substitute forages largely determined the economic value of the federal grazing permit. It is widely believed that the complement between public and private lands contributes greatly to the economics of western ranching and our analysis clearly shows that to be the case. Economic losses estimated here from reducing or changing seasons of grazing use on public lands are annual values. Capitalizing these annual values at any reasonable rate suggests a significant "permit value" and contribution from holding the federal grazing permit.

Western ranches vary greatly in financial resources (Gentner and Tanaka 2002). For those ranches with limited off-ranch wealth and income, reducing public land grazing capacity by even marginal amounts was found to greatly impact the ability of ranchers to meet annual financial obligations and to repay debt. We provided an estimate of what percentage of the time the representative ranches would be unable to meet the cash flow requirements assumed in the model when grazing policies were changed. Yet, in reality, how many ranchers will potentially be forced from the business as policies change cannot be determined because debt loads and off-ranch income are highly variable and unknown. The level of commitment to remain on the ranch is also variable and unknown.

Ranch-level impact estimates of how ranch returns would change if public land grazing levels and allowed seasons of use change are generic. The assessment and impact estimates apply to any situation where public land grazing are reduced or spring grazing is eliminated. As related specifically to sage-grouse, eliminating public land AUMs or removing grazing during the spring are options that have been discussed (Clifford 2002). Hopefully less drastic management options can be adopted. "The Gunnison Sage-Grouse Working Group recognizes the need to be opportunistic and carry out specific conservation actions as situations present themselves", as an example (USDI-BLM 2001, p. 7). What this analysis shows is that, if less drastic management options cannot be found and grazing use on public lands is curtailed or allowed seasons of use altered in the name of protecting the sage-grouse, the economic impact to western public land ranchers will be significant.

How the Census Bureau Measures Poverty

Following the Office of Management and Budget's (OMB) Statistical Policy Directive 14, the Census Bureau uses a set of money income thresholds that vary by family size and composition to determine who is in poverty. If a family's total income is less than the family's threshold, then that family and every individual in it is considered in poverty. The official poverty thresholds do not vary geographically, but they are updated for inflation using Consumer Price Index (CPI-U). The official poverty definition uses money income before taxes and does not include capital gains or noncash benefits (such as public housing, Medicaid, and food stamps).

Income Used to Compute Poverty Status (Money Income)

- Includes earnings, unemployment compensation, workers' compensation, Social Security, Supplemental Security Income, public assistance, veterans' payments, survivor benefits, pension or retirement income, interest, dividends, rents, royalties, income from estates, trusts, educational assistance, alimony, child support, assistance from outside the household, and other miscellaneous sources.
- Noncash benefits (such as food stamps and housing subsidies) **do not** count.
- Before taxes
- Excludes capital gains or losses.
- If a person lives with a family, add up the income of all family members. (Non-relatives, such as housemates, do not count.)

Measure of Need (Poverty Thresholds)

Poverty thresholds are the dollar amounts used to determine poverty status.
Each person or family is assigned one out of 48 possible poverty thresholds [XLS - 48k]
Thresholds vary according to:

- Size of the family
- Ages of the members

The same thresholds are used throughout the United States (do not vary geographically).
Updated annually for inflation using the Consumer Price Index for All Urban Consumers (CPI-U).
Although the thresholds in some sense reflect families needs,

- They are intended for use as a statistical yardstick, not as a complete description of what people and families need to live.
- Many government aid programs use a different poverty measure, the Department of Health and Human Services (HHS) poverty guidelines , or multiples thereof.

Poverty thresholds were originally derived in 1963-1964, using:

- U.S. Department of Agriculture food budgets designed for families under economic stress.
- Data about what portion of their income families spent on food.

Computation

If total family income is less than the threshold appropriate for that family,

- The family is in poverty.
- All family members have the same poverty status.
- For individuals who do not live with family members, their own income is compared with the appropriate threshold.

If total family income equals or is greater than the threshold, the family (or unrelated individual) is not in poverty.

Example
Family A has five members: two children, their mother, father, and great-aunt.
Their threshold was $27,517 in 2011. (See poverty thresholds for 2011). [XLS - 48k]
Suppose the members' incomes in 2011 were:

Mother	$10,000
Father	8,000
Great-aunt	10,000
First Child	0
Second Child	0
Total Family Income	**$28,000**

Compare total family income with their family's threshold:
Income / Threshold = $28,000 / $27,517 = 1.02
Since their income was greater than their threshold, Family A is not "in poverty" according to the official definition.
The income divided by the threshold is called the **Ratio of Income to Poverty**.

-- Family A's ratio of income to poverty was 1.02.

The difference in dollars between family income and the family's poverty threshold is called the **Income Deficit** (for families in poverty) or **Income Surplus** (for families above poverty)

-- Family A’s income surplus was $483 (or $28,000 - $27,517).

People Whose Poverty Status Cannot Be Determined
Unrelated individuals under age 15 (such as foster children):

- Income questions are asked of people age 15 and older.
- If someone is under age 15 and not living with a family member, we do not know their income.
- Since we cannot determine their poverty status, they are excluded from the "poverty universe" (table totals).

People in:

- Institutional group quarters (such as prisons or nursing homes)
- College dormitories
- Military barracks
- Living situations without conventional housing (and who are not in shelters)

Authority Behind Official Poverty Measure
The official measure of poverty was established by the Office of Management and Budget (OMB) in Statistical Policy Directive 14
To be used by federal agencies in their statistical work.
Government aid programs do not have to use the official poverty measure as eligibility criteria.

- Many government aid programs use a different poverty measure, the Department of Health and Human Services (HHS) poverty guidelines , or variants thereof.
- Each aid program may define eligibility differently.

Official poverty data come from the Current Population Survey (CPS) Annual Social and Economic Supplement (ASEC), formerly called the Annual Demographic Supplement or simply the "March Supplement."

Alex, Julie,

Attached are tables comparing the preferred to the proposed alternative for each of the subregions – for the BLM (FS should not change much) – that you probably already have. Madelyn and some others in FS may be relying on these to ground truth their effects analyses – to make sure no substantial differences in effects are being missed. Seems they could also ground truth socio-econ effects?

Also – there's a more detailed table for NWCO subregion that is handy – wish we had these for all subregions.

Again – this may be duplicative material for you.

Chris

Overview of major changes between Draft EIS and Proposed Plan
NWCO GrSG Proposed Plan
March 17th, 2015

	Draft EIS (NOA August 16, 2013) Preferred Alternative	Proposed Plan (target NOA May 29, 2015)
Disturbance Cap	5% cap in PHMA in ecological sites that support sagebrush – calculated by CO Management Zone	3% cap in PHMA calculated by CO Management Zone
Unleased Fluid Minerals	Apply NSO stipulation for fluid mineral leasing in PHMA. Apply NSO stipulation for fluid mineral leasing in ADH within a minimum distance of 0.6-mile from active leks. Within ADH, prohibit surface occupancy within a minimum of 4 miles from active leks during lekking, nesting, and early brood rearing. Surface disturbance within ecological sites that support sagebrush in PHMAs would not exceed 5 percent within the corresponding Colorado MZ.	No new leasing 1 mile from active leks in ADH (Blickley, 2012, Harju, 2012, Patricelli 2012). No surface occupancy in PHMA and within 2 miles of active leks in GHMA. 3% disturbance cap in PHMAs with disturbances limited to 1 per 640 density calculated by CO Management Zone would apply to new lease activities. No new leasing in PHMAs if disturbance cap exceeds 3% for the CO Management Zone or 1 per 640 is exceeded. No activity associated with construction, drilling, or completions within 4 miles from active leks during lekking, nesting, and early brood rearing (March 1-July 15). Authorized Officer could grant an exception, modification, or waiver in consultation with the State of Colorado. Any lands leased in PHMAs are subject to the restrictions of 1 disturbance per 640 acres calculated by CO management zone to allow clustered development
Leased Fluid Minerals	Prohibit surface occupancy or disturbance within 4 miles of a lek during lekking, nesting, and early brood rearing. Limit permitted disturbances to 5 percent in any Colorado MZ.	Within 1 mile of active leks, disturbance, disruptive activities and occupancy are precluded. If it is determined that this restriction would render the recovery of fluid minerals infeasible or uneconomic, considering the lease as a whole, or where development of existing leases requires that disturbance density exceeds 1 per 640, and/or 3% disturbance cap, use the criteria below to site proposed lease activities to meet GRSG habitat objectives and require mitigation as described in **Appendix X** (Mitigation).

	Draft EIS (NOA August 16, 2013) Preferred Alternative	Proposed Plan (target NOA May 29, 2015)
		In PHMAs and within 4 miles of an active lek, the criteria below would be applied to guide development of the lease or unit that would result in the fewest impacts possible to sage-grouse. Based on site-specific conditions, prohibit construction, drilling and completion within PHMAs within 4 miles of a lek during lekking, nesting, and early brood rearing (March 1 through July 15). In consultation with the State of Colorado, this timing limitation may be adjusted based on application of the criteria below (paraphrased here). - Location - Evaluation of threats vs. benefits - Evaluation of specific terrain and habitat features To authorize an activity based on the criteria above, the environmental record of review must show no significant direct disturbance, displacement, or mortality of GRSG.
Lands and Realty	(PHMA) Make GRSG PHMAs avoidance areas for new ROW permits. (PHMA) Make PHMAs exclusion areas for large transmission lines (greater than 230 kilovolts, per guidance in BLM Instruction Memorandum 2013-118, Revised Implementation Guidance for the Interagency Transmission Memorandum of Understanding (BLM 2013b). Manage 68,000 acres as avoidance areas for large transmission lines (greater than 230 kilovolts). Any new projects within PHMAs would be subject to the 5 percent disturbance cap.	(PHMA) Make areas within GRSG PHMAs avoidance areas for BLM ROW permits or USFS SUA permits. (GHMA) Make areas within GRSG GHMAs avoidance areas for BLM ROW permits or USFS SUA permits. No new roads or above-ground structures would be authorized within 1 mile of an active lek. Manage PHMAs and GHMAs as avoidance areas for high voltage (greater than 100 kilovolts) transmission lines, except for the transmission projects specifically identified below. All authorizations in these areas must comply with the conservation measures outlined in this Proposed LUPA, including RDFs/PDFs (**Appendix X**) and avoidance criteria as outlined above. TransWest Express and Energy Gateway South Transmission Lines: The proposed projects, including mitigation measures, would be subject to the standards outlined in the

	Draft EIS (NOA August 16, 2013) Preferred Alternative	Proposed Plan (target NOA May 29, 2015)
		mitigation framework (Section XX) to ensure impacts to GRSG and GRSG habitat have been adequately addressed. **<still waiting for WO approval to use this language>** Any new projects within PHMAs would be subject to the 3 percent disturbance cap.
Wind Energy	No similar action.	(PHMA) Make priority GRSG habitat management areas exclusion areas for wind energy development. (GHMA) Make GHMAs avoidance areas for wind energy development.
Industrial Solar	No similar action.	(PHMA) Make priority GRSG habitat management areas exclusion areas for Industrial Solar projects. (GHMA) Make GHMAs avoidance areas for Industrial Solar projects.
Salable Minerals	(PHMA) Consider allowing existing mineral material sale sites to continue operations. Consider allowing expansion of existing mineral material sales sites. Where practicable, limit permitted disturbances, as defined in **Appendix F**, Disturbance Cap Management, to 5 percent in any Colorado MZ. Where disturbance exceeds 5 percent in any Colorado MZ make additional, effective mitigation necessary to offset the resulting loss of GRSG habitat.	(PHMA) Close PHMAs to new mineral material sales. However, these areas would remain open to free use permits and the expansion of existing active pits, only if the following criteria are met: • The activity is within the Biologically Significant Unit (BSU) and the project area disturbance cap; • The activity is subject to the provisions set forth in the mitigation framework (**Appendix X**); • All applicable required/preferred design features are applied; and, [if applicable] the activity is permissible under the regional screening criteria (**Section XX**).
Nonenergy Leasable Minerals	(PHMA) Consider allowing expansion of existing nonenergy mineral leases. Where practicable, limit permitted disturbances, as defined in **Appendix F**, Disturbance Cap Management, to 5 percent in any Colorado MZ. Where disturbance exceeds 5 percent in any Colorado MZ make additional, effective mitigation necessary to offset the resulting loss of GRSG habitat.	<u>New non-energy mineral leases:</u> No new non-energy mineral leasing in PHMAs. <u>Existing non-energy mineral leases:</u> Apply the following conservation measures as COAs where applicable and feasible: Preclude new surface occupancy on existing leases within 1 mile of active leks. (Blickley, 2012, Harju, 2012, Patricelli 2012).

	Draft EIS (NOA August 16, 2013) Preferred Alternative	Proposed Plan (target NOA May 29, 2015)
		If the lease is entirely within 1 mile of an active lek, require any development to be placed in the area of the lease least harmful to sage-grouse based on vegetation, topography, or other habitat features (See **Appendix E**, Stipulations Applicable to Fluid Mineral Leasing and Land Use Authorizations). Preclude new surface disturbance on existing leases within 2 miles of active leks within PHMAs. If the lease is entirely within 2 miles of an active lek, require any development to be placed in the area of the lease least harmful to sage-grouse based on vegetation, topography, or other habitat features (See **Appendix E**, Stipulations Applicable to Fluid Mineral Leasing and Land Use Authorizations). Limit permitted disturbances to 1 per 640 acres average across the landscape in PHMAs. Disturbances may not exceed 3% in PHMAs in any CO Management Zone. Based on site-specific conditions, prohibit surface occupancy or disturbance within PHMAs within 4 miles of a lek during lekking, nesting, and early brood rearing (March 1 through July 15).

Oregon Comparison of Draft and Final EIS Allocations

Subject: BLM SGSE - annual O&G production for MT, ND, SD plans
Attachments: MT oil gas production RMP data 062714.xlsx

Hey Alex,

Attached is production information. The "revised" data are what you want. The notes are helpful. Let me know if you have questions.

I'm close to getting the 9-plan data. Did you get data for the other Wyoming plans?

Josh

Subject: BLM SGSE - grazing input on proposed plans
Attachments: Grazing Data Request for ID MT.docx; Grazing Data Request for NV CA.docx; Grazing Data Request for NWCO.docx; Grazing Data Request for OR.docx; Grazing Data Request for UT.docx

Josh, Julie, Stewart, Chris,

In preparation for the socioeconomic analysis of impacts of the proposed plan for the GRSG RMP/EISs, we prepared the attached requests for input from BLM and USFS grazing specialists on the impacts of the proposed plans on grazing. The requests ask for the number of open and closed AUMs under the proposed plans, relative to current management. We understand grazing specialists might still not have information about the proposed plans to answer and we may still have other questions for the grazing specialists, after we see the proposed plans ourselves. We are sharing now because the input requests contain information on the sources of data used so far (something Josh and Chris were asking for) and because it will give you a chance to provide any input on the requests themselves ahead of time, if you wish to do so. I shared a few of these earlier this week with Chris, who was asking for them. The input requests assume there will be no revisions in the data provided for the alternatives already analyzed (i.e. no change in habitat boundaries). If there are changes in the habitat boundaries from previous analysis, we may need to modify these a bit.

If you have any comments on the content or format of these requests please do let me know. We are preparing requests for input from other resource areas as well.

(Note: please keep Laura Johnson copied on future emails: she will be helping me manage our work load during this final stretch)

Thanks,

Alex

Data Sources:

- BLM data:
    1. Active AUMs and Active AUMs in ADH from data collected by John Courtright on June 03, 2013. The data was uploaded to ICF’s FTP site by Josh Sidon on July 09, 2013. It is a large file (21MB) originally titled *“Active_Allotment_Range_Summary_JohnC.xlsx.”*
    2. Billed AUMs as a share of active AUMs data from comparing active AUMs by FO in 2011 with billed average between 2000 and 2011, as provided to ICF by Josh on August 07, 2012 in the files *“National_20_Years_Bills_2012-8-1”* and *“County_term_uths_allots_AUMs_2012-8-3.”*
- USFS data:
    1. Active (“permitted”) AUMs from data provided by Dustin Bambrough on June 20, 2013, in a file called “*ID_MT_PermittedUse06192013*.”

2. Active ("permitted") AUMs in ADH from data provided by Dustin Bambrough on July 16, 2013 in a file called *"ID_MT_PermittedUseGRSGHabitat06202013REVISED*." Note: Table R-1 shows 187 less Active AUMs in ADH for the Beaverhead-Deerlodge NF than what is shown in the Excel file. This must be due an adjustment per follow-up conversations, possibly the removal of an allotment (e.g. Bivens Creek or Dry Canyon).
3. Billed (authorized) as a share of active (permitted) we agreed to use 100%.

Based on exchanges with Dominika Lepak (BLM) and Dustin Bambrough (USFS) between June 05, 2013 and July 16, 2013, management alternatives were assumed to impact AUMs as follows:

Alternatives A, B, D and E – all AUMs remain open

Alternative C – AUMs in ADH are closed

Alternative F – 25% reduction in active and billed AUMs in ADH (scenario not accounting for the possibility that an initial reduction in AUMs on BLM-administered lands could lead to the loss of additional AUMs due to seasonal limitations in the availability of grazing areas – low scenario. A high scenario was also estimated multiplying the loss in AUMs in the low scenario by an adjustment factor estimated based on Torell et al. 2014. *Ranch-Level Economic Impacts of Altering Grazing Policies on Federal Land to Protect the Greater Sage-Grouse*, to account for seasonal closures

Please provide the expected reduction in active and billed AUMs in the Proposed Plan relative to current management (Alternative A)

Data Request – Impacts of Management Alternatives on Grazing – Nevada/California:

To:

BLM: Julie Suhr Pierce, Mike Tietmeyer

USFS: Chris Miller, Dustin Bambrough

Table R-1 below shows active AUMs in the study area, by alternative, used in the draft EIS. The data in this table is NOT AUMs in GRSG habitat, but rather in the entire study area. The data is consistent with the following AUMs in GRSG habitat in the study area, as used in Appendix K of the DEIS:

Forest Service	275,248 AUMs
California BLM	172,231 AUMs
Nevada BLM	1,762,997 AUMs

Table R-1
Estimated Active Annual Animal Unit Months by Alternative for the Study Area

Agency	Initial	Alternatives A, B, D, E and G	Alternative C	Alternative F
		Active		
Forest Service	276,191	276,191	943	104,161
California BLM	191,733	191,733	19,502	84,089
Nevada BLM	2,088,722	2,088,722	325,725	986,849
Socioeconomic Study Area	2,556,646	2,556,646	346,170	1,175,098

Data Sources:

- BLM data:
  1. Active AUMs for 2011 by FO and share of Active AUMs billed (based on 2000-2011 average) from RAS query of 07/03/2012.
  2. Active AUMs in GRSG habitat from Appendix K of Draft EIS, provided by Josh Sidon in email of 06/17/2014.
- USFS data:
  1. Active ("permitted") AUMs for the H-T NF sent by Josh Sidon in email of 06/03/2013 based on conversations with Chris Miller and Dustin Bambrough.
  2. Active ("permitted") AUMs in GRSG habitat from Appendix K of Draft EIS, provided by Josh Sidon in email of 06/17/2014
  3. Billed (authorized) as a share of active (permitted) for H-T NF assumed 85%, based on 2000-2011 Avg.

Based on previous information provided by BLM (Mike Tietmeyer) and FS (Dustin Bambrough), management alternatives were assumed to impact AUMs as follows (*where Alternative G is the draft proposed plan*):

Alternatives A, B, D, E, and G – forage availability remains the same as under current management

Alternative C – all AUMs in GRSG habitat closed

Alternative F – 62.5 percent of active AUMs in GRSG habitat closed (25 percent of the area in GRSG habitat must be rested each year. Of the remaining 75 percent, 50 percent must be set aside).

In addition, a high impact scenario was also estimated multiplying the loss in AUMs in the scenario above by an adjustment factor estimated based on Torell et al. 2014. *Ranch-Level Economic Impacts of Altering Grazing Policies on Federal Land to Protect the Greater Sage-Grouse*). This high impact scenario accounts for additional losses of AUMs due to seasonal closures.

Please provide expected reduction in active AUMs in the revised Proposed Plan, or confirm that the active AUMs remain the same as those under Alternatives A, B, D and E.

Data Request – Impacts of Management Alternatives on Grazing – Idaho/Montana:

To:

BLM: Erin Jones, Josh Sidon

USFS: Chris Miller, Dustin Bambrough

Table M.11 below shows active and billed AUMs in the study area, in and out of ADH. (Note: billed AUMs were edited with respect to the draft EIS to account for historic averages)

Table M.1
Estimated Annual Animal Unit Months

	Alternative A					
	Active			Billed		
Item	Cattle and Other	Sheep	Total	Cattle and Other	Sheep	Total
Initial AUMs (Alternative A)	388,346	88,306	476,652	278,963	60,732	339,695
Share in ADH	70.69%	70.69%	70.69%	70.69%	70.69%	70.69%
AUMs in ADH	274,527	62,424	336,951	197,203	42,932	240,134
AUMs not in ADH (Alternative C)	113,820	25,881	139,701	81,761	17,800	99,561

Data Sources:

- BLM data:
    1. Active and billed AUMs from data provided to ICF by Josh on August 07, 2012 in the files *"National_20_Years_Bills_2012-8-1"* and *"County_term_uths_allots_AUMs_2012-8-3."*
    2. The share of AUMs in ADH was assumed to be 70.69%, based on the ratio of 476,652 total active AUMs in the study area for both BLM and FS, and 336,951 AUMs in ADH in the study area, for both BLM and FS. The number 336,951 came from draft range management ch. 4 sent by Erin Jones on 02/08/2013. (note: this number was in a table but seems to have been removed for the draft EIS. The table is reproduced below):

	Number of Allotments in ADH	**Current permitted AUMS**	**leases/permittees**
Little Snake Field Office	291	141,661	280
Colorado River Valley Field Office	48	12,895	45
Grand Junction Field Office	43	10,919	39
White River Field Office	159	111,516	151
Routt National Forest	26	19,482	23
Kremmling Field Office	236	31,742	224
Roan Plateau Planning Area	15	8,736	18

TOTAL	**818**	**336,951**	**780**

- USFS data:
    1. Active ("permitted") AUMs (73,213) from data provided by Dustin Bambrough and forwarded by Chris Miller on March, 07, 2013, in a file called "*RouttNFPermitted&Authorized*."
    2. Billed (authorized) as a share of active (permitted) assumed 100%
    3. The share of AUMs in ADH was assumed to be 70.69% for both BLM and FS together, as explained above. This included 19,482 AUMs in ADH for the Routt NF (see table above), which is consistent with data provided by Dustin Bambrough and forwarded by Chris Miller on March, 07, 2013, in a file called "*RouttAUMs*."
    4. Note: percentage distribution of AUMs among cattle and sheep are for the Medicine Bow-Routt NF for 2011. This distribution comes from file titled "*miller_request_authorizedAUMs.xls*," sent by Chris Miller in email of 02/06/2013.

Based on input provided by Erin Jones (BLM) on 12/04/2012 and Dustin Bambrough (USFS) through Chris Miller email of 03/08/2013, all AUMs were considered open under Alternative A, and all AUMs in ADH were considered closed under Alternative C. Impacts under Alternative B were assumed to be the mid-point between impacts under Alternatives A and C. Impacts under Alternative D were assumed to be the mid-point between impacts under Alternatives A and B.

Please provide expected reduction in active and billed AUMs in the Proposed Plan relative to current management (Alternative A)

Data Request – Impacts of Management Alternatives on Grazing – Oregon:

To:

BLM: Stewart Allen, Jeanne DeBenedetti Keyes

Table R-1 below shows active and billed AUMs in GRSG habitat by FO used in the draft EIS.

Table R-1
Estimated Active Annual Animal Unit Months for Allotments in GRSG Habitat by Alternative for the Study Area

Field Office	Initial	Alternatives A, B, and E	Alternative C	Alternative D	Alternative F
Andrews	93,885	93,885	0	93,852	35,207
Baker	35,861	35,861	0	35,842	13,448
Central Oregon	52,555	52,555	0	52,555	19,708
Deschutes	19,307	19,307	0	19,307	7,240
Jordan and Malheur	402,788	402,788	0	399,728	151,046
Lakeview	162,227	162,227	0	156,587	60,835
Three Rivers	157,994	157,994	0	157,753	59,248
Socioeconomic Study Area	924,617	924,617	0	915,624	346,732

Data Sources:

- Active AUMs in GRSG habitat from data provided by Jeanne DeBenedetti Keyes on September 24, 2013 in a file titled "*LivestockGrazing_AUMS_Oregon_9232013*."

Based on exchanges with Jeanne DeBenedetti Keyes in September and October of 2013 (emails from Jeanne from September 30, October 01 and October 30), management alternatives were assumed to impact AUMs as follows:

Alternatives A, B, and E – Active AUMs in PPMA and PGMA remain open or closed as in current management (current management has 178,766 acres in GRSG habitat closed for grazing)

Alternative D – removes all Research Natural Areas (RNAs) with at least 20 percent of PPMA acres and 50 percent of PGMA acres. Closures to these areas would be voluntary or by termination.

Alternative F - 25 percent of the acreage in GRSG habitat would be rested each year and not available for grazing. In addition, Alternative F assumed a target utilization of only 25 percent of the non-rested acreage in GRSG habitat. This target utilization would be attempted by setting active AUMs at 50 percent of the non-rested acreage in GRSG habitat. This would result in the targeted 25 percent utilization of the non-rested area, if livestock operators follow NRCS stocking rate guides (that typically result in 50 percent use of the authorized area). Therefore, under Alternative F, active AUMs were set at 0.75 x 0.5 = 37.5 percent of the active AUMs under current management.

In addition, a high impact scenario was also estimated multiplying the loss in AUMs in the scenario above by an adjustment factor estimated based on Torell et al. 2014. *Ranch-Level Economic Impacts of Altering Grazing Policies on Federal Land to Protect the Greater Sage-Grouse*). This high impact scenarios accounts for additional losses of AUMs due to seasonal closures.

Please provide expected reduction in active and billed AUMs in the Proposed Plan relative to current management (Alternative A)

Data Request – Impacts of Management Alternatives on Grazing – Utah:

To:

BLM: Julie Suhr Pierce, Alan Bass

USFS: Chris Miller, Dustin Bambrough

Table W-1 below shows active and billed AUMs in GRSG habitat by FO and NF and by alternative. (*Note, Table W-1 was edited with respect the table in the draft EIS to make the data shown for BLM consistent with what we show for USFS – i.e., only AUMs in GRSG habitat*).

Table W. 1
Estimated Annual Animal Unit Months on Federal Lands, 2011

	Active			Billed		
	Alternative A, B, D and E	Alternative C1	Alternative C2	Alternative A, B, D and E	Alternative C1	Alternative C2
Cedar City FO	73,587	0	44,152	46,543	0	27,926
Fillmore FO	27,181	0	16,309	16,177	0	9,706

Kanab FO	8,991	0	5,395	4,421	0	2,653
Moab FO	0	0	0	0	0	0
Price FO	12,845	0	7,707	6,582	0	3,949
Richfield FO	15,430	0	9,258	10,401	0	6,241
Salt Lake FO	98,028	0	58,817	76,515	0	45,909
Vernal FO	91,689	0	55,013	46,947	0	28,168
Sawtooth NF	12,348	0	7,409	12,348	0	7,409
Dixie NF	38,843	0	23,306	38,843	0	23,306
Fishlake NF	69,707	0	41,824	69,707	0	41,824
Manti-Lasal NF	55,561	0	33,337	55,561	0	33,337
Uinta-Wasatch-Cache NF	44,441	0	26,665	44,441	0	26,665
Ashley NF	43,329	0	25,997	43,329	0	25,997
Total	593,900	0	356,341	472,777	0	283,667

Data Sources:

- BLM data:
    1. Active AUMs from RAS as of August of 2012, sent by Josh Sidon on 08/07/2012. The data is in file titled "*count_term_auths_AUMs_2012-8-3.xlsx*."
    2. Billed AUMs from RAS over 20 years (to 2012), sent by Josh Sidon on 08/07/2012. The data is in file titled "*National_20_Years_Bills_2012-8-1.xlsx*."
    3. Loss of active and billed AUMs under Alternative C1 based on information provided by Alan Bass on 05/09/2103 to Josh Sidon in file titled "*Sage Grouse allotment se by field office and state*." Estimates for Active and Billed AUMs for Alternative C2 assume 60

percent of the AUMs made unavailable under Alternative C1 are made unavailable under Alternative C2

- USFS data:
    1. Active ("permitted") AUMs come from data provided by Dustin Bambrough on April 01, 2013, in file called "*UT_LivestockGrazing_AreaTotals_03_06_2013*." Data corresponds only to AUMs in portion of NFs within the study area and with sage-grouse habitat.
    2. Distribution of active AUMs among cattle, sheep and other, from data sent by Chris Miller on 02/06/2013 in file titled "miller_request_authorizedAUMs.xls."
    3. Billed (authorized) as a share of active (permitted) we agreed to use 100%.
    4. Loss of active and billed AUMs under Alternative C1 is all of those shown for Alternative A, because numbers for FS were already restricted to AUMs in GRSG habitat. Estimates for Active and Billed AUMs for Alternative C2 assume 60 percent of the AUMs made unavailable under Alternative C1 are made unavailable under Alternative C2.

Please provide expected reduction in active and billed AUMs in the Proposed Plan relative to current management (Alternative A)

To: Sidon, Joshua B
CC: ICF_SGSE
Subject: BLM SGSE - NMV appendices for sage grouse analysis

Josh,

Following up on our conversations this week, I spoke internally with ICF team members and wanted to give you an update. We understand BLM is interested in whether ICF could support the development of documents that would provide information about non-market values related to EISs to support sage grouse habitat conservation. The specifications, as we understand them, are as follows:

- Use the framework we created for other sage-grouse EISs (e.g. NW Colorado) to assess non-market values associated with recreation, also documenting the scientific/economic principles of non-market valuation generally
- The geographic scope would include all of the Rocky Mountain EISs (WY, ND, SD, and the remainder of MT not covered by the ID / SWMT EIS).
- Because the analysis would focus on recreational value, and there are few or no quantitative predictions of changes in recreational activity across the alternatives for those EISs, the analysis would focus primarily or perhaps exclusively on baseline assessment (within a defined recent time period, e.g., 2008-2012)
- For each EIS, deliverables would comprise a Word document of a few pages, plus the summary excel tables (to facilitate BLM doing additional manipulations it deems necessary)
- BLM would need draft deliverables completed by approximately April 6, and there would be a round of review and revision between approximately April 6 and approximately April 30.

Note that ICF would need BLM to provide recreation data for the desired years from the BLM RMIS system (Report 26, I believe). We would also use data from the FS NVUM system, which is publicly available online (in addition to data on non-market valuation from the work of John Loomis, and others).

We think this would fit within the scope of the current Task Order (it is closely related to the cumulative analysis), but would require a contract modification.

Please let me know if you have any questions or want to talk about this further.
Thanks,
Rob

Follow Up Flag: Follow up
Flag Status: Flagged

Julie, Stewart, Chris,

Please find attached requests for input from resource specialists for the socioeconomic analysis of potential impacts from the proposed plans for the four sub-regional EISs of the Great Basin region. The data requests are in four folders, one for each sub-region.

I would appreciate if you could take a quick look and let me know if you have any comments or suggestions for modifications. Per Lauren's suggestion, I will then forward these requests to the sub-regional leads, copying you:

Lauren Mermejo and Randy Sharp for NV/CA
Jonathan Beck for ID/MT
Quincy Bahr for Utah
Joan Suther for Oregon

Chris, please let me know if there is anyone else you think I should forward these to at the FS.

Josh, I will be sending you similar data requests for NWCO early next week. If you take a look at the attached data requests and feel we need to change the way they are presented, please do let me know.

Lauren, as promised, I am sending these data requests today to you as well, but I would appreciate if we would wait until early next week to distribute to the resource specialist, in case Julie, Stewart, Josh or Chris suggest changes.

Please note the following:

- We included in each data request the names of those who previously provided input for the socioeconomic analysis of the remaining alternatives.
- In addition, the data requests for NV/CA, ID/MT and Utah are also directed to Julie Suhr Pierce and the data requests for Oregon are also directed to Stewart Allen, under the understanding that Julie and Stewart will be able to help communicate our data needs with the various resource specialists, if needed. I am also available to interact directly with the resources specialists, as needed.

- We have also directed all the grazing data requests to Chris Miller and Dustin Bambrough for their input. Chris, please feel free look at the other data requests for NV/CA, ID/MT and Utah, in case you feel FS input is needed (e.g, recreation, wind energy).
- Because of the short time we will have to coordinate with resource specialists, we included as much information possible on the current socioeconomic impact analysis of the remaining alternatives to give resource specialists as much background as possible on how the requested data will be used, relative to the other alternatives analyzed
- We have not yet seen the proposed plans. We may have additional questions to resource specialists when the proposed plans become available to us.

Thank you. Please feel free to contact me if you have any questions or concerns,

Alex

Data Request – Impacts of the Proposed Plan on Geothermal Development – Idaho/Montana:

To: Julie Suhr Pierce, Karen Porter

Based on input provided by Karen Porter to Josh Sidon and forwarded to ICF in June of 2013, and on review of draft sections, our conclusions on the potential economic impacts of management alternatives on geothermal development are described below:

Alternative A—Under Alternative A, the BLM predicts geothermal exploration and development activity would include 28 new exploratory and development wells with 20 production wells and 15 injection wells. Alternative A would not impact economic activity associated with geothermal leases, relative current management trends (BLM 2013i).

Alternative B—Under Alternative B, lands with high geothermal potential that overlap PPH would be closed to geothermal leasing, exploration and development, leaving approximately 39,000 acres outside of GRSG habitat open to leasing. However, the RFDS forecasts that 23 exploratory and development wells and less seismic operations than Alternative A would result in 20 production wells and 15 injection wells, which would be the same as under Alternative A, resulting in minimal or no economic impacts compared with Alternative A (BLM 2013i).

Alternatives C and F—Alternatives C and F would develop the same number of wells as Alternative B and similar outcomes as Alternatives A and B (BLM 2013i).

Alternatives D and E— Alternatives D and E would be similar to Alternative A in the number of wells and outcome (BLM 2013i).

Economic activity associated with geothermal development would be approximately the same for all alternatives, with no or minimal economic impacts compared to current management.

Request:

Please inform how the proposed plan would impact geothermal development, relative to the impacts from the remaining management alternatives described above.

Data Request – Impacts of Management Alternatives on Grazing – Idaho/Montana:

To:

BLM: Julie Suhr Pierce, Dominika Lepak

USFS: Chris Miller, Dustin Bambrough

Table R-1 below shows active and billed AUMs by FO and NS used in the draft EIS.

Data Sources:

- BLM data:
    1. Active AUMs and Active AUMs in ADH from data collected by John Courtright on June 03, 2013. The data was uploaded to ICF's FTP site by Josh Sidon on July 09, 2013. It is a large file (21MB) originally titled *"Active_Allotment_Range_Summary_JohnC.xlsx."*
    2. Billed AUMs as a share of active AUMs data from comparing active AUMs by FO in 2011 with billed average between 2000 and 2011, as provided to ICF by Josh on August 07, 2012 in the files *"National_20_Years_Bills_2012-8-1"* and *"County_term_uths_allots_AUMs_2012-8-3."*
- USFS data:
    1. Active ("permitted") AUMs from data provided by Dustin Bambrough on June 20, 2013, in a file called "*ID_MT_PermittedUse06192013*."

2. Active ("permitted") AUMs in ADH from data provided by Dustin Bambrough on July 16, 2013 in a file called *"ID_MT_PermittedUseGRSGHabitat06202013REVISED*." Note: Table R-1 shows 187 less Active AUMs in ADH for the Beaverhead-Deerlodge NF than what is shown in the Excel file. This must be due an adjustment per follow-up conversations, possibly the removal of an allotment (e.g. Bivens Creek or Dry Canyon).
3. Billed (authorized) as a share of active (permitted) we agreed to use 100%.

Based on exchanges with Dominika Lepak (BLM) and Dustin Bambrough (USFS) between June 05, 2013 and July 16, 2013, management alternatives were assumed to impact AUMs as follows:

Alternatives A, B, D and E – all AUMs remain open

Alternative C – AUMs in ADH are closed

Alternative F – 25% reduction in active and billed AUMs in ADH (scenario not accounting for the possibility that an initial reduction in AUMs on BLM-administered lands could lead to the loss of additional AUMs due to seasonal limitations in the availability of grazing areas – low scenario. A high scenario was also estimated multiplying the loss in AUMs in the low scenario by an adjustment factor estimated based on Torell et al. 2014. *Ranch-Level Economic Impacts of Altering Grazing Policies on Federal Land to Protect the Greater Sage-Grouse*, to account for seasonal closures

Request:

1. **Please provide expected reduction in active and billed AUMs in the proposed plan relative to current management (Alternative A)**
2. **Please discuss any additional costs on livestock operators imposed by the proposed plan (e.g. fencing, seasonal changes, restrictions on disturbance) and how these compare to the remaining alternatives.**

Data Request – Impacts of the Proposed Plan on Land and Realty and Travel Management – Idaho/Montana:

To: Julie Suhr Pierce, Natalie Cooper, Kelly Bockting

Based on information provided by Natalie Cooper and Kelly Bockting to Josh Sidon and forwarded to ICF in July of 2013 and on review of draft sections, our analysis of the potential economic impacts of management alternatives on land realty and travel management is described below:

Alternative A—Alternative A could result in some negative economic impacts on lands and realty and travel management associated with seasonal restrictions to road use to minimize disturbance to GRSG habitat. Alternative A would place the fewest restrictions on ROW development and route construction and maintain the largest area open to travel, among the alternatives. According to RFDS developed by BLM specialists, of the proposed 516 miles of new 500-kV transmission lines approximately 100 miles of new transmission lines could reasonably be expected to be built under Alternative A (BLM 2013i).

Alternative B—Alternative B could result in adverse impacts to economic activity related lands and realty and travel management by closing areas to ROW authorizations, limiting motorized travel on existing roads, and limiting new road construction in areas with primary GRSG habitat. In addition to restricted economic growth associated with road use and development restrictions, economic impacts would include increased costs associated with mandatory mitigation for surface disturbance that exceeds three percent for the area. Based on the RFDS, the BLM projects no new transmission lines (BLM 2013i). Alternative B would impose greater limitations and added costs to future economic investments in the study area compared with Alternative A.

Alternative C—Under Alternative C, economic impacts on lands and realty and travel management would be the same as under Alternative B.

Alternative D—Alternative D would result in economic impacts similar to those under Alternatives B and C because it would apply similar restrictions on motorized travel, except the restrictions would apply to medial and general habitat, as well as priority habitat. However, unlike as Alternatives B and C, Alternative D would not impose costs related to mandatory mitigation for surface disturbance. Costs resulting from restriction to infrastructure development under Alternative D would be greater than under Alternative A but less than under Alternatives B or C.

Alternative E—Management under Alternative E would have similar impacts as under Alternative A and fewer impacts than under Alternatives B, C, and D. The BLM estimates that Alternative E could result in some new transmission lines, depending on whether the proposed projects meet established criteria (BLM 2013i).

Alternative F—Economic impacts from Alternative F would be similar to those under Alternatives B and C, except that Alternative F would limit motorized travel in restoration areas, as well as primary habitat, and would prohibit new road construction within a four-mile buffer from leks. Economic impacts from Alternative F would be greater than impacts under all other alternatives. However, the BLM does expect that development of transmission lines would be similar to that under Alternative A, with 100 miles of new transmission lines in the foreseeable future (BLM 2013i).

Under Alternative B, C, and F, agencies would aim to remove, bury or modify existing power lines in PPMAs. Under Alternative D, “new power and communication lines (50 KV or less), outside of existing ROWs, would be buried, where physically feasible.” During the reauthorization of existing distribution lines, the physical feasibility of burying lines would also be considered. These Alternative D management actions would apply to PPMA, PMMA, and PGMA. All the action alternatives include restrictions in habitat that might require all new ROW or SUA routes to be modified or to implement mitigation.

Request:

Please inform how the impacts of the proposed plan on land and realty and travel management will differ from those described above for the remaining alternatives.

Data Request – Impacts of the Proposed Plan on Phosphate, Locatable and Salable Minerals – Idaho/Montana:

To: Julie Suhr Pierce, Karen Porter

Based on input provided by Karen Porter to Josh Sidon and forwarded to ICF in June of 2013 and in June and July of 2014, and on review of draft sections, our conclusions on the potential economic impacts of management alternatives on phosphate, salable and locatable minerals are described below:

Under Alternatives A and E, KPLAs would be open to phosphate mining. No additional lands would be withdrawn from locatable mineral entry (see **Section 4.9**, Locatable Minerals). No additional lands would be closed to mineral material disposal.

Alternatives B, C and F would close priority habitat to phosphate mining. Of the KPLAs, the only one affected would be in the Paris-Bloomington area. In December of 2012, Stonegate Agricom announced positive results of its Feasiblity Study for the development of an underground phosphate mine (known as the Paris Hills Phosphate project). The project has been estimated to have a mine life of 19 years producing a total of 16.7 million tonnes of phosephate rock ore (Agapito Associates, Inc. 2013). The proportion of these production projections that could be attributable to Federal minerals is not known. However, to the extent that Federal minerals account of a portion of estimated reserves, the closing of PPMA to leasing could remove up to 395 acres of Federal mineral estate from being accessed. Valid existing rights associated with the current lease of 65 acres would prevent this area from closure, but any development would be subject to RDFs which, as discussed in **Section 4.12** Nonenergy Leasable Minerals, would limit surface disturbance, vehicle use, siting, and design of mineral development operations, in addition to imposing reclamation requirements. If implementing RDFs is not feasible once mining operations commence on this existing lease, off-site mitigation may be required. Together these management actions could result in a reduction of phosphate recovered and increased costs of the project. Impacts under Alternative D may be relatively less because, while Alternative D closes PPMA and PMMA to future leasing and prospecting of phosphate, it allows for exceptions for lease modifications and fringe leases where valid existing rights may be affected.

No Reasonably Foreseeably Development scenario for phosphate exists that quantifies current phosphate reserves on private and public lands and forecasts production of those reserves. In the absence of this information and any proposed plans for leasing and developing Federal minerals for phosphate in GRSG habitat, it is not possible to quantify any additional potential economic impacts across alternatives over the planning horizon. With the exception of the Paris-Bloomington KPLA discussed above, no economic impacts on future phosphate development in other KPLA areas are expected due to the minimal GRSG habitat in these areas.

The potential for phosphate production from Federal lands outside of KPLA areas is generally low. Since PPMA would be closed to phosphate development under Alternatives B, C, D, and F, phosphate leasing, prospecting or mining would be affected in areas outside of KPLAs that overlap with PPMA. Furthermore, under Alternative D, management actions in PGMA would restriction exploration and development of nonenergy leasable minerals including timing restrictions, specific stipulations, and possible off-site mitigation. These management actions could affect the cost of exploration and development of phosphate in general habitat. Overall, potential economic impacts associated with phosphate-related activities under Alternatives B, C, D, and F are anticipated to be minimal given the limited amount of priority habitat in areas of southeast Idaho where phosphate occurs.

Alternatives B, C, and F would also recommend withdrawing PPMA from locatable mineral development. Mineral material disposal would be closed in PPMA and restoration of salable mineral pits no longer in use would be required to meet GRSG conservation objectives (see **Section 4.10**, Mineral Materials). Alternative D closes fewer acres to mineral material disposal, but does include restrictions across all GRSG habitat. Specifically, no new mineral material pits would be authorized within 3 km of an occupied lek and mineral disposal in GRSG habitat would be subject to timing restrictions. Alternative D would also require restoration of salable mineral pits no longer in use and would require reclamation bonds for new (commercial or non-profit) authorizations in PPMA habitat.

Economic activity associated with management of phosphate, locatable minerals and salable mineral materials would be the same for Alternatives A and E, slightly lower (due to reduced exploration activity) under Alternative D, and lower still under Alternatives B, C, and F. Any adverse impacts on mining under Alternatives B, C, and F would mostly likely be felt in counties such as Caribou and Cassia, where the mining industry is an important economic contributor for some communities and mineral activity has the highest likelihood of overlapping with GRSG habitat.

Request:

Please inform how the proposed plan would impact phosphate, locatable and salable minerals, relative to the impacts from the remaining management alternatives described above.

Data Request – Impacts of the Proposed Plan on Oil and Gas Development – Idaho/Montana:

To: Julie Suhr Pierce, Karen Porter

Input provided by Karen Porter to Josh Sidon and forwarded to ICF in June of 2013 indicates that the number of wells and production capacity would be the same for Alternatives A, D, and E. In Alternatives B, C, and F, management actions would restrict exploration and development activity to fewer than half the number of oil and gas leases and approximately two-thirds of the production capacity. The socioeconomics section currently describes the impact of management alternatives on oil and gas development as follows:

Alternative A—Alternative A would continue current trends in economic activity associated with oil and gas leases. Alternative A would drill 47 wells, including 35 wildcat wells and 12 step-out wells, over a 20 year period. The BLM estimates that 16 wells would be productive, with 28 billion cubic feet of production capacity.

Alternative B—Alternative B would result in economic impacts associated with restrictions on new surface occupancy, seasonal and methodological restrictions on exploratory drilling, limits on proposed surface disturbance for existing leases, and mandatory mitigation in priority habitats. Alternative B would also impose costs related to required full site-specific reclamation bonds to cover costs to restore the lands to pre-disturbance condition. Drilling and production would drop, compared to Alternative A, with approximately 33 wells drilled, including 27 wildcat wells and 6 step-out wells; 8 wells would be productive, with 20.5 billion cubic feet of production capacity.

Alternative C—Economic impacts under Alternative C would be similar to those under Alternative B. Alternative C would cause a reduction in economic activity by closing 80 percent of the planning area to oil and gas leases. Alternative C would result in lost economic activity related to required relinquishment of leases/authorizations (BLM 2013f), similar to those of Alternative B.

Alternative D—Alternative D would close the same number of acres of federal mineral estate with high oil and gas potential as Alternative A, and economic impacts would be similar to Alternative A.

Alternative E—Alternative E would have similar economic impacts as Alternatives A and D. Alternative E involves some restrictions to surface development to minimize impacts on GRSG habitat, which would have minor economic impacts (BLM 2013f).

Alternative F—Economic impacts under Alternative F would be similar to the impacts under Alternatives B and C (BLM 2013f).

Request:

Please inform how the proposed plan would impact oil and gas development in the planning area, relative to the impacts of the remaining management alternatives, as described above.

Data Request – Impacts of <u>All Management Alternatives</u> on Recreation – Idaho/Montana:

To:

BLM: Julie Suhr Pierce, Robin Fehlau,

USFS: Chris Miller

The DEIS socioeconomics analysis used the following information on nonlocal visits to the planning area, by alternative, to discuss potential socioeconomic impacts of management alternatives on recreation:

Table R-1
Estimated Nonlocal Visits, Average Annual (2015–2034)

Alternative	Nonlocal Day	Nonlocal Overnight on BLM	Nonlocal Overnight off BLM	Total Nonlocal
Alternative A	1,593,506	637,402	1,434,155	3,665,063
Alternative B	1,630,223	652,089	1,467,200	3,749,512
Alternative C	1,197,617	479,047	1,077,856	2,754,520
Alternative D	1,704,370	681,748	1,533,933	3,920,052
Alternative E	1,704,370	681,748	1,533,933	3,920,052
Alternative F	1,273,852	509,541	1,146,467	2,929,860

This table was produced based on data for FY 2012 from BLM's Recreation Management Information System and growth projections by alternative provided by Robin Fehlau to Josh Sidon in June of 2013. Visits to FS lands are not included because the Forest Service recreational specialist determined that the overall number of visits to the National Forests would be unchanged, because potentially affected recreational activities are unlikely to occur during times that overlap with leks, and any displaced recreational activity is likely to move to another nearby location (i.e., recreational activity will simply move rather than ceasing altogether).

<u>However, the DEIS did not include a recreation section under the argument that impacts on recreation would be expected to be negligible</u>.

Request:

1. **Please clarify whether the impacts of management alternatives on recreation would be expected to be negligible or whether the projections presented in Table R-6 should be used.**
2. **If the impacts of management alternatives on recreation area not negligible, please inform how the impacts of the proposed plan on recreation will differ from those described above for the remaining alternatives.**

Data Request – Impacts of the Proposed Plan on Wind Energy Development – Idaho/Montana:

To:

BLM: Julie Suhr Pierce, Natalie Cooper, Kelly Bockting

Based on information provided by Natalie Cooper and Kelly Bockting to Josh Sidon and forwarded to ICF in July of 2013, BLM expects approximately 465 MW of wind energy development in Idaho, none in Montana, under Alternatives A and F. BLM anticipates that Alternatives B through D may prevent wind energy development entirely. Alternative E could limit future wind energy development, with some development possible, depending on fulfillment of criteria established by the alternative (BLM 2013i). Thus, Alternatives B through E would result in lower annual output, employment, and earnings related to wind energy development compared to Alternatives A and F.

Request:

Please inform how the impacts of the proposed plan on wind energy development would compare with the impacts of the remaining management alternatives, as described above.

Data Request – Impacts of the Proposed Plan on Geothermal Development – Nevada/California:

To: Julie Suhr Pierce, David Davis

Based on information provided by David Davis in June of 2014, and on review of DEIS sections, our conclusions on the potential economic impacts of management alternatives on geothermal development are described below. Alternative G is the analysis of the draft proposed plan, as discussed in June of 2014:

Alternative A—Under Alternative A, BLM predicts geothermal exploration and development activity would proceed according to the Geothermal RFDS scenario. This entails 56 new production wells and 38 new injection
wells. As a result of these wells, 12 power plants would come online (BLM 2013h, BLM 2014x).

Alternative B—Under Alternative B, lands with high geothermal potential that overlap PPMAs would be closed to geothermal leasing, exploration, and development. It is uncertain which future geothermal projects would be located within these lands; however, it is estimated that geothermal exploration and development could be reduced by 20 to 50 percent (BLM 2013h, BLM 2014x). BLM used the midpoint of this range to estimate expected reductions in output, employment, and earnings compared to Alternative A.

Alternative C—Under Alternative C, closure of public lands to fluid mineral leasing would restrict the amount of new geothermal leasing exploration and development that would otherwise occur. It is estimated that geothermal exploration and development would be reduced by 30 to 70 percent (BLM 2013h, BLM 2014x). The BLM used the midpoint of this range to estimate expected reductions in output, employment, and earnings compared to Alternative A.

Alternative D—Under Alternative D, NSO restrictions would reduce the availability of PPMAs and PGMAs to geothermal exploration and development. As a result, it is estimated that geothermal exploration and development could be reduced by approximately 20 to 40 percent (BLM 2013h, BLM 2014x). BLM used the midpoint of this range to estimate expected reductions in output, employment, and earnings compared to Alternative A.

Alternative E—Under Alternative E, it is estimated that drilling and exploration would be close to that identified in Alternative A (BLM 2013h, BLM 2014x). Thus, BLM predicts there would be no reduction in output, employment or earnings compared to Alternative A.

Alternative F—Constraints on geothermal leasing, exploration and development in this alternative would be similar to those in Alternative C (BLM 2013h, BLM 2014x). Thus, the BLM estimated that reductions in output, employment, and earnings would be identical to those of Alternative C.

Alternative G—Under Alternative G, NSO restrictions would reduce the availability of PPMAs and PGMAs to geothermal exploration and development. As a result, it is estimated that geothermal exploration and development could be reduced by approximately 20 to 40 percent (BLM 2013h, BLM 2014x). BLM used the midpoint of this range to estimate expected reductions in output, employment, and earnings compared to Alternative A.

Request:

Please inform whether the impacts of Alternative G on geothermal development are still an accurate reflection of the potential impacts of the proposed plan. If not, please inform how our description of these impacts should be changed to accurately capture the potential impacts of the proposed plan on geothermal development.

Data Request – Impacts of the Proposed Plan on Grazing – Nevada/California:

To:

BLM: Julie Suhr Pierce, Mike Tietmeyer

USFS: Chris Miller, Dustin Bambrough

Table R-1 below shows active AUMs in the study area, by alternative, used in the draft EIS. The data in this table is NOT AUMs in GRSG habitat, but rather in the entire study area. The data is consistent with the following AUMs in GRSG habitat in the study area, as used in Appendix K of the DEIS:

Forest Service	275,248 AUMs
California BLM	172,231 AUMs
Nevada BLM	1,762,997 AUMs

Table R-1
Estimated Active Annual Animal Unit Months by Alternative for the Study Area

Agency	Initial	Alternatives A, B, D, E and G	Alternative C	Alternative F
		Active		
Forest Service	276,191	276,191	943	104,161
California BLM	191,733	191,733	19,502	84,089
Nevada BLM	2,088,722	2,088,722	325,725	986,849
Socioeconomic Study Area	2,556,646	2,556,646	346,170	1,175,098

Data Sources:

- BLM data:
  1. Active AUMs for 2011 by FO and share of Active AUMs billed (based on 2000-2011 average) from RAS query of 07/03/2012.
  2. Active AUMs in GRSG habitat from Appendix K of Draft EIS, provided by Josh Sidon in email of 06/17/2014.
- USFS data:
  1. Active ("permitted") AUMs for the H-T NF sent by Josh Sidon in email of 06/03/2013 based on conversations with Chris Miller and Dustin Bambrough.
  2. Active ("permitted") AUMs in GRSG habitat from Appendix K of Draft EIS, provided by Josh Sidon in email of 06/17/2014
  3. Billed (authorized) as a share of active (permitted) for H-T NF assumed 85%, based on 2000-2011 Avg.

Based on previous information provided by BLM (Mike Tietmeyer) and FS (Dustin Bambrough), management alternatives were assumed to impact AUMs as follows (*where Alternative G is the draft proposed plan*):

Alternatives A, B, D, E, and G – forage availability remains the same as under current management

Alternative C – all AUMs in GRSG habitat closed

Alternative F – 62.5 percent of active AUMs in GRSG habitat closed (25 percent of the area in GRSG habitat must be rested each year. Of the remaining 75 percent, 50 percent must be set aside).

In addition, a high impact scenario was also estimated multiplying the loss in AUMs in the scenario above by an adjustment factor estimated based on Torell et al. 2014. *Ranch-Level Economic Impacts of Altering Grazing Policies on Federal Land to Protect the Greater Sage-Grouse*). This high impact scenario accounts for additional losses of AUMs due to seasonal closures.

Request:

1. **Please provide expected reduction in active AUMs in the revised proposed plan relative to Alternative A, or confirm that the active AUMs remain the same as those under Alternatives A, B, D and E.**
2. **Please discuss any additional costs on livestock operators imposed by the proposed plan (e.g. fencing, seasonal changes, restrictions on disturbance) and how these compare to the remaining alternatives.**

Data Request – Impacts of the Proposed Plan on Land and Realty and Travel Management – Nevada/California:

To: Julie Suhr Pierce, Leo Drumm, Daniel Ryan

Based on input provided by Leo Drumm and Daniel Ryan to Josh Sidon in June of 2014 and on review of DEIS sections, our analysis of the potential economic impacts of management alternatives on land realty and travel management is described below. Alternative G is the analysis of the draft proposed plan, as discussed in June of 2014:

Alternative A—Alternative A would place the fewest restrictions on ROW development and route construction and maintain the largest area open to travel, among the alternatives.

Alternative B—Management actions under Alternative B to protect GRSG habitat would impact lands and realty through the exclusion of PPMA to new ROW and special use authorizations, additional criteria for land exchanges, and limitations on new mineral development and road construction. Motorized travel would be limited to existing routes in PPMAs unless BLM or Forest Service has completed travel management plans which designate specific roads (routes) for motorized travel. Routes constructed in excess of a 3 percent disturbance cap would face increased costs with mitigation resulting from the loss of habitat. Existing power lines would be evaluated for removal, burying, or modification. Alternative B would impose limitations and added costs to future economic investments in the study area compared with Alternative A.

Alternative C—Under Alternative C, impacts on ROW authorizations would be similar to Alternative B, but exclusion would apply to all GRSG habitat, affecting 7 million more acres than Alternative B. There would be no designated corridors to accommodate new ROW infrastructure. Additionally, travel management under Alternative C would have similar impacts as Alternative B, with added restrictions: route construction would require a 4-mile buffer from leks in PPMAs and PGMAs. Alternative C would impose the most limitations and added costs to future economic investments in the study area.

Alternative D—ROW development and SUAs under Alternative D would also face restrictions, but these would be more limited than under Alternatives B and C, except for wind and solar development, which remain excluded in GRSG habitat under Alternative D. Management would direct new and existing (during amendment or renewal processes) power lines to be buried unless not technically feasible. Technical feasibility would be determined on a project-by-project basis. A determination as to whether something is considered technically feasible would be based on local conditions, such as vegetation, topography, or project size. Restriction and costs to infrastructure development under Alternative D would be greater than under Alternative A but less than under Alternatives B or C.

Alternative E—Management under Alternative E would have similar impacts as Alternative A, and less than under Alternatives B, C, and D. Power lines of up to 35 kV would be buried where ground disturbance can be minimized and power lines of higher voltage would be buried when economically and technically feasible. All new ROWs in SGMA would require consultation and application of the "avoid, minimize, mitigate" process to ensure no net unmitigated loss of GRSG habitat. The Nevada Conservation Credit System may be used to achieve a goal of no net unmitigated loss of GRSG habitat.

Alternative F—Impacts from Alternative F would be the same as those under Alternative B.

Alternative G—Alternative G could impose some costs to project proponents relative to Alternative A. Designated corridors within GRSG habitat would remain open and GRSG habitat outside of designated corridors would be managed as avoidance areas, not exclusion areas, for all ROWs. Chapter 2 identifies specific conditions for siting new ROWs when avoidance is not possible. New power lines in GRSG habitat would be buried unless not technically feasible or the cost would be prohibitive. During permit renewal, amendment, or reauthorization of existing power lines, the ROW holder would be required to relocated or bury lines unless not technically feasible or contrary to policy. Technical feasibility would be determined on a project-by-project basis. A determination as to whether something is considered technically feasible would be based on local conditions, such as vegetation, topography, or project size. In addition, as in Alternative E, all disturbance would be subject to no net unmitigated loss in GRSG habitat, which could potentially result in associated mitigation costs. In the case of a hard trigger, the adaptive management response for land authorizations would change areas outside of designated corridors to exclusion areas for high voltage transmission lines (greater than or equal to 100 kV) and major pipelines (greater than or equal to 24 inch) potentially leading to increased costs to applicable projects.

Request:

Please inform how the impacts of the proposed plan on land and realty and travel management will differ from those described above for Alternative G and suggest any necessary changes.

Data Request – Impacts of the Proposed Plan on Locatable and Salable Minerals – Nevada/California:

To: Julie Suhr Pierce, Thomas (Scott) Murrellwright, Leisa Wesch

Based on input provided Scott Murrellwright, Leisa Wesch and Randy Sharp (Sharp Consultants) in June of 2014, and on review of DEIS sections, our conclusions on the potential economic impacts of management alternatives on salable and locatable minerals are described below. Alternative G is the analysis of the draft proposed plan, as discussed in June of 2014:

Locatable Minerals:

Under Alternatives B, C, and F, costs could arise for validity exams for claims or operations looking to expand in areas recommended for withdrawal. In addition, no new claims could be made to explore or mine locatable minerals in withdrawn areas which could possibly impact economic activity compared to Alternatives A, D, E, and G.

Overall, economic activity associated with management of locatable minerals would be the same for Alternatives A, D, E and G, and may be lower under Alternatives B, C, and F depending on site-specific and operator-specific conditions.

Salable Minerals

GRSG habitat management alternatives would impose restrictions on development of salable mineral production, particularly under Alternatives B, C, D, F, and G. Specifically, all new mineral material disposal would be closed in PPMA under Alternatives B, C, and F and in both PPMA and PGMA under Alternatives D and G. No areas would be closed to new mineral material disposal under Alternative E, but any new pits would require consultation and application of the “avoid, minimize, mitigate” process to ensure no net unmitigated loss of GRSG habitat. Under both Alternatives D and G, existing pits could be expanded under certain requirements (see **Section 4.14**, Minerals – Salable).

Closing areas to mineral material sales in Alternatives B, C, D, F, and G could increase costs for commercial and public users of mineral materials. Because transportation of mineral materials is typically a cost driver, especially for municipal users, closing pits could have a measurable financial impact on entities that depend on sand and gravel from BLM-administered lands. The BLM would attempt to reduce this impact by identifying new pits proximate to identified needs, but at the stage of this analysis – without knowing the location, timing, and amounts needed – it is not possible to determine the economic impacts on either municipal or commercial entities.

Overall, economic activity associated with salable mineral materials would be generally the same for Alternatives A and E, and may be lower under Alternatives B, C, D, F, and G.

Request:

Please inform whether the impacts of Alternative G on locatable and salable minerals still are still an accurate reflection of the potential impacts of the proposed plan. If not, please inform how our description of these impacts should be changed to accurately capture the potential impacts of the proposed plan on salable and locatable minerals.

Data Request – Impacts of the Proposed Plan on Oil and Gas Development – Nevada/California:

To: Julie Suhr Pierce, John Menghini

Table R-8 below reflects expected oil and gas wells drilled and producing under the various management alternatives analyzed. The table is based on input provided by John Mengini in January of 2014 and information provided on a draft proposed plan in July of 2014 (Alternative G).

Table R-8

Oil and Gas Wells and Production

Alternative	Oil Wells Expected to be Drilled			Oil Wells Expected to be Producing		
	Existing Leases	New Leases	Total	Existing Leases	New Leases	Total
A	70	30	100	14	6	20
B and F	0	0	0	0	0	0
C	30	10	40	6	2	8
D and G	40	20	60	8	4	12
E	50	30	80	10	6	16

Request:

Please confirm whether impact of the proposed plan on oil and gas production is correctly reflected in Alternative G in Table R-8.

Data Request – Impacts of the Proposed Plan on Recreation – Nevada/California:

To: Julie Suhr Pierce, Leo Drumm

Based on input provided by Leo Drumm to Josh Sidon on June 12, 2014 and on review of DEIS sections, our analysis of the potential economic impacts of management alternatives on recreation is described below. Alternative G is the analysis of the draft proposed plan, as discussed in June of 2014:

For Alternatives B through G, the net economic effect on recreational activity is not possible to quantify, but would likely be very small. The primary effect on recreational activity would be related to change in designation from open to limited for OHV use, and as noted above (and in **Section 4.18**, Recreation), BLM recreation specialists expect that use overall would not change.

Alternative A—Under Alternative A, existing recreation opportunities in the study area would be maintained. Alternative A would not result in impacts on revenue of commercial recreation service providers or managing agencies attributable to BLM SRPs and Forest Service SUAs, as it would result in no changes to current management.

Alternative B—The restrictions on BLM SRPs and Forest Service SUAs documented in **Section 4.18**, Recreation, may result in modifications for some types of permitted uses (e.g., OHV races) on PPMAs, potentially resulting in fewer opportunities for this type of event. As noted above, the OHV area designation change on PPMAs (from open to limited) may result in small changes in patterns of OHV travel in the study area, but public lands recreation specialists do not anticipate any changes in recreational use. The economic effect from recreational activity is not possible to quantify, but if there is any difference versus Alternative A from restrictions on BLM SRPs and Forest Service SUAs, it is likely to be very small.

Alternative C—Economic impacts of Alternative C with respect to BLM SRPs and Forest Service SUAs are the same as Alternative A. There would be no anticipated change in economic impacts with respect to the OHV area designation change on PPMAs and PGMAs because public lands recreation specialists do not anticipate any changes in recreational use. Thus, economic impacts with respect to recreation would be the same as in Alternative A.

Alternative D—Under Alternative D, BLM SRPs and Forest Service SUAs could be restricted for some types of permitted uses (e.g., OHV races) on PPMAs and PGMAs, which may (but would not necessarily, for the reasons noted above) result in reduced economic activity associated with these events. There would be no anticipated change in economic impacts with respect to the OHV area designation change on PPMAs and PGMAs, because public lands recreation specialists do not anticipate any changes in recreational use. The economic effect from recreational activity is not possible to quantify, but if there is any difference versus Alternative A from restrictions on BLM SRPs and Forest Service recreation permits, it is likely to be very small.

Alternative E—Alternative E would result in the same economic impacts related to recreation as in Alternative A.

Alternative F—Alternative F would result in the same economic impacts related to recreation as in Alternatives B and D.

Alternative G—Alternative G would result in similar impacts to recreation as Alternative D. Some additional closures and seasonal restrictions could occur due to travel management adjustments, based on monitoring of impacts to GRSG habitat, with additional impacts on recreation.

Request:

Please inform how the impacts of the proposed plan on recreation will differ from those described above for Alternative G and suggest any necessary changes.

Data Request – Impacts of the Proposed Plan on Wind Energy Development – Nevada/California:

To: Julie Suhr Pierce, Wendy Seley

Based on information provided by Wendy Seley and forwarded to ICF by Josh Sidon on 06/10/2014, the BLM currently has five applications for development of wind energy projects within the study area. The projected installed capacity for these projects is approximately 1,405 MW in Elko and White Pine Counties and 151 MW in Washoe and Lassen Counties, for a total of 1,556 MW. Under Alternative A, BLM expects these projects to be implemented. The BLM anticipates that none of these projects would receive approval under Alternatives B through F. The same email indicated that no wind energy development would be expected under Alternative G (the draft proposed plan).

Request:

Please confirm that none of the 1,556 MW of wind energy referred to above would be expected to develop under the proposed plan.

Data Request – Impacts of the Proposed Plan on Geothermal Development – Oregon

To: Stewart Allen, Timothy Barnes

Based on information provided by Timothy Barnes to Josh Sidon and forwarded to ICF on June 05, 2013 and on review of draft sections, our conclusions on the impact of management alternatives on geothermal development are described below:

Alternative A

Under Alternative A, the BLM projects the 170 megawatts of geothermal energy shown in **Table 4-51** to be in place by 2025.

Table 4-1
Reasonable Foreseeable Development Scenario for Geothermal Energy on BLM-Administered Lands

Area	Projected MW at 2025	BLM Field Office
Neal Hot Springs	50	Vale
Lakeview – Hot Lake Area	20	Lakeview
Summer Lake	50	Lakeview
Other Potential Locations	50	Includes Burns and Vale
Total	170	

Alternatives B and E

Access to geothermal potential could be limited. Acres open to leasing would be reduced by over one-third, compared with Alternative A, which could reduce access to geothermal potential. If these closures were to include the areas identified in the geothermal reasonably foreseeable development scenario, the development of geothermal energy could also be reduced, compared to Alternative A.

Alternatives C and F

Acres open to leasing would be reduced by approximately 75 percent. Alternatives C and F would be the most likely to constrain development of geothermal energy resources. If closures were to include the areas identified in the geothermal reasonably foreseeable development scenario, the development of geothermal energy would be reduced, relative to Alternative A.

Alternative D

Based on acres open to leasing, projected employment under Alternative D would be the same as under Alternative A. However, some decrease relative to Alternative A could occur due to NSO stipulations in buffer areas around leks.

Request:

Please inform how the proposed plan would impact geothermal development relative to the impacts of the other alternatives described above.

Data Request – Impacts of Proposed Plan on Grazing – Oregon:

To: Stewart Allen, Jeanne DeBenedetti Keyes, Bob Hopper

Table R-1 below shows active and billed AUMs in GRSG habitat by FO used in the draft EIS.

Table R-1
Estimated Active Annual Animal Unit Months for Allotments in GRSG Habitat by Alternative for the Study Area

Field Office	Initial	Alternatives A, B, and E	Alternative C	Alternative D	Alternative F
Andrews	93,885	93,885	0	93,852	35,207
Baker	35,861	35,861	0	35,842	13,448
Central Oregon	52,555	52,555	0	52,555	19,708
Deschutes	19,307	19,307	0	19,307	7,240
Jordan and Malheur	402,788	402,788	0	399,728	151,046
Lakeview	162,227	162,227	0	156,587	60,835
Three Rivers	157,994	157,994	0	157,753	59,248
Socioeconomic Study Area	924,617	924,617	0	915,624	346,732

Data Sources:

- Active AUMs in GRSG habitat from data provided by Jeanne DeBenedetti Keyes on September 24, 2013 in a file titled "*LivestockGrazing_AUMS_Oregon_9232013*."

Based on exchanges with Jeanne DeBenedetti Keyes in September and October of 2013 (emails from Jeanne from September 30, October 01 and October 30), management alternatives were assumed to impact AUMs as follows:

Alternatives A, B, and E – Active AUMs in PPMA and PGMA remain open or closed as in current management (current management has 178,766 acres in GRSG habitat closed for grazing)

Alternative D – removes all Research Natural Areas (RNAs) with at least 20 percent of PPMA acres and 50 percent of PGMA acres. Closures to these areas would be voluntary or by termination.

Alternative F - 25 percent of the acreage in GRSG habitat would be rested each year and not available for grazing. In addition, Alternative F assumed a target utilization of only 25 percent of the non-rested acreage in GRSG habitat. This target utilization would be attempted by setting active AUMs at 50 percent of the non-rested acreage in GRSG habitat. This would result in the targeted 25 percent utilization of the non-rested area, if livestock operators follow NRCS stocking rate guides (that typically result in 50 percent use of the authorized area). Therefore, under Alternative F, active AUMs were set at 0.75 x 0.5 = 37.5 percent of the active AUMs under current management.

In addition, a high impact scenario was also estimated multiplying the loss in AUMs in the scenario above by an adjustment factor estimated based on Torell et al. 2014. *Ranch-Level Economic Impacts of Altering Grazing Policies on Federal Land to Protect the Greater Sage-Grouse*). This high impact scenarios accounts for additional losses of AUMs due to seasonal closures.

Request:

1. **Please provide expected reduction in active and billed AUMs in the proposed plan relative to current management (Alternative A)**
2. **Please discuss any additional costs on livestock operators imposed by the proposed plan (e.g. fencing, seasonal changes, restrictions on disturbance) and how these compare to the remaining alternatives.**

Data Request – Impacts of the Proposed Plan on Land and Realty and Travel Management – Oregon

To: Stewart Allen, Christopher Knauf

Based on input provided by Christopher Knauf to Josh Sidon in May of 2014 and on review of draft sections, our analysis of the potential economic impacts of management alternatives on land and realty and travel management is described below:

Alternative A
Alternative A would place the fewest restrictions on ROW development and route construction and would maintain the largest area open to travel, among the alternatives; therefore, having the least impacts of the alternatives.

Alternative B
Management actions under Alternative B to protect Greater Sage-Grouse habitat would impact lands and realty through the closure of PPMA to new ROW authorizations. All cross-country motorized travel would also be prohibited except for designated routes; that is, motorized travel would be limited to existing routes. Alternative B would impose added costs to future economic investments in the Study Area, when compared to Alternative A.

Alternative C
All Greater Sage-Grouse habitat, PPMA, and PGMA would be closed to new ROW authorizations. This alternative would impose the greatest restrictions on new infrastructure development. Potential new investments in power lines, pipelines, roads and renewable energy projects requiring new ROW authorizations in Greater Sage-Grouse habitat would not occur, potentially reducing the generation of associated employment and earnings opportunities. To the extent that new projects are modified to move forward off Grater Sage-Grouse habitat, economic activity generated by the construction and operation of a modified project would support regional economic activity. However, modification to projects would typically have a cost. To the extent possible, utilities would be expected to pass these costs to consumers. Restrictions on travel management would be the same as those under Alternative A.

Alternative D
ROW development under Alternative D would also face restrictions, but these would be more limited than under Alternatives B and C. Exclusion areas in Greater Sage-Grouse habitat would be the same as under Alternative A, but PPMA would be managed as avoidance. Burial of power lines could be required when technically and financially feasible. Restrictions to travel would be the same as those under Alternative B. Restriction and costs to infrastructure development under Alternative D would be greater than under Alternative A but less than under Alternatives B or C.

Alternative E
Management under Alternative E would have impacts similar to Alternative A for land use authorizations. Impacts also are similar to Alternative A for travel management, given that only seasonal limits would be imposed near leks. Together with Alternative A, Alternative E would impose the least restrictions on infrastructure development and transport in the Study Area.

Alternative F

Impacts from Alternative F are the same as or similar to those under Alternative B, except there would be greater restrictions under Alternative F for wind energy, as previously described. New road construction or upgrades would not be allowed in Greater Sage-Grouse habitat, resulting in future potential limitations to economic activity in the area.

Restrictions to ROW development under Alternatives B, C, D, E and F could require investors to relocate or reroute infrastructure investments. When feasible, such modifications would have a cost that would typically be expected to be passed on to consumers. A 2012 WECC study, for example, provides information on transmission line costs per mile, ranging from $927 thousand to $2,967 thousand depending on voltage and whether lines are single or double circuit lines. The same study provides cost multipliers for difficult terrains, reaching up to 2.25 in the case of forested lands (WECC 2012). Because utility providers allocate costs on to their rate base, per-customer rate impacts would be greater where the ratepayer base is smaller, all else equal (i.e., given an identical fixed cost associated with burial of transmission lines). Areas with smaller/local utility providers with fewer ratepayers would be required to absorb a greater proportion of the costs of relocation or rerouting compared to areas serviced by larger, multi-state providers. Alternative D would require burial of transmission lines when technically and financially feasible. New construction costs of underground transmission lines can be between 4 and 14 times higher (PSC 2011), depending on terrain, although burial of existing lines would be a fraction of the cost of new lines. Burial of distribution lines would be considerably less, averaging under $500 per mile in rural areas (EIA 2012).

Request:

Please inform how the proposed plan would impact land and realty and travel management relative to the impacts described above for the remaining alternatives.

Data Request – Impacts of the Proposed Plan on Oil and Gas, Locatable and Salable Minerals – Oregon:

To: Stewart Allen, Timothy Barnes

Based on input provided by Timothy Barnes to Josh Sidon and forwarded to ICF on June 05 of 2013, and on review of draft sections, our conclusions on the potential economic impacts of management alternatives on oil and gas, salable and locatable minerals are described below:

Oil and gas:

Any future production of oil and gas in the Study Area would have the greatest impacts under Alternatives C and F, under which all Greater Sage-Grouse habitat would be closed for exploration. Alternatives B and E would impose fewer closures than Alternatives C and F (all PPMA in the case of Alternative B, Core Area habitat in the case of Alternative E). Alternative D would impose the fewest restrictions on future oil and gas development, after Alternative A, with buffer areas around leks and constraints on surface occupancy. Because no development of oil and gas are projected for the Study Area, no impacts of alternatives on output, employment, and earnings are expected.

Locatable minerals:

Under Alternatives A, 7 percent of the federal mineral estate decision area would remain closed for development of locatable minerals, with an additional 1 percent petitioned for withdrawal. Petitions for withdrawal require that validity exams be conducted on existing mining claims when a Notice or Plan of Operation is proposed and on notices or Plans of Operations for material changes in existing operations. This delays the start or expansion of mining operations and increases costs.

Alternatives B, E, and F would increase the federal mineral estate petitioned for withdrawal by approximately 29 percent of the federal mineral estate for locatables, in addition to the currently closed 7 percent, and Alternative C would increase the federal mineral estate petitioned for withdrawal by 63 percent, in addition to the currently closed 7 percent. Alternative D is similar to Alternative A, but it would recommend limits on surface disturbance and mitigation of impacts on Greater Sage-Grouse habitat.

No Reasonably Foreseeable Development scenario for locatable minerals was developed for this landscape level planning amendment that forecasts production of locatable minerals on Federal lands in the Study Area. In the absence of this information, it is not possible to quantify potential economic impacts across alteratives over the planning horizon. Nor is it possible to assess the extent to which development of locatiable minerals on split-estate would be affected. However, as discussed above, under Alternatives B, C, E, and F, costs could arise for validity exams for claims or operations looking to expand in areas recommended for withdrawal. In addition, no new claims could be made to explore or mine locatable minerals in withdrawn areas which could possibly impact economic activity compared to Alternatives A and D.

Salable minerals:

Under Alternative A,, approximately 18 percent of the federal mineral estate would be closed to salable minerals development. This percentage would increase to approximately 47 percent under Alternatives B, D, E, and F and to 75 percent under Alternative C. If employment were to fall proportionally to closures of federal mineral estate, the impact on salable minerals-related employment in the Study Area would be a loss of between 56 and 138 jobs under Alternatives B, D, E, and F and between 96 and 235 jobs under Alternative C. The impacts of Alternative B, D, E, F, and C could be larger due to ROW avoidance and exclusion increases in several of these alternatives relative to Alternative A. These avoidance and exclusion increases potentially affect salable minerals through increased costs of minerals development and decreased construction and derived demand for mineral materials. ROW exclusion and avoidance areas would be the greatest under Alternative C and the least under Alternatives A and E.

[..]

Relative to Alternative A, closures or restrictions to salable mineral development under Alternatives B, D, E, and F would affect locations throughout the Study Area, with large extensions in Lake, Harney and Malheur Counties. Alternative C would add closures to various locations that otherwise would remain open to salable mineral development, particularly in central and northern portions of Lake and Harney Counties.

Request:

Please inform how the proposed plan will impact oil and gas, locatable and salable minerals, relative to the impacts under other alternatives, as described above.

Data Request – Impacts of the Proposed Plan on Recreation – Oregon:

To: Stewart Allen, Christopher Knauf

Based on input provided by Christopher Knauf to Josh Sidon in May of 2014 and on review of DEIS sections, our analysis of the potential economic impacts of management alternatives on recreation is described below:

Alternative A
Existing recreation opportunities in the Study Area would be maintained. Alternative A would not result in impacts on revenue of commercial recreation service providers or managing agencies attributable to SRPs. This is because it would result in no changes to current management.

Alternatives B, D, E, and F
Overall visitation levels and the corresponding economic impact of recreation expenditures in the Study Area would not be substantially different from Alternatives A and C. However, limitations on SRPs and motorized travel restrictions could lead to some added costs to recreational users of BLM-administered lands. This could result from having to circumvent closed areas or adopting less preferred options in certain activities. These include hunting, where ATV use is prevalent for retrieving game, or other activities that make use of motorized travel. Beneficial impacts could arise from enhanced opportunities for recreation, such as backcountry camping or low-density hiking, as well as opportunities for such activities as hiking, horseback riding, and hunting in a more primitive setting. The net economic effect on recreation is not possible to quantify, and the net direction (positive or negative economic effect) is uncertain.

Alternative C
Economic impacts of Alternative C are the same as those of Alternative A. The limitations on SRPs and motorized travel restrictions of Alternatives B, D, E and F would not be implemented in Alternative C and Alternative C would result in no substantial changes to current management that could affect recreation.

Request:

Please inform how the impacts of the proposed plan on recreation will differ from those described for the other alternatives above.

Data Request – Impacts of the Proposed Plan on Wind Energy Development – Oregon:

To: Stewart Allen, Tara McLain

Based on information provided by Tara McLain and forwarded to ICF by Josh Sidon on August 19, 2013, and on review of draft sections, the socioeconomic section describes the impact of management alternatives on wind development as follows:

"Although there are many locations in the Study Area where wind development is feasible, these locations may or may not overlap with sage-grouse habitat. For the purposes of IMPLAN analysis, BLM considered that two currently existing applications for wind development in the Burns District (Harney County) would no longer occur under Alternatives B, C, and F, both projects being in PGMA, with some of the associated transmission lines and access roads in PPMA. These two projects are estimated to have, when completed, 182 MW of installed capacity. For the purposes of IMPLAN analysis only, BLM assumed that construction would be distributed over a 10-year period."

Request:

Please inform how the proposed plan would impact wind energy development relative to the impact of the other alternatives described above.

Data Request – Impacts of the Proposed Plan on Coal Development – Utah:

To: Julie Suhr Pierce

Table W.11 reflects expected coal production under the various management alternatives analyzed. The table is based on estimates provided by Julie Suhr Pierce to Josh Sidon on May 3, 2014, and forwarded to ICF.

Table W.11
Estimated Annual Average Coal Production on Federal Lands in Utah (tons), 2014-2028

	Underground	Surface	Total
Alternative A	15,291,616	1,594,667	16,886,283
Alternative B	13,150,790	0	13,150,790
Alternative C	12,080,377	0	12,080,377
Alternative D	15,291,616	1,594,667	16,886,283
Alternative E	15,291,616	1,594,667	16,886,283

For the estimation of the impacts of the alternatives on coal production, the following assumptions were made, based on information in various documents:

- 77 percent of all production is from federal mineral lands (BLM 2013b)
- New coal leases would be required for underground coal production from 2017 onwards
- BLM made the assumption for analysis purposes only that no new subsurface leasing would occur in priority habitat (for Alternative B) or occupied habitat (for Alternative C). The idea that closing GRSG habitat to new leases would effectively preclude underground coal mining represents a worst-case scenario because nothing in this alternative would preclude leasing of subsurface materials.
- The Alton coal field would generate 1,840,000 tons of coal per year starting in 2016 from surface coal mining, under Alternatives A, D and E (BLM 2011). For analytical purposes only, this coal is assumed to be produced entirely from federal lands. BLM assumed that no production would occur from the Alton coal field in Alternatives B and C, based on it being a surface mine. To the extent that some underground mining of the deposit could still occur, accessed through surrounding non-Federal lands, this assumption of no production under alternatives B and C may overstate the actual impacts of those alternatives.

Request:

Please explain how the proposed plan would affect coal production relative to Alternative A. In doing so, please feel free to use Table W.11 above or to work on the Excel spreadsheet sent by Julie to Josh on May 3, 2014, if it is easier.

Data Request – Impacts of the Proposed Plan on Grazing – Utah:

To:

BLM: Julie Suhr Pierce, Alan Bass

USFS: Chris Miller, Dustin Bambrough

Table W-1 below shows active and billed AUMs in GRSG habitat by FO and NF and by alternative. (*Note, Table W-1 was edited with respect the table in the draft EIS to make the data shown for BLM consistent with what we show for USFS – i.e., only AUMs in GRSG habitat*).

Table W. 1
Estimated Annual Animal Unit Months on Federal Lands, 2011

Dixie NF	38,843	0	23,306	38,843	0	23,306
Fishlake NF	69,707	0	41,824	69,707	0	41,824
Manti-Lasal NF	55,561	0	33,337	55,561	0	33,337
Uinta-Wasatch-Cache NF	44,441	0	26,665	44,441	0	26,665
Ashley NF	43,329	0	25,997	43,329	0	25,997
Total	593,900	0	356,341	472,777	0	283,667

Data Sources:

- BLM data:
    1. Active AUMs from RAS as of August of 2012, sent by Josh Sidon on 08/07/2012. The data is in file titled "<u>count_term_auths_AUMs_2012-8-3.xlsx</u>."
    2. Billed AUMs from RAS over 20 years (to 2012), sent by Josh Sidon on 08/07/2012. The data is in file titled "<u>National_20_Years_Bills_2012-8-1.xlsx</u>."
    3. Loss of active and billed AUMs under Alternative C1 based on information provided by Alan Bass on 05/09/2103 to Josh Sidon in file titled "<u>Sage Grouse allotment se by field office and state</u>." Estimates for Active and Billed AUMs for Alternative C2 assume 60

percent of the AUMs made unavailable under Alternative C1 are made unavailable under Alternative C2

- USFS data:
    1. Active ("permitted") AUMs come from data provided by Dustin Bambrough on April 01, 2013, in file called "*UT_LivestockGrazing_AreaTotals_03_06_2013*." Data corresponds only to AUMs in portion of NFs within the study area and with sage-grouse habitat.
    2. Distribution of active AUMs among cattle, sheep and other, from data sent by Chris Miller on 02/06/2013 in file titled "miller_request_authorizedAUMs.xls."
    3. Billed (authorized) as a share of active (permitted) we agreed to use 100%.
    4. Loss of active and billed AUMs under Alternative C1 is all of those shown for Alternative A, because numbers for FS were already restricted to AUMs in GRSG habitat. Estimates for Active and Billed AUMs for Alternative C2 assume 60 percent of the AUMs made unavailable under Alternative C1 are made unavailable under Alternative C2.

Request:

1. **Please provide expected reduction in active AUMs in the revised Proposed Plan relative to Alternative A.**
2. **Please discuss any additional costs on livestock operators imposed by the Proposed Plan (e.g. fencing, seasonal changes, restrictions on disturbance) and how these compare to the remaining alternatives.**

Data Request – Impacts of the Proposed Plan on Land and Realty and Travel Management – Utah:

To: Julie Suhr Pierce, David Jeppesen, Chris Miller (FS), David Reis (FS)

Based on review of land and realty and travel management sections and management alternatives, the socioeconomic section currently states the following:

> "To the extent that management alternatives require linear construction projects to avoid GRSG habitat or imposes additional construction requirements and constraints for projects crossing GRSG habitat, some impacts could affect the general public. Alternatives B, C and D would impose new ROW exclusions and reduction or alteration of designated corridor areas. The magnitude of this potential impact, in terms of miles of linear projects or total construction costs, could not be quantified since details of future linear projects are not known."

Request:

Please inform how the impacts of the proposed plan on land and realty and travel management compare with those described above.

Data Request – Impacts of the Proposed Plan on Locatable and Salable Minerals – Utah:

To: Julie Suhr Pierce, Jefferson McKenzie

Based on input provided by Jefferson McKenzie to Josh Sidon and forwarded to ICF on April 15, 2014 (copying Julie Suhr Pierce), and on review of DEIS sections, our main conclusions on the potential economic impacts of management alternatives on salable and locatable minerals are described below.

Locatable:

Although, potential impacts to locatable mineral development are expected to be minimal (in terms of relative production and economic activity) across all alternatives, the potential impacts do differ across alternatives. In particular, alternatives B and C recommend withdrawal from mineral entry in PPMA and mapped occupied habitat, respectively. The implications of these potential withdraws are explained in detail in Section 4.20.4. Generally, these withdraws could affect a subset or all of the 39 locatable mining operations that occur on BLM or USFS lands in GRSG occupied habitat as well as the claimants holding one of the over 2,500 claims. Any material changes to existing operations within a withdrawn area would require a validity examination. The claims would also be subject to a validity examination to determine if the claim is valid and prior to any development of the claim. Validity examinations typically cost at least $50,000 to complete and have the potential to delay the start of a locatable mineral development. In all the action alternatives where GRGS habitat would remain open, the BLM and USFS would work with claimants, to the extent possible by law, to minimize impacts to GRSG habitat which could increase costs to the claimant.

Salable:

Areas closed to mineral materials disposal would be the most under Alternative C, where no federal mineral estate within the decision area would remain open to mineral material disposal, and the least under alternatives A and E, under which 98 percent of the federal mineral estate within the decision area would remain open. There are 4,008,600 acres of federal mineral estate in the decision area. Under Alternative D, 74 percent of federal mineral estate would be closed to commercial disposal and an additional 9 percent would be closed to both commercial and noncommercial disposal.

Request:

Please inform how the impacts of the proposed plan on locatable and salable minerals compare to the descriptions above.

Data Request – Impacts of the Proposed Plan on Oil and Gas Development – Utah:

To: Julie Suhr Pierce, Tyler Ashcroft

Tables W.4 and W.5 reflect expected oil and gas wells drilled and completed and oil and gas production under the various management alternatives analyzed. The table is based on RFD provided by Tyler Ashcroft on June 18, 2014 and include information for a draft proposed plan.

Table W.4, Oil and Gas Well Numbers, presents the total number of wells drilled and completed in the Primary Socioeconomic Study Area for each alternative, relative to Alternative A.

Table W. 4
Oil and Gas Well Numbers in New and Existing Leases, Relative to Alternative A

Item	***Federal, State, and Fee Surface***	***Federal Surface***		***State and Fee Surface***
		New Leases	***Existing Leases***	
Alternative B – Wells Drilled	-329	-115	-165	-49
Alternative B – Wells Completed	-242	-93	-126	-23
Alternative C – Wells Drilled	-858	-270	-494	-94
Alternative C – Wells Completed	-670	-217	-397	-56
Alternative D – Wells Drilled	-223	-40	-165	-18
Alternative D – Wells Completed	-166	-31	-126	-9
Alternative E – Wells Drilled	0	0	0	0
Alternative E – Wells Completed	0	0	0	0
Proposed Plan – Wells Drilled	-228	-44	-165	-19
Proposed Plan – Wells Completed	-167	-35	-126	-6

Sources: Elaborated by BLM staff based on field office Reasonable Foreseeable Development Scenarios and available information

The production per well was assumed based on the typical production of existing wells in the area, or 1,471 MMCF per gas well and 200 MBO per oil well over a 20 year well life. Each well was assumed to have a 20-year life and 75 percent of its lifetime production would be reached during the 15-year period. The production that would be affected by each alternative is proportional to the share of wells affected by GRSG habitat, as appropriate for each alternative. Reductions in drilled and completed wells relative to Alternative A correspond to approximately 7 percent under alternative D and the Proposed Plan, 10 percent under Alternative B and 27 percent under Alternative C, with no reduction under Alternative E. **Table W.5**, Projected Oil and Gas Production, 15-Year Period, presents the projected quantity of oil and gas over the 15-year forecast period on federal surface and on federal, state, and fee surface.

Table W. 5
Projected Oil (MBO) and Gas (MMCF) Production in New and Existing Leases, Relative to Alternative A, 15-Year period

Item	*Federal, State, and Fee Surface*	*Federal Surface*	*State and Fee Surface*
Alternative B – Gas (MMCF)	-113,083	-101,628	-11,455
Alternative B – Oil (MBO)	-2,775	-2,580	-195
Alternative C – Gas (MMCF)	-302,842	-277,417	-25,425
Alternative C – Oil (MBO)	-9,075	-8,366	-709
Alternative D – Gas (MMCF)	-77,228	-72,791	-4,436
Alternative D – Oil (MBO)	-1,950	-1,909	-41
Alternative E – Gas (MMCF)	0	0	0
Alternative E – Oil (MBO)	0	0	0
Proposed Plan – Gas (MMCF)	-78,882	-75,183	-3,699
Proposed Plan – Oil (MBO)	-1,800	-1,827	27

Sources: Elaborated by BLM staff based on field office Reasonable Foreseeable Development Scenarios and available information.
MMCF = million cubic feet; MBO = thousand barrels

Request:

Please confirm that the impact of the proposed plan on oil and gas production is still correctly reflected in Tables W.4 and W.5, or please correct as appropriate.

Data Request – Impacts of the Proposed Plan on Phosphate – Utah:

To: Julie Suhr Pierce, Tyler Ashcroft

The current draft of the socioeconomics section discusses the potential impacts of management alternatives on phosphate production based on information provided by Tyler Ashcroft on April 17, 2014 and review of the minerals section. The socioeconomics section states the following:

"No Reasonably Foreseeably Development scenario for phosphate exists that quantifies current phosphate reserves on private and public lands and forecasts production of those reserves. In the absence of this information and any proposed plans for leasing and developing Federal lands for phosphate, it is not possible to quantify potential economic impacts across alternatives over the planning horizon. However, the areas available for phosphate leasing vary by alternative and could result in economic impacts if any party does pursue phosphate leasing and development of federal minerals. These impacts would be more likely under Alternative C that would close all federal mineral estate with phosphate potential to new leases, followed closely by Alternative B that would close 83 percent of the federal mineral estate decision area. Alternative A and E would close the fewest acres. Alternative D would close most areas to surface mining but mostly allow underground mining (Section 4.30.2)."

Request:

Please inform how the proposed plan compares to the remaining alternatives on open and closed federal mineral estate for leasing.

Data Request – Impacts of the Proposed Plan on Recreation – Utah:

To: Julie Suhr Pierce, David Jeppesen, Chris Miller (FS), David Reis (FS)

Based on input provided by David Jeppesen and forwarded by Tyler Ashcroft on April 15, 2015 and on input provided by David Reis (FS) and forwarded by Chris Miller (FS) on June 16, 2014, our analysis of the potential economic impacts of management alternatives on recreation is described below.

> "Quantifying or predicting changes in recreation use is more likely to be feasible for highly developed recreation areas. Quantifying or predicting changes in recreation in GRSG habitat in Utah is more difficult because primary recreational uses in GRSG habitat are more likely to be dispersed uses, such as hunting, driving for pleasure, general OHV use, car camping, and rock hounding. Baseline information on dispersed recreation within habitat areas is not available and thus precludes the quantification of potential changes to recreation use associated with management alternatives. In addition, the management actions considered within the range of alternatives potentially affecting recreation and travel management would not meaningfully affect how the public participates in the forms of dispersed recreation mentioned above because the majority of areas that would be closed to recreation activities such as OHV travel currently do not have mapped routes. In regards to access, recreation uses that rely on traveling cross country in or on a motorized vehicle would no longer be allowed within priority habitat. Action alternatives include measures that move BLM and FS lands designated as "Open" to cross country travel, to "Limited" to existing/designated routes within priority habitat. This change allows the BLM, FS, and the state of Utah to mitigate habitat destruction by prosecuting those who drive cross country."

Request:

Please inform whether the proposed plan would impact recreation differently from what is described above or feel free to suggest added language relative to the proposed plan.

Data Request – Impacts of the Proposed Plan on Wind Energy Development – Utah:

To: Julie Suhr Pierce, James Gazewood

Based on information provided by James Gazewood to Josh Sidon and forwarded to ICF on April 26, 2014 and review of the DEIS renewable energy section, the socioeconomics analysis assumed the following acres of BLM RFD Wind Energy within sage-grouse population areas that would be unaffected by this planning effort:

Alt. A = 17,328 acres (or 210 MW) within Hamlin and Bald Hills Areas

Alt. B = 9,998 acres (121 MW) within Hamlin Occupied Habitat (Bald Hills occupied did not touch WE RFD)

Alt. C = 9,998 acres (121 MW) within Hamlin Occupied Habitat (Bald Hills occupied did not touch WE RFD)

Alt. D = 9,998 acres (121 MW) within Hamlin Occupied Habitat (Bald Hills occupied did not touch WE RFD)

Alt. E = 17,328 acres (or 210 MW) within Hamlin and Bald Hills Areas

Request:

Please inform how the open areas to wind energy development within sage-grouse habitat under the proposed plan would compare to the remaining alternatives.

To: Sidon, Joshua B (jsidon@blm.gov)
CC: ICF_SGSE
Subject: BLM SGSE - Touching base
Attachments: summary oil and gas_v7.xlsx

Hi, Josh,

We haven't communicated in a couple of weeks. I calculated the cumulative oil and gas impacts of the GRSG management alternatives across the 10 state sage-grouse range as a share of projected oil and gas production for the 10 states, as we had discussed. I used EIA projections for the lower 48 states as a whole, since projections were not available by state. The results are only slightly lower than what we had before (see first tab of attached spreadsheet). If production were expected to grow much more in the 10 states than in the 48 as a whole, the result could be different, but I don't think we have those projections (at least I couldn't find any on the websites of the WOGCC and the COGCC).

Let me know if you want to touch base. Any news on schedule? Any news on the information we were seeking on the proposed plans? Do you think it would be useful for me to try to pursue some of the information we need on the proposed plans directly with other resource specialists, maybe copying you?

Please let me know.

Thanks,

Alex

1/ Represents lower 48 onshore and offshore supplies.

2/ Includes lease condensate.

3/ Tight oil represents resources in low-permeability reservoirs, including shale and chalk formation included in the tight oil category are Bakken/Three Forks/Sanish, Eagle Ford, Woodford, Austin Chalk, Avalon/Bone Springs, and Monterey.

4/ Marketed production (wet) minus extraction losses.

5/ Gas which occurs in crude oil reserves either as free gas (associated) or as gas in solution with cru

6/ Synthetic natural gas, propane air, coke oven gas, refinery gas, biomass gas, air injected for Btu stabilization, and manufactured gas commingled and distributed with natural gas.

Tcf = Trillion cubic feet.

Note: Totals may not equal sum of components due to independent rounding. Data for 2010 and 2 are model results and may differ slightly from official EIA data reports.

Sources: 2010 and 2011 crude oil lower 48 average wellhead price: U.S. Energy Information Administration (EIA), Petroleum Marketing Monthly, DOE/EIA-0380(2012/08) (Washington, DC, Augu 2010 and 2011 lower 48 onshore, lower 48 offshore, and Alaska crude oil production: EIA, Petroleum Supply Annual 2011, DOE/EIA-0340(2011)/1 (Washington, DC, August 2012). 2010 U.S. crude oil and natural gas reserves: EIA, U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves, DOE/EIA-0216(2010) (Washington, DC, August 2012). 2010 Alaska and total natural gas production, and supplemental gas supplies: EIA, Natural Gas Annual 2010, DOE/EIA-0131(2010) (Washington, DC, December 2011). 2010 and 2011 Henry Hub natural ga 2011 Alaska and total natural gas production, and supplemental gas supplies: EIA, Natural Gas Monthly, DOE/EIA-0130(2012/07) (Washington, DC, July 2012). Subject: Cumulative analysis

Thanks Alex. If that is current Washington Office direction, then please proceed as directed. I'm not sure but I think the comments on cumulative effects for Utah focused on phosphate. So it seems that is covered. Do you recall if we received cumulative impact comments in any of the subregions specific to O&G.

I'm sorry to see this analysis get removed given all the effort that was put in to make it happen. I suppose it uncovered some other issues that led to improved results. Thanks for you effort.

I wouldn't mind seeing the edits from Utah where "stated management was not consistent with what is in the Proposed Plan." I could see this helping us identify possible inconsistencies in other subregions too.

Hoping the finish line is close! Thanks again!

Josh

> Josh, please see below email from Quincy. My understanding per his email is that we should remove from the cumulative analysis the discussion of oil and gas cumulative estimates we were working on: only discussions of cumulative effects with neighboring areas should be included, not those across the GRSG range. Per his guidance, I will be removing. If this needs to be discussed, please let me know.

Subject: FW: Clarification

Alex,

Please see the message below from Quincy and the attached edited Chapter 4 for Utah. This subject came up this morning and was discussed during an afternoon teleconference. I asked Quincy to clarify the instructions for me so that I could send to you something definitive regarding cumulative effects analysis.

Please let me know if you have any questions.

Best,

Julie

Subject: Re: Clarification

We have been instructed that the Cumulative Effects Analysis Areas for all non-GRSG resources and uses, including minerals, should be the state or sub-region boundaries, or a specifically defined area taking into account nearby adjacent offices. However, other than GRSG, there was to be no range-wide analysis. For example, the added text to the cumulative impacts at the end of section 4.24.23 would have to be revised. Specifically, the text refers to two ways GRSG management could affect/be affected by other sub-regions of the GRSG range. The first way ("GRSG management in one sub-region may have effects that extend across sub-region borders and into counties also affected by GRSG management from other sub-regions") is encouraged. This would result in cumulative analysis that takes into account mineral developments from adjoining WY and CO counties. However, the second way ("when the GRSG range is analyzed as a whole") is what the WO direction dissuaded.

The paragraph that follows the one where the above quoted text was pulled (about phosphate) is an example of a cumulative analysis that, because it is not range-wide, is okay to retain.

Also, Skye went through the SE analysis looking for specific instances where the stated management was not consistent with what is in the Proposed Plan. Her edits are in the attached file.

Let me know if you have any questions.

Hi Alex, Laura,

You have already received the FS grazing response to SE data request for FEIS. The attached files are the draft FEIS effects for grazing, coming from FS perspective – these docs include descriptions of AUMs potentially affected (ii.e., overlap habitat as per Dustin's explanation below). Its not completely clear if/how these AUM numbers needed to be included in chapter 3 or 4 for socio-economics – but there you have it.

Let me know if you have questions,
Chris

Subject: RE: USFS Grazing Effects Analysis

Yes. The AUMs that will be reported in the FS grazing effects analysis are the AUMs associated with allotments that intersect nesting and brood rearing/summer habitat, have permitted season of use during nesting and brood rearing seasons, and have more than 200 acres that intersect nesting and brood rearing habitat within occupied GRSG habitat. These variables will change the numbers of AUMs that were reported in the DEISs due to how we did the spatial analysis for the FEIS based on the language in the FS proposed plan. I don't have Utah numbers yet, but I made a comparison table for Idaho.

Forest	Allotments in DEIS	Allotments in FEIS	Active AUMs DEIS	Permitted (Active) AUMs FEIS	Acres PPH/PGH DEIS	Allotment Acres Nesting/Brood FEIS
Beaverhead-Deerlodge	83	70	207,600	94,730	326,200	284,617
Boise	16	12	48,300	9,604	76,100	67,879
Caribou-Targhee-Curlew	66	24	336,600	76,568	316,300	137,901
Salmon-Challis	82	49	142,200	109,844	544,700	351,218

Sawtooth	72	59	172,100	114,739	475,800	458,069
Total	319	214	906,800	405,485	1,739,100	1,299,684

That said, the FS grazing effects analysis does say that implementation of management direction under the proposed plan could result in a moderate reduction of AUMs over time, and could reduce AUMs on some allotments that could impact overall permittee operation viability. These impacts would not be known until proposed plan management is implemented at the allotment level in order to achieve desired conditions and annual grazing use guidelines. We discussed ways to determine a reduction in AUMs for the proposed plan at the planning level, but haven't been able to figure this out accurately at this broad of a scale. Hope that helps.

Dustin

Subject: Re: USFS Grazing Effects Analysis

When you say "AUMs potentially impacted" do you mean AUMS associated with allotments that overlap PHMA/GHMA, where in places like ID or NV that may have changed from the DEIS? If that's what you mean, I understand. If you are referring to AUMs that may be affected based on applying the habitat objectives to a varied range condition and how that may affect operators, I have concerns. I had addressed the latter issue qualitatively in our SE submission to the SE contractor. They are almost done with the analysis. If those are the AUMs you're referencing, it may be too late to integrate them into the SE analysis, notwithstanding other concerns I have raised related to this issue on the weekly coordination calls.

Do the AUMs you're calculating tied just to allotments that overlap the redesigned PHMA/GHMA boundaries?

Idaho – Forest Service Proposed Plan Amendment Livestock Grazing Effects Analysis

Proposed Plan

Grazing management under the Proposed Plan on National Forest System (NFS) lands would be determined at the Forest unit level in order to achieve desired conditions and meet grazing use guidelines in GRSG seasonal habitats. Impacts to livestock grazing generally depend on current and site-specific biophysical conditions, livestock numbers, timing and duration of use, livestock management practices, range development and improvement levels, and permittee responsibilities, which are not easily addressed at the programmatic level. As a result, impacts on livestock grazing management would vary at a site-specific level and are described broadly for the Proposed Plan at the planning-unit scale.

Impacts from General GRSG Management

Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in table 1. Livestock grazing would be managed to maintain residual herbaceous grass height for overhead and lateral concealment for GRSG nesting and early brood rearing life stages. Wet meadows and riparian areas would be managed to sustain a rich diversity of perennial forb species relative to site potential, and winter habitat would provide sufficient sagebrush height and density for food and cover for GRSG during this seasonal period.

Management to achieve these desired conditions would directly impact livestock grazing on NFS lands. These impacts could include modification of grazing strategies or rotation schedules, changes to duration and/or the season of use, changes to the kind and class of livestock, or reduction of livestock numbers. These modifications could result in the reduction of AUMs on some allotments. Management to achieve these desired conditions would also impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation.

Indirectly, implementation of management direction to achieve desired conditions in GRSG seasonal habitat as described in table 1 could be beneficial to livestock grazing in the long-term, particularly on allotments where rangeland conditions could be improved, by implementing management direction that improves rangeland conditions. Improved rangeland condition could also contribute to increased forage production.

Table 1. Seasonal Habitat Desired Conditions for GRSG.

ATTRIBUTE	INDICATORS	DESIRED CONDTION
BREEDING AND NESTING [1,2,3] (Seasonal Use Period March 1-June 15) Apply 6.2 miles from active leks. [4]		
Lek Security	Proximity of trees [5]	Trees or other tall structures are none to uncommon within 1.86 miles of leks [6,7]

ATTRIBUTE	INDICATORS	DESIRED CONDTION
	Proximity of sagebrush to leks [6]	Adjacent protective sagebrush cover within 328 feet of lek [6]
Cover	Seasonal habitat extent [7]	>80% of the breeding and nesting habitat
	Sagebrush canopy cover[6,7,8]	15 to 25%
	Sagebrush height [7] Arid sites [6,7,9] Mesic sites [6,7,10]	 12 to 32 inches 16 to 32 inches
	Predominant sagebrush shape [6]	>50% in spreading [11]
	Perennial grass canopy cover [6,7] Arid sites [7,9] Mesic sites [7,10]	 ≥10% ≥15%
	Perennial grass height [6,7,8]	Provide overhead and lateral concealment from predators [7]
	Perennial forb canopy cover [6,7,8] Arid sites [9] Mesic sites [10]	 ≥5%[6,7] ≥10%[6,7]
BROOD-REARING/SUMMER[1] (Seasonal Use Period June 16-October 31)		
Cover	Seasonal habitat extent [7]	>40% of the brood-rearing/summer habitat
	Sagebrush canopy cover [6,7,8]	10 to 25%
	Sagebrush height [7,8]	16 to 32 inches
	Perennial grass canopy cover and forbs [7,8]	>15%
	Riparian areas/mesic meadows	Proper Functioning Condition [12]
	Upland and riparian perennial forb availability [6,7]	Preferred forbs are common with several preferred species present [13]
WINTER[1] (Seasonal Use Period November 1-February 28)		
Cover and Food	Seasonal habitat extent [6,7,8]	>80% of the winter habitat
	Sagebrush canopy cover above snow [6,7,8]	>10%
	Sagebrush height above snow [6,7,8]	>10 inches [14]

[1] Seasonal dates can be adjusted; that is, start and end dates may be shifted either earlier or later, but the amount of days cannot be shortened or lengthened by the local unit.

[9] 10–12 inch precipitation zone; *Artemisia tridentata wyomingensis* is a common big sagebrush sub-species for this type site (HAF 2014).

[10] ≥12 inch precipitation zone; *Artemisia tridentata vaseyana* is a common big sagebrush sub-species for this type site (HAF 2014).

[11] Sagebrush plants with a spreading shape provide more protective cover than sagebrush plants that are more tree- or columnar shaped (HAF 2014).

[12] Existing land management plan desired conditions for riparian areas/wet meadows (spring seeps) may be used in place of properly functioning conditions, if appropriate for meeting greater sage-grouse habitat requirements.

[13] Preferred forbs are listed in HAF Table III-2 (HAF 2014). Overall total forb cover may be greater than that of preferred forb cover since not all forb species are listed as preferred in Table III-2.

[14] The height of sagebrush remaining above the snow depends upon snow depth in a particular year. Intent is to manage for tall, healthy, sagebrush stands.

Impacts from Adaptive Management

Adaptive management measures under the Proposed Plan could have direct impacts on livestock grazing if it is determined that domestic livestock grazing is a causal factor in the deviation from GRSG conservation objectives. These impacts could include the cessation of livestock grazing or modification of numbers or season of use, which would reduce AUMs.

Impacts from Lands and Realty Management
Under the Proposed Plan, special use authorizations, land ownership adjustments, and land withdrawals would be restricted or mitigated to avoid or reduce adverse impacts to GRSG in priority and general habitat. This management direction would limit the direct and indirect impacts of development and surface disturbance on rangelands where livestock grazing is permitted. However, impacts could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Wind and Solar
Management direction prohibiting solar and wind development in priority habitat and imposing restrictions on development in general habitat would limit any impacts associated with ground disturbances from development of these resources. This management direction would limit the direct impacts of development and surface disturbances on existing rangelands, which would be beneficial to livestock grazing. However, this may shift impacts in areas outside of priority and general GRSG habitats, which could indirectly impact rangelands and grazing conditions through increased development.

Impacts from GRSG Habitat Management
Restoration activities under this alternative that reduce invasive annual grasses and other invasive plant species, conifers, and the spread and intensity of wildfire in GRSG seasonal habitats would be beneficial to livestock grazing because these activities will improve rangeland conditions and increase forage production in the long-term. Restrictions that temporarily close areas to grazing could impact permittees and operations in the short-term.

Impacts from Livestock Grazing Management
Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in table 1. Livestock grazing would also be managed in order to maintain residual perennial grass height to provide for adequate GRSG nesting cover according to the guidelines described in table 2.

Current direction for livestock grazing use in most Forest Plans in the planning areas is generally less restrictive than direction described under the Proposed Plan (Table 3). Therefore, grazing use guidelines under the Proposed Plan would directly impact livestock grazing management on NFS lands. Impacts could include modification of grazing strategies or rotation schedules, changes to the season of use, changes to kind and class of livestock, closure of a portion of an allotment, or reduction of livestock numbers. Implementation of this management direction could result in the reduction of AUMs on some allotments.

Table 2. Proposed Plan Grazing Guidelines for GRSG Seasonal Habitat.

Seasonal Habitat	Grazing Guidelines
Breeding and nesting [1] within 6.2 miles of occupied leks	Perennial grass height: [2] When grazing occurs during breeding and nesting season (March 1 to July 15) manage

	for upland perennial grass height of 7 inches [3,4,5] When grazing occurs post breeding and nesting season (July 16 to October 31) manage for 4 inches [4,5,6] of perennial grass height.
Brood rearing and summer [1]	Retain an average stubble height of 4 inches for herbaceous riparian/mesic meadow vegetation [7,8]
Winter [1]	≤35% use of sagebrush

[1] For descriptions of Seasonal Habitat and Seasonal Periods of GRSG see table 1.

[2] Grass heights only apply in breeding and nesting habitat with ≥10% sagebrush cover to support nesting.

[3] Holloran et al. 2005 *GRSG nesting habitat selection and success in Wyoming*.

[4] Average droop height, assuming current vegetation composition has the capability to achieve these heights. Heights will be measured at the end of the nesting period (Connelly, 2000).

[5] Hagen C., J.W. Connelly, and M.A. Schroeder. 2007. *A meta-analysis of GRSG Centrocercus urophasianus nesting and brood-rearing habitats*. Wildlife Biology 13(1): 42-50.

[6] Stubble height to be measured at the end of the growing season.

[7] Crawford et al. 2004. Ecology and Management of GRSG and GRSG habitat. “In riparian brood-rearing habitat, GRSG prefer the lower vegetation (5-15 cm (2-6 in) vs. 30-50 cm (12-20 in); Oakleaf 1971, Neel 1980, Klebenow 1982, Evans 1986) and succulent forb growth stimulated by moderate livestock grazing (Neel 1980, Evans 1986). “Moderate use equates to a 10-cm residual stubble height for most grasses and sedges.”

[8] Stubble height to be measured in the meadow areas used by GRSG for brood-rearing (not on the hydric greenline).

Table 3. Current Land and Resource Management Plan (Forest Plan) direction for livestock grazing use.

Forest/Grassland Plan	**Existing Upland Use Level[1]**	**Existing Riparian Use Level[1]**
Beaverhead-Deerlodge	40% - 65%	▪ 3”-6” SH[2]
Boise	40% - 50%	▪ 45% ▪ 4” SH
Caribou	35% - 55%	▪ 4”- 6” SH
Targhee	35% - 55%	▪ 4” SH ▪ 30% Browse[3]
Curlew	50% - 60%	▪ Use levels established at site specific level or in AMP
Salmon	▪ 25% - 65% ▪ 3” - 6” SH	▪ 25% - 65% ▪ 3”- 6” SH
Challis	None (Defers to AMP)	▪ Use levels established at site specific level or in AMP ▪ 50% Browse
Sawtooth	40% - 50%	▪ 45% or 4” SH

[1] As described in the current Land Resource Management Plan. Ranges vary according to grazing system (e.g., rest or deferred), season of use (e.g., early or late), range condition (e.g., satisfactory or unsatisfactory), vegetation type (e.g., alpine or non-native seeding), or other categories (e.g., greenline, key area, age class).

[2] SH – Stubble Height

[3] Annual utilization of current year’s growth of woody vegetation

Implementation of these guidelines could also directly impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation. Impacts would occur at the allotment scale as management direction is incorporated into permits, allotment management plans, and annual operating instructions. Management direction for livestock grazing under the Proposed Plan could decrease grazing in some allotments, and possibly overall operation viability. The level and intensity of impacts could vary on a site specific basis with permitted grazing likely decreasing moderately over time as permits are modified to achieve desired conditions and meet annual grazing use guidelines.

Grazing use guidelines under the Proposed Plan would impact about XXX allotments, XXX total acres, and XXX total AUMs in nesting and brood rearing habitats. Grazing use guidelines that limit forage use to 7 inches for perennial grasses during nesting season and 4 inches post nesting season would impact about XXX acres in nesting habitat within active grazing allotments (Table 4).

Table 4. Grazing Allotment Acres and AUMs intersecting GRSG Seasonal Habitat on National Forests and Grasslands within the EIS planning area.

Forest/Grassland	Allotment Acres in Nesting Habitat[1]	Allotment Acres In Brood Rearing/Summer Habitat[2]	Allotments in Nesting and Brood Rearing/Summer Habitat	Total AUMs for Allotments in Nesting and Brood Rearing/Summer Habitat[3]
Beaverhead-Deerlodge				
Boise				
Caribou-Targhee				
Curlew				
Salmon-Challis				
Sawtooth				

[1] Acres in active allotments with permitted dates during nesting season that intersect nesting habitat and have greater than 200 acres in occupied GRSG habitat.

[2] Acres in active allotments with permitted dates during brood rearing/summer season that intersect brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

[3] Total AUMs for active allotments with permitted dates during nesting and brood rearing/summer season that intersect nesting and brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

Under the Proposed Plan sheep camps would not be located within 1.2 miles from the perimeter of a lek during lekking season and trailing of livestock during breeding and nesting seasons would be minimized during breeding and nesting seasons. This management direction would result in the need to modify grazing practices with increased costs for permittees in these areas.

Additional constraints under the Proposed Plan would also apply to structural range improvements in priority GRSG habitat compared to current plan direction. These include prohibiting fence construction or reconstruction within 1.2 miles from the perimeter of occupied leks unless the collision risk can be mitigated through design features or markings, not constructing new permanent livestock facilities (e.g., windmills, water tanks, corrals) within 1.2 miles from the perimeter of occupied leks, and not constructing water developments in priority habitat unless they are beneficial to GRSG.

Prohibitions on new structural improvements could limit the ability of permittees to effectively distribute livestock resulting in increases in time and costs to permittees and potentially the full use permitted AUMs. Although these constraints could increase the amount of time permittees spend to manage livestock on NFS lands, it should allow sufficient flexibility that permittees could continue to utilize structural range improvements to effectively distribute livestock.

Under the Proposed Plan, the Forest Service would consider closure of grazing allotments, pastures, or portions of pastures, or managing the allotment as a forage reserve as opportunities as opportunities arise where removal of livestock would enhance the ability to achieve desired habitat conditions as described in table 1. These actions would occur according to applicable regulations and, if implemented, would result in the reduction of overall available AUMs.

Managing livestock grazing to achieve the desired conditions in table 1 and livestock use guidelines in table 3 may indirectly benefit rangeland conditions by increasing vegetation productivity and increasing forage in the long term. This in turn would provide managers and permittees better management options, especially on those allotments where livestock numbers are approaching a sustainability threshold or during drought and other disturbances such as wildfire.

Impacts from Fire Management

Under the Proposed Plan, measures to protect GRSG habitat from fire and associated fire operations would be beneficial to livestock grazing, especially in the 12-inch or less precipitation zone, because it would help prevent expansion of non-native invasive species such as cheatgrass. Although management to suppress and control the spread of wildfire under the Proposed Plan would decrease the risk of disturbance from wildfire in GRSG habitat, fires outside of GRSG habitat would possibly be at risk of decreased suppression efforts. Management direction to protect GRSG habitat from fire in higher elevation sagebrush habitats (i.e., mountain big sagebrush) could indirectly negatively impact livestock grazing in the long-term as sagebrush potentially increases and forage production decreases.

Impacts from Wild Horse and Burro Management

Under Proposed Plan, wild horse and burro populations should be managed within appropriate management levels, or adjusted, to restore, enhance, or maintain GRSG desired habitat conditions as described in table 1. This management direction would be beneficial to livestock grazing in the long-term by increasing vegetation productivity and increasing forage production, particularly where rangeland conditions could be improved.

Impacts from Recreation Management

Under the Proposed Plan new recreation special use authorizations and expansion of special use authorizations would be restricted in priority habitat management areas. In addition, terms and conditions that that protect or restore GRSG habitat would be included in new special use authorizations and existing permits and operating plans would be modified to protect and/or restore GRSG habitat. Temporary recreation uses that result in the loss of GRSG habitat would not be authorized, and new recreational facilities or expansion of existing recreational facilities (e.g., roads, trails, campgrounds) would not be approved in priority habitat unless the development results in a net conservation gain to GRSG and/or their habitats.

This management direction would limit the direct and indirect impacts of recreation development on rangelands where livestock grazing is permitted. This management direction would have beneficial impacts to livestock grazing by reducing disturbances to rangelands from development and disturbances to livestock. However, impacts from recreation management could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Road/Transportation Management

Under the Proposed Plan new road or trail and construction would be prohibited in GRSG habitat, and road construction within riparian and mesic meadows would be restricted. This direction would be beneficial to livestock grazing by reducing impacts from roads rangeland and riparian areas. This could indirectly improve forage production and improve overall rangeland conditions. However, impacts from roads and transportation could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Minerals Management

Under the Proposed Plan, new fluid mineral leases would require a no surface occupancy stipulation in priority habitat and controlled surface use and timing restrictions in general habitat. New leases would be prioritized in non-habitat first and then in the least suitable habitat for GRSG.

For existing leases under the Proposed Plan, leaseholders would be required to avoid and minimize surface disturbing and disruptive activities in priority habitat for leases that are not yet developed. In addition, reclamation plans would be designed to restore habitat to desired conditions described in table 1. Fluid mineral operations would be mitigated in priority habitat to reduce soil compaction to improve vegetation reestablishment and keep GRSG habitat disturbance to a minimum.

Surface disturbances would also be prohibited for unleased coal mines in priority habitat as well as other mitigation measures to reduce disturbances for leased coal mines and associated facilities. Locatable mineral, non-energy leasable, and mineral material operations in priority habitat would be mitigated to protect GRSG habitat.

Minerals management direction under the Proposed Plan would have positive impacts for livestock grazing in priority and general GRSG habitats because development and surface disturbance would be limited, and the potential from development related disturbance of rangeland and forage resources would be reduced. However, impacts from new and existing mineral leases could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

03/24/2015

Nevada – Forest Service Proposed Plan Amendment Livestock Grazing Effects Analysis

Proposed Plan
Grazing management under the Proposed Plan on National Forest System (NFS) lands would be determined at the Forest unit level in order to achieve desired conditions and meet grazing use guidelines in GRSG seasonal habitats. Impacts to livestock grazing generally depend on current and site-specific biophysical conditions, livestock numbers, timing and duration of use, livestock management practices, range development and improvement levels, and permittee responsibilities, which are not easily addressed at the programmatic level. As a result, impacts on livestock grazing management would vary at a site-specific level and are described broadly for the Proposed Plan at the planning-unit scale.

Impacts from General GRSG Management
Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in tables 1a and 1b. Livestock grazing would be managed to maintain residual herbaceous grass height for overhead and lateral concealment for GRSG nesting and early brood rearing life stages. Wet meadows and riparian areas would be managed to sustain a rich diversity of perennial forb species relative to site potential, and winter habitat would provide sufficient sagebrush height and density for food and cover for GRSG during this seasonal period.

Management to achieve these desired conditions would directly impact livestock grazing on NFS lands. These impacts could include modification of grazing strategies or rotation schedules, changes to duration and/or the season of use, changes to the kind and class of livestock, or reduction of livestock numbers. These modifications could result in the reduction of AUMs on some allotments. Management to achieve these desired conditions would also impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation.

Indirectly, implementation of management direction to achieve desired conditions in GRSG seasonal habitat as described in tables 1a and 1b could be beneficial to livestock grazing in the long-term, particularly on allotments where rangeland conditions could be improved, by implementing management direction that improves rangeland conditions. Improved rangeland condition could also contribute to increased forage production.

Table 1a. Seasonal Habitat Desired Conditions for Greater Sage-grouse (Ecoregion 342).

ATTRIBUTE	INDICATORS	DESIRED CONDTION
BREEDING AND NESTING [1,2,3] (Seasonal Use Period March 1-June 30) Apply 4.0 miles from active leks. [15]		
Lek Security	Proximity of Pinyon-and/or Juniper [4]	Pinyon and/or Juniper none to uncommon within 1.86 miles (3 km) of leks [5,6]
	Proximity of sagebrush to leks [5]	Adjacent protective sagebrush cover within 328 feet of lek [5]
Cover	Seasonal habitat extent [6]	>80% of the breeding and nesting habitat
	Sagebrush canopy cover [5,6,7]	> 20%
	Sagebrush height [6] Arid sites [5,6,9] Mesic sites [5,6,10]	> 12>16
	Predominant sagebrush shape [5]	>50% in spreading [11]
	Perennial grass cover [5,6] Arid sites [6,9] Mesic sites [6,10]	≥10% ≥15%
	Perennial grass height [5,6,7]	Provide overhead and lateral concealment from predators [6]
	Perennial forb canopy cover [5,6,7] Arid sites [9] Mesic sites [10]	≥5%[5,6] ≥10%[5,6]
BROOD-REARING/SUMMER[1] (Seasonal Use Period May 15 to September 15)		
Cover	Seasonal habitat extent [6]	>40% of the brood-rearing/summer habitat
	Sagebrush canopy cover [5, 6,7]	10 to 25%
	Sagebrush height [6,7]	> 16
	Perennial grass canopy cover and forbs [6,7]	>15%
	Riparian areas/mesic meadows	Proper Functioning Condition [13]
	Upland and riparian perennial forb availability [5,6]	Preferred forbs are common with several preferred species present [12]
WINTER/FALL[1] (Seasonal Use Period September 1 to February 28)		
Cover and Food	Seasonal habitat extent [5,6,7]	>80% of the winter habitat
	Sagebrush canopy cover above snow [5,6,7]	>10%
	Sagebrush height above snow [5,6,7]	>10 inches [14]

[1] Seasonal dates can be adjusted; that is, start and end dates may be shifted either earlier or later, but the amount of days cannot be shortened or lengthened by the local unit.

[9] 10–12 inch precipitation zone; *Artemisia tridentata wyomingensis* is a common big sagebrush sub-species for this type site (HAF 2014).

[10] ≥12 inch precipitation zone; *Artemisia tridentata vaseyana* is a common big sagebrush sub-species for this type site (HAF 2014).

[11] Sagebrush plants with a spreading shape provide more protective cover than sagebrush plants that are more tree- or columnar shaped (HAF 2014).

[12] Preferred forbs are listed in HAF Table III-2 (HAF 2014). Overall total forb cover may be greater than that of preferred forb cover since not all forb species are listed as preferred in Table III-2.

[13] Existing land management plan desired conditions for riparian areas/wet meadows (spring seeps) may be used in place of properly functioning conditions, if appropriate for meeting greater sage-grouse habitat requirements.

ATTRIBUTE	INDICATORS	DESIRED CONDTION
[14] The height of sagebrush remaining above the snow depends upon snow depth in a particular year. Intent is to manage for tall, healthy, sagebrush stands. [15] Buffer distance may be changed only if 3 out of 5 years of telemetry studies indicate the 4 miles is not appropriate.		

Table 1b. Seasonal Habitat Desired Conditions for Greater Sage-grouse (Ecoregion 341).

ATTRIBUTE	INDICATOR	DESIRED CONDITION
GENERAL/LANDSCAPE-LEVEL		
Cover (Nesting)	Seasonal Habitat Needed	>65% of the landscape in sagebrush cover[1]
	Annual Grasses	< %5[3]
Security (Nesting)	Conifer encroachment	<3% phase I (>0% to <25% cover) No phase II (25 – 50% cover) No phase III (>50% cover)
Cover and Food (Winter)	Conifer encroachment	<5% phase I (>0% to <25% cover) No phase II (25 – 50% cover) No phase III (>50% cover)
	Sagebrush extent	>85% sagebrush land cover
LEK		
Cover	Availability of sagebrush cover	Has adjacent sagebrush cover[7,15]
Security [4]	Pinyon and/or Juniper cover	<3% landscape canopy cover within 1 km of leks[2]
	Proximity of tall structures (1 meter above shrub canopy)	None within 3 miles (5 kilometers)[6,6]
NESTING		
Cover	Sagebrush canopy cover	≥20%[11,12]
	Residual and live perennial grass cover	≥10% if shrub cover <25%[2,6,5]
	Annual grass cover [5]	<5%[13]
	Perennial grass height	Provide overhead and lateral concealment from predators[7]
	Total shrub cover	≥30%[5,11]
Security	Proximity of tall structure (1 meter above shrub canopy)	None within 3 miles[16]
BROOD-REARING/SUMMER		
Cover	Sagebrush canopy cover	10%-25%[7]
	Perennial grass canopy cover and forbs	>15% combined perennial grass and forb canopy cover[7]
Cover and Food	Perennial forb canopy cover	≥5% arid (<10 inches precipitation) ≥15% mesic (> 10 inches or meadow system)
Food	Riparian Areas/Meadows	Proper Functioning Condition[1,15]
	Understory species richness (in the vicinity of riparian areas/meadows)	≥ 5 preferred forb species present[3,4]
Security	Riparian Area/Meadow Interspersion with adjacent sagebrush	Has adjacent sagebrush cover[7,15]
WINTER		
Cover and Food	Sagebrush canopy cover	≥10% above snow depth[7]
	Sagebrush height	>9.8 inches (25 centimeters) above snow depth[7]

[1] Upland standards are based on indicators for canopy and ground cover, including litter, live vegetation, and rock, appropriate to the ecological potential of the site.

[2] In addition, if upland rangeland health standards are being met.

[3] Standard considered in addition to Proper Functioning Condition (PFC). Includes all mesic plant species.

[4] Applicable to Phase I and Phase II pinyon and/or juniper.

ATTRIBUTE	INDICATOR	DESIRED CONDITION
[6]Does not include fences.		

Impacts from Adaptive Management

Adaptive management measures under the Proposed Plan could have direct impacts on livestock grazing if it is determined that domestic livestock grazing is a causal factor in the deviation from GRSG conservation objectives. These impacts could include the cessation of livestock grazing or modification of numbers or season of use, which would reduce AUMs.

Impacts from Lands and Realty Management

Under the Proposed Plan, special use authorizations, land ownership adjustments, and land withdrawals would be restricted or mitigated to avoid or reduce adverse impacts to GRSG in priority and general habitat. This management direction would limit the direct and indirect impacts of development and surface disturbance on rangelands where livestock grazing is permitted. However, impacts could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Wind and Solar

Management direction prohibiting solar and wind development in priority habitat and imposing restrictions on development in general habitat would limit any impacts associated with ground disturbances from development of these resources. This management direction would limit the direct impacts of development and surface disturbances on existing rangelands, which would be beneficial to livestock grazing. However, this may shift impacts in areas outside of priority and general GRSG habitats, which could indirectly impact rangelands and grazing conditions through increased development.

Impacts from GRSG Habitat Management

Restoration activities under this alternative that reduce invasive annual grasses and other invasive plant species, conifers, and the spread and intensity of wildfire in GRSG seasonal habitats would be beneficial to livestock grazing because these activities will improve rangeland conditions and increase forage production in the long-term. Restrictions that temporarily close areas to grazing could impact permittees and operations in the short-term.

Impacts from Livestock Grazing Management

Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in tables 1a and 1b. Livestock grazing would also be managed in order to maintain residual perennial grass height to provide for adequate GRSG nesting cover according to the guidelines described in table 2.

Current direction for livestock grazing use in most Forest Plans in the planning areas is generally less restrictive than direction described under the Proposed Plan (Table 3). Therefore, grazing use guidelines under the Proposed Plan would directly impact livestock grazing management on NFS lands. Impacts could include modification of grazing strategies or rotation schedules, changes to the season of use, changes to kind and class of livestock, closure of a portion of an allotment, or reduction of livestock numbers. Implementation of this management direction could result in the reduction of AUMs on some allotments.

Table 2. Proposed Plan Grazing Guidelines for GRSG Seasonal Habitat.

Seasonal Habitat	Grazing Guidelines
Breeding and nesting [1] within 4 miles of occupied leks	Perennial grass height: [2] When grazing occurs during breeding and nesting season (March 1 to June 30) manage for upland perennial grass height of 7 inches [3,4,5] When grazing occurs post breeding and nesting season (May 15 to September 15) manage for 4 inches [4,5,6] of perennial grass height.
Brood rearing and summer [1]	Retain an average stubble height of 4 inches for herbaceous riparian/mesic meadow vegetation [7,8]
Winter [1]	≤35% use of sagebrush

[1] For descriptions of Seasonal Habitat and Seasonal Periods of GRSG see tables 1a and 1b.

[2] Grass heights only apply in breeding and nesting habitat with ≥10% sagebrush cover to support nesting.

[3] Holloran et al. 2005 *GRSG nesting habitat selection and success in Wyoming*.

[4] Average droop height, assuming current vegetation composition has the capability to achieve these heights. Heights will be measured at the end of the nesting period (Connelly, 2000).

[5] Hagen C., J.W. Connelly, and M.A. Schroeder. 2007. *A meta-analysis of GRSG Centrocercus urophasianus nesting and brood-rearing habitats*. Wildlife Biology 13(1): 42-50.

[6] Stubble height to be measured at the end of the growing season.

[7] Crawford et al. 2004. Ecology and Management of GRSG and GRSG habitat. “In riparian brood-rearing habitat, GRSG prefer the lower vegetation (5-15 cm (2-6 in) vs. 30-50 cm (12-20 in); Oakleaf 1971, Neel 1980, Klebenow 1982, Evans 1986) and succulent forb growth stimulated by moderate livestock grazing (Neel 1980, Evans 1986). “Moderate use equates to a 10-cm residual stubble height for most grasses and sedges.”

[8] Stubble height to be measured in the meadow areas used by GRSG for brood-rearing (not on the hydric greenline).

Table 3. Current Land and Resource Management Plan (Forest Plan) direction for livestock grazing use.

Forest Plan	Existing Upland Use Level[1]	Existing Riparian Use Level[1]
Humboldt	55% - 65%	▪ 35% - 70% ▪ 35% Browse[2]
Toiyabe	30% - 55%	▪ 45% - 65%

[1] As described in the current Land Resource Management Plan. Ranges vary according to grazing system (e.g., rest or deferred), season of use (e.g., early or late), range condition (e.g., satisfactory or unsatisfactory), vegetation type (e.g., alpine or non-native seeding), or other categories (e.g., greenline, key area, age class).

[2] Annual utilization of current year’s growth of woody vegetation

Implementation of these guidelines could also directly impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation. Impacts would occur at the allotment scale as management direction is incorporated into permits, allotment management plans, and annual operating instructions. Management direction for livestock grazing under the Proposed Plan could decrease grazing in some allotments, and possibly overall operation viability. The level and intensity of impacts could vary on a site specific basis with permitted grazing likely decreasing moderately over time as permits are modified to achieve desired conditions and meet annual grazing use guidelines.

Grazing use guidelines under the Proposed Plan would impact about XXX allotments, XXX total acres, and XXX total AUMs in nesting and brood rearing habitats. Grazing use guidelines that limit forage use to 7 inches for perennial grasses during nesting season and 4 inches post nesting season would impact about XXX acres in nesting habitat within active grazing allotments (Table 4).

Table 4. Grazing Allotment Acres and AUMs intersecting GRSG Seasonal Habitat on the Humboldt-Toiyabe National Forest within the EIS planning area.

Allotment Acres in Nesting Habitat[1]	Allotment Acres In Brood Rearing/ Summer Habitat[2]	Allotments in Nesting and Brood Rearing/ Summer Habitat	Total AUMs for Allotments in Nesting and Brood Rearing/ Summer Habitat[3]

[1] Acres in active allotments with permitted dates during nesting season that intersect nesting habitat and have greater than 200 acres in occupied GRSG habitat.

[2] Acres in active allotments with permitted dates during brood rearing/summer season that intersect brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

[3] Total AUMs for active allotments with permitted dates during nesting and brood rearing/summer season that intersect nesting and brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

Under the Proposed Plan sheep camps would not be located within 1.2 miles from the perimeter of a lek during lekking season and trailing of livestock during breeding and nesting seasons would be minimized during breeding and nesting seasons. This management direction would result in the need to modify grazing practices with increased costs for permittees in these areas.

Additional constraints under the Proposed Plan would also apply to structural range improvements in priority GRSG habitat compared to current plan direction. These include prohibiting fence construction or reconstruction within 1.2 miles from the perimeter of occupied leks unless the collision risk can be mitigated through design features or markings, not constructing new permanent livestock facilities (e.g., windmills, water tanks, corrals) within 1.2 miles from the perimeter of occupied leks, not constructing water developments in priority habitat unless they are beneficial to GRSG, and installing and maintaining wildlife escape ramps when vertical embankments in water troughs or open water facilities pose a drowning risk to birds.

Prohibitions on new structural improvements could limit the ability of permittees to effectively distribute livestock resulting in increases in time and costs to permittees and potentially the full use permitted AUMs. Additional maintenance requirements for existing structural improvements could increase the amount of time permittees spend to on maintenance as well as additional material and labor costs. Although these constraints could increase the amount of time permittees spend to manage livestock on NFS lands, it should allow sufficient flexibility that permittees could continue to utilize structural range improvements to effectively distribute livestock.

Under the Proposed Plan, the Forest Service would consider closure of grazing allotments, pastures, or portions of pastures, or managing the allotment as a forage reserve as opportunities as opportunities arise where removal of livestock would enhance the ability to achieve desired habitat conditions as described in tables 1a and 1b. These actions would occur according to applicable regulations and, if implemented, would result in the reduction of overall available AUMs.

Managing livestock grazing to achieve the desired conditions in tables 1a and 1b and livestock use guidelines in table 3 may indirectly benefit rangeland conditions by increasing vegetation productivity and increasing forage in the long term. This in turn would provide managers and permittees better management options, especially on those allotments where livestock numbers are approaching a sustainability threshold or during drought and other disturbances such as wildfire.

Impacts from Fire Management

Under the Proposed Plan, measures to protect GRSG habitat from fire and associated fire operations would be beneficial to livestock grazing, especially in the 12-inch or less precipitation zone, because it would help prevent expansion of non-native invasive species such as cheatgrass. Although management to suppress and control the spread of wildfire under the Proposed Plan would decrease the risk of disturbance from wildfire in GRSG habitat, fires outside of GRSG habitat would possibly be at risk of decreased suppression efforts. Management direction to protect GRSG habitat from fire in higher elevation sagebrush habitats (i.e., mountain big sagebrush) could indirectly negatively impact livestock grazing in the long-term as sagebrush potentially increases and forage production decreases.

Impacts from Wild Horse and Burro Management

Under Proposed Plan, wild horse and burro populations should be managed within appropriate management levels, or adjusted, to restore, enhance, or maintain GRSG desired habitat conditions as described in tables 1a and 1b. This management direction would be beneficial to livestock grazing in the long-term by increasing vegetation productivity and increasing forage production, particularly where rangeland conditions could be improved.

Impacts from Recreation Management

Under the Proposed Plan new recreation special use authorizations and expansion of special use authorizations would be restricted in priority habitat management areas. In addition, terms and conditions that that protect or restore GRSG habitat would be included in new special use authorizations and existing permits and operating plans would be modified to protect and/or restore GRSG habitat. Temporary recreation uses that result in the loss of GRSG habitat would not be authorized, and new recreational facilities or expansion of existing recreational facilities (e.g., roads, trails, campgrounds) would not be approved in priority habitat unless the development results in a net conservation gain to GRSG and/or their habitats.

This management direction would limit the direct and indirect impacts of recreation development on rangelands where livestock grazing is permitted. This management direction would have beneficial impacts to livestock grazing by reducing disturbances to rangelands from development and disturbances to livestock. However, impacts from recreation management could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Road/Transportation Management

Under the Proposed Plan new road or trail and construction would be prohibited in GRSG habitat, and road construction within riparian and mesic meadows would be restricted. This direction would be beneficial to livestock grazing by reducing impacts from roads rangeland and riparian areas. This could indirectly improve forage production and improve overall rangeland conditions. However, impacts from roads and transportation could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Minerals Management

Under the Proposed Plan, new fluid mineral leases would require a no surface occupancy stipulation in priority habitat and controlled surface use and timing restrictions in general habitat. New leases would be prioritized in non-habitat first and then in the least suitable habitat for GRSG.

For existing leases under the Proposed Plan, leaseholders would be required to avoid and minimize surface disturbing and disruptive activities in priority habitat for leases that are not yet developed. In addition, reclamation plans would be designed to restore habitat to desired conditions described in tables 1a and 1b. Fluid mineral operations would be mitigated in priority habitat to reduce soil compaction to improve vegetation reestablishment and keep GRSG habitat disturbance to a minimum.

Surface disturbances would also be prohibited for unleased coal mines in priority habitat as well as other mitigation measures to reduce disturbances for leased coal mines and associated facilities. Locatable mineral, non-energy leasable, and mineral material operations in priority habitat would be mitigated to protect GRSG habitat.

Minerals management direction under the Proposed Plan would have positive impacts for livestock grazing in priority and general GRSG habitats because development and surface disturbance would be limited, and the potential from development related disturbance of rangeland and forage resources would be reduced. However, impacts from new and existing mineral leases could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Northwest Colorado – Forest Service Proposed Plan Amendment Livestock Grazing Effects Analysis

Proposed Plan

Grazing management under the Proposed Plan on National Forest System (NFS) lands would be determined at the Forest unit level in order to achieve desired conditions and meet grazing use guidelines in GRSG seasonal habitats. Impacts to livestock grazing generally depend on current and site-specific biophysical conditions, livestock numbers, timing and duration of use, livestock management practices, range development and improvement levels, and permittee responsibilities, which are not easily addressed at the programmatic level. As a result, impacts on livestock grazing management would vary at a site-specific level and are described broadly for the Proposed Plan at the planning-unit scale.

Impacts from General GRSG Management

Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in table 1. Livestock grazing would be managed to maintain residual herbaceous grass height for overhead and lateral concealment for GRSG nesting and early brood rearing life stages. Wet meadows and riparian areas would be managed to sustain a rich diversity of perennial forb species relative to site potential, and winter habitat would provide sufficient sagebrush height and density for food and cover for GRSG during this seasonal period.

Management to achieve these desired conditions would directly impact livestock grazing on NFS lands. These impacts could include modification of grazing strategies or rotation schedules, changes to duration and/or the season of use, changes to the kind and class of livestock, or reduction of livestock numbers. These modifications could result in the reduction of AUMs on some allotments. Management to achieve these desired conditions would also impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation.

Indirectly, implementation of management direction to achieve desired conditions in GRSG seasonal habitat as described in table 1 could be beneficial to livestock grazing in the long-term, particularly on allotments where rangeland conditions could be improved, by implementing management direction that improves rangeland conditions. Improved rangeland condition could also contribute to increased forage production.

Table 1. Seasonal Habitat Desired Conditions for GRSG.

ATTRIBUTE	INDICATORS	DESIRED CONDTION
BREEDING AND NESTING [1,2,3] (Seasonal Use Period March 1-June 15) Apply 4 miles from active leks. [4]		
Lek Security	Proximity of trees [5]	Trees or other tall structures are none to uncommon within 1.86 miles of leks [6,7]

ATTRIBUTE	INDICATORS	DESIRED CONDTION
	Proximity of sagebrush to leks [6]	Adjacent protective sagebrush cover within 328 feet of lek [6]
Cover	Seasonal habitat extent [7]	>80% of the breeding and nesting habitat
	Sagebrush canopy cover [6,7,8]	15 to 25%
	Sagebrush height [7] Arid sites [6,7,9] Mesic sites [6,7,10]	 12 to 32 inches 16 to 32 inches
	Predominant sagebrush shape [6]	>50% in spreading [11]
	Perennial grass canopy cover [6,7] Arid sites[7,9] Mesic sites [710]	 ≥10% ≥15%
	Perennial grass height [6,7,8]	Provide overhead and lateral concealment from predators [7]
	Perennial forb canopy cover [6,7,8] Arid sites [9] Mesic sites [10]	 ≥5%[6,7] ≥10%[6,7]
BROOD-REARING/SUMMER[1] (Seasonal Use Period June 16-October 31)		
Cover	Seasonal habitat extent [7]	>40% of the brood-rearing/summer habitat
	Sagebrush canopy cover [6,7,8]	10 to 25%
	Sagebrush height [7,8]	16 to 32 inches
	Perennial grass canopy cover and forbs [7,8]	>15%
	Riparian areas/mesic meadows	Proper Functioning Condition [12]
	Upland and riparian perennial forb availability [6,7]	Preferred forbs are common with several preferred species present [13]
WINTER[1] (Seasonal Use Period November 1-February 28)		
Cover and Food	Seasonal habitat extent [6,7,8]	>80% of the winter habitat
	Sagebrush canopy cover above snow [6,7,8]	>10%
	Sagebrush height above snow [6,7,8]	>10 inches [14]

[1] Seasonal dates can be adjusted; that is, start and end dates may be shifted either earlier or later, but the amount of days cannot be shortened or lengthened by the local unit.

[9] 10–12 inch precipitation zone; *Artemisia tridentata wyomingensis* is a common big sagebrush sub-species for this type site (HAF 2014).

[10] ≥12 inch precipitation zone; *Artemisia tridentata vaseyana* is a common big sagebrush sub-species for this type site (HAF 2014).

[11] Sagebrush plants with a spreading shape provide more protective cover than sagebrush plants that are more tree- or columnar shaped (HAF 2014).

[12] Existing land management plan desired conditions for riparian areas/wet meadows (spring seeps) may be used in place of properly functioning conditions, if appropriate for meeting greater sage-grouse habitat requirements.

[13] Preferred forbs are listed in HAF Table III-2 (HAF 2014). Overall total forb cover may be greater than that of preferred forb cover since not all forb species are listed as preferred in Table III-2.

[14] The height of sagebrush remaining above the snow depends upon snow depth in a particular year. Intent is to manage for tall, healthy, sagebrush stands.

Impacts from Adaptive Management

Adaptive management measures under the Proposed Plan could have direct impacts on livestock grazing if it is determined that domestic livestock grazing is a causal factor in the deviation from GRSG conservation objectives. These impacts could include the cessation of livestock grazing or modification of numbers or season of use, which would reduce AUMs.

Impacts from Lands and Realty Management

Under the Proposed Plan, special use authorizations, land ownership adjustments, and land withdrawals would be restricted or mitigated to avoid or reduce adverse impacts to GRSG in priority and general habitat. This management direction would limit the direct and indirect impacts of development and surface disturbance on rangelands where livestock grazing is permitted. However, impacts could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Wind and Solar

Management direction prohibiting solar and wind development in priority habitat and imposing restrictions on development in general habitat would limit any impacts associated with ground disturbances from development of these resources. This management direction would limit the direct impacts of development and surface disturbances on existing rangelands, which would be beneficial to livestock grazing. However, this may shift impacts in areas outside of priority and general GRSG habitats, which could indirectly impact rangelands and grazing conditions through increased development.

Impacts from GRSG Habitat Management

Restoration activities under this alternative that reduce invasive annual grasses and other invasive plant species, conifers, and the spread and intensity of wildfire in GRSG seasonal habitats would be beneficial to livestock grazing because these activities will improve rangeland conditions and increase forage production in the long-term. Restrictions that temporarily close areas to grazing could impact permittees and operations in the short-term.

Impacts from Livestock Grazing Management

Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in table 1. Livestock grazing would also be managed in order to maintain residual perennial grass height to provide for adequate GRSG nesting cover according to the guidelines described in table 2.

Current direction for livestock grazing use in most Forest Plans in the planning areas is generally less restrictive than direction described under the Proposed Plan (Table 3). Therefore, grazing use guidelines under the Proposed Plan would directly impact livestock grazing management on NFS lands. Impacts could include modification of grazing strategies or rotation schedules, changes to the season of use, changes to kind and class of livestock, closure of a portion of an allotment, or reduction of livestock numbers. Implementation of this management direction could result in the reduction of AUMs on some allotments.

Table 2. Proposed Plan Grazing Guidelines for GRSG Seasonal Habitat.

Seasonal Habitat	Grazing Guidelines
Breeding and nesting [1] within 4 miles of occupied leks	Perennial grass height: [2] When grazing occurs during breeding and nesting season (March 1 to June 15) manage

	for upland perennial grass height of 7 inches [3,4,5] When grazing occurs post breeding and nesting season (June 16 to October 31) manage for 4 inches [4,5,6] of perennial grass height.
Brood rearing and summer [1]	Retain an average stubble height of 4 inches for herbaceous riparian/mesic meadow vegetation [7,8]
Winter [1]	≤35% use of sagebrush

[1] For descriptions of Seasonal Habitat and Seasonal Periods of GRSG see table 1.

[2] Grass heights only apply in breeding and nesting habitat with ≥10% sagebrush cover to support nesting.

[3] Holloran et al. 2005 *GRSG nesting habitat selection and success in Wyoming*.

[4] Average droop height, assuming current vegetation composition has the capability to achieve these heights. Heights will be measured at the end of the nesting period (Connelly, 2000).

[5] Hagen C., J.W. Connelly, and M.A. Schroeder. 2007. *A meta-analysis of GRSG Centrocercus urophasianus nesting and brood-rearing habitats*. Wildlife Biology 13(1): 42-50.

[6] Stubble height to be measured at the end of the growing season.

[7] Crawford et al. 2004. Ecology and Management of GRSG and GRSG habitat. "In riparian brood-rearing habitat, GRSG prefer the lower vegetation (5-15 cm (2-6 in) vs. 30-50 cm (12-20 in); Oakleaf 1971, Neel 1980, Klebenow 1982, Evans 1986) and succulent forb growth
stimulated by moderate livestock grazing (Neel 1980, Evans 1986). "Moderate use equates to a 10-cm residual stubble height for most grasses and sedges."

[8] Stubble height to be measured in the meadow areas used by GRSG for brood-rearing (not on the hydric greenline).

Table 3. Current Land and Resource Management Plan (Forest Plan) direction for livestock grazing use.

Forest Plan	Existing Upland Use Level[1]	Existing Riparian Use Level[1]
Routt	0% - 55%	4"- 6" SH[2]

[1] As described in the current Land Resource Management Plan. Ranges vary according to grazing system (e.g., rest or deferred), season of use (e.g., early or late), range condition (e.g., satisfactory or unsatisfactory), vegetation type (e.g., alpine or non-native seeding), or other categories (e.g., greenline, key area, age class).

[3] SH – Stubble Height[2]

Implementation of these guidelines could also directly impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation. Impacts would occur at the allotment scale as management direction is incorporated into permits, allotment management plans, and annual operating instructions. Management direction for livestock grazing under the Proposed Plan could decrease grazing in some allotments, and possibly overall operation viability. The level and intensity of impacts could vary on a site specific basis with permitted grazing likely decreasing moderately over time as permits are modified to achieve desired conditions and meet annual grazing use guidelines.

Grazing use guidelines under the Proposed Plan would impact about XXX allotments, XXX total acres, and XXX total AUMs in nesting and brood rearing habitats. Grazing use guidelines that limit forage use to 7 inches for perennial grasses during nesting season and 4 inches post nesting season would impact about XXX acres in nesting habitat within active grazing allotments (Table 4).

Table 4. Grazing Allotment Acres and AUMs intersecting GRSG Seasonal Habitat in Northwest Colorado on the Routt portion of the Medicine Bow-Routt National Forest within the EIS planning area

Allotment Acres in Nesting Habitat[1]	Allotment Acres In Brood Rearing/Summer	Allotments in Nesting and Brood Rearing/Summer	Total AUMs for Allotments in Nesting and Brood Rearing/Summer Habitat[3]

	Habitat[2]	**Habitat**	

[1] Acres in active allotments with permitted dates during nesting season that intersect nesting habitat and have greater than 200 acres in occupied GRSG habitat.

[2] Acres in active allotments with permitted dates during brood rearing/summer season that intersect brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

[3] Total AUMs for active allotments with permitted dates during nesting and brood rearing/summer season that intersect nesting and brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

Under the Proposed Plan sheep camps would not be located within 1.2 miles from the perimeter of a lek during lekking season and trailing of livestock during breeding and nesting seasons would be minimized during breeding and nesting seasons. This management direction would result in the need to modify grazing practices with increased costs for permittees in these areas.

Additional constraints under the Proposed Plan would also apply to structural range improvements in priority GRSG habitat compared to current plan direction. These include prohibiting fence construction or reconstruction within 1.2 miles from the perimeter of occupied leks unless the collision risk can be mitigated through design features or markings, not constructing new permanent livestock facilities (e.g., windmills, water tanks, corrals) within 1.2 miles from the perimeter of occupied leks, and not constructing water developments in priority habitat unless they are beneficial to GRSG.

Prohibitions on new structural improvements could limit the ability of permittees to effectively distribute livestock resulting in increases in time and costs to permittees and potentially the full use permitted AUMs. Although these constraints could increase the amount of time permittees spend to manage livestock on NFS lands, it should allow sufficient flexibility that permittees could continue to utilize structural range improvements to effectively distribute livestock.

Under the Proposed Plan, the Forest Service would consider closure of grazing allotments, pastures, or portions of pastures, or managing the allotment as a forage reserve as opportunities as opportunities arise where removal of livestock would enhance the ability to achieve desired habitat conditions as described in table 1. These actions would occur according to applicable regulations and, if implemented, would result in the reduction of overall available AUMs.

Managing livestock grazing to achieve the desired conditions in table 1 and livestock use guidelines in table 3 may indirectly benefit rangeland conditions by increasing vegetation productivity and increasing forage in the long term. This in turn would provide managers and permittees better management options, especially on those allotments where livestock numbers are approaching a sustainability threshold or during drought and other disturbances such as wildfire.

Impacts from Fire Management

Under the Proposed Plan, measures to protect GRSG habitat from fire and associated fire operations would be beneficial to livestock grazing, especially in the 12-inch or less precipitation zone, because it would help prevent expansion of non-native invasive species such as cheatgrass. Although management to suppress and control the spread of wildfire under the Proposed Plan would decrease the risk of disturbance from wildfire in GRSG habitat, fires outside of GRSG habitat would possibly be at risk of decreased suppression efforts. Management direction to protect GRSG habitat from fire in higher elevation sagebrush habitats (i.e., mountain big sagebrush) could indirectly negatively impact livestock grazing in the long-term as sagebrush potentially increases and forage production decreases.

Impacts from Wild Horse and Burro Management

Under Proposed Plan, wild horse and burro populations should be managed within appropriate management levels, or adjusted, to restore, enhance, or maintain GRSG desired habitat conditions as described in table 1. This management direction would be beneficial to livestock grazing in the long-term by increasing vegetation productivity and increasing forage production, particularly where rangeland conditions could be improved.

Impacts from Recreation Management

Under the Proposed Plan new recreation special use authorizations and expansion of special use authorizations would be restricted in priority habitat management areas. In addition, terms and conditions that that protect or restore GRSG habitat would be included in new special use authorizations and existing permits and operating plans would be modified to protect and/or restore GRSG habitat. Temporary recreation uses that result in the loss of GRSG habitat would not be authorized, and new recreational facilities or expansion of existing recreational facilities (e.g., roads, trails, campgrounds) would not be approved in priority habitat unless the development results in a net conservation gain to GRSG and/or their habitats.

This management direction would limit the direct and indirect impacts of recreation development on rangelands where livestock grazing is permitted. This management direction would have beneficial impacts to livestock grazing by reducing disturbances to rangelands from development and disturbances to livestock. However, impacts from recreation management could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Road/Transportation Management

Under the Proposed Plan new road or trail and construction would be prohibited in GRSG habitat, and road construction within riparian and mesic meadows would be restricted. This direction would be beneficial to livestock grazing by reducing impacts from roads rangeland and riparian areas. This could indirectly improve forage production and improve overall rangeland conditions. However, impacts from roads and transportation could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Minerals Management

Under the Proposed Plan, new fluid mineral leases would require a no surface occupancy stipulation in priority habitat and controlled surface use and timing restrictions in general habitat. New leases would be prioritized in non-habitat first and then in the least suitable habitat for GRSG.

For existing leases under the Proposed Plan, leaseholders would be required to avoid and minimize surface disturbing and disruptive activities in priority habitat for leases that are not yet developed. In addition, reclamation plans would be designed to restore habitat to desired conditions described in table 1. Fluid mineral operations would be mitigated in priority habitat to reduce soil compaction to improve vegetation reestablishment and keep GRSG habitat disturbance to a minimum.

Surface disturbances would also be prohibited for unleased coal mines in priority habitat as well as other mitigation measures to reduce disturbances for leased coal mines and associated facilities. Locatable mineral, non-energy leasable, and mineral material operations in priority habitat would be mitigated to protect GRSG habitat.

Minerals management direction under the Proposed Plan would have positive impacts for livestock grazing in priority and general GRSG habitats because development and surface disturbance would be limited, and the potential from development related disturbance of rangeland and forage resources would be reduced. However, impacts from new and existing mineral leases could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Utah – Forest Service Proposed Plan Amendment Livestock Grazing Effects Analysis

Proposed Plan

Grazing management under the Proposed Plan on National Forest System (NFS) lands would be determined at the Forest unit level in order to achieve desired conditions and meet grazing use guidelines in GRSG seasonal habitats. Impacts to livestock grazing generally depend on current and site-specific biophysical conditions, livestock numbers, timing and duration of use, livestock management practices, range development and improvement levels, and permittee responsibilities, which are not easily addressed at the programmatic level. As a result, impacts on livestock grazing management would vary at a site-specific level and are described broadly for the Proposed Plan at the planning-unit scale.

Impacts from General GRSG Management

Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in table 1. Livestock grazing would be managed to maintain residual herbaceous grass height for overhead and lateral concealment for GRSG nesting and early brood rearing life stages. Wet meadows and riparian areas would be managed to sustain a rich diversity of perennial forb species relative to site potential, and winter habitat would provide sufficient sagebrush height and density for food and cover for GRSG during this seasonal period.

Management to achieve these desired conditions would directly impact livestock grazing on NFS lands. These impacts could include modification of grazing strategies or rotation schedules, changes to duration and/or the season of use, changes to the kind and class of livestock, or reduction of livestock numbers. These modifications could result in the reduction of AUMs on some allotments. Management to achieve these desired conditions would also impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation.

Indirectly, implementation of management direction to achieve desired conditions in GRSG seasonal habitat as described in table 1 could be beneficial to livestock grazing in the long-term, particularly on allotments where rangeland conditions could be improved, by implementing management direction that improves rangeland conditions. Improved rangeland condition could also contribute to increased forage production.

Table 1. Seasonal Habitat Desired Conditions for GRSG.

ATTRIBUTE	INDICATORS	DESIRED CONDTION
BREEDING AND NESTING [1,2,3] (Seasonal Use Period March 1-June 15) Apply 4 miles from active leks. [4]		
Lek Security	Proximity of trees [5]	Trees or other tall structures are none to uncommon within 1.86 miles of leks [6,7]

ATTRIBUTE	INDICATORS	DESIRED CONDTION
	Proximity of sagebrush to leks [6]	Adjacent protective sagebrush cover within 328 feet of lek [6]
Cover	Seasonal habitat extent [7]	>80% of the breeding and nesting habitat
	Sagebrush canopy cover [6,7,8]	15 to 25%
	Sagebrush height [7]	
	Arid sites [6,7,9]	12 to 32 inches
	Mesic sites[6,7,10]	16 to 32 inches
	Predominant sagebrush shape [6]	>50% in spreading [11]
	Perennial grass canopy cover [6,7]	
	Arid sites [7,9]	≥10%
	Mesic sites [7,10]	≥15%
	Perennial grass height [6,7,8]	Provide overhead and lateral concealment from predators [7]
	Perennial forb canopy cover [6,7,8]	
	Arid sites [9]	≥5%[6,7]
	Mesic sites [10]	≥10%[6,7]
BROOD-REARING/SUMMER[1] (Seasonal Use Period June 16-October 31)		
Cover	Seasonal habitat extent [7]	>40% of the brood-rearing/summer habitat
	Sagebrush canopy cover [6,7,8]	10 to 25%
	Sagebrush height [7,8]	16 to 32 inches
	Perennial grass canopy cover and forbs [7,8]	>15%
	Riparian areas/mesic meadows	Proper Functioning Condition [12]
	Upland and riparian perennial forb availability [6,7]	Preferred forbs are common with several preferred species present [13]
WINTER[1] (Seasonal Use Period November 1-February 28)		
Cover and Food	Seasonal habitat extent [6,7,8]	>80% of the winter habitat
	Sagebrush canopy cover above snow [6,7,8]	>10%
	Sagebrush height above snow [6,7,8]	>10 inches [14]

[1] Seasonal dates can be adjusted; that is, start and end dates may be shifted either earlier or later, but the amount of days cannot be shortened or lengthened by the local unit.

[8] Connelly, J. K. Reese, and M. Schroder. 2003. *Monitoring of Greater sage-grouse habitats and populations*. Station Bulletin 80, Contribution 979. University of Idaho, College of Natural Resources Experiment Station. Moscow, ID.

[9] 10–12 inch precipitation zone; *Artemisia tridentata wyomingensis* is a common big sagebrush sub-species for this type site (HAF 2014).

[10] ≥12 inch precipitation zone; *Artemisia tridentata vaseyana* is a common big sagebrush sub-species for this type site (HAF 2014).

[11] Sagebrush plants with a spreading shape provide more protective cover than sagebrush plants that are more tree- or columnar shaped (HAF 2014).

[12] Existing land management plan desired conditions for riparian areas/wet meadows (spring seeps) may be used in place of properly functioning conditions, if appropriate for meeting greater sage-grouse habitat requirements.

[13] Preferred forbs are listed in HAF Table III-2 (HAF 2014). Overall total forb cover may be greater than that of preferred forb cover since not all forb species are listed as preferred in Table III-2.

[14] The height of sagebrush remaining above the snow depends upon snow depth in a particular year. Intent is to manage for tall, healthy, sagebrush stands.

Impacts from Adaptive Management

Adaptive management measures under the Proposed Plan could have direct impacts on livestock grazing if it is determined that domestic livestock grazing is a causal factor in the deviation from GRSG conservation objectives. These impacts could include the cessation of livestock grazing or modification of numbers or season of use, which would reduce AUMs.

Impacts from Lands and Realty Management

Under the Proposed Plan, special use authorizations, land ownership adjustments, and land withdrawals would be restricted or mitigated to avoid or reduce adverse impacts to GRSG in priority and general habitat. This management direction would limit the direct and indirect impacts of development and surface disturbance on rangelands where livestock grazing is permitted. However, impacts could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Wind and Solar

Management direction prohibiting solar and wind development in priority habitat and imposing restrictions on development in general habitat would limit any impacts associated with ground disturbances from development of these resources. This management direction would limit the direct impacts of development and surface disturbances on existing rangelands, which would be beneficial to livestock grazing. However, this may shift impacts in areas outside of priority and general GRSG habitats, which could indirectly impact rangelands and grazing conditions through increased development.

Impacts from GRSG Habitat Management

Restoration activities under this alternative that reduce invasive annual grasses and other invasive plant species, conifers, and the spread and intensity of wildfire in GRSG seasonal habitats would be beneficial to livestock grazing because these activities will improve rangeland conditions and increase forage production in the long-term. Restrictions that temporarily close areas to grazing could impact permittees and operations in the short-term.

Impacts from Livestock Grazing Management

Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in table 1. Livestock grazing would also be managed in order to maintain residual perennial grass height to provide for adequate GRSG nesting cover according to the guidelines described in table 2.

Current direction for livestock grazing use in most Forest Plans in the planning areas is generally less restrictive than direction described under the Proposed Plan (Table 3). Therefore, grazing use guidelines under the Proposed Plan would directly impact livestock grazing management on NFS lands. Impacts could include modification of grazing strategies or rotation schedules, changes to the season of use, changes to kind and class of livestock, closure of a portion of an allotment, or reduction of livestock numbers. Implementation of this management direction could result in the reduction of AUMs on some allotments.

Table 2. Proposed Plan Grazing Guidelines for GRSG Seasonal Habitat.

Seasonal Habitat	Grazing Guidelines
Breeding and nesting [1] within 4 miles of occupied leks	Perennial grass height: [2] When grazing occurs during breeding and nesting season (March 1 to June 15) manage

	for upland perennial grass height of 7 inches [3,4,5] When grazing occurs post breeding and nesting season (June 16 to October 30) manage for 4 inches [4,5,6] of perennial grass height.
Brood rearing and summer [1]	Retain an average stubble height of 4 inches for herbaceous riparian/mesic meadow vegetation [7,8]
Winter [1]	≤35% use of sagebrush

[1] For descriptions of Seasonal Habitat and Seasonal Periods of GRSG see table 1.

[2] Grass heights only apply in breeding and nesting habitat with ≥10% sagebrush cover to support nesting.

[3] Holloran et al. 2005 *GRSG nesting habitat selection and success in Wyoming*.

[4] Average droop height, assuming current vegetation composition has the capability to achieve these heights. Heights will be measured at the end of the nesting period (Connelly, 2000).

[5] Hagen C., J.W. Connelly, and M.A. Schroeder. 2007. *A meta-analysis of GRSG Centrocercus urophasianus nesting and brood-rearing habitats*. Wildlife Biology 13(1): 42-50.

[6] Stubble height to be measured at the end of the growing season.

[7] Crawford et al. 2004. Ecology and Management of GRSG and GRSG habitat. "In riparian brood-rearing habitat, GRSG prefer the lower vegetation (5-15 cm (2-6 in) vs. 30-50 cm (12-20 in); Oakleaf 1971, Neel 1980, Klebenow 1982, Evans 1986) and succulent forb growth
stimulated by moderate livestock grazing (Neel 1980, Evans 1986). "Moderate use equates to a 10-cm residual stubble height for most grasses and sedges."

[8] Stubble height to be measured in the meadow areas used by GRSG for brood-rearing (not on the hydric greenline).

Table 3. Current Land and Resource Management Plan (Forest Plan) direction for livestock grazing use.

Forest Plan	**Existing Upland Use Level[1]**	**Existing Riparian Use Level[1]**
Ashley	None (Defers to AMP)	▪ 50% Browse[2]
Dixie	50% - 60%	▪ 50% - 60% ▪ 50% Browse
Fishlake	40% - 60%	▪ 1.5" – 6" SH[3] ▪ 40% - 50% Browse
Manti-La Sal	40% - 65%	▪ 30% - 60% ▪ 4"- 5" SH
Sawtooth	40% - 50%	▪ 45% or 4" SH
Uinta	▪ 40% - 60% ▪ 6"- 7" SH[4]	▪ 35% - 65% ▪ 2"- 6" SH ▪ 6"- 7" SH[4] ▪ 35% - 50% Browse
Wasatch-Cache	▪ 50% - 60% ▪ 50% Browse	▪ 30% - 60% ▪ 3"- 5" SH ▪ 50% Browse

[1] As described in the current Land Resource Management Plan. Ranges vary according to grazing system (e.g., rest or deferred), season of use (e.g., early or late), range condition (e.g., satisfactory or unsatisfactory), vegetation type (e.g., alpine or non-native seeding), or other categories (e.g., greenline, key area, age class).

[2] Annual utilization of current year's growth of woody vegetation

[3] SH – Stubble Height

[4] Applies to GRSG breeding habitat through June 15 in the Vernon and Strawberry Reservoir Management Areas respectively.

Implementation of these guidelines could also directly impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation. Impacts would occur at the allotment scale as management direction is incorporated into permits, allotment management plans, and annual operating instructions. Management direction for livestock grazing under the Proposed Plan could decrease grazing in some allotments, and possibly overall operation viability. The level and intensity of impacts could vary on a site specific basis with permitted grazing likely decreasing moderately over time as permits are modified to achieve desired conditions and meet annual grazing use guidelines.

Grazing use guidelines under the Proposed Plan would impact about XXX allotments, XXX total acres, and XXX total AUMs in nesting and brood rearing habitats. Grazing use guidelines that limit forage use to 7 inches for perennial grasses during nesting season and 4 inches post nesting season would impact about XXX acres in nesting habitat within active grazing allotments (Table 4).

Table 4. Grazing Allotment Acres and AUMs intersecting GRSG Seasonal Habitat on National Forests within the EIS planning area.

Forest/Grassland	Allotment Acres in Nesting Habitat[1]	Allotment Acres In Brood Rearing/Summer Habitat[2]	Allotments in Nesting and Brood Rearing/Summer Habitat	Total AUMs for Allotments in Nesting and Brood Rearing/Summer Habitat[3]
Ashley	[4]	[4]	[4]	
Dixie				
Fishlake				
Manti-La Sal				
Sawtooth				
Uinta-Wasatch-Cache	[4]	[4]	[4]	

[1] Acres in active allotments with permitted dates during nesting season that intersect nesting habitat and have greater than 200 acres in occupied GRSG habitat.

[2] Acres in active allotments with permitted dates during brood rearing/summer season that intersect brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

[3] Total AUMs for active allotments with permitted dates during nesting and brood rearing/summer season that intersect nesting and brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

[4] Acres in Wyoming on the Ashley and Uinta-Wasatch-Cache National Forests

Under the Proposed Plan sheep camps would not be located within 1.2 miles from the perimeter of a lek during lekking season and trailing of livestock during breeding and nesting seasons would be minimized during breeding and nesting seasons. This management direction would result in the need to modify grazing practices with increased costs for permittees in these areas.

Additional constraints under the Proposed Plan would also apply to structural range improvements in priority GRSG habitat compared to current plan direction. These include prohibiting fence construction or reconstruction within 1.2 miles from the perimeter of occupied leks unless the collision risk can be mitigated through design features or markings, not constructing new permanent livestock facilities (e.g., windmills, water tanks, corrals) within 1.2 miles from the perimeter of occupied leks, and not constructing water developments in priority habitat unless they are beneficial to GRSG.

Prohibitions on new structural improvements could limit the ability of permittees to effectively distribute livestock resulting in increases in time and costs to permittees and potentially the full use permitted AUMs. Although these constraints could increase the amount of time permittees spend to manage livestock on NFS lands, it should allow sufficient flexibility that permittees could continue to utilize structural range improvements to effectively distribute livestock.

Under the Proposed Plan, the Forest Service would consider closure of grazing allotments, pastures, or portions of pastures, or managing the allotment as a forage reserve as opportunities as opportunities arise where removal of livestock would enhance the ability to achieve desired habitat conditions as described in table 1. These actions would occur according to applicable regulations and, if implemented, would result in the reduction of overall available AUMs.

Managing livestock grazing to achieve the desired conditions in table 1 and livestock use guidelines in table 3 may indirectly benefit rangeland conditions by increasing vegetation productivity and increasing forage in the long term. This in turn would provide managers and permittees better management options, especially on those allotments where livestock numbers are approaching a sustainability threshold or during drought and other disturbances such as wildfire.

Impacts from Fire Management

Under the Proposed Plan, measures to protect GRSG habitat from fire and associated fire operations would be beneficial to livestock grazing, especially in the 12-inch or less precipitation zone, because it would help prevent expansion of non-native invasive species such as cheatgrass. Although management to suppress and control the spread of wildfire under the Proposed Plan would decrease the risk of disturbance from wildfire in GRSG habitat, fires outside of GRSG habitat would possibly be at risk of decreased suppression efforts. Management direction to protect GRSG habitat from fire in higher elevation sagebrush habitats (i.e., mountain big sagebrush) could indirectly negatively impact livestock grazing in the long-term as sagebrush potentially increases and forage production decreases.

Impacts from Wild Horse and Burro Management

Under Proposed Plan, wild horse and burro populations should be managed within appropriate management levels, or adjusted, to restore, enhance, or maintain GRSG desired habitat conditions as described in table 1. This management direction would be beneficial to livestock grazing in the long-term by increasing vegetation productivity and increasing forage production, particularly where rangeland conditions could be improved.

Impacts from Recreation Management

Under the Proposed Plan new recreation special use authorizations and expansion of special use authorizations would be restricted in priority habitat management areas. In addition, terms and conditions that that protect or restore GRSG habitat would be included in new special use authorizations and existing permits and operating plans would be modified to protect and/or restore GRSG habitat. Temporary recreation uses that result in the loss of GRSG habitat would not be authorized, and new recreational facilities or expansion of existing recreational facilities (e.g., roads, trails, campgrounds) would not be approved in priority habitat unless the development results in a net conservation gain to GRSG and/or their habitats.

This management direction would limit the direct and indirect impacts of recreation development on rangelands where livestock grazing is permitted. This management direction would have beneficial impacts to livestock grazing by reducing disturbances to rangelands from development and disturbances to livestock. However, impacts from recreation management could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Road/Transportation Management

Under the Proposed Plan new road or trail and construction would be prohibited in GRSG habitat, and road construction within riparian and mesic meadows would be restricted. This direction would be beneficial to livestock grazing by reducing impacts from roads rangeland and riparian areas. This could indirectly improve forage production and improve overall rangeland conditions. However, impacts from roads and transportation could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Minerals Management

Under the Proposed Plan, new fluid mineral leases would require a no surface occupancy stipulation in priority habitat and controlled surface use and timing restrictions in general habitat. New leases would be prioritized in non-habitat first and then in the least suitable habitat for GRSG.

For existing leases under the Proposed Plan, leaseholders would be required to avoid and minimize surface disturbing and disruptive activities in priority habitat for leases that are not yet developed. In addition, reclamation plans would be designed to restore habitat to desired conditions described in table 1. Fluid mineral operations would be mitigated in priority habitat to reduce soil compaction to improve vegetation reestablishment and keep GRSG habitat disturbance to a minimum.

Surface disturbances would also be prohibited for unleased coal mines in priority habitat as well as other mitigation measures to reduce disturbances for leased coal mines and associated facilities. Locatable mineral, non-energy leasable, and mineral material operations in priority habitat would be mitigated to protect GRSG habitat.

Minerals management direction under the Proposed Plan would have positive impacts for livestock grazing in priority and general GRSG habitats because development and surface disturbance would be limited, and the potential from development related disturbance of rangeland and forage resources would be reduced. However, impacts from new and existing mineral leases could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Wyoming – Forest Service Proposed Plan Amendment Livestock Grazing Effects Analysis

Proposed Plan

Grazing management under the Proposed Plan on National Forest System (NFS) lands would be determined at the Forest unit level in order to achieve desired conditions and meet grazing use guidelines in GRSG seasonal habitats. Impacts to livestock grazing generally depend on current and site-specific biophysical conditions, livestock numbers, timing and duration of use, livestock management practices, range development and improvement levels, and permittee responsibilities, which are not easily addressed at the programmatic level. As a result, impacts on livestock grazing management would vary at a site-specific level and are described broadly for the Proposed Plan at the planning-unit scale.

Impacts from General GRSG Management

Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in table 1. Livestock grazing would be managed to maintain residual herbaceous grass height for overhead and lateral concealment for GRSG nesting and early brood rearing life stages. Wet meadows and riparian areas would be managed to sustain a rich diversity of perennial forb species relative to site potential, and winter habitat would provide sufficient sagebrush height and density for food and cover for GRSG during this seasonal period.

Management to achieve these desired conditions would directly impact livestock grazing on NFS lands. These impacts could include modification of grazing strategies or rotation schedules, changes to duration and/or the season of use, changes to the kind and class of livestock, or reduction of livestock numbers. These modifications could result in the reduction of AUMs on some allotments. Management to achieve these desired conditions would also impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation.

Indirectly, implementation of management direction to achieve desired conditions in GRSG seasonal habitat as described in table 1 could be beneficial to livestock grazing in the long-term, particularly on allotments where rangeland conditions could be improved, by implementing management direction that improves rangeland conditions. Improved rangeland condition could also contribute to increased forage production.

Table 1. Seasonal Habitat Desired Conditions for GRSG.

ATTRIBUTE	INDICATORS	DESIRED CONDITION
AREAS MANAGED FOR BREEDING AND NESTING [1,2,3] (Seasonal Use Period March 15-June 30) Apply 5.3 miles from occupied leks. [4]		
Lek Security	Proximity of trees[5]	Trees or other tall structures are none to uncommon within 1.86 miles of leks[6,7]

ATTRIBUTE	INDICATORS	DESIRED CONDITION
	Proximity of sagebrush to leks[6]	Adjacent protective sagebrush cover within 328 feet of lek[6]
Cover	Seasonal habitat extent[7]	>80% of the breeding and nesting habitat
	Sagebrush canopy cover [6,7,8]	15 to 25%
	Sagebrush height[7]	
	Arid sites[7,9]	8 to 32 inches in black sage and 12 to 32 inches in all other areas
	Mesic sites[7,10]	All Wyoming NFs: 16 to 32 inches
	Predominant sagebrush shape[6]	>50% in spreading[11]
	Perennial grass canopy cover [6, 7]	
	Arid sites[6,7,9]	≥10%
	Mesic sites[6,7,10]	≥15%
	Perennial grass height[6,7,8]	Provide overhead and lateral concealment from predators[6]
	Perennial forb canopy cover [6,7,8]	
	Arid sites[9]	≥5%[6,7]
	Mesic sites[10]	≥10%[6,7]
AREAS MANAGED FOR BROOD-REARING/SUMMER[1] (Seasonal Use Period July 1-November 30)		
Cover	Seasonal habitat extent[7]	>40% of the brood-rearing/summer habitat
	Sagebrush canopy cover [6,7,8]	10 to 25%
	Sagebrush height[7,8]	8 to 20 inches in black sage and 12 to 32 inches in all other areas
	Perennial grass canopy cover and forbs [7,8]	>15%
	Riparian areas/mesic meadows	Proper Functioning Condition [12]
	Upland and riparian perennial forb availability[6,7]	Preferred forbs are common with several preferred species present[13]
WINTER[1] (Seasonal Use Period December 1-March 14)		
Cover and Food	Seasonal habitat extent[6,7,8]	>80% of the winter habitat
	Sagebrush canopy cover above snow[6,7,8]	>10%
	Sagebrush height above snow[6,7,8]	>10 inches[14]

[1] Seasonal dates can be adjusted; that is, start and end dates may be shifted either earlier or later, but the amount of days cannot be shortened or lengthened by the local unit.

[8] Connelly, J. K. Reese, and M. Schroder. 2003. *Monitoring of Greater sage-grouse habitats and populations*. Station Bulletin 80, Contribution 979. University of Idaho, College of Natural Resources Experiment Station. Moscow, ID.

[9] 10–12 inch precipitation zone; *Artemisia tridentata wyomingensis* is a common big sagebrush sub-species for this type site (HAF 2014).

[10] ≥12 inch precipitation zone; *Artemisia tridentata vaseyana* is a common big sagebrush sub-species for this type site (HAF 2014).

[11] Sagebrush plants with a spreading shape provide more protective cover than sagebrush plants that are more tree- or columnar shaped (HAF 2014).

[13] Existing land management plan desired conditions for riparian areas/wet meadows (spring seeps) may be used in place of properly functioning conditions, if appropriate for meeting greater sage-grouse habitat requirements.

[13] Preferred forbs are listed in HAF Table III-2 (HAF 2014). Overall total forb cover may be greater than that of preferred forb cover since not all forb species are listed as preferred in Table III-2.

[14] The height of sagebrush remaining above the snow depends upon snow depth in a particular year. Intent is to manage for tall, healthy, sagebrush stands.

Impacts from Adaptive Management
Adaptive management measures under the Proposed Plan could have direct impacts on livestock grazing if it is determined that domestic livestock grazing is a causal factor in the deviation from GRSG conservation objectives. These impacts could include the cessation of livestock grazing or modification of numbers or season of use, which would reduce AUMs.

Impacts from Lands and Realty Management
Under the Proposed Plan, special use authorizations, land ownership adjustments, and land withdrawals would be restricted or mitigated to avoid or reduce adverse impacts to GRSG in priority and general habitat. This management direction would limit the direct and indirect impacts of development and surface disturbance on rangelands where livestock grazing is permitted. However, impacts could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Wind and Solar
Management direction prohibiting solar and wind development in priority habitat and imposing restrictions on development in general habitat would limit any impacts associated with ground disturbances from development of these resources. This management direction would limit the direct impacts of development and surface disturbances on existing rangelands, which would be beneficial to livestock grazing. However, this may shift impacts in areas outside of priority and general GRSG habitats, which could indirectly impact rangelands and grazing conditions through increased development.

Impacts from GRSG Habitat Management
Restoration activities under this alternative that reduce invasive annual grasses and other invasive plant species, conifers, and the spread and intensity of wildfire in GRSG seasonal habitats would be beneficial to livestock grazing because these activities will improve rangeland conditions and increase forage production in the long-term. Restrictions that temporarily close areas to grazing could impact permittees and operations in the short-term.

Impacts from Livestock Grazing Management
Under the Proposed Plan on NFS lands, livestock grazing would be managed to achieve or maintain desired conditions in GRSG seasonal habitats as described in table 1. Livestock grazing would also be managed in order to maintain residual perennial grass height to provide for adequate GRSG nesting cover according to the guidelines described in table 2.

Current direction for livestock grazing use in most Forest Plans in the planning areas is generally less restrictive than direction described under the Proposed Plan (Table 3). Therefore, grazing use guidelines under the Proposed Plan would directly impact livestock grazing management on NFS lands. Impacts could include modification of grazing strategies or rotation schedules, changes to the season of use, changes to kind and class of livestock, closure of a portion of an allotment, or reduction of livestock numbers. Implementation of this management direction could result in the reduction of AUMs on some allotments.

Table 2. Proposed Plan Grazing Guidelines for GRSG Seasonal Habitat.

Seasonal Habitat	Grazing Guidelines
Breeding and nesting [1] within 5.3 miles of occupied leks	Perennial grass height: [2] When grazing occurs during breeding and nesting season (March 15 to June 30) manage for upland perennial grass height of 7 inches [3,4,5] When grazing occurs post breeding and nesting season (July 1 to November 30) manage for 4 inches [4,5,6] of perennial grass height.
Brood rearing and summer [1]	Retain an average stubble height of 4 inches for herbaceous riparian/mesic meadow vegetation [7,8]
Winter [1]	≤35% use of sagebrush

[1] For descriptions of Seasonal Habitat and Seasonal Periods of GRSG see table 1.

[2] Grass heights only apply in breeding and nesting habitat with ≥10% sagebrush cover to support nesting.

[3] Holloran et al. 2005 *GRSG nesting habitat selection and success in Wyoming*.

[4] Average droop height, assuming current vegetation composition has the capability to achieve these heights. Heights will be measured at the end of the nesting period (Connelly, 2000).

[5] Hagen C., J.W. Connelly, and M.A. Schroeder. 2007. *A meta-analysis of GRSG Centrocercus urophasianus nesting and brood-rearing habitats*. Wildlife Biology 13(1): 42-50.

[6] Stubble height to be measured at the end of the growing season.

[7] Crawford et al. 2004. Ecology and Management of GRSG and GRSG habitat. "In riparian brood-rearing habitat, GRSG prefer the lower vegetation (5-15 cm (2-6 in) vs. 30-50 cm (12-20 in); Oakleaf 1971, Neel 1980, Klebenow 1982, Evans 1986) and succulent forb growth stimulated by moderate livestock grazing (Neel 1980, Evans 1986). "Moderate use equates to a 10-cm residual stubble height for most grasses and sedges."

[8] Stubble height to be measured in the meadow areas used by GRSG for brood-rearing (not on the hydric greenline).

Table 3. Current Land and Resource Management Plan (Forest Plan) direction for livestock grazing use.

Forest/Grassland Plan	**Existing Upland Use Level[1]**	**Existing Riparian Use Level[1]**
Ashley	None (Defers to AMP)	▪ 50% Browse[2]
Bridger-Teton	40% - 60%	▪ 45% - 65%
Caribou	35% - 55%	▪ 4"- 6" SH
Targhee	35% - 55%	▪ 4" SH ▪ 30% Browse
Medicine Bow	0% - 55%	▪ 3"- 6" SH
Routt	0% - 55%	▪ 4"- 6" SH
Thunder Basin	None (Defers to AMP)	None (Defers to AMP)
Uinta	▪ 40% - 60% ▪ 6"- 7" SH[4]	▪ 35% - 65% ▪ 2"- 6" SH ▪ 6"- 7" SH[4] ▪ 35% - 50% Browse
Wasatch-Cache	▪ 50% - 60% ▪ 50% Browse	▪ 30% - 60% ▪ 3"- 5" SH ▪ 50% Browse

[1] As described in the current Land Resource Management Plan. Ranges vary according to grazing system (e.g., rest or deferred), season of use (e.g., early or late), range condition (e.g., satisfactory or unsatisfactory), vegetation type (e.g., alpine or non-native seeding), or other categories (e.g., greenline, key area, age class).

[2] Annual utilization of current year's growth of woody vegetation

[3] SH – Stubble Height

[4] Applies to GRSG breeding habitat through June 15 in the Vernon and Strawberry Reservoir Management Areas respectively.

Implementation of these guidelines could also directly impact permittees by increasing the amount of time permittees spend to manage livestock on NFS lands as well as the total costs to a livestock operation. Impacts would occur at the allotment scale as management direction is incorporated into permits, allotment management plans, and annual operating instructions. Management direction for livestock grazing under the Proposed Plan could decrease grazing in some allotments, and possibly overall operation viability. The level and intensity of impacts could vary on a site specific basis with permitted grazing likely decreasing moderately over time as permits are modified to achieve desired conditions and meet annual grazing use guidelines.

Grazing use guidelines under the Proposed Plan would impact about XXX allotments, XXX total acres, and XXX total AUMs in nesting and brood rearing habitats. Grazing use guidelines that limit forage use to 7 inches for perennial grasses during nesting season and 4 inches post nesting season would impact about XXX acres in nesting habitat within active grazing allotments (Table 4).

Table 4. Grazing Allotment Acres and AUMs intersecting GRSG Seasonal Habitat on National Forests and Grasslands within the EIS planning area.

Forest/Grassland	Allotment Acres in Nesting Habitat[1]	Allotment Acres In Brood Rearing/Summer Habitat[2]	Allotments in Nesting and Brood Rearing/Summer Habitat	Total AUMs for Allotments in Nesting and Brood Rearing/Summer Habitat[3]
Ashley	4	4	4	
Bridger-Teton				
Caribou-Targhee				
Medicine Bow				
Routt[5]				
Thunder Basin[5]				
Uinta- Wasatch-Cache	4	4	4	

[1] Acres in active allotments with permitted dates during nesting season that intersect nesting habitat and have greater than 200 acres in occupied GRSG habitat.

[2] Acres in active allotments with permitted dates during brood rearing/summer season that intersect brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

[3] Total AUMs for active allotments with permitted dates during nesting and brood rearing/summer season that intersect nesting and brood rearing habitat and have greater than 200 acres in occupied GRSG habitat.

[4] Acres in Wyoming on the Ashley and Uinta-Wasatch-Cache National Forests

[5] Routt and Thunder Basin National Grassland listed separately from the Medicine Bow-Routt National Forest to identify information specific to the Routt and Thunder Basin portion of the Forest in northwest Colorado and Wyoming respectively.

Under the Proposed Plan sheep camps would not be located within 1.2 miles from the perimeter of a lek during lekking season and trailing of livestock during breeding and nesting seasons would be minimized during breeding and nesting seasons. This management direction would result in the need to modify grazing practices with increased costs for permittees in these areas.

Additional constraints under the Proposed Plan would also apply to structural range improvements in priority-core GRSG habitat management areas compared to current plan direction. These include prohibiting fence construction or reconstruction within 4 miles from the perimeter of occupied leks unless the collision risk can be mitigated through design features or markings, not constructing new permanent livestock facilities (e.g., windmills, water tanks, corrals) within 0.6 miles in priority and 0.25 in general from the perimeter of occupied leks.

Prohibitions on new structural improvements could limit the ability of permittees to effectively distribute livestock resulting in increases in time and costs to permittees and potentially the full use permitted AUMs. Although these constraints could increase the amount of time permittees spend to manage livestock on NFS lands, it should allow sufficient flexibility that permittees could continue to utilize structural range improvements to effectively distribute livestock.

Under the Proposed Plan, the Forest Service would consider closure of grazing allotments, pastures, or portions of pastures, or managing the allotment as a forage reserve as opportunities as opportunities arise where removal of livestock would enhance the ability to achieve desired habitat conditions as described in table 1. These actions would occur according to applicable regulations and, if implemented, would result in the reduction of overall available AUMs.

Managing livestock grazing to achieve the desired conditions in table 1 and livestock use guidelines in table 3 may indirectly benefit rangeland conditions by increasing vegetation productivity and increasing forage in the long term. This in turn would provide managers and permittees better management options, especially on those allotments where livestock numbers are approaching a sustainability threshold or during drought and other disturbances such as wildfire.

Impacts from Fire Management

Under the Proposed Plan, measures to protect GRSG habitat from fire and associated fire operations would be beneficial to livestock grazing, especially in the 12-inch or less precipitation zone, because it would help prevent expansion of non-native invasive species such as cheatgrass. Although management to suppress and control the spread of wildfire under the Proposed Plan would decrease the risk of disturbance from wildfire in GRSG habitat, fires outside of GRSG habitat would possibly be at risk of decreased suppression efforts. Management direction to protect GRSG habitat from fire in higher elevation sagebrush habitats (i.e., mountain big sagebrush) could indirectly negatively impact livestock grazing in the long-term as sagebrush potentially increases and forage production decreases.

Impacts from Wild Horse and Burro Management

Under Proposed Plan, wild horse and burro populations should be managed within appropriate management levels, or adjusted, to restore, enhance, or maintain GRSG desired habitat conditions as described in table 1. This management direction would be beneficial to livestock grazing in the long-term by increasing vegetation productivity and increasing forage production, particularly where rangeland conditions could be improved.

Impacts from Recreation Management

Under the Proposed Plan new recreation special use authorizations and expansion of special use authorizations would be restricted in priority habitat management areas. In addition, terms and conditions that that protect or restore GRSG habitat would be included in new special use authorizations and existing permits and operating plans would be modified to protect and/or restore GRSG habitat. Temporary recreation uses that result in the loss of GRSG habitat would not be authorized, and new recreational facilities or expansion of existing recreational facilities (e.g., roads, trails, campgrounds) would not be approved in priority habitat unless the development results in a net conservation gain to GRSG and/or their habitats.

This management direction would limit the direct and indirect impacts of recreation development on rangelands where livestock grazing is permitted. This management direction would have beneficial impacts to livestock grazing by reducing disturbances to rangelands from development and disturbances to livestock. However, impacts from recreation management could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Road/Transportation Management

Under the Proposed Plan new road or trail and construction would be prohibited in GRSG habitat, and road construction within riparian and mesic meadows would be restricted. This direction would be beneficial to livestock grazing by reducing impacts from roads rangeland and riparian areas. This could indirectly improve forage production and improve overall rangeland conditions. However, impacts from roads and transportation could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Impacts from Minerals Management

Under the Proposed Plan, new fluid mineral leases would require a no surface occupancy stipulation in priority habitat and controlled surface use and timing restrictions in general habitat. New leases would be prioritized in non-habitat first and then in the least suitable habitat for GRSG.

For existing leases under the Proposed Plan, leaseholders would be required to avoid and minimize surface disturbing and disruptive activities in priority habitat for leases that are not yet developed. In addition, reclamation plans would be designed to restore habitat to desired conditions described in table 1. Fluid mineral operations would be mitigated in priority habitat to reduce soil compaction to improve vegetation reestablishment and keep GRSG habitat disturbance to a minimum.

Surface disturbances would also be prohibited for unleased coal mines in priority habitat as well as other mitigation measures to reduce disturbances for leased coal mines and associated facilities. Locatable mineral, non-energy leasable, and mineral material operations in priority habitat would be mitigated to protect GRSG habitat.

Minerals management direction under the Proposed Plan would have positive impacts for livestock grazing in priority and general GRSG habitats because development and surface disturbance would be limited, and the potential from development related disturbance of rangeland and forage resources would be reduced. However, impacts from new and existing mineral leases could be disproportionately concentrated in areas outside of priority and general GRSG habitats, which could indirectly impact grazing conditions through increased development.

Josh,

I don't have any specific comments on the data document. In the methodology document, I found a few things (which I'm sure others are aware of) that need attention. The footers need to be checked for any necessary corrections: the appendix letter in the pagination changes in some footers, and the date varies from October 2013 to June 2013…should all be June or July 2014?

I would like to see a time-frame added to the employment effects tables for the well drilling and completion as well as for wind turbine construction. Showing the number of jobs without a number of months or years of employment might be misunderstood by some readers as being long-term employment impacts.

On page R-16 (W-16), the right-hand column figure for the assessed value of federal royalties ($140,816,813) appears to need a negative sign to be added in front of it. When I have a few minutes, I'll go through all of the tables again to look for any other possible issues like that.

In general, I think the additions and edits read well and accomplish what ICF had stated as their planned objectives. I'll be away for the next hour but then will dig into the Chapter 3 and Chapter 4 sections.

Economic Impact Analysis Methodology

APPENDIX W
ECONOMIC IMPACT ANALYSIS METHODOLOGY

INTRODUCTION

This appendix describes the methods and data that underlie the economic impact modeling analysis. Input-output models such as the Impact Analysis for Planning (IMPLAN) model, an economic impact analysis model, provide a quantitative representation of the production relationships between individual economic sectors. Thus, the economic modeling analysis uses information about physical production quantities and the prices and costs for goods and services. The inputs required to run the IMPLAN model are described in the following narrative and tables. The resulting estimates from the IMPLAN model, by alternative, are in **Chapter 4**, Environmental Consequences, **Section 4.22**, Social and Economic Impacts (Including Environmental Justice). The first portion of the following information describes general aspects of the IMPLAN model and how it was used to estimate economic impacts. The remaining sections provide additional detailed data used in the analysis for livestock grazing, oil and gas, coal and wind energy.

THE IMPLAN MODEL

IMPLAN is a regional economic model that provides a mathematical accounting of the flow of money, goods, and services through a region's economy. The model provides estimates of how a specific economic activity translates into jobs and income for the region. It includes the ripple effect (also called the multiplier effect) of changes in economic sectors that may not be directly impacted by management actions, but are linked to industries that are directly impacted. In IMPLAN, these ripple effects are termed indirect impacts (for changes in industries that sell inputs to the industries that are directly impacted) and induced impacts (for changes in household spending as household income increases or decreases due to the changes in production). Because IMPLAN incorporates regional trade data, it is able to separate the economic impact received by a specific region from the impact that is felt beyond the selected geographic area. The estimates reported below for output, employment and earnings reflect only the share supported in the primary and secondary study areas.

This analysis used IMPLAN 2011. This means that parameters such as productivity and trade data reflect estimates for the study area released in the 2011 IMPLAN version. These parameters typically do not meaningfully change from one year to another and would likely not be substantially affected by more recent growth trends in employment or output in specific sectors. Prior to running the model, cost and price data were converted to a consistent dollar year (2011) using sector-specific adjustment factors from the IMPLAN model. Unless stated otherwise, t~~T~~he values in this appendix are expressed in year 2011 dollars.

The current IMPLAN model has 440 economic sectors, of which 331 are represented in the Primary and 384 are represented in the Secondary Socioeconomic Study Area counties. This analysis involved direct changes in economic activity for 38 IMPLAN economic sectors, as well as changes in all other related sectors due to the ripple effect. The IMPLAN production coefficients were modified to reflect the interaction of producing sectors in the Primary and Secondary Socioeconomic Study Areas. As a result, the calibrated model does a better job of generating multipliers and the subsequent impacts that reflect the interaction between and among the sectors in the Primary and Secondary Socioeconomic Study Areas compared to a model using unadjusted national coefficients.

Key variables used in the IMPLAN model were filled in using data specific to the Primary and Secondary Socioeconomic Study Areas, including employment estimates, labor earnings, and total industry output. This data was used to estimate labor productivity and earnings per job. As explained above, recent growth trends in employment and output in specific sectors in the study area would not likely affect these parameters.

The trade data available in the current version of IMPLAN (Version 3.0) make it possible to do multi-region analysis to track how an impact on any of the IMPLAN sectors in the study area affects production in any of the sectors in any other region of the US. For this analysis, this feature allowed the estimation of how an impact in the primary study area disperses into the secondary study area, and how these effects in the secondary study area create additional local effects in the primary study area. As a result, it was possible to estimate not only the jobs and income generation in the primary study area, but to also estimate how the economic activity in the primary study area affected jobs and income generation in the secondary study area.

In addition to analyzing impacts in the primary and secondary study area, BLM and USFS analyzed impacts to smaller regions, where socioeconomic impacts associated with oil and gas, wind energy and coal would likely be concentrated. No similar analysis was done for livestock grazing, given the relatively disperse socioeconomic impacts of althernatives through effects on livestock grazing.

LIVESTOCK GRAZING

Economic impacts from changes to livestock grazing are a function of the amount of forage available and the economic value of forage.

Forage availability was measured in animal unit months (AUMs), with one AUM defined as the amount of forage needed to feed a cow, one horse, or five sheep for one month. For Forest Service data, measurements in AUMs were also obtained. Data were obtained from the BLM's Rangeland Administration System (BLM 2012a) and from the Forest Service's INFRA range module (Forest Service 2013). Two types of AUM measures were used: Active AUMs and Billed AUMs. Active AUMs measure the amount of forage from land available for grazing. The Forest Service designates this measure "permitted" AUMs. Billed AUMs measure the amount of forage that the BLM and Forest Service bill for annually. The Forest Service uses the designation "authorized" AUMs. Impacts were estimated for the range between billed and active AUMs.

Data for Alternatives A, B, D and E were for 2011. Estimates of Active and Billed AUMs under Alternative C1 were obtained by using GIS to remove AUMs intersecting with sage-grouse habitat. In doing so, all allotments containing sage grouse habitat were considered closed for grazing (and not just the portion with sage grouse habitat). Estimates for Active and Billed AUMs for Alternative C2 assume 60 percent of the AUMs made unavailable under Alternative C1 are made unavailable under Alternative C2. **Section 4.22** discusses the possibility of Billed AUMs not being reduced in proportion to reductions in Active AUMs under Alternatives C1 and C2.

Table W.1, below, shows estimated Animal Unit Months by management unit under each Alternative. Data for National Forests corresponds only to AUMs in the portion of those National Forests within the study area and with sage-grouse habitat.~~habitat.~~

Sources: Calculated based on data from BLM 2012a and Forest Service 2013. Billed AUMs for Forest Service were assumed equal to active AUMs~~are a 10-year average and, for this reason, may be higher than Active AUMs in 2011~~.

The economic value of forage is estimated based on the value of production associated with the forage. Values for cattle and sheep are estimated separately, and other grazing animals are considered of negligible commercial value.

Due to price fluctuations, average per-AUM values for cattle and sheep are based on the 2002 to 2011 average value of production estimates from the (US Department of Agriculture, Economic Research Service 2012). The value for cattle is $51.19 per AUM, and the value for sheep is $58.01 per AUM in the Primary Socioeconomic Study Area (in 2011 dollars). Including indirect and induced impacts, the value of one AUM in the Primary Socioeconomic Study Area for cattle is $102.12 and for sheep is $127.11 (in 2011 dollars). **Table W.2**, Assumptions for Analysis of Impacts on Output for Livestock Grazing, shows the economic impact assumptions for cattle and sheep. The direct economic impact is the estimated change in livestock output per AUM; IMPLAN generates the indirect and induced impacts.

Table W.3, Assumptions for Analysis of Employment Impacts for Livestock Grazing, provides a summary of the employment impacts that would result, according to IMPLAN, based on unit changes in livestock AUMs.

Table W.2
Assumptions for Analysis of Impacts on Output for Livestock Grazing

Economic Impact	Primary Study Area	Primary and Secondary Study Area
	Cattle	
Direct Economic Impact ($/AUM)	$51.19	$51.19
Indirect Economic Impact ($/AUM)[1]	$44.22	$49.39
Induced Economic Impact ($/AUM)[2]	$6.71	$9.08
Total Economic Impact ($/AUM)	$102.12	$109.66
Multiplier (Total Impact/Direct Impact)	1.99	2.14
	Sheep	
Direct Economic Impact ($/AUM)	$58.01	$58.01
Indirect Economic Impact ($/AUM)[1]	$59.85	$67.76
Induced Economic Impact ($/AUM)[2]	$9.25	$12.53
Total Economic Impact ($/AUM)	$127.11	$138.30
Multiplier (Total Impact/Direct Impact)	2.19	2.38

Note: All dollar values are in 2011 dollars.

[1] Indirect impacts reflect increased demand in sectors that directly or indirectly provide supplies to the livestock industry.

[2] Induced impacts reflect increased demand in the consumer and government sectors.

Table W.3
Assumptions for Analysis of Employment Impacts for Livestock Grazing

Employment Impact	Primary Study Area	Primary and Secondary Study Area
Cattle		
Direct Employment (Jobs/1,000 AUMs)	0.559	0.559
Indirect Employment (Jobs/1,000 AUMs)	0.456	0.486
Induced Employment (Jobs/1,000 AUMs)	0.067	0.087
Total Employment (Jobs/1,000 AUMs)	1.081	1.132
Multiplier (Total Impact/Direct Impact)	1.93	2.03
Average Earnings per Job (2011 dollars)	$36,738	$36,738
Sheep		
Direct Employment (Jobs/1,000 AUMs)	0.980	0.980
Indirect Employment (Jobs/1,000 AUMs)	0.760	0.801
Induced Employment (Jobs/1,000 AUMs)	0.087	0.110
Total Employment (Jobs/1,000 AUMs)	1.827	1.891
Multiplier (Total Impact/Direct Impact)	1.86	1.93
Average Earnings per Job (2011 dollars)	$15,408	$15,408

Note: Direct, indirect, and induced employment impacts and average earnings per job are calculated using IMPLAN.

The IMPLAN sectors used to model and exogenous change in demand for livestock grazing were the following (IMPLAN sector numbers are shown in brackets): grain farming (2), all other crop farming (10), support activities for agriculture and forestry (19), residential structures maintenance and repairs (40), wholesale trade (319), truck transportation (335), banking (354), real estate (360), accounting (368), veterinary services (379), equipment repair and maintenance (417) and labor income (NA). Cattle grazing used the following additional sector: cattle ranching and farming (11). Sheep grazing used the following additional sectors: (animal production except cattle and poulty and eggs (14), retail-food and beverages (324).

OIL AND GAS

The economic impact of oil and gas reflects drilling, completion, and production activities. Estimation of drilling, completion, and production activities was done for a 15-year period (2014 to 2028). Appendix R, Oil and Gas Reasonably Foreseeable Development Scenario for Greater Sage-Grouse Occupied Habitat in Utah Sub-Region, provides a complete description fo the assumptions and methodology used in developing these estimates.

Commented [AU1]: Comment from Josh Sidon: EMPSi – please ensure we are referencing the correct appendix

The number of wells drilled and the number of wells completed under the No Action Alternative (Alternative A) were based on the average number of wells expected to be drilled or completed per year in each BLM field office's current Reasonable Foreseeable Development Scenario. Completion rates ranged from 10 percent in most counties to 85 percent for oil wells in Carbon and Duchesne counties and for gas wells in Uintah County. Drilling and completion numbers were estimated for federal surface, as well as for all surface ownership.

The BLM oil and gas specialists estimated the share of oil and gas that would intersect with GRSG habitat using GIS. The number of wells completed or drilled that would be affected by each alternative is the number that intersects with GRSG habitat, as appropriate for each alternative:

- Alternative A – Existing areas would be available for fluid mineral leasing
- Alternative B – some GRSG occupied habitat would be designated as priority habitat and would be closed to new fluid mineral leasing
- Alternative C – All GRSG occupied habitat would be designated as priority habitat and would be closed to new fluid mineral leasing
- Alternative D – Some GRSG occupied habitat would be designated as priority habitat but would not be closed to new leasing. Rather, NSO would be placed within 4-miles of an occupied lek
- Alternative E – Based on the State of Utah's Sage-Grouse Management Plan, minor constraints would be placed on management areas.
- Proposed Plan - Some GRSG occupied habitat would be designated as priority habitat but would not be closed to new leasing. Rather, all priority habitat would be managed as NSO.

Formatted: No bullets or numbering

Both ~~Only~~ wells in new leases and wells in existing leases were considered to be affected by GRSG management (see Appendix R for details). In addition, the BLM assumed that leases on state and private lands would be affected similarly to federal lands, if large areas of contiguous BLM-administered land are closed to new oil and gas leasing.

Table W.4, Oil and Gas Well Numbers, presents the total number of wells drilled and completed in the Primary Socioeconomic Study Area for each alternative, relative to Alternative A.

The production per ~~new~~ well was assumed based on the typical production of existing wells in the area, or 1,471 MMCF per gas well and 200 MBO per oil well over a 20 year well life. Each well was assumed to have a 20-year life and 75 percent of its lifetime production would be reached during the 15-year period. ~~Total oil and gas production under Alternative A was based on multiplying production per well and the number of wells drilled and completed (estimated as described above).~~ The production that would be affected by each alternative is proportional to the share of wells affected by GRSG habitat, as appropriate for each alternative. Reductions in drilled and completed wells relative to Alternative A correspond to approximately 7 percent under alternative D and the Proposed Plan, 10 percent under Alternative B and 27 percent under Alternative C, with no reduction under Alternative E. **Table W.5**, Projected Oil and Gas Production, 15-Year Period, presents the projected quantity of oil and gas over the 15-year forecast period on federal surface and on federal, state, and fee surface.

Table W. 5

Sources: Elaborated by BLM staff based on field office Reasonable Foreseeable Development Scenarios and available information.
MMCF = million cubic feet; MBO = thousand barrels

The costs of drilling and completing wells and producing oil and gas also are relevant for the economic impact analysis. Cost of completion or drilling per well were assumed to sum to $3,250,000 for vertical wells under Alternatives A, and E, wells not on federal lands, and wells on federal lands not in priority sage grouse habitat. This is ~~,~~a mid-point in the $1,500,000 to $5,000,000 range typical for the region (BLM 2013a). Directional wells were assumed to be approximately 5 percent more expensive to driil per foot and similarly costly to complete, and horizontal wells were assumed to be 30 percent more expensive to drill per foot and similarly costly to complete. Vertical wells were assumed to be 43 percent of total wells, directional wells were assumed to be 55 percent of total wells and horixontal wells were assumed to be 2 percent of total wells.

For alternatives B, C, D and the Proposed Plan, wells drilled in priority habitat on federal lands were assumed to have increased costs. These increased costs would affect both wells on existing leases and new wells. The increased costs would be a consequence of increased directional drilling, from 55 percent of total wells to 75 percent of total wells, and horizontal drilling, from 2 percent of total wells to 5 percent of total wells. In addition, increased costs would derive from required design features identified in Appendix J and off-location mitigation requirements. In Alternatives A and E, the average cost of drilling and completing a well was estimated to be $3,371,400. In Alternatives B, C, D and the proposed plan, the average cost for drilling and completing a well was estimated to be $4, 498,000. This increase in costs translates in increases local expenditures per well and, therefore, increased outcome, employment and earnings impacts per well.

The increased costs of drilling in priority habitat was assumed to impact the number of wells drilled under ~~–~~existing leases in Alternatives B, C, D and the Proposed Plan[1]. Because the reduction in the number of wells drilled in existing leases was assumed to be proportional to the increase in drilling costs under Alternatives B, C, D and the Proposed Plan. These reductions are already reflected in the number of wells drilled and completed under each alternative, relative to Alternative A, shown in **Table W.4**.

Formatted: Font: Bold

IMPLAN was used to generate output, employment, and earnings multipliers per million dollars of expenditures. These multipliers were then applied to the estimated expenditures with drilling and completion by alternative to obtain the resulting impacts.A summary of the costs of drilling and completion and impacts per well used for the economic analysis is shown in ~~.–~~**Table W.6**, Assumptions for Analysis of Economic Impacts for Oil and Gas Well Drilling and Completion, Alternatives A and E, and Wells not on Federal Lands in Priority Habitat in Alternatives B, C, D and Proposed Plan, and ~~provides a summary of the costs of drilling and completion used for the economic analysis.~~ **Table W.7**, Assumptions for Analysis of Economic Impacts for Oil and Gas Well Drilling and Completion, Wells on Federal Lands in Priority Habitat in Alternatives B, C, D and Proposed Plan. Assumptions are shown for the Primary Study Area, the Primary and Secondary Study Area and for a Three County Area consisting of Duchesne, Carbon and Uintah counties. As explained in Chapter 4.22 Social and Economic Impacts (Including Environmental Justice), these three counties are expected to bear a considerable share of the economic impacts associated with the effects of management alternatives on oil and gas development. The analysis of the three county area assumed all parameters would be the same as those used for the broader analysis of the impacts on the primary and secondary areas (e.g. sectors affected by oil and gas related expenditures, labor productivity, etc.) except that all direct expenditures previously assumed to occur in the primary study area would now only occur in the three county area.

Formatted Table

Source: Drilling and completion costs (the first row in each part of the table) were based on the mid-point of a range provided by BLM staff (BLM 2013a), $3,250,000 per well for vertical wells. Costs for directional and horizontal wells were adjusted, as explained in the text. Remaining data is from IMPLAN, as described in the text.

[1]Coalbed natural gas wells were assumed to be included in the estimate of the average cost of vertical wells. Coalbed natural gas well costs would correspond to the lower end of the range provided by BLM (2013).

[2]The local cost shares correspond to the percent of total drilling or completion costs that would be spent on goods and services purchased from the local economy and were assumed based on regional

Assumptions for Analysis of Economic Impacts for Oil and Gas Well Drilling and Completion, Wells on Federal Lands in Priority Habitat in Alternatives B, C, D and Proposed Plan

Economic Impact	Primary Study Area	Primary and Secondary Study Area	Three County Area

experience.

[3] Total impacts estimated using IMPLAN include direct, indirect, and induced impacts.

Table W.8~~7~~, Assumptions for Analysis of Economic Impacts on Output for Oil and Gas Production, provides the assumptions used to determine the economic impact associated with the production of oil and gas. For the analysis, the BLM estimated a nonlabor production cost (for gas) of $4.23 per thousand cubic feet and $82.53 per barrel of oil, in year 2011 dollars, based on data from the Energy Information Administration for the Rocky Mountain Region (Energy Information Administration 2013).

The forecasted number of wells and production used for estimating employment impacts is the same as for estimating impacts on labor earnings and output. The direct and total employment impacts attributable to drilling and completion are shown in **Table W.~~8~~9**, Assumptions for Employment Impact Analysis for Oil and Gas Well Drilling and Completion, ~~shows the direct and total employment impacts attributable to drilling and completion.~~Alternatives A and E, and Wells not on Federal Lands in Priority Habitat in Alternatives B, C, D and Proposed Plan, and **Table W.10**, Assumptions for Employment Impact Analysis for Oil and Gas Well Drilling and Completion, Wells on Federal Lands in Priority Habitat in Alternatives B, C, D and Proposed Plan

Table W.11~~9~~, Assumptions for Employment Impact Analysis for Oil and Gas Production, shows the direct and total employment impacts associated with production.

Table W.8~~7~~
Assumptions for Analysis of Economic Impacts on Output for Oil and Gas Production

Economic Impact	Primary Study Area	Primary and Secondary Study Area	Three County Area
Oil Production (per thousand barrels)			
Direct Economic Impact[1]	$82,530[2]	$82,530~~[3]~~	$82,530
Indirect Economic Impact[4]	$8,309	$12,123	$5,760
Induced Economic Impact[5]	$2,924	$4,573	$2,190
Total Economic Impact	$93,763	$99,226	$90,480

The analysis of potential changes in tax revenues is based on tax rates of 12.5 percent of taxable value for federal mineral royalties and 5 percent of taxable value for state severance taxes: Utah severance tax rates are 5 percent for value above a minimum, so 5 percent is an upper bound (University of Utah 2010). Taxable value was assumed to be 87.5 percent of value of sales based on a report for neighboring Colorado.[1] **Table W.12~~0~~**, Tax Collections from Oil and Gas Production, Annual Average, 2011 $ shows tax collections for the annual average production under each alternative in the primary study area.

The IMPLAN sectors used to model an exogenous change in demand for oil and gas well drilling were the following (IMPLAN sector numbers are shown in brackets): drilling oil and gas wells (28), support activities for oil and gas operations (29), construction of new manufacturing structures (35), constructure of other new structures (36), wholesale trade (319), truck transportation (335), telecommunications (351), commercial and industrial equipment leasing (365), architectural and engineering services (369). In the gas of oil and gas production, the sector used was oil and gas extraction (20).

COAL

The economic impact of coal production is estimated based on the volume of coal produced and the sales price of coal. BLM projected coal production in the State of Utah to 2028 based on information from the US Energy Information Administration (EIA) and the Utah Geological Survey (BLM 2013; Utah Geological Survey 2010). These projections incorporate expected future trends of related prices and quantities (e.g. the price of gas). Although these projections include coal from San Juan County, which is not part of the Study Area for this EIS, the coal from San Juan would not be affected by the choice of alternatives and therefore does not affect the comparison of alternatives. For the estimation of the impacts of the alternatives on coal production, the following assumptions were made, based on information in various documents:

- 77 percent of all production is from federal mineral lands (BLM 2013b)~~lands~~
- New coal leases would be required for underground coal production from 2017 onwards

---

[1] This was based on information available for the State of Colorado from the Colorado Oil and Gas Association (Colorado Oil and Gas Association 2011). Valuation for Utah may be slightly above or below this number.

- BLM made the assumption for analysis purposes only that no new subsurface leasing would occur in priority habitat (for Alternative B) or occupied habitat (for Alternative C). The idea that closing GRSG habitat to new leases would effectively preclude underground coal mining represents a worst-case scenario because nothing in this alternative would preclude leasing of subsurface materials.
- The Alton coal field would generate 1,840,000 tons of coal per year starting in 2016 from surface coal mining, under Alternatives A, D and E (BLM 2011). For analytical purposes only, this coal is assumed to be produced entirely from federal lands. BLM assumed that no production would occur from the Alton coal field in Alternatives B and C, based on it being a surface mine. To the extent that some underground mining of the deposit could still occur, accessed through surrounding non-Federal lands, this assumption of no production under alternatives B and C may overstate the actual impacts of those alternatives.

The estimated annual average volume of coal produced on federal lands under each alternative is presented in **Table W.11** below.

Table W.11
Estimated Annual Average Coal Production on Federal Lands in Utah (tons), 2014-2028

	Underground	Surface	Total
Alternative A	15,291,616	1,594,667	16,886,283
Alternative B	13,150,790	0	13,150,790
Alternative C	12,080,377	0	12,080,377
Alternative D	15,291,616	1,594,667	16,886,283
Alternative E	15,291,616	1,594,667	16,886,283

Source: BLM 2013b

Estimates of the impacts of coal production were developed using IMPLAN and assuming a price for underground coal of $33.80 per ton, which is the EIA's 2011 coal price estimate for Utah (EIA 2013), and a price of $23.86 per ton for surface coal. The price for surface coal is estimated as the average between the price for underground coal for Utah and the price of surface mining in Wyoming's Powder River Basin (used as a reference). The basis for this is the fact that the Alton mine coal is expected to have 10,000 BTU per pound (BLM 2011). Surface coal mined from the Powder River Basin in Wyoming contains about 8,800 BTU per pound and has an average price of $13.56 per ton. The EIA estimates the price of underground coal in Utah to be $33.80 per ton based on 11,700 BTU per pound of coal. The simple average in prices would approximate the expected BTU for the coal from the Alton mine.

Formatted

Table W.12 and **Table W.13** show the multipliers for output and employment, respectively, estimated for coal. Assumptions are showns for the Primary Study Area, the Primary and Secondary Study Area and for an Eight County Area consisting of Carbon, Emery, Sanpete, and Kane, as well as counties that could be expected to provide construction inputs, materials, transportation services and other supplies, and that are located within the primary or secondary study area. These include Sevier, Paiute, Garfield and Millard. Utah County was also considered but was not included, because it would disproportionately impact the results, given its large population and economy relative to the other counties. As explained in Chapter 4.22 Social and Economic Impacts (Including Environmental Justice), these eight counties are expected to bear a considerable share of the economic impacts associated with the effects of management alternatives on coal development and production.

Formatted Table

The IMPLAN sector used to model an exogenous change in demand for coal was coal mining (21).

Potential changes in tax revenues associated to Federal mineral royalties are estimated based on a 12.5 percent royalty rate for surface coal and 8 percent royalty rate for underground coal (BLM). The value of coal output under each alternative was estimated as discussed above. **Table W.14**, Estimated Coal Royalties in Primary Study Area, 15-Year Period shows royalties collections for the estimated production under each alternative.

Table W.14
Estimated Coal Royalties in Primary Study Area, 15-Year Period

	Alternatives A, D and E			Alternative B			Alternative C

WIND ENERGY

The economic impact of wind energy depends on the expenditures made with installation and operations of wind farms. Expenditures made in the Primary Study Area were estimated based on the amount of electricity (nameplate capacity in megawatts, MW[1]) ~~MW)~~ projected under each alternative, and the installation and operations costs per MW.

BLM projected 17,328 acres of reasonably foreseeable wind development in the Hamlin and Bald Hills Sage-Grouse population areas, under Alternative A. Using Utah's Milford Wind Corridor Project as a baseline, BLM estimated that this would correspond to approximately 210 MW of installed capacity. The same installed capacity would be projected under Alternative E. Based on GIS analysis, 121 MW would be potentially installed under Alternatives B, C and D.

Installation and operations costs per MW were obtained from default values for the State of Utah used by the Jobs and Economic Development Impact (JEDI) model. The JEDI model for wind energy was developed by the National Renewable Energy Laboratory and default values for construction and operation costs per MW were determined based on extensive interviews with power generation project developers, state tax representatives, and others in the appropriate industries (NREL 2012). Default values were based on projects of 100 MW (50 turbines of 2,000 kilowatts each) and were estimated to be, in 2008 dollars,~~2008 dollars~~, $2,000 per kilowatt for installed project costs and $20 per kilowatt for operations and maintenance costs.~~costs~~.

Tables W.15 and W.16 below show the estimated multipliers for output and employment during installation and operations. Assumptions are showns for the Primary Study Area, the Primary and Secondary Study Area and for a Two County Area consisting of Millard and Beaver counties. As explained in Chapter 4.22 Social and Economic Impacts (Including Environmental Justice), these two counties are expected to bear a considerable share of the economic impacts associated with the effects of management alternatives on wind energy development and production.

Table W.15
Assumptions for Analysis of Impacts on Output for Wind Energy

Economic Impact	Primary Study Area	Primary and Secondary Study Area	Two County Area
Installation			
Direct Economic Impact ($/MW)	$303,774	$303,774	$303,774
Indirect Economic Impact ($/MW)[1]	$53,862	$94,884	$30,900
Induced Economic Impact ($/MW)[2]	$46,892	$67,484	$33,776
Total Economic Impact ($/MW)	$404,527	$466,142	$368,450
Multiplier (Total Impact/Direct Impact)	1.33	1.53	1.21
Operations			
Direct Economic Impact ($/MW)	$17,176	$17,176	$17,176
Indirect Economic Impact ($/MW)[1]	$572	$845	$384
Induced Economic Impact ($/MW)[2]	$5,390	$6,664	$3,883

Table W.16
Assumptions for Analysis of Impacts on Employment for Wind Energy

Employment Impact	Primary Study Area	Primary and Secondary Study Area	Two County Area
Installation			
Direct Employment (jobs/MW)	1.77	1.77	1.77
Indirect Employment (jobs/MW)	0.37	0.57	0.22
Induced Employment (jobs/MW)	0.45	0.61	0.31
Total Employment Impact (jobs/MW)	2.58	2.94	2.30
Multiplier (Total Impact/Direct Impact)	1.46	1.67	1.30
Average Earnings per Job (2011 dollars)	$40,834	$42,141	$40,177
Operations			
Direct Employment (jobs/MW)	0.24	0.24	0.24
Indirect Employment (jobs/MW)	0.01	0.01	0.00[3]
Induced Employment (jobs/MW)	0.05	0.06	0.04
Total Employment Impact (jobs/MW)	0.29	0.30	0.28
Multiplier (Total Impact/Direct Impact)	1.24	1.28	1.17
Average Earnings per Job (2011 dollars)	$41,985	$42,157	$42,037

Source: IMPLAN. Note: All dollar values are in 2011 dollars.

[1] Indirect impacts reflect increased demand in sectors that directly or indirectly provide supplies to the installation and operations of wind farms.

[2] Induced impacts reflect increased demand in the consumer and government sectors.

The IMPLAN sectors used to model an exogenous change in demand for wind energy development were the following (IMPLAN sector numbers are shown in brackets): sand and gravel mining (26), ready-mix concrete manufacturing (161), wholesale trade (319), retail-building materials and garden supply (323), hotels and motels (411), food services and drinking places (413), labor income change (NA). In the case of wind energy operations, the IMPLAN sectors used were the following: electrical power (31), nonresidential maintenance and power (39), wholesale trade (319), retail – motor vehicle and parts (320), retail – building materials and garden supply (323), retail – gasoline stations (326), other state and local government enterprises (432), labor income change (NA), state and local government – non-educational (NA), state and local government – educational (NA). Unlike other sectors modeled in IMPLAN for this EIS, the state and local government sector was included when modeling wind energy operations following the NREL JEDI model on which the model for this EIS was based.

Reminder: GBR/RMR Sage Grouse Weekly Subregional NEPA Project Managers Weekly Conference Call

Wednesday; 9AM PT / 10AM MT

[redacted]

Tentative agenda:

1. ePlanning update / SharePoint Issues – Jamie/Jim
   - Reminder for PMs to work with NOC on dates for incorporating chapters/appendices into ePlanning
   - Gale Saltus, SharePoint contact – 303-236-5258 or gsaltus@blm.gov
2. National, State Director, and SOL updates – Jessica/Matthew/Sarah
3. Regional Updates – Lauren and Johanna
   - North Dakota IDT Briefing – comments from IDT
4. BER, Consistency Framework, and Cumulative Effects Analysis update – David/Vicki/Frank/Drew Vankat
5. Admin Record
   - Need contact info each Great Basin SR AR POC
6. Scheduling and Status – reminder to keep updating schedule and status tracking sheets
7. Chapters 3 and 4
   - Standard text for Lands with Wilderness Characteristics (see attachment)
   - Geothermal resources in fluid minerals
   - Reminder that level of analysis should be targeted to scope and issues
   - Indicators and assumptions for key resources (will be provided via separate email)
   - Habitat definitions - PPH/PGH – any other terms being used for the BLM/FS alt?
8. Other items
9. Unresolved action items from last couple of calls:
   - Project leads: let Jim Wood know if you have any needs for inputting into ePlanning that can be done now.
   - Project leads: work with data managers and CEA team representatives to determine what data layers will be provided for the landscape report according

to the Draft Landscape Report Proposed Data Layers handout. Change question marks to yes or no and provide refinements to questions.

- Lauren: work with Tom and Gordon to set up another call clarifying the HAF. Clearly state purpose of the call with meeting invitations.
- Project leads: reminder to keep updating the schedule and the tracking sheet.
- Brent will work with Johanna regarding Idaho/southwest Montana website concerns. Johanna will discuss these with Mitch Snow.
- Lauren will to talk to Sandra regarding the NV/CA Vista contract to determine if the NV/CA contract can be used for other subregions.
- Matt will develop summary of national planning strategy for subregions to include in their Chapter 1 sections.
- Jim Wood and Pam Bode will discuss scheduling USFS ePlanning training.
- Lauren: follow up with Jessica regarding FAA MOU.
- Brent: send DOD email to Matt regarding MOU.
- Lauren: follow up with Joan regarding Vista.
- Lauren: send John Thompson language regarding 90-day comment period extension.

10. Outstanding Action Items from Reno mtg:

- Lauren and Johanna will provide decision language for use of Required Design Features (BMPs) for the alternatives.

- Matt Magalletti to follow up regarding USFS control over leasing and whether they determine lands open/closed to leasing in their land use plans

Subject: Fwd: Wyoming Sage-grouse oil and gas production
Attachments: O&GProdTablesState.xlsx

Alex -

Here's O&G production data for the 9-plan. Note - they only went out 8 years. Again let me know if you have questions.

Josh

Hi Josh. Hello Jessica, too.

Josh, in response to your question yesterday, here is the summary data from the economic analysis for oil and gas production. See columns B and C of the annual tab for production volumes. There are no O/G wells in the MBNF, so there's no file for that unit.

Note that these production estimates include co-production, which may not be included in production estimates for the other regions. I believe the contributions of oil from gas wells are very small, but gas from oil wells is substantial.

Also, FYI and convenience, I've copied below the methodology used, from our technical report.

If you have any questions, let us know!

Cheers,

Richard

Information on production of oil and gas was provided by the BLM's RMG and BLM field and district office staff. This information included the number of wells drilled each year by alternative for each field office or planning unit (from the RFD), the percent of wells that were oil versus gas, the percent of wells completed, production decline curves for oil and gas wells, and estimates of cross production from both oil and gas wells. This information was used to develop total oil and gas production estimates by year for each alternative and each field office or planning unit.

The procedure to determine total production was as follows. For each year, the number of wells completed was broken down into oil and gas wells based on the breakdown assumptions per field office and planning unit provided by BLM staff. For each well type, the average first year production rate (volume) from the annual decline curves for each field office and planning unit (as provided by RMG) was then applied to determine the total production from first-year wells. In subsequent years, the appropriate average production rates from the decline curves were applied to the number of second year wells, third year wells, and so on. Total production was then summed across all the well age cohorts for each year within the analysis period. Co-production volume was calculated based on the numbers of wells of each type and the co-production rates from the RMG, and added to the total production volume.

Importance: High

As I looked at these files a little closer – it appears there is some detailed ROW numbers for UT (which are moot for now), some highly qualitative ROW effects for ID, and a missing document for NV. I sent an email to Madelyn requesting NV file and if/when more quantitative information might be available for ID.

So, probably not much help for now – I'll send whatever else comes in.
Chris

Here's a streamlined alternative matrix for NV and a summary of alts for ID. I have individual more detailed alts for ID, if you'd like, but the summary will likely be sufficient.

I understand that the contractor wanted a response by 5/17 . . . better late than never, I suppose. My apology for the unavoidable delay and any problems it might have caused.

Rather than trying to craft a statement that adequately addresses the need (as I understand it), I thought it might be helpful to send you the alternative matrix for UT, which will provide specific, detailed information that might be most helpful in providing the data/information needed. I've highlighted in yellow the lands and realty section and a simple "find" will locate the section using "lands and realty."

Subject: social econ Qs for UT

Hi all,

Given that the econ contractor is being asked to complete the chap 4 section without having other sections of chapter 4 from which to work from, Rob Fetter at ICF has crafted a set of questions to solicit information for specialists to try and solicit information in absence of having chapter 4. I have highlighted areas in the attached file, along with your names in comment bubbles, that you may be able to provide some information to help out ICF so they have something to work with. Could you take a look at those areas and see if you would like to provide some feedback for UT (as well as NV and ID/MT subregions – but UT is priority at the moment) by end of this week?

Ron – we continue to try and work with Tim and Dustin to get the grazing AUM data to ICF but there is a long list of GIS requests – so there's a bottle neck that's keeping us from getting the data in time to ICF. We may not be able to get FS grazing economic impacts in on time for this draft of the UT subregional chapter 4. Hopefully having a gap is ok for that. Also curious to know if you received any more feedback from forests about ROWs (as indicated in Rob's email below)?

Sorry again about the chaotic nature of these requests (perhaps you've already received these requests from someone else), but this has been a coordination struggle.

Thanks,
Chris

To: Miller, Chris J -FS; Uriarte, Alex
Cc: Uriarte, Alex
Subject: RE: FS data status

Chris,

The main thing we are still waiting for on Utah is grazing data from Dustin – see the attached spreadsheet. Also, your email of 5/9 indicated that Ron Rodriguez still might be checking with UT forests about utility/energy corridor effects, and Ron's email didn't seem to address that point. So, if there's an update on that that would be great.

I also wanted to send you this set of questions we asked BLM regarding "qualitative" effects – these are the questions we were going to review their chapter 4 sections for, but when they were not able to send us the ch4 sections they asked for questions instead. I believe most/all of these will not apply for FS resources (or have been / will be addressed in existing data requests, such as the ROW question) but wanted to send these to you anyway.

Sorry for the delay – I know it's late in the day now. Nonetheless, if you have time to talk that would be great.

Rob

To: Fetter, Rob; Uriarte, Alex
Subject: FS data status

Hi Rob, Alex,

Did you want to talk to day about data needs/updates? I might be unavailable for much of the time between Tuesday and Thursday this week.

I know that the ID subregional team is having an id team meeting beginning tomorrow and they will be discussing social/economic issues from 930 to 11am MT – would either or both of you be available at that time in case they want you to participate?

Chris

Alternatives

Please provide a description of the alternatives (brief is fine – we would just like some information to characterize them). Do the alternatives result in deterministic closure/open/restricted use areas, or are there zones in which a certain amount of disturbance will be permitted, up to a cap, but it is not currently known where the disturbance will be permitted and where the cap will bind?

Cumulative

If there is already a list of past, present and reasonably foreseeable future projects that the cumulative effects analysis will take into consideration, please provide it.

We would especially like to know if the sage grouse management actions in neighboring sub-regions should be considered as reasonably foreseeable future actions.

If there is guidance on the expected level of geographic detail for the cumulative analysis, or other aspects of the cumulative analysis, please provide it.

Cross-Cutting (e.g., could be lands and realty, travel management, oil and gas, locatable or salable minerals, grazing, and/or recreation)

Given the pattern of land ownership in some areas – especially areas where there are blocks of state land surrounded by federal land – does BLM (or FS) foresee impacts on the value of state lands, or the ability of operators, developers or other users, to access resources on state lands, resulting from the alternatives? If so, please characterize this as much as possible, including geographic region of effect, restrictions on seasonality or timing, and nature / extent of impact.

Commented [MCJ-1]: Ron, Glen?

Note: Bill Stevens brought up this issue in the fall. He noted that the state is likely to argue that any restrictions on BLM lands that surround state in-holdings will adversely impact the value of those state lands. For example, if surrounding BLM lands are closed to grazing, any isolated state sections will lose all their value for that resource, eliminating any fee revenue to the state from grazing. Similarly, restrictions on minerals development on BLM lands could reduce the value of minerals development on state lands (although Bill allowed that he does not think this is as likely as the grazing scenario).

Land and Realty

Is there any information about how the alternatives would affect land management, including transmission line ROWs, in a way that could result in economic impacts? For instance, if developers would incur additional mitigation costs if they choose to develop ROWs in or near habitat, this could result in economic impacts. Is this a possibility? (If so, please characterize it, including information about where, what types of ROWs would be affected, and to what extent.) Are there other types of impacts where management of lands, realty or ROWs might result in economic impacts?

Commented [MCJ-2]: Madelyn?

Travel Management

Is there any information about how the alternatives would affect travel management in a way that could result in economic impacts? For instance, if travel would be restricted or banned in certain areas or for certain seasons, this could result in reduced economic activity or higher costs for some business and residential users of access routes. Is this a possibility? (If so, please characterize it, including available information about where, what types of travel routes would be affected, what the affected travel routes are currently used for, and the extent and nature of the restrictions.) Are there other types of impacts where travel management might result in economic impacts?

Commented [MCJ-3]: Ron, Glen?

Salable Minerals

Does the team predict the alternatives would have any impacts on development or production of salable minerals? For instance, these might manifest due to seasonal restrictions, restrictions on travel or access routes, or some other mechanism. If there would be impacts, such that production of salable minerals might differ across the alternatives, please characterize the expected differences in production with respect to geography, timing, and by alternative.

Commented [MCJ-4]: Dale?

Locatable Minerals

Does the team predict the alternatives would have any impacts on development or production of locatable minerals? For instance, these might manifest due to seasonal restrictions, restrictions on travel or access routes, or some other mechanism. If there would be impacts, such that production of locatable minerals might differ across the alternatives, please characterize the expected differences in production with respect to geography, timing, and by alternative.

Commented [MCJ-5]: Dale?

Grazing

In alternatives C1 and C2, would ranchers have to bear the costs of fencing or other barriers to avoid their cattle moving onto public lands that are currently open to grazing, but would be closed in the alternatives?

Is it common for ranchers to have their cattle graze on both Federal and neighboring State (SITLA) lands, and is there information on how much grazing would be affected in SITLA lands by alternatives C1 and C2? If grazing on State lands would be affected, we would appreciate as much geographic detail as possible (ideally county level).

Any idea of the extent to which some grazing operations might became no longer viable under alternatives C1 and C2 and in what counties that might happen? Any idea for how this might vary by size of operator or other ranch characteristics?

Recreation

We understand the recreation specialist expects the alternatives will not have systematic impacts on recreation that would result in quantifiable differences among RVDs. We are wondering if that person would project more subtle changes, even if not quantifiable. For instance, last fall, BLM's Bill Stevens speculated that:

Commented [MCJ-6]: Dave?

- Offices with recent RMP’s will not likely show much recreation change from the sage grouse EIS, with the possible exception of (sage grouse) hunting. Most of these plans greatly limit cross-country OHV use, with travel limited to existing or designated roads.
- Field offices without recent RMP’s may show more differences, especially where cross-country OHV use is currently allowed within sage grouse areas.

Another possibility is that sage grouse habitat conservation actions might create a condition in which there would be more opportunities for relatively primitive recreation activities (e.g., backcountry camping) and fewer opportunities for relatively developed activities (e.g., OHV use). Even if these differences cannot be quantified in terms of changes in RVDs, it may still be valuable to address them qualitatively. So - whether or not these specific ideas would be borne out - the upshot of our question is whether the recreation specialist believes there would be any differences in recreation activity across the alternatives, and how those would be characterized.

If there are differences, we would appreciate getting as much detail as possible on geographic location as well as types of activities.

Commented [dr7]: It’s possible that sage grouse habitat could limit developed and dispersed recreation once we overlay existing habitat over current recreation activities and see where those effects could be.
An example: a campground that’s been there for years, and we discover that campground is adjacent to a lek, or within primary habitat. Do we close it? Move it?
An example: dispersed recreation activities abound. Motorized and non-motorized. Again, overlays will determine impacts and effects. People hiking too close to leks and primary habitat. Move the trail? Motorized OHV creates too much noise and dust,…keep it, or re-route it, or close it?
I realize I’m talking about project-level NEPA here, but for the EIS and a programmatic look, these are the kinds of impacts I think about regarding recreation.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
Note: Management identified in the alternatives will not apply in instances where the management in the No Action Alternative are more restrictive. For example, if an existing RMP decision closes an area to fluid mineral leasing (e.g., because of an ACEC or WSA), an alternative that considers making overlapping GRSG habitat NSO would not change the closed area to NSO; rather, the closed area present in the No Action Alternative would continue as sufficient to also meet the management under the alternative in this example.				
Theme: No Action Alternative	Theme: NTT Recommendations	Theme: NTT+ Measures Proposed by Conservation Groups During Scoping	Theme: Sub-Regional Alternative	Governor's EO – State of Utah (Wyoming for portions of Uinta & Ashley NF)
Special Status Species – Greater Sage-Grouse (GRSG)				
GOAL:				
With exception of the Uinta LRMP, goals have not been developed specifically for greater sage-grouse (GRSG). However, all LUPs include a goal to work with partners to protect, maintain, and enhance habitat for special status species.	Maintain and/or increase Greater Sage-Grouse (GRSG) abundance and distribution by conserving, enhancing or restoring the sagebrush ecosystem upon which populations depend in cooperation with other conservation partners.	Maintain and increase current Greater Sage-Grouse (GRSG) abundance and distribution by conserving, enhancing or restoring the sagebrush ecosystem.	Maintain or increase state-wide Greater Sage-Grouse (GRSG) populations by conserving, enhancing or restoring the sagebrush ecosystem upon which populations depend in cooperation with other conservation partners. Maximize benefits to GRSG habitats and populations in priority habitat.	Protect, maintain, improve and enhance Greater Sage-Grouse (GRSG) populations and habitats within the State of Utah established Sage-Grouse Management Areas. (For the purposes of this planning document, identified habitat within the Sage-Grouse Management Areas identified by the State of Utah is priority habitat under Alternative E1.)
Objectives:				
In general, older plans do not include objectives specific to GRSG. More recent plans (those completed after 2000) may include an objective to advance conservation of the GRSG and GRSG habitat, although a mechanism for achieving GRSG specific objectives is infrequently identified.	Designate priority sage-grouse habitats for each Western Association of Fish and Wildlife Agencies (WAFWA) management zone across the current geographic range of sage-grouse that are large enough to stabilize populations in the short term and enhance populations over the long term. Protect priority sage-grouse habitats from anthropogenic disturbances that will reduce distribution or abundance of sage-grouse.	Establish a system of sagebrush reserves to anchor recovery efforts by protecting the highest quality habitats.	Identify and protect priority sage-grouse habitats from anthropogenic and natural disturbances that will reduce distribution or abundance of sage-grouse.	Protect habitat which provides for the year-round life-cycle needs of the GRSG. Sustain the best-of-the-best existing GRSG populations. Perpetuate conditions necessary to ensure recruitment of a continuing population within the aggregate state population. Enhance or improve GRSG habitat that has been impaired or altered through restoration or rehabilitation activities. Eliminate the threats facing the GRSG while balancing the economic and social needs of the residents of Utah. Sustain the best-of-the-best existing sage-grouse populations and increase populations through habitat restoration and rehabilitation.
Recently completed BLM plans include a management action to implement the most recent *UDWR Strategic Management Plan for Sage-Grouse* (UDWR, 2000), the *BLM National Sage Grouse Habitat Conservation Strategy* (BLM, 2004), and	To maintain or increase current populations of GRSG, manage or restore priority habitat so that at least 70% of the land cover provides adequate sagebrush habitat to meet sage-grouse needs.	Restore and maintain sagebrush steppe to its ecological potential in priority, general and restoration GRSG habitat.	Within priority habitat where sagebrush is the current or potential dominant vegetation type or is a primary species within the various states of the ecological site description, maintain or restore vegetation to provide habitat for lekking, nesting, brood rearing,	Enhance an average of 25,000 acres of GRSG habitat in priority habitat annually. Increase the total amount of GRSG habitat acreage within and adjacent to priority habitat by an average of 50,000 acres per

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
recommendations from local sage-grouse working groups, to protect, maintain, enhance, and restore GRSG populations and habitat. A few plans including more detailed habitat objectives that include land cover.			winter, and transition areas. Desired cover percentages and heights for sagebrush, grasses, and forbs in seasonal habitats will follow habitat guidelines from scientific literature (e.g., Connelly et al. 2000, Hagen et al. 2007). Adjustments from the guidelines may be made, but must be based on documented regional variation of habitat characteristics (e.g., sagebrush type, ecological site potential), quantitative data from population and habitat monitoring, and evaluation of local research.	year, through management actions targeting Opportunity Areas.
No similar action.	No similar action.	Increase GRSG populations to a level where they are viable and secure from local extirpation events, and eventually to a level that allows for an annual harvestable surplus.	No similar action.	Sustain an average male lek count of 4,100 males (based on a ten-year rolling average on a minimum of 200 monitored leks) in the priority habitat, and increase the population of males to an average of 5,000 (based on the same ten-year rolling average on a minimum of 200 monitored leks) within the priority habitat. Maintain viable populations within each SGMA. Ensure a path for birds to migrate within SGMAs on a seasonal basis, and ensure a long-term genetic connection between populations as needed. Should the population trends within a population area temporarily or permanently suffer from the effects of factors such as wildfire, management controls in the other SGMAs will be adjusted to achieve the other objectives listed above.
Under current management, there is no designated general habitat.	Quantify and delineate general habitat for capability to provide connectivity among priority areas.	No similar action.	Delineate and manage occupied GRSG habitat outside priority habitat as general habitat. Maintain general habitat for continued use by GRSG and manage according to the decisions identified below and with mitigations identified on a case-by-case basis to address local ecological variations, but allow for mitigating impacts within general habitat through off-site mitigation (e.g., improve or increase habitat in priority habitat or opportunity areas).	GRSG habitat outside priority habitat would not be managed for the conservation of the species. No specific management actions are provided for this habitat.

Within the mapped priority and general habitat there may be areas that lack the principle habitat components necessary for GRSG, including but not limited to rock outcrops, alkaline flats, pinyon/juniper ecological sites, or towns. These areas of non-habitat would be identified during site-specific project review by agency biologists, in discussion with UDWR and other agencies, as appropriate. Decisions associated with priority or general habitat would apply to areas with or ecologically capable of supporting GRSG habitat. The decisions may be excepted if it can be shown that the action would occur in a non-habitat area and the following conditions are met:

access through GRSG habitat to the activity in the non-habitat area occurs only on existing routes, and no new roads, maintenance, or improvements to roads would be required within GRSG habitat,
no activity would be permitted or authorized if it would establish a valid existing right that would subsequently require construction of new routes within GRSG habitat for access,
access to the activity for construction, maintenance, etc. would be required to avoid applicable GRSG sensitive seasons (i.e., breeding, brood-rearing, winter) and time periods (2-hours before sunrise to 2-hours after sunrise near leks during breeding season),
the non-habitat does not provide

Non-habitat areas within mapped priority habitat include lands that do not contribute to the annual life-cycle of sage-grouse. Effort has been made to minimize the amount of non-habitat within priority habitat, but given the topographic, physiographic and land cover features within Utah and the scale and detail of mapping, the inclusion of some non-habitat was unavoidable.

No specific management provisions are proposed for non-habitat areas within priority habitat, except to consider noise and permanent structure stipulations around a lek, and to note that, birds may fly over the non-habitat as they connect to other populations or seasonal habitat areas. (Corridors may or may not be included as habitat within the population area, depending on local conditions, topography, and other factors. Corridors are important to GRSG, but may not require restrictions on human activity. As a general rule, it will be adequate to avoid removal of sagebrush and to minimize development that would create a physical barrier to GRSG movement in these areas.)

The maps contain representations of the boundaries for informational purposes, but are not meant to represent a survey-grade boundary and are not intended to be the final authority for habitat delineation issues. Parties should discuss with the DWR to determine the precise delineation of habitat as part of the coordination process for any</td>

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			important connectivity between habitats, • impacts to adjacent priority habitat areas can be reduced or eliminated (e.g., sound, tall structures). Adjust priority and general habitat boundaries within population area boundaries based on habitat condition, restoration efforts, population data, and discussions with UDWR. Adjustments will be based on the ability to meet GRSG goals and priority habitat objectives. Proposed projects within population areas will consider impacts to GRSG and potential mitigation measures when preparing site-specific planning and environmental compliance documents.	particular development proposal. If in the review of any proposal or other action, differences between the maps and the on-the-ground situation become apparent, the on-the-ground boundaries should control. Refine maps of habitat, non-habitat, and opportunity areas during implementation. Map refinement efforts should be coordinated among federal, state and local agencies, and private landowners who may choose to participate. On-the-ground projects may contribute to this refined mapping for the project area. Priority habitat should be reviewed annually through the coordination efforts of the Public Lands Policy Coordination Office (PLPCO). Review should include, for example, changes in the distribution of disturbance, the increases in habitat through enhancement or improvement, decreases in habitat through wildfire or other events, status of population numbers, and related items. Adjustments to priority habitat will be reviewed every five years, unless large-scale events such as wildfire, and successful annual events, such as habitat enhancement or improvement, necessitate a more frequent adjustment. Adjustments may include expansion or constriction of the external boundaries and a redrawing of the internal boundaries among habitat, non-habitat and opportunity areas.
Recently completed BLM plans include a management action to implement the most recent *UDWR Strategic Management Plan for Sage-Grouse* (UDWR, 2000), the *BLM National Sage Grouse Habitat Conservation Strategy* (BLM, 2004), and recommendations from local sage-grouse working groups, to protect, maintain, enhance, and restore GRSG populations and habitat. A few plans (e.g., Vernal RMP, Uinta LRMP)	Develop quantifiable habitat and population objectives with WAFWA and other conservation partners at the management zone and/or other appropriate scales. Develop a monitoring and adaptive management strategy to track whether these objectives are being met, and allow for revisions to management approaches if they are not.	No similar action.	Increase the amount and functionality of seasonal habitats within priority habitat: • Maintain or increase canopy cover and average patch size of sagebrush in perennial grasslands. As applicable, Utah prairie dog habitat requirements shall be taken into consideration when the maintenance of or increases in sagebrush canopy cover and patch size are considered. • Maintain or increase the amount, condition and connectivity of seasonal	Enhance an average of 25,000 acres of GRSG habitat in priority habitat annually. Increase the total amount of GRSG habitat acreage within and adjacent to priority habitat by an average of 50,000 acres per year, through management actions targeting Opportunity Areas. Manage activities within priority habitat based on a hierarchical protocol that provides as follows:

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
including more detailed habitat objectives such as desired seral sage, percent canopy cover, or height. Other than the abovementioned decision, and basic planning allocations, management actions specific to GRSG are not present in most land use plans.			habitats within, and where applicable, between population areas. • Protect and improve GRSG migration/ movement corridors. • Reduce conifer encroachment within GRSG priority habitat. • Maintain or improve understory (grass, forb) and/or riparian condition within breeding and late brood-rearing habitats. • Reduce the extent of annual grasslands adjacent to priority habitat where objectives are not being met. Develop a monitoring and adaptive management strategy to track whether the habitat objectives are being met, and allow for revisions to management approaches if they are not.	1. Avoidance of disturbance to habitat or birds by an activity is the preferred option; 2. Minimization of the disturbance is desired if the disturbance cannot be avoided in greater sage-grouse habitat, with mitigation for the effects of the minimization decisions; and finally 3. Mitigation of the disturbance from an activity within sage grouse habitat is required if a disturbance cannot be avoided. Manage areas identified as priority habitat to avoid surface disturbance to the greatest degree possible. Coordinate with the DWR when land use which may result in a disturbance is contemplated. All existing uses are explicitly recognized by this alternative and shall not be affected by the implementation of this alternative. The sage-grouse conservation measures identified in the associated NEPA documents for each of these projects would continue to be implemented to protect GRSG and its habitat. Provisions of this plan would not be added to the measures identified each specific project.
No similar action.	Manage priority sage-grouse habitats so that discrete anthropogenic disturbances cover less than 3% of the total sage-grouse habitat regardless of ownership. Anthropogenic features include but are not limited to paved highways, graded gravel roads, transmission lines, substations, wind turbines, oil and gas wells, geothermal wells and associated facilities, pipelines, landfills, homes, and mines. • In priority habitats where the 3% disturbance threshold is already exceeded from any source, no further anthropogenic disturbances will be permitted by the BLM or the Forest	Limit discrete surface disturbance in priority GRSG habitat to one instance per section of GRSG habitat regardless of ownership, with no more than 3% surface disturbance (or, where stipulated, implement the disturbance cap prescribed in the applicable state conservation plan, whichever is more protective). The 3% cap includes existing and all new initial disturbance to the landscape, interim mitigation and restoration efforts notwithstanding. Discrete disturbances include but are not limited to highways, roads, transmission lines, substations, wind turbines, oil and gas wells, heavily grazed areas, range developments, severely burned	Protect priority habitat from fragmentation by anthropogenic disturbances that will reduce distribution or abundance of GRSG by managing priority habitat so that discrete anthropogenic disturbances cover less than 5% of the area within priority habitat used by a population of GRSG, regardless of ownership. While the BLM and FS do not have any regulatory authority to influence the amount of disturbance that will occur on state or private land, when determining whether development is appropriate on Federal lands, disturbances on private and state lands will count towards the 5% disturbance cap.	The provisions of this alternative include, under certain circumstances, a general limit on new permanent disturbance of 5% of habitat on state or federally managed lands within any particular State of Utah Sage-Grouse Management Area. The fundamental purpose of this provision is to limit the effects of a large amount of disturbance to the existing habitat or activities of the GRSG. The cumulative calculation of permanent disturbance in any population area, and specific habitats within a population area, is the aggregate of the various project, land use, or natural event disturbances, as modified by the effects of rehabilitation,

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
	Service until enough habitat has been restored to maintain the area under this threshold (subject to valid existing rights). • In this instance, an additional objective will be designated for the priority area to prioritize and reclaim/restore anthropogenic disturbances so that 3% or less of the total priority habitat area is disturbed within 10 years.	areas, pipelines, landfills, mines, and vegetation treatment that reduces sagebrush cover. As additional research on the 3% cap becomes available, revise this prescription, as necessary, to conserve GRSG. For an area to no longer be considered disturbed under the 3% cap, disturbances need to be restored/reclaimed, where technically and legally feasible (e.g., valid existing rights, split estate lands). The objective of long-term restoration/reclamation is to make areas with disturbance useable by GRSG. For long-term restoration of priority habitat with discrete surface disturbances to be considered successful, GRSG must be documented to have used the area.	When considering implementation-level actions, the 5% disturbance calculation would include all discrete anthropogenic disturbances within a biologically based disturbance calculation area, which must be contained within the priority habitat of a GRSG population area. The disturbance calculation area would be identified during the site-specific project planning/NEPA phase, but the following would be taken into account when determining what would be included/excluded: • Developed agriculture lands should generally be excluded. • Areas of priority habitat that have burned but have not recovered to the extent of being able to provide habitat for GRSG should generally be excluded from the baseline disturbance calculation area for which the 5% is calculated (though the burned areas are still priority habitat), unless the proposed disturbance is within the burned area. (For example, a potential disturbance calculation area is 2,000 acres and does not have any existing disturbance, thereby allowing up to 100 acres of total disturbance. If 1,000 acres of the area burns, the calculation area should be adjusted to exclude the 1,000 burned acres, reducing potential disturbance in the remaining area to 50 acres. If the proposed disturbance is within the burned area, the calculation area should include the entire 2,000 acres, but the disturbance would still be limited to 50 acres.) • Developed private lands that are no longer used by GRSG (e.g., towns, airports, reservoirs) would be excluded. However, other dispersed disturbances would be considered disturbance (e.g., cabins, access roads, community pits, etc.). Discrete disturbances should be	restoration or other mitigation actions. Many of the State of Utah Sage-Grouse Management Areas extend into two or more counties. In such cases, the 5% limitation shall be apportioned to each county in proportion to the total amount of habitat within the larger area. Because of the highly discontinuous nature of GRSG habitat in Utah, each of the State of Utah Sage-Grouse Management Areas is a composite of habitat, non-habitat and opportunity areas. In many cases, it may be difficult to discern whether an existing dispersed use is part of habitat or non-habitat, and thereby make an accurate calculation of the base for the limitation calculation difficult to determine. As part of the implementation of this alternative, such issues should be brought to the interagency review effort coordinated by the PLPCO to insure consistency in interpretation throughout the state. In addition, if it should become sufficiently apparent that an accurate determination of the base for the limitation calculation is not feasible, then the interagency coordination effort may propose and seek approval for an alternative measurement of, or technique to measure, the cumulative effects of disturbance. The area of permanent disturbance is the area within a spatial polygon defined by the outside limits of the actual disturbed area, plus the area outside of this polygon where effects of the project, based on the type of project, could be expected to cause a disturbance to GRSG. Allowances must be made to include the temporal effects of any temporary disturbance, if any such effects are expected. The calculation of the spatial extent of each proposed project or land use, or the area of a

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			consolidated and localized as much as possible, though total areas with discrete disturbances cannot exceed 5% in the identified disturbance calculation area. This could result in small areas where existing and proposed disturbances exceed 5% if total disturbances in the identified disturbance calculation area equals or is less than 5%. Anthropogenic features include but are not limited to paved highways, graded gravel roads, transmission lines, substations, wind turbines, oil and gas wells, geothermal wells and associated facilities, pipelines, landfills, homes, and mines. In priority habitats where the 5% disturbance threshold is already exceeded from any source, no further discrete anthropogenic disturbances will be permitted by the BLM or the Forest Service until enough habitat has been restored to maintain the area under this threshold (subject to valid existing rights). In these areas, reclaim and/or restore discrete anthropogenic disturbances, where technically and legally feasible, so that 5% or less of the disturbance calculation area is disturbed. Restoration/Reclamation of Surface Disturbances: An area with surface disturbance is not excluded from the 5% until it has been successfully reclaimed (short-term) and restored (long-term). The objective of long-term restoration/reclamation in priority habitat is to provide for the needs of GRSG. Providing habitat could include, but is not limited to restoring landforms and vegetative communities to reflect the potential for the given ecological site, as well as restoring hydrologic systems and other wildlife habitat components. To ensure that the long-term objective will be reached through human and natural processes, actions will be taken to	natural event, such as wildfire, to be employed in this calculation, is defined as part of the definition of disturbance. The base upon which this calculation is made may be increased through successful rehabilitation or restoration of habitat, or other mitigation actions as appropriate.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			ensure standards are met for soil site stability, hydrologic function, and integrity of the biotic communities. Specific restoration/reclamation objectives will be identified through the NEPA process, but for final restoration/reclamation to be judged successful within priority habitat, the following general objectives must be met: • Areas where the landform has been altered (e.g., well pads, production facilities, roads, pipelines, utility corridors, etc.) have been re-contoured to blend in with adjacent undisturbed areas, approximating the original landform. • A self-sustaining, vigorous, diverse, native (or otherwise approved) plant community is established on the site, with a density sufficient to control erosion and invasive plants (e.g., cheatgrass, non-native thistles, knapweeds) and can reestablish wildlife habitat and/or forage production. At a minimum, the established plant community will consist of species included in the seed mix and/or desirable species occurring in the surrounding natural vegetation. Permanent vegetative cover will be determined successful when the percent cover of desirable perennial species is consistent with GRSG habitat objectives and the ecological site description. Monitoring for restoration must extend for a reasonable time frame, generally for 5 years, but considering ecological site potential and environmental conditions (e.g., drought). At the end of the initial monitoring period, the ID team would determine if the site has potential for further restoration/reclamation beyond the 5 years, based on site potential and environmental conditions. Plants must be resilient as evidenced by well-	

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			developed root systems and flowers; shrubs must be well established and not comprised mainly of seedlings that may not survive until the following year. • Erosion features are equal to or less than surrounding area and erosion control is sufficient so that water naturally infiltrates into the soil and gullying, headcutting, slumping, and deep or excessive rilling (greater than 3 inches) is not observed. • The site is free of State- or county-listed noxious weeds, anthropogenic debris and equipment, and contaminated soil. [Example of site-specific requirement: Given that cheatgrass is common in portions of the Project Area, it may not be possible to totally eliminate this invasive species from the reclaimed area.] • Final reclamation success and approval for final abandonment (for disturbances caused by permitted activities) will be subject to an interdisciplinary review of available monitoring data and final monitoring reports. An interdisciplinary team consisting of, at a minimum, a wildlife biologist, a rangeland management specialist, and another resource specialist (e.g., natural resources specialist) will evaluate the monitoring plan (from the NEPA or POD documents), and review the regular and final monitoring reports and provide the Authorized Officer with a recommendation as to whether or not objectives have been met. For non-permitted activities (e.g., reclamation of user created roads), successful restoration/reclamation occurs when the area meets the four criteria noted above, as determined by an interdisciplinary review of inventory/monitoring information.	
Most LUPs include a management action	No similar action.	No similar action.	Do not allow discrete anthropogenic	Within priority habitat in seasonal GRSG

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
that prohibits surface disturbing or other disruptive within GRSG breeding and nesting habitat within a certain distance and between certain dates. The protect buffers around leks vary from 0.5 miles and 3.1 miles. In general, recently completed plans include a larger protective buffer. Recently completed plans also include a management action that prohibits surface disturbing activity or disruptive activities during certain dates in winter habitat.			disturbances or activities disruptive to GRSG (including scheduled maintenance activities) within priority habitat in seasonal GRSG habitats during the corresponding seasonal use periods: • In breeding and nesting habitat from Feb 15 – Jun 15 • In brood rearing habitat from Apr 15 – Jul 15 • In winter habitat from Nov 15 – Mar15 In addition, the following use restrictions would be applied to discretionary activities within priority habitat, as applicable: • the activity meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); • the activity meets permanent (structure persists through subsequent breeding season) tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography); and • environmental compliance documents associated with the activity consider how to limit habitat fragmentation. Exceptions to the seasonal restrictions and use restrictions could be granted by the Field Manager/Forest Supervisor under the following conditions: • if surveys determine that the lek is not active that year (based on DWR lek survey protocol), and the proposed activity will not take place beyond the	habitats during the corresponding seasonal use periods, avoid activities (construction, vehicle noise, etc.) that will disturb GRSG use of the seasonal area by employing seasonal stipulations as follows: • In leks (for lek attendance or breeding) from Feb 15 – May 15. • In nesting or brood-rearing areas from Apr 1 – Aug 15. • In winter habitat from Nov 15 – Mar 15. Specific time and distance determinations for all these seasonal stipulations would be based on site-specific conditions for all these seasonal stipulations, in coordination with the local UDWR biologist. In addition, the following management provisions would be applied to the applicable areas within priority GRSG habitat: Leks • Avoid disturbance within this area, if possible. Project proponents must demonstrate why avoidance is not possible. • If avoidance is not possible, use minimization as appropriate to the area. • If minimization is not sufficient, mitigation is required (see mitigation section below). • New permanent disturbance, including structures, fences, and buildings, should not be located within the lek itself. • No permanent disturbance within one mile of the lek, unless it is not visible to the sage-grouse using the lek. • Fences should not be located on or adjacent to leks where bird collisions would be expected to occur. If required, the construction

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			season being excepted; • if surveys determine that the lek is no longer occupied, and the proposed activity will not take place beyond the season being excepted; • if the project plan and NEPA document demonstrate that impacts from the proposed action can be adequately mitigated; • if the potential short-term impacts from the action are off-set by long-term improvement to the quantity or quality of habitat (e.g., seedings, juniper reduction). Additionally, the Field Manager/Forest Supervisor may modify the seasonal restrictions and use restrictions under the following conditions: • if portions of the area do not include habitat (lacking the principle habitat components of GRSG habitat) or are outside the current defined area, as determined by the BLM/FS in discussion with the UDWR, and indirect impacts would be mitigated; • if documented local variations (e.g., higher/lower elevations) or annual climactic fluctuations (e.g., early/late spring, long and/or heavy winter) reflect a need to change the given dates in order to better protect when GRSG use a given area, and the proposed activity will not take place beyond the season being excepted.	of any fences near the lek should follow the standards identified in the NRCS fence collision risk tool (NRCS/CEAP Conservation Insight Publication “Applying the Sage Grouse Fence Collision Risk Tool to Reduce Bird Strikes”). • A disturbance outside the lek should not produce noise which rises more than 10 db above the background level at the edge of the lek during breeding season. • Implement time-of-day stipulations during the season when the lek is occupied (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise). <u>Nesting and Brood-Rearing Areas</u> • Avoid disturbance within these areas, if possible. Project proponents must demonstrate why avoidance is not possible. • If avoidance is not possible, use minimization as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic features to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation to provide food and shelter). • If minimization is not sufficient, mitigation is required (see mitigation section below). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting habitat within the population area’s priority habitat. • Employ noise stipulations which allow no more than 10 db rise above ambient noise levels at the edge of the lek.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
				Winter Habitat • Avoid disturbance within the area, if possible. Project proponents must demonstrate why avoidance is not possible. • If avoidance is not possible, minimize as appropriate to the area. Minimization provisions include, for example, the location of development in habitat of least importance, of by locating development to take advantage of topographic screening. • If minimization is not sufficient, mitigation is required (see mitigation section below). • Cumulative new permanent disturbance should not exceed 5% of the surface area of winter habitat within the population area's priority habitat. • Manage the area to maintain maximum amount of sagebrush, especially tall sagebrush, which would be available to greater sage-grouse above snow during a severe winter. Tall sagebrush is capable of standing above heavier than normal snowfall. • Sagebrush treatment projects within this area need pre-approval by the appropriate regulatory agency in coordination with the DWR. Sagebrush treatment projects within winter habitat should maintain 80% of the available habitat as tall sagebrush; 20% of the habitat can be managed for younger age classes, if appropriate. Other Habitats • Avoid disturbance in the area if possible. Project proponents must demonstrate why avoidance is not possible.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
				- If avoidance is not possible, minimize as appropriate to the area. Minimization provisions include, for example, the location of development in habitat of least importance, or by locating development to take advantage of topographic screening. - If minimization is not sufficient, mitigation is required (see mitigation section below). - Mitigation must produce lands capable of supporting GRSG as habitat before the proposed disturbance occurs, though birds do not need to be using the mitigated area. The proponent of the disturbance must demonstrate that the mitigation conditions have been met. - Cumulative new permanent disturbance should not exceed 5% of the surface area of other habitat within the population area's priority habitat. - Manage the lands to avoid barriers to migration, if applicable.
No similar action.	No similar action.	No similar action.	The BLM will allow other agencies to jointly manage predator populations within their various authorities, and will not take any predator population measures unilaterally. Apply standards for development activities within priority and general habitat to reduce opportunities for GRSG predators, such as limiting food sources (trash reduction), nesting, cover, or perches. Apply actions specific to the predators of concern for the given GRSG population (e.g., ravens, red fox, badgers, raccoons, raptors).	Predation control and management should be managed by Wildlife Services, Department of Agriculture and Food, in coordination with the Division of Wildlife Resources. Eliminate or minimize external food sources for corvids, particularly dumps, waste transfer facilities, and road kill. Apply habitat management practices (e.g. grazing management, vegetation treatments) that decrease the effectiveness of predators.
Under current management plans, there is no designated general habitat.	Conserve, enhance or restore sage-grouse general habitat and connectivity to promote movement and genetic diversity, with emphasis on those habitats occupied by	No similar action.	Conserve GRSG general habitat to maintain existing habitat and maintain connectivity between populations, or if necessary, to provide for opportunities to improve priority	GRSG habitat outside priority habitat would not be managed for the conservation of the species. No specific management actions are provided for this habitat.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
	GRSG.		habitat and opportunity areas. Do not allow discrete anthropogenic disturbances or activities disruptive to GRSG (including scheduled maintenance activities) within general habitat in seasonal GRSG habitats during the corresponding seasonal use periods: • In breeding and nesting habitat from Feb 15 – Jun 15 • In brood rearing habitat from Apr 15 – Jul 15 • In winter habitat from Nov 15 – Mar15 In addition, the following use restrictions will be applied to discretionary activities within general habitat, as applicable: • the activity meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); • the activity meets permanent (structure persists through subsequent breeding season) tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography); and • environmental compliance documents associated with the activity consider how to limit habitat fragmentation. Exceptions to the seasonal restrictions and use restrictions could be granted Field Manager/Forest Supervisor under the following conditions: • if surveys determine that the lek is not	

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			active that year (based on DWR lek survey protocol), and the proposed activity will not take place beyond the season being excepted; • if surveys determine that the lek is no longer occupied, and the proposed activity will not take place beyond the season being excepted; • if the project plan and NEPA document demonstrate that impacts from the proposed action can be adequately mitigated; • if the potential short-term impacts from the action are off-set by long-term improvement to the quantity or quality of habitat (e.g., seedings, juniper reduction). Additionally, the Field Manager/Forest Supervisor may modify the seasonal restrictions and use restrictions under the following conditions: • if portions of the area do not include habitat (lacking the principle habitat components of GRSG habitat) or are outside the current defined area, as determined by the BLM/FS in discussion with the UDWR, and indirect impacts would be mitigated; • if documented local variations (e.g., higher/lower elevations) or annual climactic fluctuations (e.g., early/late spring, long and/or heavy winter) reflect a need to change the given dates in order to better protect when GRSG use a given area, and the proposed activity will not take place beyond the season being excepted. Application of the above use restrictions and meeting objectives within general habitat may be waived by the Field Manager/Forest Supervisor if off-site mitigation is successfully completed in priority habitat or opportunity	

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			areas, following discussion with BLM/FS and UDWR. Even in situations where use restrictions are waived in general habitat, to avoid direct disturbance and/or mortality of birds, disturbances will not be approved during the sensitive seasons.	
No opportunity areas identified in current management plans. Most LUPs contain objectives for maintaining improving, or restoring sagebrush plant communities. The level of detail varies depending on the age of the land use plan. All LUPs address vegetation treatments for improvement of wildlife habitat overall or to provide increased forage for wildlife, livestock, and wild horses and burros. Recent plans may include management actions that purposely restore or enhance sage-grouse habitat.	Assess general sage-grouse habitats to determine potential to replace lost priority habitat caused by perturbations and/or disturbances and provide connectivity between priority areas. • These habitats should be given some priority over other general GRSG habitats that provide marginal or substandard GRSG habitat. • Restore historical habitat functionality to support GRSG populations guided by objectives to maintain or enhance connectivity. • Enhance general GRSG habitat such that population declines in one area are replaced elsewhere within the habitat.	Identify GRSG restoration habitat and prioritize areas for implementation of restoration projects based on environmental variables that improve chances for project success. Restoration habitat is degraded or fragmented habitat that is currently unoccupied by GRSG, but might be useful to the species if restored to its potential natural community. Prioritize areas for restoration based on their potential importance to GRSG and the likelihood of successfully restoring sagebrush communities. Passive restoration is preferred for restoring these areas over active restoration methods.	Opportunity areas are areas adjacent to priority habitat that currently do not contribute to the life cycle of GRSG but that offer the best potential for creating additional habitat through restoration or rehabilitation. These areas will be delineated at the Field Office level, in discussion with the UDWR, to account for regional variation. Land uses (e.g. minerals, OHV use, realty) within opportunity areas will be managed in such a manner as to maintain and improve habitat conditions. When assessing authorization of actions in opportunity areas, consider and analyze measures that would reduce or eliminate direct, indirect, and cumulative effects from infrastructure or development. Manage opportunity areas so as not to preclude future mitigation options. Additional management and vegetation treatments may also be applied to opportunity areas to maintain their potential to meet GRSG habitat objectives and provide additional GRSG habitat. Discrete anthropogenic disturbances should not be authorized in areas that have been previously treated with the intent of improving or creating new GRSG habitat. Off-site mitigation for actions or authorizations within general habitat could occur in these areas. When and if opportunity areas reach the landscape sagebrush cover objectives for priority habitat and monitoring shows that GRSG are using the site, they will be added to priority habitat, in discussion with UDWR. Identify opportunity areas to determine where	Opportunity areas are those portions of a State of Utah Sage-Grouse Management Areas that currently do not contribute to the life cycle of sage-grouse but are areas where restoration or rehabilitation efforts can provide additional habitat when linked to existing sage-grouse populations. Opportunity areas may be transformed into either habitat or non-habitat based upon natural events or management choices, and may be used to mitigate disturbance within habitat as appropriate. Opportunity areas may be employed to meet improvement, restoration or rehabilitation goals, or as mitigation areas for disturbance within habitat. If this occurs, an opportunity area may become habitat and be managed as such, especially as part of the calculation for disturbance limitations. Alternatively, opportunity areas may be employed as the site for disturbances which are diverted from habitat, or other economic proposals not involving habitat, and therefore become non-habitat. In either event, boundaries of the priority habitat, or the land types within, should be adjusted accordingly.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			habitat could be restored and/or to provide connectivity between priority areas. Where ecologically applicable, restore historical habitat functionality to support GRSG populations guided by objectives to maintain or enhance connectivity.	
No similar action.	No similar action.	No similar action.	The use restrictions, stipulations, seasonal constraints, etc. included for GRSG habitat are intended to be the initial and not the entirety of the protections. Project proponents and BLM/FS offices should develop additional mitigation measures at the project level to address the site-specific issues and impacts associated with local effects of specific projects. The mitigation actions developed at the project level must be based on current scientific recommendations. Mitigation actions could include some or all of the following: • avoiding the impact altogether by not taking a certain action or parts of an action, • minimizing impacts by limiting the degree of magnitude of the action and its implementation, • repairing, rehabilitation, or restoring the affected area, • reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action, or • compensating for the impact by replacing or providing substitute resources or environments. While beneficial to the understanding of the species, money for research or monitoring is not mitigation for impacts to habitat, as it does not offset the impacts to the birds. Mitigation includes actions that are designed to create new habitat or ameliorate disturbances by the creation of or protection of other habitat, either within the same	Mitigation actions are designed to create new habitat or ameliorate disturbances by the creation of or protection of other habitat. Mitigation for a disturbance must be shown to be effective in the time-frame of the activity, not at some future date. Effective mitigation does not require that birds are immediately present using the land, only that the habitat is capable of supporting birds as part of their yearly life-cycle. However mitigation should be performed in areas which have the highest likelihood of occupation by the species. The amount of mitigation, if required, should be calculated based on the effects generated within priority habitat inside a population area. Prioritize areas for habitat improvement to make best use of mitigation funds. Mitigation for a disturbance should not necessarily be tied to reclamation efforts at the actual site of the disturbance. Mitigation may occur locally, elsewhere in the same population area, or in another population area, based on the location, which offers greater potential for enhancing GRSG populations, so long as the location of the mitigation does not result in the loss of resiliency, representation or redundancy of the species in Utah. The Public Lands Policy Coordination Office, with assistance from the Division of Wildlife Resources, Bureau of Land Management, Forest Service, Natural Resources Conservation Service, Department of Natural Resources, Department of Agriculture and Food, and other entities, shall coordinate and oversee the creation and operation of a Greater

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			population or in other areas of the State. The preference is that mitigation for impacts within priority habitat will occur within the same population area of the impact. For off-site mitigation associated with mitigation of actions within general habitat, project proponents will work closely with the BLM and DWR to identify priority habitat or opportunity areas where off-site mitigation could occur. The ratio for mitigation, either onsite or off-site, will be set at the project level and will depend on the type and quality of the habitat being affected and the nature of the action affecting the habitat. While mitigative exchange values will not be set in this planning process, they need to follow the guiding principles of not trading short-term gains for long-term losses. For compensatory mitigation (either onsite or off-site), actions should consider the type and quality of habitat being impacted by a project and the proportional impact a project will have the population. In turn, proposed mitigation actions should address the same type and quality of habitat that may be impacted (e.g., breeding, nesting, brood-rearing, wintering, transitional habitats). The value of the habitat may increase if the birds use the area for more than one time of the year, if it is relatively higher in quality, or if the type of habitat is a limiting factor for the local population. Similarly, mitigation should account for the proportional impact a project will have to a specific population (if a given project impacts 1% of wintering habitat versus 30% of the wintering habitat). Mitigation that trades impacts to areas that are meeting habitat objectives with creation of areas that do not meet habitat objectives, even in high offsetting ratios, will not be accepted. Mitigation does not require that birds are immediately present using the land, only that the habitat meets habitat objectives	Sage-Grouse Mitigation Bank in Utah. The operation of this Mitigation Bank will seek to rehabilitate or restore lands as habitat prior to need, as well as coordinate the mitigation for development or other effects upon the habitat of the GRSG. Once operational, contributions to the Bank will be welcome. Mitigation may be required in nesting and brood-rearing areas, winter habitat, and other priority habitat. Examples of successful mitigation for various GRSG habitat types include the following: Leks • Removal of trees on or adjacent to the lek. • Removal or marking of fences on or adjacent to the lek. • Employment of off-site mitigation (e.g., use of the concept of a mitigation bank, if appropriate). Nesting and Brood-Rearing Areas • Removal of trees to no more than 5% cover (the close to 0% the better) and maintenance of at least 10% sagebrush cover. • Maintain forb cover greater than 10% and greater than 10% grass cover during nesting and brood-rearing season. • Maintain or improve wet meadows, when present. • Installation of green-strips or firebreaks to protect existing nesting habitat. • Employment of off-site mitigation (e.g., use of the concept of a mitigation bank, if appropriate). • Mitigation should be calculated at a minimum of a 4:1 ratio starting with the first acre disturbed. Winter Habitat • Removal of trees to less than 5% cover (the closer to 0% the better) and maintenance of at least 10% sagebrush

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			for grasses and forbs. However mitigation should be performed in areas which have the highest likelihood of occupation by the species.	cover. • Installation of green-strips or firebreaks to protect existing winter habitat. • Employment of off-site mitigation (e.g., use of the concept of a mitigation bank, if appropriate). • Mitigation should be calculated at a 4:1 ratio starting with the first acre disturbed. <u>Other Habitats</u> • Removal of trees to less than 5% cover and maintenance of at least 10% sage brush cover. • Maintain forb cover greater than 10% and grass cover greater than 10% during nesting/brood-rearing season. • Maintain or improve wet meadows, when present. • Installation of green-strips or firebreaks to protect existing habitat. • Employment of off-site mitigation (e.g., use of the concept of a mitigation bank, if appropriate). • Mitigation should be calculated at a 1:1 ratio with first acre disturbed. Mitigation must produce lands capable of supporting GRSG habitat before the proposed disturbance occurs, though birds do not need to be using the mitigated area. The proponent of the disturbance must demonstrate that the conditions have been met. Before mitigated areas are considered to be habitat within a priority habitat area, a preponderance of the evidence must indicate that GRSG are occupying the mitigated area. Habitat altered by fire shall not be removed from priority habitat until rehabilitation or restoration of the burned areas is determined to be unsuccessful or not feasible.

No similar action.	All ROWs in Priority Habitat Make priority sage-grouse habitat areas exclusion areas for new ROWs permits.	All ROWs in Priority Habitat Occupied sage-grouse habitat areas shall be exclusion areas for new ROWs permits.	Above-Ground Linear ROWs (e.g., transmission lines, distribution lines, telephone lines): Priority habitat within 4 miles of an occupied lek, if the lek is located within priority habitat, would be designated as an exclusion area for new above-ground linear ROWs. Priority habitat beyond 4 miles of an	All ROWs in Priority Habitat Management stipulations and conditions should focus on mitigating direct disturbance during construction. Should new research demonstrate indirect impacts to greater sage-grouse production, additional mitigation measures may be required. Priority habitat would be designated as an

Table 2-2 – Description of Alternatives A, B, C$_1$, C$_2$, D, and E$_1$

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			occupied lek, if the lek is located within priority habitat, would be designated as an avoidance area for new above-ground linear ROWs. Development within the avoidance areas could occur if: • the GRSG population trend within the disturbance calculation area is stable; • the development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); • the development meets tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography); • the development does not occur during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter); and • the development does not exceed the 5% disturbance limit. Areas within 1 mile of an occupied lek, if the lek is located within priority habitat, whether the area is in occupied or unoccupied GRSG habitat, would be designated as an exclusion area for new above-ground linear ROWs. Areas outside priority habitat and within 4 miles of an occupied lek, if the lek is located within priority habitat, would be designated as an avoidance area for new ROWs. Development within the avoidance areas could occur if: • the GRSG population trend within the disturbance calculation area is stable;	avoidance area for new ROWs. Apply stipulations as follows, as well as best management practices accepted by industry and state and federal agencies: • New permanent disturbance, including structures, fences, and buildings, should not be located within the occupied lek itself. • No permanent disturbance within 1 mile of an occupied lek, unless it is not visible to the sage-grouse using the lek. • A disturbance outside the lek should not produce noise which rises more than 10 db above the ambient (background) level at the edge of the lek during breeding season. • Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise) • Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats: o On leks from Feb 15 – May 15 to avoid activities that will disturb lek attendance or breeding. o In nesting and brood-rearing areas from Apr 1 – Aug 15. o In winter habitat from Nov 15 – Mar 15. o Specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist. • Avoid disturbance within priority habitat, if possible. Project proponents must demonstrate why avoidance is not possible. • If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the

Table 2-2 – Description of Alternatives A, B, C$_1$, C$_2$, D, and E$_1$

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			• the development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); and • the development meets tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography). Above-Ground Site-Type ROWs (not wind/solar) (e.g., communication towers, cell towers): Areas within 1 mile of an occupied lek that is located within priority habitat, whether the area is in occupied or unoccupied GRSG habitat, would be designated as an exclusion area for new above-ground site-type ROWs (excluding wind or solar). Priority habitat beyond 1 mile of an occupied lek, if the lek is located within priority habitat, would be designated as an avoidance area for new above-ground site-type ROWs. Development within the avoidance areas could occur if: • the development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); • the development meets tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by	least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area's priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable. Engage in reclamation efforts as projects are completed. Recognize that stipulations for other species (e.g. raptors) may impede the ability to effectively reclaim disturbed areas, and remove those barriers in order to achieve immediate and effective reclamation, if otherwise allowable by law.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography); • the development does not occur during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter); and • the development does not exceed the 5% disturbance limit. Exceptions to the avoidance area could be granted by the Field Manager/Forest Supervisor if the new ROW were constructed entirely within the footprint of an existing site-type ROW, if the new development meets noise restrictions, and if the development does not occur during sensitive seasonal periods. Underground/On-Ground ROWs (e.g., buried and surface pipelines, roads) Priority habitat would be designated as an avoidance area for new permanent underground and on-ground linear ROWs. Development within the avoidance areas could occur if: • the GRSG population trend within the disturbance calculation area is stable; • the long-term development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); • there are no above ground structures or operational facilities associated with the ROW; • the construction of the development does not occur during sensitive seasonal periods (i.e., breeding and	

Table 2-2 – Description of Alternatives A, B, C$_1$, C$_2$, D, and E$_1$

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			nesting, brood rearing, winter); and • the surface disturbance from the development does not exceed the 5% disturbance limit.	
No similar action.	Consider the following exceptions: • Within designated ROW corridors encumbered by existing ROW authorizations: new ROWs may be co-located only if the entire footprint of the proposed project (including construction and staging), can be completed within the existing disturbance associated with the authorized ROWs. • Subject to valid, existing rights: where new ROWs associated with valid existing rights are required, co-locate new ROWs within existing ROWs or where it best minimizes GRSG impacts. Use existing roads, or realignments as described above, to access valid existing rights that are not yet developed. If valid existing rights cannot be accessed via existing roads, then build any new road constructed to the absolute minimum standard necessary, and add the surface disturbance to the total disturbance in the priority area. If that disturbance exceeds 3% for that area, then make additional effective mitigation necessary to offset the resulting loss of GRSG.	Consider the following exceptions: • Subject to valid, existing rights: where new ROWs associated with valid existing rights are required, co-locate new ROWs within existing ROWs or where it best minimizes GRSG impacts. Use existing roads, or realignments as described above, to access valid existing rights that are not yet developed. If valid existing rights cannot be accessed via existing roads, then build any new road constructed to the absolute minimum standard necessary, and add the surface disturbance to the total disturbance in the priority area. If that disturbance exceeds 3% for that area, then make additional mitigation that has been demonstrated to be effective to offset the resulting loss of sage-grouse habitat.	The BLM may grant new FLPMA Title 5 ROWs for existing roads within GRSG priority habitat so long as the road would remain in the existing condition and same physical location (as is, where is), unless a realignment would benefit GRSG. Seasonal restrictions (breeding and nesting, brood rearing, winter) would be placed on maintenance of new Title 5 ROWs to minimize disruption of GRSG, subject to the exceptions noted in the SSS section. New above-ground linear ROWs within exclusion areas in priority habitat are limited to location in designated corridors. Where new ROWs associated with valid existing rights are required within priority habitat, co-locate new ROWs as close as technically possible to existing ROWs or where it best minimizes GRSG impacts. Use existing roads, or realignments as described above, to access valid existing rights within priority habitat that are not yet developed. If valid existing rights cannot be accessed via existing roads, then build any new road constructed to the absolute minimum standard necessary, and add the surface disturbance to the total disturbance in the priority area. If that disturbance exceeds 5% for that area, then make additional effective mitigation necessary to offset the resulting loss of GRSG.	For electrical transmission lines, and where feasible and consistent with federally required electrical separation standards, site new linear transmission features in existing corridors, or at a minimum, in concert with existing linear features in GRSG habitat. Siting linear features accordingly shall be deemed to be mitigation for the siting of that linear feature. Mitigation for the direct effects of construction is still required.
Designate ROW corridors within GRSG habitat as identified on Map 2.X (177,700 acres)	Designate ROW corridors within GRSG priority habitat as identified on Map 2.X (130,200 acres). Undesignate ROW corridors that currently do not have any ROWs authorized in them (47,500 acres).	Undesignate all designated ROW corridors within GRSG occupied habitat as identified on Map 2.X. New ROWs are excluded from GRSG occupied habitat.	Designate ROW corridors within GRSG priority habitat as identified on Map 2.X: • Retain 89,400 acres of existing designated ROW corridor • Retain 48,400 acres of existing designated ROW corridor, but stipulate new developments be limited to	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			subsurface use only - Undesignate 39,700 acres of existing designated ROW corridor - Designate 31,700 acres as new designated ROW corridor While new ROWs can be developed within designated ROW corridors, the preference is to avoid GRSG habitat altogether. If this is not possible, development will be limited to the designated corridors. New designated corridors within priority habitat will not exceed 3,500 feet in width. New above-ground ROWs within designated corridors will be constructed as close as technically feasible to existing above-ground lines to limit disturbance to the smallest footprint.	
No similar action.	Evaluate and take advantage of opportunities, to remove, bury, or modify existing power lines within priority sage-grouse habitat areas.	Same as Alternative B.	During renewal, amendment, or reauthorization of existing permits, evaluate and where appropriate, work with existing ROW holders to modify existing power lines within priority sage-grouse habitat areas to mitigate impacts of existing powerlines, taking into account the potential impacts of the mitigation (relocation, burying, etc.) with the existing impacts of the line.	No similar action.
All LUPs include management actions that require reclamation/restoration of disturbed areas that are no longer used in support of authorized actions.	Where existing leases or ROWs have had some level of development (road, fence, well, etc.) and are no longer in use, reclaim the site by removing these features and restoring the habitat.	Same as Alternative B.	Same as Alternative B.	No similar action.
<u>No similar action.</u>	<u>All ROWs</u>: Make general sage-grouse habitat areas “avoidance areas” for new ROWs.	No similar action.	<u>All ROWs</u>: General habitat within 1 mile of an occupied lek, if the lek is located within general habitat, would be designated as an avoidance area for new ROWs. Development within the avoidance areas could occur if: - the development (during construction and after) meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to	GRSG habitat outside priority habitat would not be managed for the conservation of the species. No specific management actions are provided for this habitat.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			two hours after sunrise and sunset during breeding season); • the structures remaining after development meet tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography); and • the development does not occur during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter). General habitat within and beyond the 1.0 mile avoidance area would require discussion with UDWR during project implementation, and implementation of best management practices (e.g., anti-perch devices for raptors, etc.). The avoidance area could be waived, except for the seasonal restrictions, if off-site mitigation coordinated with BLM/FS and UDWR is successfully completed in priority habitat or opportunity areas.	
Most LUPs include a management action that encourages placement of new ROWs in designated utility corridors and/or co-location of new ROWs adjacent to existing ROWs.	Where new ROWs are necessary in general habitat, co-locate new ROWs within existing ROWs where possible.	No similar action.	Same as Alternative B.	GRSG habitat outside priority habitat would not be managed for the conservation of the species. No specific management actions are provided for this habitat.
Land Tenure: Make approximately 24,400 acres of land within in sage grouse habitat available for FLPMA Section 203 sale (Figure X.X). In order to be considered for any form of land tenure adjustment, all lands not specifically identified for disposal must meet criteria included in FLPMA and in each LUP.	Land Tenure: Retain public ownership of priority GRSG habitat. Consider exceptions where there is mixed ownership, and land exchanges would allow for additional or more contiguous federal ownership patterns within the priority GRSG habitat area. Under priority GRSG habitat areas with minority federal ownership, include an	Land Tenure: Same as Alternative B, without exceptions for disposal to consolidate ownership that would be beneficial to GRSG. No BLM or FS lands within occupied habitat would be available for land tenure adjustments.	Land Tenure: Same as Alternative B, so long as potential land exchanges benefit GRSG, and do not negatively impact other federally listed threatened or endangered species. Approximately 5,540 acres of general habitat would still be available for disposal through FLMPA Section 203 sale (Figure X.X).	Land Tenure: No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
	additional, effective mitigation agreement for any disposal of federal land. As a final preservation measure consideration should be given to pursuing a permanent conservation easement. Approximately 5,490 acres of general habitat would still be available for disposal through FLMPA Section 203 sale (Figure X.X).			
Most LUPs include a management action that allows for acquisition of lands that have important resource values including crucial wildlife habitat and land tenure adjustments to improve the manageability of public lands.	Where suitable conservation actions cannot be achieved in priority habitat, seek to acquire state and private lands with intact federal mineral estate by donation, purchase or exchange in order to best conserve, enhance or restore sage-grouse habitat.	Same as Alternative B.	Same as Alternative B.	No similar action.
Withdrawal: Propose approximately 498,700 acres of federal lands and non-federal lands with federal mineral interests within GRSG habitat for mineral withdrawal.	Withdrawal: Propose federal lands and non-federal lands with federal mineral interests within priority GRSG habitat areas for mineral withdrawal (3,650,900 acres of new proposed withdrawals).	Withdrawal: Propose federal lands and non-federal lands with federal mineral interests within occupied GRSG habitat for mineral withdrawal (4,008,580 acres).	Withdrawal: Do not propose additional federal lands or non-federal lands with federal mineral interests within priority or general GRSG habitat for locatable mineral withdrawal.	Withdrawal: Do not propose additional federal lands or non-federal lands with federal mineral interests within priority or general GRSG habitat for locatable mineral withdrawal.
No similar action.	In priority habitat, do not recommend withdrawal proposals not associated with mineral activity unless the land management is consistent with GRSG conservation measures. (For example; in a proposed withdrawal for a military training range buffer area, manage the buffer area with GRSG conservation measures.)	Do not approve withdrawal proposals not associated with mineral activity unless the land management is consistent with sage-grouse conservation measures. (For example, in a proposed withdrawal for a military training range buffer area, manage the buffer area with sage-grouse conservation measures that have been demonstrated to be effective, or according to the joint BLM-DOD management.)	No similar action.	No similar action.
Wind Energy Development				
Evaluate wind energy development on a case-by-case basis, subject to other ROW management decisions. Manage ROWs in GRSG habitat as follows: • Open to new ROWs: 3,219,000 acres • New ROWs Avoided: 67,200 acres • New ROWs Excluded: 27,600 acres Manage ROWs outside of GRSG habitat but in population areas as follows: • Open to new ROWs: 2,344,400 acres	Make priority GRSG habitat areas exclusion areas for new leases or ROWs permits (2,781,700 acres).	Do not site wind energy development in occupied GRSG habitat (3,313,800 acres).	Priority habitat would be designated as exclusion areas for wind energy development (2,760,300 acres). Manage wind energy development in GRSG habitat as follows: • Open – 522,500 acres • Avoided – 9,400 acres • Excluded – 2,781,900 acres Manage wind energy development outside of GRSG habitat but in population areas as	Priority habitat would be available for wind energy development, though it would be designated as an avoidance area for wind energy development. Manage wind energy development in GRSG habitat as follows: • Open to new ROWs: 632,200 acres • New ROWs Avoided: 2,654,000 acres • New ROWs Excluded: 27,600 acres Manage wind energy development outside of

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
• New ROWs Avoided: 50,800 acres • New ROWs Excluded: 74,900 acres			follows: • Open – 1,925,200 acres • Avoided – 462,500 acres • Excluded – 82,400 acres Areas outside priority habitat and within 4 miles of an occupied lek located within priority habitat would be designated as an avoidance area for wind energy development. Development within the avoidance areas can occur if: • the development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); and • the development meets tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography); Exclude wind energy development within 1.0 mile (including priority, general, or non-habitat areas) of occupied leks located in either priority or general habitat. The exclusion could be waived outside of priority habitat if applicable seasonal restrictions are implemented (breeding and nesting, brood rearing, winter) and if off-site mitigation coordinated with BLM/FS and UDWR is successfully completed in priority or opportunity habitat. Development within general habitat beyond the 1.0 mile exclusion area would require	GRSG habitat but in population areas as follows: • Open to new ROWs: 2,292,000 acres • New ROWs Avoided: 103,200 acres • New ROWs Excluded: 74,900 acres Apply stipulations as follows, as well as best management practices accepted by industry and state and federal agencies: • New permanent disturbance, including structures, fences, and buildings, should not be located within the occupied lek itself. • No permanent disturbance within 1 mile of an occupied lek, unless it is not visible to the sage-grouse using the lek. • A disturbance outside the lek should not produce noise which rises more than 10 db above the ambient (background) level at the edge of the lek during breeding season. • Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise) • Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats: o On leks from Feb 15 – May 15 to avoid activities that will disturb lek attendance or breeding. o In nesting and brood-rearing areas from Apr 1 – Aug 15. o In winter habitat from Nov 15 – Mar 15. o Specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist. • Avoid disturbance within priority habitat, if possible. Project proponents must demonstrate why avoidance is not

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			discussion with UDWR during project implementation, and implementation of best management practices, including potential off-site mitigation in priority habitat or opportunity areas.	possible. • If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area's priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable. Engage in reclamation efforts as projects are completed. Recognize that stipulations for other species (e.g. raptors) may impede the ability to effectively reclaim disturbed areas, and remove those barriers in order to achieve immediate and effective reclamation, if otherwise allowable by law.
	No similar action.	Site wind energy development at least five miles from occupied GRSG leks.	No similar action.	No similar action.
Solar Energy Development (Utility Scale)				
Make priority sage-grouse habitat areas exclusion areas for new utility scale solar development.	Make priority sage-grouse habitat areas exclusion areas for new leases or ROWs permits (2,781,700 acres).	Industrial solar projects will be prohibited in ACECs and occupied habitats (3,313,800 acres).	Priority habitat would be designated as exclusion areas for solar energy development (2,760,300 acres). Manage solar energy development in GRSG habitat as follows: • Open – 522,500 acres • Avoided – 9,400 acres • Excluded – 2,781,900 acres Manage solar energy development outside of GRSG habitat but in population areas as follows:	Priority habitat would be available for solar energy development, though it would be designated as an avoidance area for solar energy development. Manage solar energy development in GRSG habitat as follows: • Open to new ROWs: 632,200 acres • New ROWs Avoided: 2,654,000 acres • New ROWs Excluded: 27,600 acres Manage solar energy development outside of GRSG habitat but in population areas as

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			• Open – 1,925,200 acres • Avoided – 462,500 acres • Excluded – 82,400 acres Areas outside priority habitat and within 4 miles of an occupied lek located within priority habitat, excluding designated solar energy zones, would be designated as an avoidance area for solar energy development. Development within the avoidance areas can occur if: • the development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); and • the development meets tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography); Exclude solar energy development within 1.0 mile (including priority, general, or non-habitat areas) of occupied leks located in either priority or general habitat. The exclusion could be waived outside of priority habitat if applicable seasonal restrictions are implemented (breeding and nesting, brood rearing, winter) and if off-site mitigation coordinated with BLM/FS and UDWR is successfully completed in priority or opportunity habitat. Development within general habitat beyond the 1.0 mile exclusion area would require	follows: • Open to new ROWs: 2,292,000 acres • New ROWs Avoided: 103,200 acres • New ROWs Excluded: 74,900 acres Apply stipulations as follows, as well as best management practices accepted by industry and state and federal agencies: • New permanent disturbance, including structures, fences, and buildings, should not be located within the occupied lek itself. • No permanent disturbance within 1 mile of an occupied lek, unless it is not visible to the sage-grouse using the lek. • A disturbance outside the lek should not produce noise which rises more than 10 db above the ambient (background) level at the edge of the lek during breeding season. • Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise) • Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats: o On leks from Feb 15 – May 15 to avoid activities that will disturb lek attendance or breeding. o In nesting and brood-rearing areas from Apr 1 – Aug 15. o In winter habitat from Nov 15 – Mar 15. o Specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist. • Avoid disturbance within priority habitat, if possible. Project proponents must demonstrate why avoidance is not possible.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			discussion with UDWR during project implementation, and implementation of best management practices, including potential off-site mitigation in priority habitat or opportunity areas.	• If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area's priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable. Engage in reclamation efforts as projects are completed. Recognize that stipulations for other species (e.g. raptors) may impede the ability to effectively reclaim disturbed areas, and remove those barriers in order to achieve immediate and effective reclamation, if otherwise allowable by law.
Habitat Restoration/Vegetation Management				
In most LUPs, either no priorities are established or prioritization is given to projects that benefit multiple resources (e.g., livestock, wildlife, wild horses and burros, special status species).	Prioritize implementation of restoration projects based on environmental variables that improve chances for project success in areas most likely to benefit GRSG. Prioritize restoration in seasonal habitats that are thought to be limiting GRSG distribution and/or abundance.	Prioritize implementation of restoration projects based on environmental variables that improve chances for project success in areas most likely to benefit GRSG. Prioritize restoration in seasonal habitats that are thought to be limiting sage-grouse distribution and/or abundance and where factors causing degradation have already been addressed.	Where necessary to meet habitat objectives, treat GRSG priority habitat and opportunity areas to maintain and expand healthy GRSG habitat (e.g., conifer encroachment areas, areas with or at threat to be converted to annual grasslands, areas without a proper shrub/grass/forb composition for the applicable seasonal habitat and ecological site, fuel breaks, areas without a healthy mosaic of habitat types for the various GRSG life stages). Prioritize implementation of restoration/treatment projects based on environmental variables that improve	Protection of GRSG habitat is the primary focus of conservation efforts, but many locations can be reclaimed or restored by active vegetation management actions. For example: • removal of encroaching conifers may create new habitat or increase the carrying capacity of habitat and thereby expand grouse populations, or • the distribution of water into wet meadow areas may improve seasonal brood-rearing range and enhance greater sage-grouse recruitment. Aggressively remove encroaching conifers

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			chances for project success in areas most likely to benefit GRSG. Prioritize restoration in seasonal habitats that are identified as the limiting factor for GRSG distribution and/or abundance. Use cooperative planning efforts to develop and implement habitat restoration projects. Expertise and ideas from entities such as local landowners, local GRSG working groups, and other federal, state, county, and private organizations should be solicited and considered in development of projects. Consider design features that will contribute to the most favorable conditions for success when planning and implementing restoration/vegetation treatment projects. Considerations should include: • Review of available plant species and their adaptation to the site when developing seed mixes. • The need to reduce non-native annual grass densities and competition through herbicide, targeted grazing, tillage, prescribed fire, etc. • Assessment of on-site vegetation to ascertain if enough desirable perennial vegetation exists to consider the use of passive restoration techniques. • Use of site preparation techniques that retain existing desirable vegetation. • Use of "mother plant" techniques or planting of satellite populations of desirable plants to serve as seed sources. • The need for post-treatment control of non-native annual grass and other invasive species.	and other plant species to expand GRSG habitat where possible. Sagebrush treatment projects within nesting and winter habitat should be limited and require pre-approval by the appropriate regulatory agency in discussions with DWR. Sagebrush treatment projects should maintain 80% of the available habitat as sagebrush within the project area; 20% of the habitat can be managed for younger age classes of sagebrush, if appropriate. These treatments are generally recommended only to improve brood-rearing habitat, but need to be carefully considered before use in winter and other habitat. Within priority habitat, GRSG stipulations should take precedence over stipulations for other species if conflicts occur, if otherwise allowable by law. Design water developments to enhance mesic habitat for use by greater sage-grouse and maintain adequate vegetation in wet meadows. Within SGMAs, greater sage-grouse stipulations should take precedence over stipulations for other species if conflicts occur, if otherwise allowable by law.
Most LUPs contain objectives for maintaining improving, or restoring sagebrush plant communities. The level of detail varies depending on the age of the land use plan.	Include GRSG habitat parameters as defined by Connelly et al. (2000), Hagen et al. (2007) or if available, State GRSG Conservation plans and appropriate local information in	Include sage-grouse habitat objectives in habitat restoration projects. Make meeting these objectives within occupied sage-grouse habitat the highest restoration priority.	Include GRSG habitat objectives in restoration/treatment projects within priority habitat and opportunity areas. There will be objectives for short-term and long-term	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
All LUPs address vegetation treatments for improvement of wildlife habitat overall or to provide increased forage for wildlife, livestock, and wild horses and burros. Recently completed BLM plans include a management action to implement the most recent *UDWR Strategic Management Plan for Sage-Grouse* (UDWR, 2000), the *BLM National Sage Grouse Habitat Conservation Strategy* (BLM, 2004). A few plans (e.g., Vernal RMP, Uinta LRMP) including more detailed habitat objectives such as desired seral sage, percent canopy cover, or height.	habitat restoration objectives. Make meeting these objectives within priority GRSG habitat areas the highest restoration priority.		habitat conditions, and they should include specific objectives for the establishment of sagebrush cover and height, as well as cover and heights for understory perennial grasses and forbs necessary for GRSG seasonal habitats. The restoration/treatment objectives should take into consideration ecological site potential of the area(s) and the need for a mosaic of habitat conditions across the landscape. Make meeting the GRSG objectives for the restoration/treatment project one of the primary priorities for the project and subsequent land uses, recognizing that managing for other special status species may result in treatment objectives that may not meet GRSG seasonal habitat objectives (e.g., winter habitat cover requirements vs. creation of Utah prairie dog habitat). Where GRSG habitat overlaps with that of federally listed threatened or endangered species (e.g., Utah prairie dogs), assemble species-specific experts to develop conservation and recovery objectives and allow habitat treatments that will benefit both species.	
All recent LUPs include management actions that promote use of native species where possible. Older plans typically do not include a similar management action.	Require use of native seeds for restoration based on availability, adaptation (ecological site potential), and probability of success. Where probability of success or adapted seed availability is low, non-native seeds may be used as long as they support GRSG habitat objectives.	Same as Alternative B.	Prioritize the use of native seeds for restoration in priority GRSG habitat and opportunity areas based on availability, adaptation (ecological site potential), and probability of success. Where probability of success or adapted seed availability is low, non-native seeds may be used as long as they support GRSG habitat objectives. Re-establishment of appropriate sagebrush species/subspecies and important understory plants, relative to site potential, shall be the principle objective for rehabilitation efforts.	No similar action.
All LUPs, which are written in accordance with applicable program direction, include management actions that allow the administrating agency to make adjustments to livestock grazing, wild horse and burro management, and travel management on a case-by case basis following restoration	Design post restoration management to ensure long term persistence. This could include changes in livestock grazing management, wild horse and burro management and travel management, etc., to achieve and maintain the desired condition of the restoration effort that benefits GRSG.	Same as Alternative B.	Same as Alternative B.	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
activities.				
Allow commercial seed collection on a case-by-case basis.	No similar action.	No similar action.	Identify areas where commercial seed or live plant collection in GRSG priority habitat could occur. Limit collection to levels that ensure long-term maintenance of the GRSG habitat objectives. Locations, species allowed for collection, and limits on the amounts to be collected will be developed on a case-by-case basis following environmental review of annual site-specific conditions. Collection during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter) will include mitigation, developed to reflect the site-specific conditions on the ground, that could include, but is not necessarily limited to, restrictions on the timing and method of collection activities, limiting the number of individuals collecting, providing portions of collected seeds for use in local restoration projects, etc.	No similar action.
Most LUPs do not include a similar action. A few plans include management actions that encourage use of native species from local sources when possible.	Consider potential changes in climate when proposing restoration seedings when using native plants. Consider collection from the warmer component of the species current range when selecting native species.	Same as Alternative B.	Allow for seed collection and use in restoration/reclamation activities. Prioritize use of seed from areas as close as possible to where the seed will be used to capture local adaptations.	No similar action.
No similar action. Most LUPs do not include specific management actions related to seedings. Plans do include generic decisions that allow maintenance of existing range improvements, which includes maintenance of historical seedings. Recently completed LUPs promote use of native species when conducting restoration activities. This would include restoration projects conducted in areas that have perennial grass cover. Older plans do not include a similar management action.	Restore native (or desirable) plants and create landscape patterns which most benefit GRSG.	Exotic seedings will be rehabbed, interseeded, or restored to recover sagebrush in areas to expand occupied habitats. Complete active restoration of crested wheatgrass seedings. This can be accomplished, following targeted restoration planning to expand, reconnect or recover habitats required by GRSG by: • Inter-seeding sagebrush seed or seedlings. • Removal of crested wheatgrass through plowing while minimizing use of herbicides. Subsequent re-seeding with local native ecotypes. In all cases, local native plant ecotype seeds	Diversify the perennial grass and forb components through additional seeding in areas where monotypic stands resulting from historical seedings have been recolonized by sagebrush	Aggressively remove cheatgrass and other invasive species, and rehabilitate areas to provide additional habitat for GRSG where possible.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
		and seedlings must be used. Perform active restoration of cheatgrass infestation areas.		
Most LUPs contain objectives for maintaining improving, or restoring sagebrush plant communities. The level of detail varies depending on the age of the land use plan. All LUPs address vegetation treatments for improvement of wildlife habitat overall or to provide increased forage for wildlife, livestock, and wild horses and burros. Recent LUPs may include management actions that purposely restore or enhance sage-grouse habitat.	Make re-establishment of sagebrush cover and desirable understory plants (relative to ecological site potential) the highest priority for restoration efforts.	Composition, function, and structure of native vegetation communities will meet ecological site description (ESD) (or the Forest Service equivalent) and will provide for healthy, resilient, and recovering GRSG habitat components.	Desired cover percentages and heights for sagebrush, grasses, and forbs in seasonal habitats will follow habitat guidelines from scientific literature (e.g., Connelly et al. 2000, Hagen et al. 2007). Adjustments from the guidelines may be made, but must be based on documented regional variation of habitat characteristics (e.g., sagebrush type, ecological site potential), quantitative data from population and habitat monitoring, and evaluation of local research.	No similar action.
No similar action.	In fire prone areas where sagebrush seed is required for GRSG habitat restoration, consider establishing seed harvest areas that are managed for seed production and are a priority for protection from outside disturbances.	Same as Alternative B.	No similar action.	No similar action.
No similar action.	No similar action.	Avoid sagebrush reduction/treatments to increase livestock or big game forage in occupied habitat and include plans to restore high-quality habitat in areas with invasive species.	No similar action.	No similar action.
Integrated Invasive Species Management				
Implement noxious weed and invasive species control using integrated weed management actions per national guidance and local weed management plans in cooperation with State and Federal agencies, affected counties, and adjoining private lands owners.	Integrated Vegetation Management would be used to control, suppress, and eradicate, where possible, noxious and invasive species per BLM Handbook H-1740-2.	Same as Alternative B.	Same as Alternative B.	No similar action.
In most LUPs, either no priorities are established or prioritization is given to projects that benefit multiple resources (e.g., livestock, wildlife, wild horses and burros, special status species).	No similar action.	Develop and implement methods for prioritizing and restoring sagebrush steppe invaded by nonnative plants.	Same as Alternative C.	Aggressively respond to new infestations to keeping invasive species from spreading. Every effort should be made to identify and treat new infestations before they become larger problems. Additionally containment of known infestations in or near sagebrush habitats should be a high priority for all land management agencies.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
No similar action.	No similar action.	In GRSG habitat, ensure that soil cover and native herbaceous plants are at their ESD potential to help protect against invasive plants.	No similar action.	No similar action.
Fire and Fuels Management				
Under current management, there is no designated priority habitat. Design projects to minimize the size of wildfire and prevent the further loss of sagebrush. Existing LUPs typically do not include specific management decisions regarding implementation of fuels treatments in sagebrush habitat. In general, both prescribed fire and non-fire fuels treatments are allowed.	In priority habitat, design and implement fuels treatments with an emphasis on protecting existing sagebrush ecosystems. • Do not reduce sagebrush canopy cover to less than 15% unless a fuels management objective requires additional reduction in sagebrush cover to meet strategic protection of priority GRSG habitat and conserve habitat quality for the species. • Closely evaluate the benefits of the fuel break against the additional loss of sagebrush cover in the EA process. • Apply appropriate seasonal restrictions for implementing fuels management treatments according to the type of seasonal habitats present in a priority area. • Allow no treatments in known winter range unless the treatments are designed to strategically reduce wildfire risk around or in the winter range and will maintain winter range habitat quality. • Do not use fire to treat sagebrush in less than 12-inch precipitation zones (e.g., Wyoming big sagebrush or other xeric sagebrush species; Connelly et al. 2000, Hagen et al. 2007, Beck et al. 2009). However, if as a last resort and after all other treatment opportunities have been explored and site specific variables allow, the use of prescribed fire for fuel breaks that would disrupt the fuel continuity across the landscape could be considered, in stands where cheatgrass is a very minor component in the understory (Brown 1982). • Monitor and control invasive vegetation	Design and implement fuels treatments with an emphasis on protecting existing sagebrush ecosystems. • Do not reduce sagebrush canopy cover to less than 15% unless a fuels management objective requires additional reduction in sagebrush cover to meet strategic protection of occupied GRSG habitat and conserve habitat quality for the species. • Closely evaluate the benefits of the fuel break against the additional loss of sagebrush cover in the EA process. • Apply appropriate seasonal restrictions for implementing fuels management treatments according to the type of seasonal habitats present. • Allow no fuels treatments in known winter range unless the treatments are designed to strategically reduce wildfire risk around or in the winter range and will maintain winter range habitat quality. • Do not use fire to treat sagebrush in less than 12-inch precipitation zones (e.g., Wyoming big sagebrush or other xeric sagebrush species; Connelly et al. 2000, Hagen et al. 2007, Beck et al. 2009). However, if as a last resort and after all other treatment opportunities have been explored and site specific variables allow, the use of prescribed fire for fuel breaks that would disrupt the fuel continuity across the landscape could be considered, in stands where cheatgrass is a very minor component in the understory (Brown 1982). • Livestock grazing should be excluded from burned areas until woody and	In priority habitat and opportunity areas, design and implement fuels treatments and other range/habitat treatments with an emphasis on maintaining, protecting, and expanding sagebrush ecosystems. • Maintain or enhance sagebrush canopy cover and community structure within GRSG priority habitat to match GRSG habitat objectives unless fuels management objectives requires additional reduction in sagebrush cover to meet strategic protection of priority GRSG habitat or opportunity areas. • Consider comprehensive treatment options, including chemical applications and follow up treatments, to ensure post-treatment success of meeting GRSG habitat and treatment objectives. • Develop a system of fuel breaks to protect larger intact blocks of GRSG habitat. First priority is to protect sagebrush areas that are more-or-less intact and functioning as GRSG habitat by separating or isolating areas dominated by annual grasses. • Avoid constructing fuel breaks through large areas of intact GRSG habitat. • When possible, locate fuel breaks along existing roads, rights-of-way, and other suitable topographic or natural features (e.g., areas devoid of vegetation, rock outcrops). • Closely evaluate the benefits of the fuel break against the additional loss of sagebrush cover in the environmental review process. • Apply seasonal restrictions (identified in the special status species- GRSG	Habitat loss due to fire and replacement of (burned) native vegetation by invasive plants is the single greatest threat to GRSG in Utah. While unscheduled fires may occur, response to fire can have a large impact on the severity of the effects, especially over time as rehabilitation or restoration continues. Implement the following: • Create and implement a statewide fire agency agreement(s) that will eliminate jurisdictional boundaries and allow for immediate response to natural fire in priority habitat. • Allow use of fire-retardant vegetation that will buffer areas of high quality GRSG habitat from catastrophic fire. • Use prescriptive fire with caution in sagebrush habitat. The Western Association of Fish and Wildlife Agencies has prepared information that explains the risks from using prescribed fire in xeric sagebrush habitats. • Prescribed fire should only be used at higher elevations and in a manner designed prescriptively to benefit GRSG. • Conduct effective research into controlling fire size and protecting remaining GRSG areas that are adjacent to high-risk cheatgrass areas. • Focus research efforts on effective reclamation and restoration of landscapes altered by wildfire. • Within winter habitat, manage to maintain maximum amount of sagebrush, especially tall sagebrush, which would be available to GRSG above snow during a severe winter. Tall

Table 2-2 – Description of Alternatives A, B, C$_1$, C$_2$, D, and E$_1$

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
	post-treatment. • Rest treated areas from grazing for two full growing seasons unless vegetation recovery dictates otherwise (WGFD 2011). • Require use of native seeds for fuels management treatment based on availability, adaptation (site potential), and probability of success (Richards et al. 1998). Where probability of success or native seed availability is low, non-native seeds may be used as long as they meet GRSG habitat objectives (Pyke 2011). • Design post fuels management projects to ensure long term persistence of seeded or pre-treatment native plants. This may require temporary or long-term changes in livestock grazing management, wild horse and burro management, travel management, or other activities to achieve and maintain the desired condition of the fuels management project (Eiswerth and Shonkwiler 2006).	herbaceous plants achieve GRSG habitat objectives. • Where burned GRSG habitat cannot be fenced from other unburned habitat, the entire area (e.g., allotment/pasture) should be closed to grazing until recovered. • Design post fuels management projects to ensure long term persistence of seeded or pre-treatment native plants, including sagebrush. This may require temporary or long-term changes in livestock grazing management, wild horse and burro management, travel management, or other activities to achieve and maintain the desired condition of the fuels management project (Eiswerth and Shonkwiler 2006).	section above) for implementing fuels management treatments according to the type of seasonal habitats present in a priority area. • Prior to conducting any fuels/habitat treatments in known winter range, work closely with UDWR to design the treatment to either strategically reduce wildfire risk around or in the winter range or to specifically maintain, increase, or enhance areas of vegetation to function as important winter range (for habitat associated with years of average snowfall and habitat for years with abnormally high snowfall amounts). • Allow the use of prescribed fire within priority GRSG habitat if other treatment opportunities have been explored, where site specific variables allow (will not likely result in long-term loss of sagebrush), and in areas where risk of conversion to exotic annual dominance is low and/or could be mitigated by chemical or other means. Prescribed fire in areas of low elevation Wyoming sagebrush should be avoided. • Monitor and control invasive vegetation post-treatment. • Rest treated areas from grazing for two full growing seasons (per BLM policy) unless vegetation recovery dictates otherwise. • Prioritize the use of native seeds for fuels management treatment based on availability, adaptation (site potential), and probability of success. Where probability of success or native seed availability is low, non-native seeds may be used as long as they result in meeting GRSG habitat objectives. When reseeding, consider using fire resistant native and non-native species on a case-by-case basis to provide for	sagebrush is capable of standing above heavier than normal snowfall. • Sagebrush treatment projects within winter habitat need pre-approval by the appropriate regulatory agency in coordination with the DWR. Sagebrush treatment projects within winter habitat should maintain 80% of the available habitat as tall sagebrush; 20% of the habitat can be managed for younger age classes, if appropriate. • Coordinate the needs and efforts related to sage-grouse with the State of Utah committee that was formed to develop a collaborative process to protect the health and welfare by reducing the size and frequency of catastrophic fires.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			fire breaks, protecting large areas of GRSG priority habitat. - Design post fuels management to ensure long term persistence of seeded or desirable residual plants. During planning for the treatments, address the temporary or long-term changes in livestock grazing management, wild horse and burro management, travel management, or other activities that are needed to achieve and maintain the desired condition of fuels management projects in priority habitat.	
Design projects to minimize the size of wildfire and prevent the further loss of sagebrush.	Design fuels management projects in priority GRSG habitat to strategically and effectively reduce wildfire threats in the greatest area. This may require fuels treatments implemented in a more linear versus block design.	No similar action.	When designing fuels management projects in priority GRSG habitat, strategically design the treatment to provide the greatest benefit (improve habitat condition, minimize future threat of wildfire, etc.) over the largest area. In some areas, this may require fuels treatments implemented in a more linear versus block design to limit the spread of fire, where other areas could be implemented to reduce fire severity and intensity and improve habitat resilience.	No similar action.
No similar action.	During fuels management project design, consider the utility of using livestock to strategically reduce fine fuels (Diamond et al. 2009), and implement grazing management that will accomplish this objective Davies et al. 2011 and Launchbaugh et al. 2007). Consult with ecologists to minimize impacts to native perennial grasses.	No similar action.	During fuels management project design, consider the use of targeted livestock grazing to strategically reduce fine fuels and, if used, implement grazing management that will accomplish this objective. If implementing targeted grazing, implement measures to minimize impacts to native perennial grasses.	Consider the use of prescriptive grazing to specifically reduce fire size and intensity on all types of landownership, where appropriate. This could be particularly effective in areas where cheatgrass is encroaching on sagebrush habitat. This will require cooperation and coordination among different land managers and owners and livestock owners. In some cases feed supplementation and water hauling may need to be utilized to obtain the desired results.
Prioritize fire suppression to protect human life, human safety, and high value resources. Design fuels treatment projects to minimize the size of wildfire and prevent the further loss of sagebrush.	No similar action.	Mowing of grass will be used in any fuelbreak fuels reduction project (roadsides or other areas).	Proactively protect priority GRSG habitat from fire through strategic wildfire suppression planning. Planning measures may include: - Strategically placed fuel breaks that reduce fuel loading and continuity (e.g., mowing vegetation along roadsides, grazing strategies, herbicide	Create and implement a statewide fire agency agreement(s) that will eliminate jurisdictional boundaries and allow for immediate response to natural fire in priority habitat. These should include fire suppression actions recommended locally, including, but not limited to: - first strike agreements that allow

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			application), or that alter vegetation structure and/or composition (e.g., fire resistant vegetation or green-strip seedings). - Pre-planning of wildfire suppression tactics in important GRSG habitat. - Prioritizing suppression of wildfire in priority habitats. - Conducting burn-out/backfiring operations in a manner that minimizes the loss of sagebrush when possible (e.g., considering use of bulldozers to create anchor lines that may help decrease the size of burnout operations). - Updating strategic planning documents to account for prioritization of GRSG habitats in suppression efforts. - Other applicable fire management strategies.	aggressive fire control on an all-land jurisdictional basis; - allocation of resources to maintain enhanced abilities of all fire agencies to combat ignitions in priority habitat. - allocation of resources to immediately commence restoration of habitats impacted by wildfire by all responsible agencies; and - removal or establishment of waiver provisions for procedural barriers that may impact the ability of responsible agencies to respond to wildfire with effective reclamation or rehabilitation, such as federal raptor stipulations, cultural assessments, and the like.
Under current management there is no designated priority habitat. Prioritize fire suppression to protect human life and high value resources.	In priority GRSG habitat areas, prioritize suppression, immediately after life and property, to conserve the habitat.	Same as Alternative B.	Same as Alternative B. In addition, within priority habitat, prioritize suppression in areas of solid sagebrush. Limit placement of fire infrastructure (e.g., fire camps, helipads, etc.) in areas of solid sagebrush.	Fire by natural ignition should be addressed as a serious threat.
Under current management there is no designated general habitat. Prioritize fire suppression to protect human life and high value resources.	In general GRSG habitat, prioritize suppression where wildfires threaten priority GRSG habitat.	No similar action.	In general GRSG habitat or in opportunity areas where treatment/seeding has occurred to improve habitat, prioritize suppression where wildfires threaten adjacent priority GRSG habitat.	GRSG habitat outside priority habitat would not be managed for the conservation of the species. No specific management actions are provided for this habitat.
The Best Management Practices found in Appendix XX were provided at part of WO IM 2011-138. As such, they would be applied as best management practices to fuels and fire management action as a matter of compliance to BLM policy.	Follow Best Management Practices (WO IM 2011-138, see Appendix XX.)	Same as Alternative B.	Follow the applicable and technically feasible Required Design Features and policies outlined in Appendix XX.	No similar action.
Recently completed LUPs promote use of native species when conducting restoration activities.	Prioritize native seed allocation for use in GRSG habitat in years when preferred native seed is in short supply. This may require reallocation of native seed from ES&R projects outside of priority GRSG habitat to those inside it. Use of native plant seeds for ES&R seedings is required based on availability, adaptation (site potential), and	Same as Alternative B.	Prioritize the use of native seeds for restoration in priority GRSG habitat and opportunity areas based on availability, adaptation (ecological site potential), and probability of success. Where probability of success or adapted seed availability is low, non-native seeds may be used as long as they support GRSG habitat objectives. Re-	Allow use of fire-retardant vegetation that will buffer areas of high quality GRSG habitat from catastrophic fire.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
	probability of success (Richards et al. 1998). Where probability of success or native seed availability is low, non-native seeds may be used as long as they meet GRSG habitat conservation objectives (Pyke 2011). Re-establishment of appropriate sagebrush species/subspecies and important understory plants, relative to site potential, shall be the highest priority for rehabilitation efforts.		establishment of appropriate sagebrush species/subspecies and important understory plants, relative to site potential, shall be the principle objective for rehabilitation efforts.	
All LUPs, which are written in accordance with applicable program direction, include management actions that allow the administrating agency to make adjustments to livestock grazing, wild horse and burro management, and travel management on a case-by case basis following restoration activities.	Design post Emergency Stabilization and Rehabilitation (ES&R)/Burned Area Emergency Rehabilitation (BAER) management to ensure long term persistence of seeded or pre-burn native plants. This may require temporary or long-term changes in livestock grazing, wild horse and burro, and travel management, etc., to achieve and maintain the desired condition of ES&R projects to benefit GRSG (Eiswerth and Shonkwiler 2006).	Same as Alternative B.	Same as Alternative B. In addition, establish fuel breaks/green strips through the ES&R efforts to be proactive in future management.	Immediate, proactive means to reduce or eliminate the spread of invasive species, particularly cheatgrass, after a wildfire, is a high priority.
No similar action.	Consider potential changes in climate (Miller at al. 2011) when proposing post-fire seedings using native plants. Consider seed collections from the warmer component within a species' current range for selection of native seed. (Kramer and Havens 2009).	Same as Alternative B.	No similar action.	No similar action.
No similar action.	No similar action.	Establish and strengthen networks with seed growers to assure availability of native seed for ES&R projects.	No similar action.	No similar action.
No similar action.	No similar action.	Post fire recovery must include establishing adequately sized exclosures (free of livestock grazing) that can be used to assess recovery.	To assist in monitoring long-term recovery efforts, consider establishing short-term exclosures free from livestock grazing within priority habitat that has been burned. When the area has met applicable GRSG habitat objectives, the exclosures may be removed, unless they can be maintained through long-term maintenance or if more long-term monitoring is necessary for determination of GRSG objectives.	No similar action.
Energy Development (applicable to all types of minerals and all minerals development activities)				
No similar action.	No similar action.	No similar action.	No similar action.	Within priority habitat, limit or ameliorate impacts through the use of the general

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
				stipulations identified in the Sage-Grouse section. Engage in reclamation efforts as projects advance or are completed. Recognize that stipulations for other species (e.g. raptors) may impede the ability to effectively reclaim disturbed areas, and remove those barriers in order to achieve immediate and effective reclamation, if otherwise allowable by law. Prioritize areas for habitat improvement to make best use of mitigation funds.
Non-Energy Leasable Minerals				
Under current management there is no designated priority habitat. Manage non-energy leasable minerals on federal lands and non-federal lands with federal mineral interests within GRSG habitat as follows: • Open to Leasing Consideration – 3,870,080 acres • Closed to Leasing – 138,500 acres Recent plans may apply stipulations identified for fluid mineral leasing to all surface disturbing activities.	Close federal lands and non-federal lands with federal mineral interests within priority habitat to non-energy leasable mineral leasing. This includes not permitting any new leases to expand an existing mine. Manage non-energy leasable minerals on federal lands and non-federal lands with federal mineral interests within GRSG habitat as follows: • Open to Leasing Consideration – 667,280 acres • Closed to Leasing – 3,341,300 acres	Close federal lands and non-federal lands with federal mineral interests within occupied GRSG habitat to non-energy leasable mineral leasing (4,008,580 acres). This includes not permitting any new leases to expand an existing mine.	<u>Proposed Leases Associated with Surface Mining:</u> Manage non-energy leasable minerals on federal lands and non-federal lands with federal mineral interests within GRSG habitat as follows: • Open to Leasing Consideration – 705,680 acres • Closed to Leasing with Development by Surface Mining – 2,905,100 acres • Closed to All Leasing– 397,800 acres Priority habitat would be closed to new leasing or lease modification of surface non-energy leasable minerals. This includes not issuing or modifying leases to expand existing mines that would result in surface mining. New or modified leases in areas outside priority habitat and within 4 miles of an occupied lek located within priority habitat would have use stipulations attached. Development within these areas could occur if: • the development meets noise restrictions both during development and after development (noise at	Manage non-energy leasable minerals on federal lands and non-federal lands with federal mineral interests within GRSG habitat as follows: • Open to Leasing Consideration – 3,870,080 acres • Closed to Leasing – 138,500 acres Consider leasing federal lands and non-federal lands with federal mineral interests within priority habitat for non-energy leasable minerals. Limit or ameliorate impacts from mineral leasing and development through the use of the following stipulations: • New permanent disturbance, including structures, fences, and buildings, should not be located within the occupied lek itself. • No permanent disturbance within 1 mile of an occupied lek, unless it is not visible to the sage-grouse using the lek. • New permanent tall structures should not be located within one mile of the lek, if visible by the birds within the lek. • A disturbance outside the lek should not produce noise which rises more than 10 db above the ambient (background) level at the edge of the

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); and • the structures remaining after development meet tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography). General habitat within 1 mile of an occupied lek, if the lek is located within general habitat, would have no surface disturbance stipulations associated with leasing of surface non-energy leasable minerals. This could effectively close these areas to surface mining, although the stipulation could be waived if off-site mitigation coordinated with BLM/FS and UDWR is successfully completed in priority habitat or opportunity areas. Leases Associated with Sub-Surface Mining: Consider leasing priority habitat for non-energy leasable minerals that would be extracted through sub-surface mining. Require the following stipulations, as applicable, as part of any new mining leases or lease modification for sub-surface non-energy mines: • Avoid placement of appurtenant facilities within priority GRSG habitat. • If placement of facilities outside of priority GRSG habitat is not technically feasible while still protecting GRSG habitat, surface disturbances associated with the lease can be	lek during breeding season. • Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise) • Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats: o On leks from Feb 15 – May 15 to avoid activities that will disturb lek attendance or breeding. o In nesting and brood-rearing areas from Apr 1 – Aug 15. o In winter habitat from Nov 15 – Mar 15. o Specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist. • Avoid disturbance within priority habitat (nesting and brood-rearing areas, winter habitat, other habitat), if possible. Project proponents must demonstrate why avoidance is not possible. • If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area's priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			permitted if they meet the following criteria: o No surface facilities (e.g., mine entrances, vent shafts, etc.) would be located within 1 mile of an occupied lek that is located within priority habitat. o the long-term development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season), including from supporting traffic along roads; o restrictions on permanent (facility remains in place during breeding season) tall structures are required (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography) to minimize increases in predation and area avoidance by grouse; o the construction of the development does not occur during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter); avoidance periods and necessary mitigation may be dependent on site specific conditions and noise levels; o the surface disturbance from the development does not exceed the 5% disturbance limit; and o Additional mitigation methods applicable to the specific project are conducted, including off-site	• Recognize that surface vents associated with underground mining are essential for human safety, and must be permitted under the provisions of this alternative.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			mitigation. If the above criteria cannot be met, do not grant new leases or modifications.	
Under current management there is no designated general habitat. Recent plans may apply stipulations identified for fluid mineral leasing to all surface disturbing activities.	No similar action.	No similar action.	Consider leasing general habitat for non-energy leasable minerals that would be extracted through sub-surface mining. Minimize surface-disturbing or disrupting activities (including operations and maintenance) where needed to reduce the impacts of human activities on GRSG habitats. Consider applying the criteria identified for priority habitat. Use additional, onsite or off-site mitigation to offset impacts as technically appropriate (determined by local options/needs). Determine which measures are needed to protect general GRSG habitat during activity level planning. The above mitigation strategy may be waived if off-site mitigation coordinated with BLM/FS and UDWR is successfully completed in priority habitat or opportunity areas.	GRSG habitat outside priority habitat would not be managed for the conservation of the species. No specific management actions are provided for this habitat.
No similar action.	No similar action.	No similar action.	Commercial prospecting activities associated with non-energy leasable minerals would be required to comply to the following criteria: • Surface disturbance from the activity does not exceed the 5% disturbance limit; • The non-casual use activity does not occur during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter); • Any facilities associated with prospecting activities will be removed before the next breeding season; and • Any disturbances will be reclaimed.	Commercial prospecting activities associated with non-energy leasable minerals would be required to comply with the same stipulations identified for leasing and development, above.
No similar action. Individual land use plans may contain an appendix that outlines BMPs that are applied on a case-by-case basis.	For existing non-energy leasable mineral leases in priority habitat, in addition to the solid minerals required design features (RDF) (Appendix E of the NTT Report), follow the same RDFs applied to Fluid Minerals (Appendix D of the NTT Report), when wells are used for solution mining.	Same as Alternative B.	For existing non-energy leasable mineral leases in priority habitat, apply the applicable solid minerals RDFs (Appendix E of the NTT Report) and Fluid Minerals RDFs (Appendix D of the NTT Report) when permitting site-specific projects on the lease (e.g., wells used for solution mining), unless at least one	No similar action.

required as identified during the leasing process to protect GRSG habitat. If, upon receipt of a coal lease application, the BLM and the State of Utah “jointly agree” that the federal lands contain GRSG habitat that is “of high interest to the state and which are essential for maintaining [this] priority wildlife…species,” the area shall be considered unsuitable for further coal leasing consideration.			wildlife…species,” the area shall be considered unsuitable for further coal leasing consideration.	• Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise) • Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats: o On leks from Feb 15 – May 15 to avoid activities that will disturb lek attendance or breeding. o In nesting and brood-rearing areas from Apr 1 – Aug 15. o In winter habitat from Nov 15 – Mar 15. o Specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist. • Avoid disturbance within priority habitat (nesting and brood-rearing areas, winter habitat, other habitat), if possible. Project proponents must demonstrate why avoidance is not possible. • If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area’s priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable.
Leases Associated with Sub-Surface Mining:	Leases Associated with Sub-Surface Mining:	Leases Associated with Sub-Surface Mining:	Leases Associated with Sub-Surface Mining:	Leases Associated with Sub-Surface Mining:

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
Under current management there is no designated priority habitat. Most LUPs do not identify areas that are specifically closed to coal leasing. Recent LUPs apply stipulations identified for fluid mineral leasing to all surface disturbing activities.	Grant no new mining leases unless all surface disturbances (appurtenant facilities) are placed outside of the priority GRSG habitat area.	Same as Alternative B.	Consider leasing priority habitat for coal that would be extracted through sub-surface mining. Require the following stipulations, as applicable, as part of any new mining leases or lease modification for sub-surface coal mines: • Avoid placement of appurtenant facilities within priority GRSG habitat. • If placement of facilities outside of priority GRSG habitat is not technically feasible while still protecting GRSG habitat, surface disturbances associated with the lease can be permitted if they meet the following criteria: o No surface facilities (e.g., mine entrances, vent shafts, etc.) would be located within 1 mile of an occupied lek that is located within priority habitat. o the long-term development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season), including from supporting traffic along roads; o restrictions on permanent (facility remains in place during breeding season) tall structures are required (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography) to minimize increases in predation and area avoidance by grouse; o the construction of the	Consider leasing priority habitat for coal that would be extracted through sub-surface mining. Impacts would be limited or ameliorated through adherence to the following stipulations: • New permanent disturbance, including structures, fences, and buildings, should not be located within the occupied lek itself. • No permanent disturbance within 1 mile of an occupied lek, unless it is not visible to the sage-grouse using the lek. • New permanent tall structures should not be located within one mile of the lek, if visible by the birds within the lek. • A disturbance outside the lek should not produce noise which rises more than 10 db above the ambient (background) level at the edge of the lek during breeding season. • Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise) • Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats: o On leks from Feb 15 – May 15 to avoid activities that will disturb lek attendance or breeding. o In nesting and brood-rearing areas from Apr 1 – Aug 15. o In winter habitat from Nov 15 – Mar 15. o Specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist. • Avoid disturbance within priority habitat (nesting and brood-rearing areas, winter habitat, other habitat), if possible. Project proponents must

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			development does not occur during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter); avoidance periods and necessary mitigation may be dependent on site specific conditions and noise levels; o Surface disturbance from the development does not exceed the 5% disturbance limit; and o Additional mitigation methods applicable to the specific project are conducted, including off-site mitigation. If the above criteria cannot be met, do not grant new leases or modifications.	demonstrate why avoidance is not possible. • If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area's priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable. • Recognize that surface vents associated with underground mining are essential for human safety, and must be permitted under the provisions of this alternative.
Under current management there is no designated general habitat. Most LUPs do not identify areas that are specifically closed to coal leasing. Recent LUPs apply stipulations identified for fluid mineral leasing to all surface disturbing activities.	No similar action.	No similar action.	Consider leasing general habitat for coal that would be extracted through sub-surface mining. Minimize surface-disturbing or disrupting activities (including operations and maintenance) where needed to reduce the impacts of human activities on GRSG habitats. Consider applying the criteria identified for priority habitat. Use additional, onsite or off-site mitigation to offset impacts as technically appropriate (determined by local options/needs). Determine which measures are needed to protect general GRSG habitat during activity level planning. The above mitigation strategy may be waived if off-site mitigation coordinated with BLM/FS and UDWR is successfully completed in priority habitat or opportunity areas.	GRSG habitat outside priority habitat would not be managed for the conservation of the species. No specific management actions are provided for this habitat.
Under current management there is no designated priority habitat. Exploration	No similar action.	No similar action.	Exploration activities within priority habitat needed to meet data adequacy standards	Exploration activities within priority habitat would be required to comply with the same

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
activities are required to comply with season stipulations (i.e., brooding/nesting and winter).			associated with potential coal leasing would be required to comply to the following criteria: • Surface disturbance from the activity does not exceed the 5% disturbance limit; • The activity does not occur during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter); • Any facilities associated with exploration activities will be removed before the next breeding season; and • Any disturbances will be reclaimed.	stipulations identified for leasing and development, above.
No similar action.	For coal mining operations on existing leases: *Sub-surface mining:* in priority GRSG habitat areas, place any new appurtenant facilities outside of priority areas. Where new appurtenant facilities associated with the existing lease cannot be located outside the priority GRSG habitat area, co-locate new facilities within existing disturbed areas. If this is not possible, then build any new appurtenant facilities to the absolute minimum standard necessary.	Same as Alternative B.	Same as Alternative B	No similar action.
All land use plans include management actions based on specific program direction. These management actions require the BLM to consider measures that would reduce or eliminate impact of human activities during activity level planning.	For coal mining operations on existing leases: In general habitat, apply minimization of surface-disturbing or disrupting activities (including operations and maintenance) where needed to reduce the impacts of human activities on important seasonal GRSG habitats. Apply these measures during activity level planning. Use additional, effective mitigation to offset impacts as appropriate (determined by local options/needs).	Same as Alternative B.	Same as Alternative B	GRSG habitat outside priority habitat would not be managed for the conservation of the species. No specific management actions are provided for this habitat.
Locatable Minerals				
Under current management there is no designated priority habitat. 498,700 acres of occupied sage-grouse habitat are proposed withdrawal from mineral entry.	its habitat from conflicting locatable mineral potential and development (3,650,900 acres. • Make any existing claims within the withdrawal area subject to validity exams or buy out. Include claims that have been subsequently determined to be null and void in the proposed withdrawal. • In plans of operations required prior to any proposed surface disturbing activities, include the following: o Additional, effective mitigation in perpetuity for conservation (In accordance with existing policy, WO IM 2008-204). Example: purchase private land and mineral rights or severed federal mineral rights within the priority area and deed to US Government). o Consider seasonal restrictions if deemed effective.	its habitat from conflicting locatable mineral potential and development (4,008,580 acres). Everything else, same as Alternative B.	withdrawal would be available for locatable mineral entry. To the extent allowable by law, work with claimants to apply the seasonal restrictions and use restrictions for priority and general habitats identified in the Special Status Species section above. To the extent consistent with the rights of a mining claimant under existing laws and regulations, limit surface disturbance from locatable mineral development in priority habitat to under the 5% disturbance limit, or provide for enhancement of priority habitat through on-site and/or off-site mitigation.	withdrawal would be available for locatable mineral entry. To the extent allowable by laws and regulations and to the extent the claimant would be willing to apply the standards, impacts would be limited or ameliorated through the use of the following stipulations: • New permanent disturbance, including structures, fences, and buildings, should not be located within the occupied lek itself. • No permanent disturbance within 1 mile of an occupied lek, unless it is not visible to the sage-grouse using the lek. • New permanent tall structures should not be located within one mile of the lek, if visible by the birds within the lek. • A disturbance outside the lek should not produce noise which rises more than 10 db above the ambient (background) level at the edge of the lek during breeding season. • Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise) • Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats: o On leks from Feb 15 – May 15 to avoid activities that will disturb lek attendance or breeding. o In nesting and brood-rearing areas from Apr 1 – Aug 15. o In winter habitat from Nov 15 – Mar 15. o Specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist. • Avoid disturbance within priority habitat

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
				(nesting and brood-rearing areas, winter habitat, other habitat), if possible. Project proponents must demonstrate why avoidance is not possible. • If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area's priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable. • Recognize that surface vents associated with underground mining are essential for human safety, and must be permitted under the provisions of this alternative.
No similar action.	Make applicable Best Management Practices (see Appendix E) mandatory as Conditions of Approval within priority GRSG habitat.	Same as Alternative B.	Apply the design features identified in Appendix E (of the NTT report), to the extent allowable by law, unless at least one of the following can be demonstrated in the NEPA analyses associated with the specific project: • A specific design feature is documented to not be applicable to the site-specific conditions of the project/activity; • A proposed design feature or best management practice is determined to provide equal or better protection for GRSG or its habitat; • Analyses conclude that following a specific feature will provide no more protection to GRSG or its habitat than not following it, for the specific project being proposed.	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
Mineral Materials				
Manage mineral materials in GRSG habitat as follows: • open to mineral materials development: 3,935,080 acres • closed to mineral materials development: 73,500 acres Recent LUPs apply stipulations identified for fluid mineral leasing to all surface disturbing activities.	Manage mineral materials in GRSG habitat as follows: • open to mineral materials development: 668,580 acres • closed to mineral materials development: 3,340,000 acres	Manage mineral materials in GRSG habitat as follows: • open to mineral materials development: 0 acres • closed to mineral materials development: 4,008,580 acres	Manage mineral materials in GRSG habitat as follows: • open to mineral materials development: 688,280 acres • closed to commercial mineral materials development, open to non-commercial: 2,967,500 acres • closed to mineral materials development: 352,800 acres	Manage mineral materials in GRSG habitat as follows: • open to mineral materials development: 3,935,080 acres • closed to mineral materials development: 73,500 acres

Same as previous decision.	Close priority habitat to mineral material sales.	Close occupied habitat to mineral material sales.	Priority and general habitat within 1 mile of an occupied lek would be closed to mineral materials.
			Priority habitat beyond 1 mile of an occupied lek that is located within priority habitat would be closed to commercial development of mineral materials.
			Non-commercial development of mineral materials (e.g., community pits, free-use permits) within priority habitat beyond 1 mile of an occupied lek, if the lek is located within priority habitat, could only occur if the following conditions are met:
			• the development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season);
			• the development meets tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography);
			• initial activity within the development
				Priority habitat would be open to mineral materials. Impacts would be limited or ameliorated through the use of the following stipulations:
				• New permanent disturbance, including structures, fences, and buildings, should not be located within the occupied lek itself.
				• No permanent disturbance within 1 mile of an occupied lek, unless it is not visible to the sage-grouse using the lek.
				• New permanent tall structures should not be located within one mile of the lek, if visible by the birds within the lek.
				• A disturbance outside the lek should not produce noise which rises more than 10 db above the ambient (background) level at the edge of the lek during breeding season.
				• Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise)
				• Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats:
				  o On leks from Feb 15 – May 15 to avoid activities that will disturb lek attendance or breeding.
				  o In nesting and brood-rearing areas from Apr 1 – Aug 15.
				  o In winter habitat from Nov 15 – Mar 15.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			does not occur during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter); • new disturbance associated with the development does not result in total disturbance exceeding the 5% disturbance limit. • where possible, the development is located adjacent to the footprint of existing disturbances; and • extraction or crushing operations do not occur in GRSG habitat during seasonal restriction times; however, removal of material from existing stockpiles would be allowed. • new developments are located within 0.25 mile of existing roads. Development of mineral materials within general habitat beyond 1 mile of an occupied lek, if the lek is located within general habitat, could occur if: • the development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); • the development meets tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography); • initial activity within the development does not occur during sensitive seasonal periods (i.e., breeding and nesting, brood rearing, winter).	o Specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist. • Avoid disturbance within priority habitat (nesting and brood-rearing areas, winter habitat, other habitat), if possible. Project proponents must demonstrate why avoidance is not possible. • If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area's priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			General habitat within and beyond the 1.0 mile avoidance area would require discussion with UDWR during project implementation, and implementation of best management practices (e.g., anti-perch devices for raptors, etc.). The stipulations within general habitat (closure or restrictions) could be waived, except for the seasonal stipulations, if off-site mitigation coordinated with BLM/FS and UDWR is successfully completed in priority habitat or opportunity areas.	
No similar action.	In priority habitat, restore mineral materials pits no longer in use to meet GRSG habitat conservation objectives.	Same as Alternative B.	No similar action.	No similar action.
FLUID MINERALS				
Manage fluid mineral leasing in GRSG habitat as follows: • open to leasing, subject to standard stipulations: 1,333,380 acres • open to leasing, subject to controlled surface use (CSU) and/or timing stipulations: 1,300,400 acres • open to leasing, subject to no surface occupancy (NSO) stipulations: 483,500 acres • closed to leasing: 138,500 acres • no fluid minerals allocation: 187,000 acres • planning decision not mapped: 565,800 acres Manage fluid minerals outside of GRSG habitat but in population areas as follows: • open to leasing, subject to standard stipulations: 893,100 acres • open to leasing, subject to CSU and/or timing stipulations: 580,700 acres • open to leasing, subject to NSO stipulations: 594,100 acres • closed to leasing: 196,800 acres • no fluid minerals allocation: 285,700 acres	Manage fluid mineral leasing in GRSG habitat as follows: • open to leasing, subject to standard stipulations: 246,680 acres • open to leasing, subject to CSU and/or timing stipulations: 255,900 acres • open to leasing, subject to NSO stipulations: 24,400 acres • closed to leasing: 3,341,300 acres • no fluid minerals allocation: 43,400 acres • planning decision not mapped: 96,900 acres Manage fluid minerals outside of GRSG habitat but in population areas the same as Alternative A. - planning decision not mapped: 234,500 acres				
Unleased Federal Fluid Mineral Estate				
Unleased Areas within Priority Habitat: Under current management there is no designated priority habitat. Fluid mineral leasing in sage grouse occupied habitat will be managed as discussed above. Most LUPs include a management action that prohibits surface disturbing or other disruptive within GRSG breeding and nesting habitat within a certain distance and between certain dates. The protect buffers around leks vary from 0.25 miles and 3.1 miles. In general, recently completed plans include a larger protective buffer. Recently completed plans also include a management action that prohibits surface disturbing activity or disruptive activities during certain dates in winter habitat.	Unleased Areas within Priority Habitat: Close priority GRSG habitat areas to fluid mineral leasing. Upon expiration or termination of existing leases, do not accept nominations/expressions of interest for parcels within priority areas.	Unleased Areas within Priority Habitat: No new leases or permits will be issued in occupied GRSG habitat. Upon expiration or termination of existing leases, do not accept nominations/expressions of interest for parcels within occupied habitat.	Unleased Areas within Priority Habitat: Areas outside GRSG priority habitat but within 1 mile of an occupied lek, if the lek is located within priority habitat, would be open to leasing fluid minerals, subject to NSO stipulations. Priority habitat within 4 miles of an occupied lek, if the lek is located within priority habitat, would be designated as open to oil and gas leasing subject to NSO stipulations. Priority habitat beyond 4 miles of an occupied lek, if the lek is located within priority habitat, would be designated as open to oil and gas leasing subject to controlled surface use stipulations (see list below) and the following timing stipulations: • Winter habitat from Nov 15 – Mar 15 • Brood rearing habitat from Apr 15 – Jul 15 • Breeding and nesting habitat from Feb 15 – Jun 15 Where leasing/development is allowed within priority habitat, development could occur if it adhered to the following controlled surface use stipulations: • the development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); • the development meets tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to	Unleased Areas within Priority Habitat: Priority habitat would be designated as open to oil and gas leasing subject to controlled surface use stipulations (see list below) and the timing stipulations. Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats (specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist): • Winter habitat from Nov 15 – Mar 15. • Nesting and brood-rearing areas from Apr 1 – Aug 15. • On leks from Feb 15 – May 15 Where leasing/development is allowed within priority habitat, impacts from development would be limited or ameliorated through the use of the following controlled surface use stipulations: • New permanent disturbance, including structures, fences, and buildings, should not be located within the occupied lek itself. • No permanent disturbance within 1 mile of an occupied lek, unless it is not visible to the sage-grouse using the lek. • New permanent tall structures should not be located within one mile of the lek, if visible by the birds within the lek. • A disturbance outside the lek should not produce noise which rises more than 10 db above the ambient (background) level at the edge of the lek during breeding season. • Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise)

Project proponents must demonstrate why avoidance is not possible. • If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area’s priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			permitting process unless at least one of the following can be demonstrated in the NEPA analyses associated with the specific project: • A specific design feature is documented to not be applicable to the site-specific conditions of the project/activity; • A proposed design feature or best management practice is determined to provide equal or better protection for GRSG or its habitat; • Analyses conclude that following a specific feature will provide no more protection to GRSG or its habitat than not following it, for the specific project being proposed. A minimum lease size of 640 contiguous acres of federal mineral estate would be applied within priority habitat. Smaller parcels may be leased only when 640 contiguous acres of federal mineral estate is not available and leasing is necessary to remain in compliance with laws, regulations and policy; for example, to protect the federal mineral estate from drainage or to commit the federal mineral estate to unit or communitization agreements.	
Allow geophysical exploration in areas that are not closed to fluid mineral leasing. Geophysical exploration in GRSG habitat shall be subject to seasonal restrictions discussed above.	Allow geophysical exploration within priority GRSG habitat areas to obtain exploratory information for areas outside of and adjacent to priority GRSG habitat areas. Allow geophysical operations only by helicopter-portable drilling methods and in accordance with seasonal timing restrictions and/or other restrictions that may apply.	No new geophysical exploration permits will be issued.	Allow geophysical exploration within occupied sage-grouse habitat areas to obtain exploratory information. Geophysical exploration shall be subject to seasonal restrictions that preclude activities in breeding, nesting, brood rearing and winter habitats during their season of use by GRSG.	Allow geophysical exploration within priority GRSG habitat to obtain exploratory information. Geophysical exploration would be subject to the same seasonal and controlled surface use stipulations as would be applied to leases within priority habitat.
Under current management there is no designated general habitat. Fluid mineral leasing in sage grouse occupied habitat will be managed as discussed above.	No similar action.	No general habitat is identified.	Unleased Areas within General Habitat: Areas within 1 mile of an occupied lek, if the lek is located within general habitat,, whether the area is in occupied or unoccupied GRSG habitat, would be open to leasing fluid minerals, subject to NSO stipulations.	GRSG habitat outside priority habitat would not be managed for the conservation of the species. No specific management actions are provided for this habitat.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			General habitat beyond 1 mile of an occupied lek, if the lek is located within general habitat, would be designated as open to oil and gas leasing subject to controlled surface use stipulations (see list below) and the following timing stipulations: • Winter habitat from Nov 15 – Mar 15 • Brood rearing habitat from Apr 15-Jul 15 • Breeding and nesting habitat from Feb 15-Jun 15 Where leasing/development is allowed within general habitat, development could occur if it adhered to the following controlled surface use stipulations: • the development meets noise restrictions (noise at occupied leks does not exceed 10 decibels above ambient sound levels from two hours before to two hours after sunrise and sunset during breeding season); and • the development meets tall structure restrictions (a tall structure is any man-made structure that has the potential to disrupt lekking or nesting birds by creating new perching/nesting opportunities and/or decrease the use of an area; a determination as to whether something is considered a tall structure would be determined based on local conditions such as vegetation or topography). General habitat within and beyond the 1.0 mile NSO area would require coordination with UDWR during project implementation, and implementation of best management practices (e.g., anti-perch devices for raptors, etc.). The design features identified in Appendix D (of the NTT report) would be attached as lease notices to all new leases in general	

Table 2-2 – Description of Alternatives A, B, C$_1$, C$_2$, D, and E$_1$

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			habitat and would be applied during the permitting process unless at least one of the following can be demonstrated in the NEPA analyses associated with the specific project: • A specific design feature is documented to not be applicable to the site-specific conditions of the project/activity; • A proposed design feature or best management practice is determined to provide equal or better protection for GRSG or its habitat; • Analyses conclude that following a specific feature will provide no more protection to GRSG or its habitat than not following it, for the specific project being proposed. The stipulations within general habitat (closure or restrictions) could be waived, except for the seasonal stipulations, if off-site mitigation coordinated with BLM/FS and UDWR is successfully completed in priority habitat or opportunity areas.	
Leased Federal Fluid Mineral Estate				
No similar action.	In priority habitat, apply the following conservation measures through RMP implementation decisions (e.g., approval of an Application for Permit to Drill, Sundry Notice, etc.) and upon completion of the environmental record of review (43 CFR 3162.5), including appropriate documentation of compliance with NEPA. In this process evaluate, among other things: 1. Whether the conservation measure is “reasonable” (43 CFR 3101.1-2) with the valid existing rights; and 2. Whether the action is in conformance with the approved RMP.	Apply the following conservation measures (rows) as Conditions of Approval at the project and well permitting stages, and through RMP implementation decisions and upon completion of the environmental record of review (43 CFR § 3162.5), including appropriate documentation of compliance with NEPA. In this process evaluate, among other things: 1. Whether the conservation measure is “reasonable” (43 CFR § 3101.1-2) with the valid existing rights; and 2. Whether the action is in conformance with the approved RMP.	In priority habitat, apply the following conservation measures (rows) through implementation decisions (e.g., approval of an Application for Permit to Drill, Sundry Notice, etc.) and upon completion of the environmental record of review (43 CFR 3162.5), including appropriate documentation of compliance with NEPA. In this process evaluate, among other things: 1. Whether the conservation measure is “reasonable” (43 CFR 3101.1-2) with the valid existing rights; and 2. Whether the action is in conformance with the approved RMP.	All existing uses are explicitly recognized by this alternative and shall not be affected by the implementation of this alternative. The sage-grouse conservation measures identified in the associated NEPA documents for each of these projects would continue to be implemented to protect GRSG and its habitat. Provisions of this plan would not be added to the measures identified each specific project.
No similar action. Measures that reduce or eliminate impacts to GRSG are considered on a case-by-case basis during implementation level planning.	Do not allow new surface occupancy on federal leases within priority habitats, this includes winter concentration areas (Doherty et al. 2008, Carpenter et al. 2010) during any time of the year. Consider an exception: • If the lease is entirely within priority	Same as Alternative B.	Apply the 5% disturbance limitation for development within priority habitat. Where GRSG conservation opportunities exist, work in cooperation with operators in priority and general habitat to minimize	All existing uses are explicitly recognized by this alternative and shall not be affected by the implementation of this alternative. The sage-grouse conservation measures identified in the associated NEPA documents for each of these projects would continue to

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
	habitats, apply a 4-mile NSO around the lek, and limit permitted disturbances to 1 per section with no more than 3% surface disturbance in that section. • If the entire lease is within the 4-mile lek perimeter, limit permitted disturbances to 1 per section with no more than 3% surface disturbance in that section. Require any development to be placed at the most distal part of the lease from the lek, or, depending on topography and other habitat aspects, in an area that is less demonstrably harmful to GRSG.		habitat loss, fragmentation, and direct and indirect effects to GRSG and habitat. Issue Written Orders of the Authorized Officer (43 CFR 3161.2) requiring reasonable protective measures consistent with the lease terms where necessary to avoid or minimize effects to GRSG populations and habitat. In areas where GRSG populations have been substantially diminished, and where few birds remain, include actions in the authorization (e.g., siting/designing infrastructure, hastened habitat restoration) that will minimize habitat loss and promote restoration of habitat when development activities cease. In addition to considering opportunities for onsite mitigation, cooperate with project proponents to develop and consider implementing appropriate off-site mitigation that the BLM/FS, coordinating with the respective state wildlife agency, determines would avoid or minimize habitat and population-level effects. Where possible, off-site mitigation should occur within the same population area where the impact is incurred. When developing such mitigation, consider compensating for the short-term and long-term direct and indirect loss of GRSG and its habitat. For geophysical exploration activities, include seasonal timing limitations and BMPs as permit conditions of approval to eliminate or minimize surface-disturbing and disruptive activities within nesting and brood-rearing habitat and winter concentration areas. Ensure authorizations under Onshore Oil and Gas Order No. 7 (Disposal of Produced Water) consider the potential impacts to GRSG from West Nile virus and develop	be implemented to protect GRSG and its habitat. Provisions of this plan would not be added to the measures identified each specific project.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			appropriate mitigation measures.	
Most LUPs include a management action that prohibits surface disturbing or other disruptive within GRSG breeding and nesting habitat within a certain distance and between certain dates. The protect buffers around leks vary from 0.25 miles and 3.1 miles. In general, recently completed plans include a larger protective buffer. Recently completed plans also include a management action that prohibits surface disturbing activity or disruptive activities during certain dates in winter habitat.	Apply a seasonal restriction on exploratory drilling that prohibits surface-disturbing activities during the nesting and early brood-rearing season in all priority GRSG habitat during this period.	Apply a seasonal restriction on exploratory drilling that prohibits surface-disturbing activities during the nesting and brood-rearing season in all occupied sage-grouse habitat during this period. This seasonal restriction shall also apply to related activities that are disruptive to GRSG, including vehicle traffic and other human presence.	Same as Alternative B.	Allow exploratory drilling within priority GRSG habitat, subject to the same seasonal and controlled surface use stipulations as would be applied to leases within priority habitat.
No similar action.	BLM should closely examine the applicability of categorical exclusions in priority habitat. If extraordinary circumstances review is applicable, BLM should determine whether those circumstances exist.	Same as Alternative B.	No similar action.	No similar action.
No similar action.	Complete Master Development Plans in lieu of Application for Permit to Drill (APD)-by-APD processing for all but wildcat wells.	Same as Alternative B.	Within priority habitat, operators must submit a site-specific plan of development for roads, wells, pipelines and other infrastructure prior to any development being authorized. The BLM will evaluate the plan through the NEPA process.	No similar action.
No similar action.	When permitting APDs on existing leases that are not yet developed, the proposed surface disturbance cannot exceed 3% for that area. Consider an exception if: • Additional, effective mitigation is demonstrated to offset the resulting loss of GRSG (see Objectives). o When necessary, conduct additional, effective mitigation in 1) priority GRSG habitat areas or – less preferably – 2) general GRSG habitat (dependent upon the area-specific ability to increase GRSG populations). o Conduct additional, effective mitigation first within the same population area where the impact is realized, and if not possible then conduct mitigation within the same	When permitting APDs on existing leases that are not yet developed, the proposed surface disturbance cannot exceed 3% per section for that area. Consider an exception if: • Additional, effective mitigation is demonstrated to offset the resulting loss of GRSG (see Objectives). o When necessary, conduct additional, effective mitigation in 1) priority GRSG habitat areas or – less preferably – 2) general GRSG habitat (dependent upon the area-specific ability to increase GRSG populations). o Conduct additional, effective mitigation first within the same population area where the impact is realized, and if not possible then	Same as Alternative B, but with a 5% disturbance ceiling.	All existing uses are explicitly recognized by this alternative and shall not be affected by the implementation of this alternative. The sage-grouse conservation measures identified in the associated NEPA documents for each of these projects would continue to be implemented to protect GRSG and its habitat. Provisions of this plan would not be added to the measures identified each specific project.

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
	Management Zone as the impact, per 2006 WAFWA Strategy – pg 2-17.	conduct mitigation within the same Management Zone as the impact, per 2006 WAFWA Strategy – pg 2-17.		
No similar action. Current policy allows unitization to occur on a case-by-case basis.	Require unitization when deemed necessary for proper development and operation of an area (with strong oversight and monitoring) to minimize adverse impacts to GRSG according to the Federal Lease Form, 3100-11, Sections 4 and 6.	Same as Alternative B.	Encourage unitization when deemed necessary for proper development and operation of an area (with strong oversight and monitoring) to minimize adverse impacts to GRSG according to the Federal Lease Form, 3100-11, Sections 4 and 6.	No similar action.
Most LUPs include a management action that allows for acquisition of lands that have important resource values including crucial wildlife habitat and land tenure adjustments to improve the manageability of public lands. In order to be considered for any form of land tenure adjustment, all lands not specifically identified for disposal must meet criteria included in the LUPs.	Identify areas where acquisitions (including federal mineral rights) or conservation easements, would benefit GRSG habitat.	Same as Alternative B.	Same as Alternative B.	No similar action.
No similar action. Current policy provides for the establishment of reclamation bonds on a case-by-case basis.	For future actions, require a full reclamation bond specific to the site in accordance with 43 CFR 3104.2, 3104.3, and 3104.5. Insure bonds are sufficient for costs relative to reclamation (Connelly et al. 2000, Hagen et al. 2007) that would result in full restoration of the lands to the condition it was found prior to disturbance. Base the reclamation costs on the assumption that contractors for the BLM will perform the work.	Same as Alternative B.	Same as Alternative B.	No similar action.
No similar action. Individual land use plans may contain an appendix that outlines BMPs that are applied on a case-by-case basis.	Make applicable Best Management Practices (BMPs, see Appendix D of the NTT Report) mandatory as Conditions of Approval within priority GRSG habitat.	Same as Alternative B.	The design features identified in Appendix D (of the NTT report) would be attached as mandatory Conditions of Approval during development of a lease unless at least one of the following can be demonstrated in the NEPA analyses associated with the specific project: • A specific design feature is documented to not be applicable to the site-specific conditions of the project/activity; • A proposed design feature or best management practice is determined to provide equal or better protection for GRSG or its habitat;	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
			• Analyses conclude that following a specific feature will provide no more protection to GRSG or its habitat than not following it, for the specific project being proposed.	
No similar action.	No similar action.	Any oil, gas, geothermal activity will be conducted to maximize avoidance of impacts, based on evolving scientific knowledge of impacts.	No similar action.	No similar action.
Mineral Split Estate				
Under current management, there is no priority habitat. Decision included in current management plans apply to both federal surface and mineral estate.	Where the federal government owns the mineral estate in priority habitat, and the surface is in non-federal ownership, apply the conservation measures applied on public lands.	Same as Alternative B.	Same as Alternative B.	Because the surface estate is the key to conservation of habitat, the GRSG habitat has been mapped according to surface ownership. However, implementation of his alternative will have to accommodate the dominant nature of the mineral estate, and react accordingly.
No similar action. Under current management, there is no priority habitat. Decision included in current management plans apply to both federal surface and mineral estate. Individual land use plans may contain an appendix that outlines BMPs that are applied on a case-by-case basis.	Where the federal government owns the surface, and the mineral estate is in non-federal ownership in priority habitat, apply appropriate Fluid Mineral BMPs (see Appendix D of the NTT Report) to surface development.	Same as Alternative B.	Where the federal government owns the surface, and the mineral estate is in non-federal ownership in priority habitat, the design features identified in Appendix D (of the NTT Report) would be attached as a lease notice to all new leases and as mandatory Conditions of Approval on existing leases unless at least one of the following can be demonstrated in the NEPA analyses associated with the specific project: • A specific design feature is documented to not be applicable to the site-specific conditions of the project/activity; • A proposed design feature or best management practice is determined to provide equal or better protection for GRSG or its habitat; • Analyses conclude that following a specific feature will provide no more protection to GRSG or its habitat than not following it, for the specific project being proposed..	No similar action.
Comprehensive Travel and Transportation Management				
Manage OHV use in GRSG habitat as follows: • Open to cross-country use: 797,000	Manage OHV use in GRSG habitat as follows: • Open to cross-country use: 34,600	Manage OHV use in GRSG habitat as follows: • Open to cross-country use: 0 acres	Manage OHV use in GRSG habitat as follows: • Open to cross-country use: 77,000	Manage OHV use in GRSG habitat as follows: • Open to cross-country use: 351,700

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
acres - Limited to existing routes: 437,400 acres - Limited to designated routes: 1,217,700 acres - Closed: 32,200 acres - No decision mapped: 15,100 acres - Forest Service: 814,400 acres (The Forest Service does not use similar OHV management categories. OHV use on National Forest Lands within the planning area is limited to roads, trails, and areas that have been designated through a transportation planning process.)	acres - Limited to existing routes: 1,213,500 acres - Limited to designated routes: 1,217,700 acres - Closed: 32,200 acres - No decision mapped: 1,400 acres - Forest Service: 814,400 acres (The Forest Service does not use similar OHV management categories. OHV use on National Forest Lands within the planning area is limited to roads, trails, and areas that have been designated through a transportation planning process.)	- Limited to existing routes: 1,249,500 acres - Limited to designated routes: 1,217,700 acres - Closed: 32,200 acres - No decision mapped: 0 acres - Forest Service: 814,400 acres (The Forest Service does not use similar OHV management categories. OHV use on National Forest Lands within the planning area is limited to roads, trails, and areas that have been designated through a transportation planning process.)	acres - Limited to existing routes: 1,166,500 acres - Limited to designated routes: 1,217,700 acres - Closed: 32,200 acres - No decision mapped: 6,000 acres - Forest Service: 814,400 acres (The Forest Service does not use similar OHV management categories. OHV use on National Forest Lands within the planning area is limited to roads, trails, and areas that have been designated through a transportation planning process.)	acres - Limited to existing routes: 888,000 acres - Limited to designated routes: 1,217,700 acres - Closed: 32,200 acres - No decision mapped: 9,800 acres - Forest Service: 814,400 acres (The Forest Service does not use similar OHV management categories. OHV use on National Forest Lands within the planning area is limited to roads, trails, and areas that have been designated through a transportation planning process.)
Under current management, there is no priority habitat. OHV use will be managed as identified in the area-designations above.	In priority habitat, limit motorized travel to existing roads, primitive roads, and trails at a minimum, until such time as travel management planning is complete and routes are either designated or closed.	Same as Alternative B.	Priority habitat areas that do not have designated routes in a Travel Management Plan would be managed at least as limited to existing routes (i.e., could maintain existing OHV closures) until a Travel Management Plan designates routes. Priority habitat areas that have undergone Travel Management Planning with route designation would be managed at least as limited to designated routes (i.e., could maintain existing OHV closures). In these areas, existing route designations would be reviewed and adjusted where impacts to GRSG from route presence or use may exist.	Priority habitat areas with nesting and winter habitat that do not have designated routes in a Travel Management Plan would be managed at least as limited to existing routes (i.e., could maintain existing OHV closures) until a Travel Management Plan designates routes. Priority habitat areas with nesting and winter habitat that have undergone Travel Management Planning with route designation would be managed at least as limited to designated routes (i.e., could maintain existing OHV closures). In these areas, existing route designations would be reviewed and adjusted where impacts to GRSG from route presence or use may exist.
Under current management there is no designated priority habitat. No similar action. Under current policy, the need for permanent or seasonal road closures is evaluated during travel management planning.	In priority habitat, travel management should evaluate the need for permanent or seasonal road or area closures.	No similar action.	No similar action.	No similar action.
Consider route and trail modifications (new or existing) on a case-by-case basis. Identify travel management areas and prioritize travel management planning in	Complete activity level plans within five years of the record of decision. During activity level planning, where appropriate, designate routes in priority habitat with current administrative/agency purpose or need to	Same as Alternative B.	Complete transportation plans in accordance with National BLM Travel Management guidance, requiring the BLM to maintain a current action plan and planning schedule to most effectively target available resources.	Counties should adopt and enforce travel management plans that include consideration for greater sage-grouse.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
areas where it would provide the most resource benefit.	administrative access only.		The following GRSG population areas are Utah's top priority areas to designate comprehensive travel plans: • Sheeprocks GRSG population area • Bald Hills GRSG population area • Box Elder GRSG population area • Rich GRSG population area • Ibapah GRSG population area • Hamlin Valley GRSG population area	
Under current management there is no designated priority habitat. Consider route and trail modifications (new or existing) on a case-by-case basis using the designation criteria.	In priority habitat, limit route construction to realignments of existing designated routes if that realignment has a minimal impact on sage-grouse habitat, eliminates the need to construct a new road, or is necessary for motorist safety.	Limit route construction to realignments of existing designated routes if that realignment has a minimal impact on sage-grouse habitat, eliminates the need to construct a new road, or is necessary for motorist safety. Mitigate any impacts with to offset the loss of GRSG habitat.	Travel systems would be managed with an emphasis on improving the sustainability of the travel network in a comprehensive manner to minimize impacts to GRSG, maintain motorist safety, and prevent unauthorized cross country travel while meeting access needs. To do so, it may be necessary to improve portions of existing routes, close existing routes or create new routes that meet user group needs, thereby reducing the potential for pioneering unauthorized routes. The emphasis of the comprehensive travel and transportation planning within priority habitat would be placed on having a neutral or positive effect on sage grouse habitat.	No similar action.
No similar action. Allow upgrades to existing roads on a case-by-case basis subject to site-specific environmental review.	In priority habitat, allow no upgrading of existing routes that would change route category (road, primitive road, or trail) or capacity unless the upgrading would have minimal impact on sage-grouse habitat, is necessary for motorist safety, or eliminates the need to construct a new road.	Allow no upgrading of existing routes that would change route category (road, primitive road, or trail) or capacity unless it is necessary for motorist safety, or eliminates the need to construct a new road. Any impacts shall be mitigated with methods that have been demonstrated to be effective to offset the loss of GRSG habitat.	No similar action.	No similar action.
All LUPs include management actions that encourage the administrating agency to follow best management practices that reduce or minimize the impacts of development, including use of existing roads where possible.	In priority habitat, use existing roads, or realignments as described above to access valid existing rights that are not yet developed. If valid existing rights cannot be accessed via existing roads, then build any new road constructed to the absolute minimum standard necessary, and add the surface disturbance to the total disturbance in the priority area. If that disturbance exceeds 3 % for that area, then make additional, effective mitigation necessary to	Same as Alternative B using a 4-mile buffer to determine road route. Prohibit new road construction within 4 miles of occupied GRSG leks, and avoid new road construction in occupied GRSG habitat.	Same as Alternative B, except apply a 5% disturbance ceiling (rather than a 3%) and plan for new routes in consideration of larger transportation network objectives and needs.	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
	offset the resulting loss of GRSG habitat.			
No similar action. The need for restoration of linear disturbances (unauthorized routes) is identified during the implementation level travel management process or on a case-by-case basis.	In priority habitat, conduct restoration of roads, primitive roads and trails not designated in travel management plans. This also includes primitive route/roads that were not designated in Wilderness Study Areas and within lands with wilderness characteristics that have been selected for protection.	Same as Alternative B.	In priority habitat, conduct restoration of roads, primitive roads and trails not designated for motorized or non-motorized travel in travel management plans.	No similar action.
When reseeding roads, primitive roads and trails use appropriate seed mixes and consider the use of transplanted sagebrush.	When reseeding roads, primitive roads and trails in priority habitat, use appropriate seed mixes and consider the use of transplanted sagebrush.	When reseeding closed roads, primitive roads and trails, use appropriate native seed mixes and require the use of transplanted sagebrush.	Same as Alternative B.	No similar action.
No similar action.	No similar action.	No similar action.	No similar action.	Develop an educational process to advise OHV users of the potential for conflict with GRSG.
Recreation and Visitor Services				
Consider SRPs on a case-by-case basis. Consider measures that will minimize impacts to important resources or resource values.	Only allow special recreation permits (SRPs) (BLM) or recreation special use permits (FS) in priority habitat that have neutral or beneficial effects to priority habitat areas.	Only allow special recreation permits that have demonstrated neutral or beneficial affects to occupied habitat areas.	Same as Alternative B.	Limit or ameliorate impacts from recreation activities through the use of the following stipulations: • New permanent disturbance, including structures, fences, and buildings, should not be located within the occupied lek itself. • No permanent disturbance within 1 mile of an occupied lek, unless it is not visible to the sage-grouse using the lek. • New permanent tall structures should not be located within one mile of the lek, if visible by the birds within the lek. • A disturbance outside the lek should not produce noise which rises more than 10 db above the ambient (background) level at the edge of the lek during breeding season. • Apply time-of-day stipulations when the lek is active (e.g., no activity from 2-hours before sunrise to 2-hours after sunrise) • Avoid activities (construction, vehicle noise, etc.) in the following seasons and habitats: o On leks from Feb 15 – May 15 to avoid activities that will disturb lek
No similar action.	No similar action.	No similar action.	Evaluate existing SRPs for adverse effects to GRSG and their habitat. Modify or cancel the permit, as appropriate, to avoid or mitigate effects of habitat alterations or other physical disturbances to GRSG (e.g., breeding, brood-rearing, migration patterns, or winter survival). Identify permit stipulations that require the permittee to implement any necessary habitat restoration activities after SRP events. Restoration activities must be consistent with GRSG habitat objectives as determined by the BLM field office in collaboration with UDWR.	

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
				attendance or breeding. o In nesting and brood-rearing areas from Apr 1 – Aug 15. o In winter habitat from Nov 15 – Mar 15. o Specific time and distance determinations for seasonal stipulations would be based on site-specific conditions, in coordination with the local UDWR biologist. • Avoid disturbance within priority habitat (nesting and brood-rearing areas, winter habitat, other habitat), if possible. Project proponents must demonstrate why avoidance is not possible. • If avoidance in priority habitat is not possible, minimize as appropriate to the area (e.g., try to minimize effects by locating development in habitat of the least importance, take advantage of topographic to screen the disturbance, or maintaining and enhancing wet meadow and riparian vegetation). • After minimization, mitigation is required (see mitigation section). • Cumulative new permanent disturbance should not exceed 5% of surface area of nesting, winter, or other habitat, within the population area's priority habitat. • Manage priority habitat to avoid barriers to migration, if applicable.
No similar action.	No similar action.	Seasonally prohibit camping and other non-motorized recreation within 4 miles of occupied GRSG leks.	No similar action.	No similar action.
Livestock Grazing				
Continue to make GRSG habitat available for livestock grazing. Active AUMs for livestock grazing would be 329,521 on BLM lands and 265,373 on FS lands, though the number of AUMs on a permit may be adjusted during site-specific evaluations conducted during	No similar action.	Alt C1: Make occupied GRSG habitat unavailable to livestock grazing for the life of the plan. Alt C2: Within allotments that overlap occupied GRSG habitat, reduce permitted AUMs by 131,808 permitted	Continue to make GRSG priority and general habitat available for livestock grazing. Active AUMs for livestock grazing would be 329,521 on BLM lands and 265,373 on FS lands, though the number of AUMs on a permit may be adjusted during site-specific evaluations	Continue to make GRSG priority and general habitat available for livestock grazing. Active AUMs for livestock grazing would be 329,521 on BLM lands and 265,373 on FS lands. Existing grazing operations would utilize recognized rangeland best management

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
term permit renewals, Allotment Management Plan (AMP) development, or other appropriate implementation activity. Additionally, temporary adjustments can be made annually to livestock numbers, the number of AUMs, season of use, and other aspects of grazing within the terms and conditions of the permit based on the permittees livestock operation and/or an evaluation of a variety of forage and resource site-specific conditions.		This would result in a reduction of up to 329,521 permitted AUMs on BLM lands and 265,373 permitted AUMs on FS lands (if all allotments witih any overlap with GRSG habitat were closed in their entirety; closing just the portions of allotments within GRSG habitats, if possible, could reduce this number).	AUMs on BLM lands and 106,149 permitted AUMs on FS lands. Reductions by allotment will occur by Field Office based on a review of the site-specific information (e.g., range condition, utilization levels, type and condition of GRSG habitat). Based on the Field Office review, the reductions in AUMs would occur in allotments that overlap occupied GRSG habitat, whether partial reductions in active use or closing specific allotments. The reductions would be implemented during renewal of term grazing permits. The resulting AUMs available for permitting for livestock grazing would be 197,713 on BLM lands and 159,224 on FS lands.	conducted during term permit renewals, Allotment Management Plan (AMP) development, or other appropriate implementation activity. Additionally, temporary adjustments can be made annually to livestock numbers, the number of AUMs, season of use, and other aspects of grazing within the terms and conditions of the permit based on the permittees livestock operation and/or an evaluation of a variety of forage and resource site-specific conditions.	practices to increase the necessary vegetation, and thereby increase the potential for nesting success and population recruitment Should site-specific concerns be raised about the effect of grazing upon GRSG habitat, and such effects are documented over a sufficiently long time-frame, corrective management actions should be addressed through the application of best management practices, including consideration of those identified by the Department of Agriculture and Food's Grazing Improvement Program.
No similar action.	Within priority GRSG habitat, incorporate GRSG habitat objectives and management considerations into all BLM and FS grazing allotments through AMPs or permit renewals and/or FS Annual Operating Instructions.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	Same as Alternative B.	No similar action.
Consider adjustments to allotment boundaries that provide for single unit or landscape level grazing approaches to habitat improvement on a case-by-case basis.	In priority habitat, work cooperatively on integrated ranch planning within GRSG habitat so operations with deeded/BLM and/or FS allotments can be planned as single units.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	In priority habitat, consult, cooperate, and coordinate with other land owners and management agencies (e.g., private, SITLA) to develop plans which provide for single unit or landscape level approaches to habitat improvement. In priority habitat with unfenced private and SITLA lands within a grazing allotment that are under exchange of	No similar action.

Table 2-2 – Description of Alternatives A, B, C$_1$, C$_2$, D, and E$_1$

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
				use agreements or percent public land use, manage the allotment as a single unit that will have the same management as the public lands.	
Manage rangeland resources to maintain healthy, sustainable, rangeland ecosystems and to restore degraded rangelands in accordance with Utah's Standards for Rangeland Health or standards or guidelines established in individual Forest Service LRMPs. Standard 3 requires that desired species including native, threatened, endangered, and special status species are maintained at a level appropriate for the site and species as indicated by: a) Frequency, diversity, density, age class, and productivity of desired native species necessary to ensure reproductive capability and survival. b) Habitats connected at a level to enhance species survival. c) Native species reoccupy habitat niches and voids caused by disturbances unless management objectives call for introduction or maintenance of nonnative species. d) Habitats for threatened, endangered, and special status species managed to provide for recovery and move species toward de-listing. e) Appropriate amount, type, and distribution of vegetation reflecting the presence of 1) the DPC, where identified in a land use plan conforming to these Standards, or 2) where the DPC is not identified, a community that sustains the desired level of productivity and properly functioning ecological processes. Complete rangeland health assessments for each allotment at least once every ten years for consideration during the permit renewal process.	Prioritize completion of land health assessments (FS may use other analyses) and processing grazing permits within priority GRSG habitat areas. Focus this process on allotments that have the best opportunities for conserving, enhancing or restoring habitat for GRSG. Utilize BLM Ecological Site Descriptions (ESDs) (or comparable FS methods) to conduct land health assessments to determine if standards of range-land health are being met.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	Evaluate Utah's Rangeland Health Standards (RHS) (FS may use other analyses) and process grazing permits within priority GRSG habitat areas. Focus management activities on allotments found not to be achieving RHS and that have the best opportunities for conserving, enhancing or restoring habitat for GRSG. When completing land health assessments, incorporate appropriate indicators and protocols to assess the condition of GRSG habitat considering the objectives (e.g., percent cover and height of sagebrush, grasses, forbs, other shrubs, etc.) (Doherty et al. 2011). Use ESDs or USFS equivalent and/or other appropriate information, including GRSG habitat objectives, as the basis to determine DPC or other community within proper functioning ecological processes for conducting land health assessments to evaluate the achievement or non-achievement of rangeland health standards.	No similar action.

Table 2-2 – Description of Alternatives A, B, C$_1$, C$_2$, D, and E$_1$

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
Monitor vegetation trends (including composition, cover, and age class), noxious weeds, riparian Proper Functioning Condition (PFC), etc. as part of the grazing management program. BLM plans do not contain grazing management decisions specific to conserving sage-grouse habitat. Forest Service LUPs contain specific management actions for permitted livestock grazing that take in to consideration established habitat management objectives.					
No similar action.	In priority habitat, conduct land health assessments that include (at a minimum) indicators and measurements of structure/condition/composition of vegetation specific to achieving GRSG habitat objectives (Doherty et al. 2011). If local/state seasonal habitat objectives are not available, use GRSG habitat recommendations from Connelly et al. 2000 and Hagen et al. 2007.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	Within priority habitat where sagebrush is the current or potential dominant vegetation type or is a primary species within the various states of the ecological site description, maintain or restore vegetation to provide habitat for lekking, nesting, brood rearing, winter, and transition areas. Desired cover percentages and heights for sagebrush, grasses, and forbs in seasonal habitats will follow habitat guidelines from scientific literature (e.g., Connelly et al. 2000, Hagen et al. 2007). Adjustments from the guidelines may be made, but must be based on documented regional variation of habitat characteristics (e.g., sagebrush type, ecological site potential), quantitative data from population and habitat monitoring, and evaluation of local research.	No similar action.
No similar action.	Develop specific objectives to conserve, enhance or restore priority GRSG habitat based on ESDs (or comparable FS methods) and assessments (including within wetlands and riparian areas). If an effective grazing system that meets GRSG habitat requirements is not already in place, analyze at least one alternative that conserves, restores or enhances GRSG habitat in the NEPA document prepared for the permit renewal.	Alt C1: No similar action.	Alt C2: No similar action.	Same as Alternative B.	Consider GRSG seasonal habitat requirements when managing sagebrush rangelands. Considerations to be taken into account include the following: Leks • Be cautious of man-made structures on lek sites. • Reduce shrub encroachment and maintain the "open" area that characterizes a typical lek site. • Identify the location of leks through discussions with DWR biologists.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
					Nesting/Early Brood-Rearing • Maintain and enhance the existing sagebrush/plant communities. • Manage these areas to increase herbaceous cover by sustaining a mosaic of sagebrush and open areas. • Avoid repeated, annual heavy use of these areas by implementing periodic rest and/or deferment periods during the critical growing season. Late Brood-Rearing • Avoid continuous (season-long) grazing of wet meadows and riparian habitats, especially under drought conditions when temperatures are high. Winter • Carefully manage levels of browsing or activities in sagebrush areas that constitute GRSG habitat that would reduce GRSG access to these areas for food and cover. • The potential impact of livestock grazing on winter habitat can be positive or negative depending on scale and location of use
Consider changes to season of use on a case-by-case basis when resource conditions indicate that a change is needed.	No similar action.	Alt C1: No similar action.	Alt C2: Within GRSG habitat, change season of use so that no grazing occurs during the growing season. Based on sub-regional climate variations, growing season will be determined on a permit-by-permit basis.	No similar action.	No similar action.
Consider range improvements and/or adjust permit terms and conditions on a case-by-case basis as necessary to meet land health standards or habitat objectives identified in	In priority habitat, manage for vegetation composition and structure consistent with ecological site potential and within the reference state to achieve GRSG seasonal	Alt C1: No similar action.	Alt C2: In occupied GRSG habitat, manage for vegetation composition	In priority GRSG habitat, manage for vegetation composition and structure consistent with the objectives for GRSG seasonal habitats, as described above.	Address incompatible grazing strategies through established rangeland management practices consistent with the maintenance or enhancement of habitat.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
individual LUPs. Changes may include, but are not limited to: 1) Rotation systems (e.g., rest rotation, deferred rotation); 2) Season or timing of use; 3) Distribution of livestock use; 5) Type of livestock; 6) Class of livestock; 7) Duration of grazing use and rest periods.	habitat objectives. Implement management actions (grazing decisions, Annual Operating Instructions [FS only], AMP/Conservation Plan development, or other agreements) to modify grazing management to meet seasonal GRSG habitat requirements. Consider singly, or in combination, changes in: 1) Season or timing of use; 2) Numbers of livestock (includes temporary non-use or livestock removal); 3) Distribution of livestock use; 4) Intensity of use; and 5) Type of livestock (e.g., cattle, sheep, horses, llamas, alpacas and goats).		and structure consistent with ecological site potential and within the reference state to achieve GRSG habitat objectives. Implement management actions (grazing decisions, AMP/Conservation Plan development, or other plans or agreements) to modify grazing management to meet seasonal sage-grouse habitat requirements. Consider singly, or in combination, changes in: 1) Season, timing, and/or frequency of livestock use; 2) Numbers/AUMs of livestock (includes temporary non-use or livestock removal); 3) Distribution of livestock use; 4) Intensity of livestock use; and 5) Type of livestock (e.g., cattle, sheep, horses, llamas, alpacas and goats).	Develop and implement the terms and conditions needed to meet these objectives through the permit renewal process or other appropriate implementation action. In general habitat and opportunity areas, consider GRSG habitat objectives when making livestock grazing decisions. As necessary to meet land health standards and objectives for priority GRSG habitat, implement management actions (e.g., AMP, term permit renewals, grazing decisions, other agreements) to modify grazing management to meet seasonal GRSG habitat objectives, as outlined above. Consider singly, or in combination, changes in the following: 1) Rotation systems (e.g., rest rotation, deferred rotation); 2) Season or timing of use; 3) Distribution of livestock use; 4) Intensity of use (e.g., objectives for utilization or stubble height); 5) Type of livestock (e.g., cattle, sheep, horses, and goats), unless such a change conflicts with other species management; 6) Class of livestock (e.g., yearlings vs. cow-calf pairs) 7) Duration of grazing use and rest periods	Carefully manage the "time," "timing," and "intensity" of grazing in sagebrush/GRSG habitats to provide for the seasonal needs of GRSG. Specific prescriptions can be applied through more intensive management to address special needs or weak links in the biological year of GRSG production. Where time controlled grazing is not an option, moderate use of occupied GRSG habitats will usually leave mosaic or patchy areas where some plants are ungrazed. Managing for moderate utilization levels (40%) after the period of rapid vegetation growth may provide enough residual cover for GRSG nesting and early brood-rearing the subsequent spring. Evaluation of GRSG nesting and escape cover must be determined on a site-specific basis. Livestock operations with a small amount of nesting habitat should consider special management activities to protect nesting and early brood-rearing areas. Lighter use of areas may be warranted. In areas with large tracts of contiguous habitat, livestock producers should manage the vegetation on a rotational grazing basis, which may leave 10 - 20 percent of the area ungrazed periodically in combination with deferring or altering timing of grazing in other areas. In areas where GRSG nesting is common, managing for moderate use of plant growth across the landscape would be appropriate. Well-managed ranches with comprehensive grazing strategies that include short-term or duration grazing, higher levels of use may be acceptable, provided these higher levels of use include rested vegetation in nearby areas.
No similar action. Livestock grazing program/policy direction allows the BLM to	During drought periods, prioritize evaluating effects of the drought in priority GRSG	Alt C1: No similar action.	Alt C2: During drought	During drought periods, prioritize evaluating effects of the drought in priority GRSG	No similar action.

Table 2-2 – Description of Alternatives A, B, C$_1$, C$_2$, D, and E$_1$

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
make changes to livestock grazing in response to drought conditions. Changes may include adjusting livestock numbers based on available forage or shortening the season of use.	habitat areas relative to their needs for food and cover. Since there is a lag in vegetation recovery following drought, ensure that post-drought management allows for vegetation recovery that meets GRSG needs in priority GRSG habitat areas.		periods, prioritize evaluating effects of drought in sage-grouse habitat areas relative to their biological needs, as well as drought effects on ungrazed reference areas. Since there is a lag in vegetation recovery following drought (Thurow and Taylor 1999; Cagney et al. 2010), ensure that post-drought management allows for vegetation recovery that meets sage-grouse needs in sage-grouse habitat areas based on GRSG habitat objectives.	habitat areas relative to their needs for food and cover. Initiate emergency management measures (e.g. delaying turnout, adjusting the amount and/or duration of livestock grazing, implement other terms of the permit) during times of drought to protect sage grouse habitat. Implement post-drought management to allow for vegetation recovery that meets GRSG needs in priority GRSG habitat areas.	
Manage, maintain, protect, and restore riparian and wetland areas to the proper functioning condition (PFC).	Manage riparian areas and wet meadows for proper functioning condition (FS: or other similar methodology) within priority GRSG habitats.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	Same as Alternative A.	Design water developments to enhance mesic habitat for use by GRSG and maintain adequate vegetation in wet meadows. Within priority habitat, GRSG stipulations should take precedence over stipulations for other species if conflicts occur, if otherwise allowable by law.
Manage, maintain, protect, and restore riparian and wetland areas to the proper functioning condition (PFC).	Within priority and general GRSG habitats, manage wet meadows to maintain a component of perennial forbs with diverse species richness relative to site potential (e.g., reference state) to facilitate brood rearing. Also conserve or enhance these wet meadow complexes to maintain or increase amount of edge and cover within that edge to minimize elevated mortality during the late brood rearing period.	Alt C1: No similar action.	Alt C2: Within GRSG habitats, manage wet meadows to maintain a component of perennial forbs with diverse species richness and productivity relative to site potential (e.g., reference state) to facilitate brood rearing. Also conserve or enhance these wet meadow complexes to maintain or increase	Same as Alternative B.	Design water developments to enhance mesic habitat for use by GRSG and maintain adequate vegetation in wet meadows. Within priority habitat, GRSG stipulations should take precedence over stipulations for other species if conflicts occur, if otherwise allowable by law.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
			the amount of edge and cover within that edge to minimize elevated mortality during the late brood-rearing period.		
No similar action.	Where riparian areas and wet meadows meet proper functioning condition (FS – or meet standards using other similar methodology), strive to attain reference state vegetation relative to the ecological site description.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	No similar action.	Design water developments to enhance mesic habitat for use by GRSG and maintain adequate vegetation in wet meadows. Within priority habitat, GRSG stipulations should take precedence over stipulations for other species if conflicts occur, if otherwise allowable by law.
Manage rangeland resources to maintain healthy, sustainable, rangeland ecosystems and to restore degraded rangelands in accordance with Utah's Standards for Rangeland Health or standards or guidelines established in individual Forest Service LRMPs. Rangeland health standards require that riparian areas be managed for PFC.	Within priority GRSG habitat, reduce hot season grazing on riparian and meadow complexes to promote recovery or maintenance of appropriate vegetation and water quality. Utilize fencing/herding techniques or seasonal use or livestock distribution changes to reduce pressure on riparian or wet meadow vegetation used by GRSG in the hot season (summer).	Alt C1: No similar action.	Alt C2: No similar action.	Within priority GRSG habitat and opportunity areas, assess livestock grazing in riparian and meadow complexes and ensure recovery or maintenance of appropriate vegetation and water quality. Where recovery or maintenance is not occurring and the causal factor is livestock grazing, reduce pressure on riparian or wet meadow vegetation used by GRSG in the summer by adjusting grazing management practices (e.g., use fencing/herding techniques, or changes in seasonal use or livestock distribution). Consider applying the same to general habitat.	Continue livestock grazing strategies that have proven effective in maintaining and enhancing GRSG habitat, unless compelling and credible cause-and-effect evidence indicates a disturbance exists. Address incompatible grazing strategies through established rangeland management practices consistent with the maintenance or enhancement of habitat. Design water developments to enhance mesic habitat for use by GRSG and maintain adequate vegetation in wet meadows. Within priority habitat, GRSG stipulations should take precedence over stipulations for other species if conflicts occur, if otherwise allowable by law.
Consider authorization of new water developments on a case-by-case basis taking into consideration impacts to other resources and resource values.	Authorize new water development for diversion from spring or seep source only when priority GRSG habitat would benefit from the development. This includes developing new water sources for livestock as part of an AMP/conservation plan to improve GRSG habitat.	Alt C1: No similar action.	Alt C2: Authorize no new water developments for diversion from spring or seep sources within sage-grouse habitat~~.~~	Limit authorization of new water developments within GRSG priority habitat to projects that would have a neutral effect or be beneficial to priority GRSG habitat (such as by shifting livestock use away from critical areas). New developments that divert surface water must be designed to maintain continuity of predevelopment riparian or wet meadow vegetation and hydrology.	Design water developments to enhance mesic habitat for use by GRSG and maintain adequate vegetation in wet meadows. Within priority habitat, GRSG stipulations should take precedence over stipulations for other species if conflicts occur, if otherwise allowable by law.
Consider modifications to existing water developments on a case-by-case basis taking into consideration impacts to other resources.	Analyze springs, seeps and associated pipelines to determine if modifications are necessary to maintain the continuity of the predevelopment riparian area within priority GRSG habitats. Make modifications where	Alt C1: No similar action.	Alt C2: Analyze springs, seeps and associated water developments to determine if	Within priority GRSG habitat evaluate existing water developments (springs, seeps, etc and their associated pipelines) to determine if modifications are necessary to maintain or improve riparian areas and	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
	necessary, considering impacts to other water uses when such considerations are neutral or beneficial to GRSG.		modifications are necessary to maintain the continuity of the predevelopment riparian area within sage-grouse habitats. Make modifications where necessary, including dismantling water.	GRSG habitat. Make modifications where necessary, considering impacts to other water uses when such considerations are neutral or beneficial to GRSG.	
Allow treatments that provide benefits for multiple resources. Additional forage will be appropriate to livestock, wild horses and burros (where applicable), and wildlife.	In priority habitat, only allow treatments that conserve, enhance or restore GRSG habitat (this includes treatments that benefit livestock as part of an AMP/Conservation Plan to improve GRSG habitat).	Alt C1: No similar action.	Alt C2: Ensure that vegetation creates landscape patterns which most benefit sage-grouse. Only allow treatments that are demonstrated to benefit GRSG and retain sagebrush height and cover consistent with GRSG habitat objectives (this includes treatments that benefit livestock as part of an AMP/Conservation Plan to improve sage-grouse habitat).	In priority habitat, ensure that vegetation and rangeland treatments conserve, enhance or restore GRSG habitat (this includes treatments that benefit livestock). Do not authorize treatments that have a negative effect on meeting GRSG habitat objectives.	No similar action.
Most LUPs do not include specific management actions related to seedings. Plans do include generic decisions that allow maintenance of existing range improvements, which includes maintenance of historical seedings. Recently completed LUPs promote use of native species when conducting restoration activities. This would include restoration projects conducted in areas that have perennial grass cover. Older plans do not include a similar management action.	Evaluate the role of existing seedings that are currently composed of primarily introduced perennial grasses in and adjacent to priority GRSG habitats to determine if they should be restored to sagebrush or habitat of higher quality for GRSG. If these seedings are part of an AMP/ Conservation Plan or if they provide value in conserving or enhancing the rest of the priority habitats, then no restoration would be necessary. Assess the compatibility of these seedings for GRSG habitat or as a component of a grazing system during the land health assessments.	Alt C1: No similar action.	Alt C2: Evaluate the role of existing seedings that are currently composed of primarily introduced perennial grasses in and adjacent to sage-grouse habitat to determine if they should be restored to sagebrush or habitat of higher quality for sage-grouse. If these seedings provide value in conserving or enhancing GRSG	Evaluate the role of existing seedings that are currently composed of primarily introduced perennial grasses in and adjacent to priority-sage-grouse habitat to determine if they should be restored to sagebrush or habitat of higher quality for sage-grouse. If these provide value in conserving or enhancing GRSG habitats, then no restoration would be necessary. Assess the compatibility of these seedings for sage-grouse habitat during the land health assessments.	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
			habitat~~s~~, then no restoration would be necessary. Assess the compatibility of these seedings for sage-grouse habitat during the land health assessments.		
Consider structural range improvements on a case-by-case basis to provide for livestock grazing while maintaining rangeland health.	In priority habitat, design any new structural range improvements and location of supplements (salt or protein blocks) to conserve, enhance, or restore GRSG habitat through an improved grazing management system relative to GRSG objectives. Structural range improvements, in this context, include but are not limited to: cattleguards, fences, exclosures, corrals or other livestock handling structures; pipelines, troughs, storage tanks (including moveable tanks used in livestock water hauling), windmills, ponds/reservoirs, solar panels and spring developments. Potential for invasive species establishment or increase following construction must be considered in the project planning process and monitored and treated post-construction.	<u>Alt C1:</u> No similar action.	<u>Alt C2:</u> Avoid all new structural range developments and location of supplements (salt or protein blocks) in occupied GRSG habitat unless independent peer-reviewed studies show that the range improvement structure or nutrient supplement placement benefits GRSG. Structural range developments, in this context, include but are not limited to cattleguards, fences, exclosures, corrals or other livestock handling structures; pipelines, troughs, storage tanks (including moveable tanks used in livestock water hauling), windmills, ponds/reservoirs, solar panels and spring developments. Potential for invasive species establishment or increase following construction must be considered in the project planning	In priority habitat, design any new structural range improvements to conserve, enhance, or restore GRSG habitat through an improved grazing management system relative to GRSG objectives. Structural range improvements, in this context, include but are not limited to: cattleguards, fences, exclosures, corrals or other livestock handling structures; pipelines, troughs, storage tanks (including moveable tanks used in livestock water hauling), windmills, ponds/reservoirs, solar panels and spring developments. Potential for invasive species establishment or increase following construction must be considered in the project planning process and monitored and treated post-construction.	Locate livestock fences away from leks and employ the NRCS fence standards (see NRCS/CEAP Conservation Insight Publication "Applying the Sage Grouse Fence Collision Risk Tool to Reduce Bird Strikes.")

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
			process and monitored and treated post-construction. Consider the comparative cost of changing grazing management instead of constructing additional range developments.		
No similar action.	When developing or modifying water developments in priority habitat, use applicable best management practices (BMPs, see NTT Appendix C) to mitigate potential impacts from West Nile virus.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	When developing or modifying water developments in priority habitat, use applicable best management practices and best available science to mitigate potential impacts from West Nile virus.	No similar action.
Consider modifications to existing structural range improvements on a case-by-case basis taking into consideration impacts to other resources.	In priority habitat, evaluate existing structural range improvements and location of supplements (salt or protein blocks) to make sure they conserve, enhance or restore GRSG habitat.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	In priority habitat, evaluate and assess the need to modify existing improvements to make sure they are neutral, conserve, enhance, or restore GRSG habitat.	No similar action.
No similar action.	To reduce outright GRSG strikes and mortality, remove, modify or mark fences in high risk areas within priority GRSG habitat based on proximity to lek, lek size, and topography.	Alt C1: No similar action.	Alt C2: Remove, modify or mark fences in areas of moderate or high risk of GRSG strikes within sage-grouse habitat based on proximity to lek, lek size, and topography.	Same as Alternative B.	Fences should not be located on or adjacent to leks where bird collisions would be expected to occur. Employ NRCS fence collision risk tool (NRCS/CEAP Conservation Insight Publication "Applying the Sage Grouse Fence Collision Risk Tool to Reduce Bird Strikes").
Implement noxious weed and invasive species control using integrated weed management actions per national guidance and local weed management plans in cooperation with State and Federal agencies, affected counties, and adjoining private lands owners.	In priority habitat, monitor for, and treat invasive species associated with existing range improvements.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	In priority habitat, monitor for and treat noxious weeds and evaluate the need to treat invasive species associated with existing range improvements.	Aggressively respond to new infestations to keeping invasive species from spreading. Every effort should be made to identify and treat new infestations before they become larger problems. Additionally containment of known infestations in or near sagebrush habitats should be a high priority for all land management agencies.
No similar action.	Maintain retirement of grazing privileges as an option in priority GRSG areas when the current permittee is willing to retire grazing on all or part of an allotment. Analyze the adverse impacts of no livestock use on wildfire and invasive species threats in evaluating retirement proposals.	Alt C1: No similar action.	Alt C2: Same as Alternative B.	When grazing permits are offered for relinquishment, which authorize grazing within priority GRSG habitat, use the relinquished AUMs to implement improved grazing management practices that will enhance and restore GRSG habitat. Analyze the effects of decreased or discontinued grazing on GRSG habitat conditions,	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C		Alternative D	Alternative E1
				possible changes in wildfire and invasive species risks, and the socioeconomics of the area.	
No similar action.	No similar action.	Alt C1: No similar action.	Alt C2: Establish and maintain sufficiently large areas free of livestock as reference areas to aid in describing ecological site potential and as a measure of the comparative effects of livestock grazing—and relief from livestock grazing—on GRSG populations.	No similar action.	No similar action.
No similar action.	No similar action.	Alt C1: No similar action.	Alt C2: Any vegetation treatment plan must include pretreatment data on wildlife and habitat condition, establish non-grazing exclosures, and include long-term monitoring where treated areas are monitored for at least three years before grazing returns. Continue monitoring for five years after livestock are returned to the area, and compare to treated, ungrazed exclosures, as well as untreated areas.	No similar action.	No similar action.
Wild Horses and Burros					
Manage wild horse and burro population levels within established Appropriate Management Levels (AML) to ensure a balance among wild horses, wildlife, livestock, and other resources.	Manage wild horse and burro population levels within established Appropriate Management Levels (AML).	Alt C1: Same as Alternative B.	Alt C2: Associated with the 25% reduction of livestock grazing, reduce wild horse AML by 25%. While the use	Same as Alternative B.	Same as Alternative A.

Table 2-2 – Description of Alternatives A, B, C$_1$, C$_2$, D, and E$_1$

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
		could still occur every year (as opposed to the rest system of once every 4 years for livestock grazing), this would result in a similar reduction in grazing pressure on vegetation in priority GRSG habitat.		
Prioritize wild horse/burro gathers based on monitoring data.	Prioritize wild horse/burro gathers in priority GRSG habitat, unless removals are necessary in other areas to prevent catastrophic environmental issues, including herd health impacts.	Same as Alternative B.	Same as Alternative B.	Same as Alternative A.
Prepare or amend herd management area plans on an as needed basis	Within priority habitat, develop or amend herd management area plans (HMAPs) to incorporate GRSG habitat objectives and management considerations for all BLM herd management areas (HMAs).	Same as Alternative B.	No similar action.	Same as Alternative A.
Periodically evaluate and make adjustments to AMLs based on monitoring data.	For all HMAs within priority GRSG habitat, prioritize the evaluation of all AMLs based on indicators that address structure/condition/composition of vegetation and measurements specific to achieving GRSG habitat objectives.	No similar action.	Same as Alternative B.	Same as Alternative A.
No similar action.	Coordinate with other resources (Range, Wildlife, and Riparian) to conduct land health assessments to determine existing structure/condition/composition of vegetation within all BLM HMAs.	Same as Alternative B.	No similar action.	No similar action.
No similar action.	When conducting NEPA analysis for wild horse/burro management activities, water developments or other rangeland improvements for wild horses in priority GRSG habitat, address the direct and indirect effects to GRSG populations and habitat. Implement any water developments or rangeland improvements using the criteria identified for domestic livestock identified above in priority habitats.	Same as Alternative B.	When considering wild horse/burro management activities, water developments or other rangeland improvements for wild horses in priority GRSG habitat, use the criteria identified for domestic livestock in priority habitats.	No similar action.
Areas of Critical Environmental Concern (ACECs)				
No existing ACECs include sage-grouse as a	No similar action.	Designate and manage the following 15	No similar action.	No similar action.

Table 2-2 – Description of Alternatives A, B, C_1, C_2, D, and E_1

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E1
relevant and important value.		areas (2,233,800) as ACECs (BLM) and GRSG Zoological Areas (FS) to function as sagebrush reserves to conserve GRSG: • Three Corners/Browns Park o **Total acres – 72,600** o BLM acres – 50,100 o FS acres – 22,500 • Diamond Mountain o **Total acres – 139,500** o BLM acres – 110,300 o FS acres – 29,200 • Little Mountain/Halfway Hollow o **Total acres – 74,900** o BLM acres – 60,700 o FS acres – 14,200 • Blue Mountain o **Total acres – 18,900** o BLM acres – 18,900 o FS acres – 0 • Emery o **Total acres – 11,500** o BLM acres – 0 o FS acres – 11,500 • Parker Mountain o **Total acres – 350,500** o BLM acres – 201,800 o FS acres – 148,700 • Southern Mountain Valleys o **Total acres – 171,300** o BLM acres – 105,300 o FS acres – 66,000 • Buckskin Valley o **Total acres – 46,000** o BLM acres – 34,900 o FS acres – 11,100 • Black Mountains o **Total acres – 256,800** o BLM acres – 256,800 o FS acres – 0 • Southern Great Basin o **Total acres – 101,000** o BLM acres – 101,000 o FS acres – 0 • Sheep Creek Mountains

No similar action.	No similar action.	Manage the relevant and important values for the 15 GRSG ACECs/GRSG Zoological Areas as identified above. In addition, implement the following management for these areas: • Manage the GRSG ACECs/Zoological Areas to minimize anthropogenic disturbances to GRSG, consistent with valid existing rights. • Prioritize withdrawal from mineral location in the ACECs/Zoological Areas. Make any existing claims within the ACECs/Zoological Areas subject to validity patent examinations. • Require Plans of Operations for any Notice level locatable mineral per 43 CFR 3809 regulations. • Prioritize the removal of infrastructure (including unneeded mining or ROW equipment, roads, range developments and fencing).	No similar action.	No similar action.

BLM Greater Sage-Grouse Planning Proposed Alternatives Summary Table

Idaho and Southwestern Montana Sub-Regional Greater Sage-Grouse Planning Strategy EIS	**BLM Field Offices/ Forest Service Forest Addressed**	*BLM Idaho*: Birds of Prey NCA; Bruneau FO; Challis FO; Craters of the Moon NM; Four Rivers FO; Jarbidge FO; Salmon FO; Owyhee FO; Pocatello FO; Shoshone FO; Burley FO; Upper Snake FO *BLM Montana:* Dillon FO *Forest Service Idaho:* Boise National Forest; Salmon-Challis National Forest; Targhee, Curlew National Grasslands; Caribou National Forest; Sawtooth (including a small portion in Utah) *Forest Service Montana:* Beaverhead-Deerlodge National Forest

Range of alternatives considered with a brief summary of what they address.

	Alternative A No Action	**Alternative B**	**Alternative C**	**Alternative D**	**Alternative E**	**Alternative F**
Source, Origination and Scope:	Compilation of all existing plans in occupied habitat for both BLM and FS.	NTT Report applied to BLM and Forest Service occupied habitat.	Environmental Citizen Group based alternative + NTT Report 'Plus' applied to all BLM and FS occupied habitat and potentially other areas.	Sub-Regional alternative applies to BLM and FS occupied habitat in Idaho, Montana and Utah. Montana BLM/FS will continue current management direction with additional management actions responding to issues and NTT consistency.	State Alternative for BLM and FS occupied habitat in Idaho and Utah portion of Sawtooth NF. Composed of Idaho and Utah Governor's alternative. No Governor's Alternative in Montana; however, existing management was developed through coordination between BLM/FS and Montana Fish Wildlife and Parks.	Environmental Citizen Groups based alternative + NTT Report 'Plus' for BLM and FS occupied habitat.
Habitat Categorization	No delineation of occupied sage-grouse habitat.	Occupied sage-grouse habitat is categorized into Priority Habitat and General Habitat areas as described in the April 2012 map, with associated management.	All occupied habitat is managed similarly.	Occupied habitat is categorized into three delineations in Idaho (Core, Priority and General), and two in Montana and Utah (Priority and General), with associated management.	*Idaho*: Occupied habitat is categorized into three delineations (Core, Important and General) with associated management. *Montana and Utah:* Occupied habitat is categorized into two delineations (Priority and General); with associated management.	All occupied habitat is categorized into Priority and General areas, with potentially other areas, each with associated management.

Fire Management and Wildfire	Continue to manage under current guidance.	Prioritize Suppression immediately after life and property. Fuels Management projects to reduce fine fuels, including targeted grazing. Implement fuel breaks to protect sagebrush. Prioritize native seed allocation to sage-grouse habitat areas. Maintain 15% canopy cover post fuels treatment. Adjust management activities to support successful restoration post rehabilitation.	Manage vegetation for good or better ecological condition. Focus fuel breaks on areas of human habitation or significant disturbances.	Same as Alt. B, in addition: Preposition initial attack resources to higher fire occurrence areas. Use knowledgeable Resource Advisors on extended attack fire, and train fire fighters regarding sagebrush management during fire suppression activities. Ensure long term persistence of seeded or pre-burn native plants. Use chemical, mechanical, and seeding treatments with appropriate plant materials to stabilize sites and prevent dominance of invasive, annual vegetation, and noxious weeds. Use native plant materials were appropriate and practicable. Use the warmer adapted variety of a species range when reseeding following fire to address potential climate change.	Incorporate BLM IM-2011-138 to reduce the number and size of wildfires in sage-grouse habitat including: Develop state-specific sage-grouse localized maps for use in prioritizing suppression. Preposition initial attack resources to higher fire occurrence areas. Use knowledgeable Resource Advisors on extended attack fire, and train fire fighters regarding sagebrush management during fire suppression activities. Design fuel treatments to protect existing sagebrush ecosystems. **Core and Important Areas**: Prioritize suppression in sage-grouse habitats immediately after human safety and structure protection. Interagency coordination, including mutual aid agreements. Create and maintain effective fuel breaks in strategic locations. **Core Areas**: Evaluate and decrease wildfire response time by 25% Evaluate the current fire suppression baseline and	Mow grass within fire breaks. Exclude livestock from burned areas until woody and herbaceous vegetation meet sage-grouse habitat objectives. Construct and utilize livestock exclosures to monitor fire restoration progress.

					develop a consistent plan that improves on this baseline by 25%. Add additional initial attack resources and pre-position resources to the West Owyhee Conservation Area. **Important Areas:** Evaluate and decrease wildfire response time by 20% in the West Owyhee Conservation Area. Decrease wildfire response time in all other conservation areas by 15%. Evaluate the current fire suppression baseline and develop a consistent plan that improves on this baseline by 15%. **General Areas:** Emphasize fire suppression efforts, recognizing other local, regional and national fire suppression priorities. Use livestock to reduce fine fuels and maintain fuel breaks where appropriate. Reduce human caused fires, with additional prevention programs. Develop more aggressive fuels reduction strategies.	

Invasive Species	Continue to treat invasive species as directed under current policy. Existing Coordinated Weed Management Areas and management remain without adjustment. Wash all fire fighting vehicles prior to deployment.	Same as No Action.	Wash project vehicles when leaving infested areas. Treat infested areas focusing on mechanical treatment before the use of herbicides. Do not graze infested areas until native vegetation is restored. Quarantine livestock before entering public lands when coming from infested areas.	Same as No Action.	**All Habitat Areas:** Wash all fire fighting vehicles prior to deployment. **Core Areas**: Manage to prevent invasion. Actively manage exotic undesirable species sufficient to prevent invasion into other management zones. **Core and Important Areas**: Monitor and treat invasives for at least 3 years following fire. **Important Areas**: Manage to treat infestations without impairing sage-grouse populations. Actively pursue eradication or control of invasives that threaten sage-grouse habitat. **Important and General Areas:** Establish an effective monitoring system to determine effectiveness of treatment. Actively manage exotic undesirable species sufficient to prevent invasion into other management areas. **General Areas:** Employ aggressive measures in cooperation with CWMAs. Aggressively pursue eradication or control of invasives that pose a risk to sage-grouse habitat.	Restrict activities that spread invasives. Treat invasives after fire in sagebrush habitat. Ensure that soil and plants are at Ecological Potential in sage-grouse habitat to reduce vulnerability of invasion.

Infrastructure	Continue to manage existing and proposed infrastructure projects and rights-of-way under current guidance.	No new authorizations in Priority habitat unless development occurs within existing developed footprint.	No new ROW authorizations unless development occurs within existing developed footprint.	Core, Priority and General areas designated as ROW avoidance areas. Exlcude development of larger (>50kV) transmission facilities, wind testing and development, solar development, commercial geothermal development, nuclear development, oil and gas development, airports, paved roads, graded gravel roads, and landfills, in Core areas.	Core and Important areas identified as ROW avoidance areas. Core areas – no new infrastructure except for in place upgrades. Important areas – new infrastructure can be authorized if specific criteria are met.	Same as Alternative A.
Habitat Restoration and Vegetation Management	Continue to manage under current guidance.	Prioritize restoration efforts based on the likelihood of success and considering Connelly 2000 and Hagen 2007. Reestablishment of sagebrush cover is highest priority.	Same as Alternative B and reestablish sagebrush cover on exotic seedings, and do not remove sagebrush cover in order to improve forage production.	Utilize Habitat Assessment Protocols and Rangeland Health Assessments to determine habitat quality and priorities. Utilize best available tools for restoration efforts. Protect priority sage-grouse habitat from fire through strategic wildfire suppression planning. Planning measures may include: strategically placed fire resistant vegetation or green-strip seedings; strategically placed pre-treated areas that reduce fine fuels through mowing vegetation along roadsides, grazing strategies, herbicide application, etc.; pre-planning of wildfire suppression tactics in important sage-grouse habitat; prioritizing suppression of wildfire in priority habitats; conducting burn-out/backfiring operations in a manner that minimizes the loss of sagebrush.	Same as Alternative A	Same as Alternative C.

Leased Fluid Minerals	Continue to manage under current guidance.	No surface occupancy (NSO) within priority habitat. Limit disturbance to 3% and apply a 4 mile NSO buffer around leks if lease is entirely within priority habitat. Conservation measures would be applied. Applies to split estate as well.	Same as Alternative B.	Limit future lease disturbance to 3% (1 drill pad per section) in Core areas. Prohibit surface activities on future leases within a buffer around leks in Priority areas.	State Director may authorize oil and gas development if provisions are made in Core Areas. In Important Areas development is allowed on future leases if it will not cause a decline in sage-grouse populations.	Same as Alternative A.
Unleased Fluid Minerals	Continue to manage under current guidance.	Close priority areas to leasing. Upon expiration of existing leases in priority areas do not accept expressions of interest. Allow geophysical exploration in priority areas only to acquire data for areas outside and adjacent to priority areas, using helicopter drill rigs with timing stipulations.	Same as Alternative B and no exploration permits allowed.	Close Core and Priority areas outside the Bear Lake Plateau to leasing and no exploration permits allowed. Allow exploration in priority areas for areas adjacent to priority areas with timing stipulations. General areas are open to leasing and exploration with timing stipulations near leks.	Same as Alternative A.	Same as Alternative C.
Non-Energy Leasable Minerals (New Leases)	Continue to manage under current guidance.	No new leases in priority habitat.	Same as Alternative B.	Close Core areas to leasing outside of Known Lease Areas. Consider leases within Core Areas in Known Lease Areas on a case-by-case basis. Consider new leases on a case-by-case basis in Priority areas. Allow new leases with stipulations in General areas.	Same as Alternative A.	Same as Alternative B.

Non-Energy Leasable Minerals (Existing Leases)	Continue to manage under current guidance.	Follow Required Design Features (RDF) for solid and fluid minerals.	Same as Alternative B.	In Core and Priority areas follow required design features and best management practices (BMP) and require habitat rehabilitation or off-site mitigation if rehabilitation is not feasible. In General areas require BMPs as conditions of approval for the mine plan.	Same as Alternative A.	Same as Alternative B.
Locatable Minerals	Continue to manage under current guidance.	Propose to withdraw all priority areas from mineral entry. Existing claims would be subject to buyout or validity examination. Make RDFs mandatory conditions of approval in priority areas.	No new mining claims allowed. Make RDFs mandatory conditions of approval in priority areas.	Same as Alternative B, in addition withdraw Core areas from mineral entry and close valid claims and require additional mitigation for sage-grouse habitat. Apply BMPs to priority and general areas as mandatory stipulations in Plans of Operation.	Same as Alternative A.	Same As Alternative C.
Saleable Minerals	Continue to manage under current guidance.	Close priority areas to mineral materials. Restore mineral material permit areas to sage-grouse habitat if no longer needed as a material source.	Same as Alternative B.	Same as Alternative B, in addition close Core areas to mineral materials and apply timing stipulations and BMPs to permits in priority areas.	Same as Alternative A.	Same as Alternative B.
Coal	Continue to manage under current guidance.	Identify all priority areas as unsuitable as set forth in 43 CFR 3461.5. No new leases in priority areas unless all surface disturbance occurs outside priority habitat. Locate mining operation	Same as Alternative B.	Same as Alternative B.	Same as Alternative A.	Same as Alternative B, and abate wastewater to reduce risk of West Nile virus.

		facilities outside of priority areas or within the footprint of existing facilities. Minimize surface disturbing activities in General areas.				
Recreation and Visitor Services	Continue to manage under current guidance.	In priority areas only permit special uses that are neutral or beneficial to sage-grouse.	Same as Alternative B.	No sage-grouse hunting permits will be approved in Core or Priority areas. All other applications will be analyzed with the goal of minimizing impacts. Minimize adverse recreation effects to sage-grouse in Recreation Management Areas.	Core and Important Areas: Prioritize Travel Planning to minimize impacts to sage-grouse and reduce the risk of wildfire. Restrict motorized use to existing routes prior to travel planning. Apply timing and seasonal restrictions on activities which demonstrate disturbance of nesting sage-grouse.	Same as Alternative B, and apply seasonal camping closures within 4 miles of active leks.
Livestock Grazing	Continue to manage under current guidance.	Incorporate sage-grouse habitat objectives into grazing permits and Allotment Management Plans in priority areas. Use integrated ranch planning in priority areas to plan grazing on all ownerships. Prioritize completion of land (range) health assessments and grazing permit NEPA analyses on allotments in priority areas with the most potential for conserving sage-grouse. Develop sage-grouse	No authorized grazing within occupied sage-grouse habitat. No new water developments in sage-grouse habitat. No new structural range improvements. Retirement of grazing would be allowed and fast tracked. Any vegetation treatments must have pre-treatment data recorded, be monitored for 3 years	Same as Alternative B; in addition: Manage riparian areas, lentic areas and wet meadows to move toward PFC in Core and Priority areas. Consider retiring grazing in Core and Priority areas.	**Core and Important Areas:** Prioritize allotments for permit renewal where populations are declining. Add sage-grouse guidelines into management plans as desired conditions, recognizing livestock grazing may not always be a causal factor in non-attainment. Prioritize completion of land (range) health assessments and grazing permit NEPA analysis on allotments in priority areas with declining sage-grouse populations. Allotment assessments will be use published characteristics of	Same as Alternative B; in addition: Reduce authorized grazing within occupied sage-grouse habitat. Maintain at least 6 inch stubble height of all species at all times in wet meadows. No new water developments in sage-grouse habitat. Avoid all new

		objectives for allotment management and analyze an alternative in permit renewal NEPA that conserves or enhances sage-grouse habitat. Implement changes to grazing management needed to meet seasonal sage-grouse requirements. During drought change grazing management as necessary to attain sage-grouse objectives. Manage riparian areas within priority areas to attain Proper Functioning Condition (PFC). Manage wet meadows in priority and general areas to maintain forbs to facilitate brood rearing needs. Authorize only new water developments in priority areas that are beneficial to sage-grouse. In priority areas only authorize treatments that benefit sage-grouse. Evaluate exotic grass seedings to determine their values for sage-grouse and manage for	after treatment.		sage-grouse habitat and comply with 43 CFR 4180.2(c). Allotment management changes must be tailored to address specific problems. Change grazing management only when monitoring indicates sage-grouse objectives are not being met. Management changes, when needed, must be tailored to specifically address habitat objectives that need improvement. **Core Areas**: Altering grazing schemes in allotments, where needed and appropriate, may be facilitated by enhanced grazing opportunities with introduced seedings or areas with lower value to sage-grouse (i.e. General areas). The unintended consequences of altering grazing use, such as possible increased risk of wildfire, must be carefully considered in any management proposal.	structural range improvements and supplement locations in occupied habitat. Any vegetation treatments must have pre-treatment data recorded; must be monitored for 3 years after treatment with no grazing and monitored for 5 years after grazing resumes.

		sage-grouse objectives. Design new structural range improvements and supplement locations to conserve sage-grouse. Evaluate existing range improvements in priority areas and design to conserve sage-grouse. Mark or remove fences that present a high risk for strikes by sage-grouse. Maintain the option to retire grazing use in priority areas on an opportunity basis. Identify those allotments where retirement of grazing would benefit sage-grouse.				
Areas of Critical Environmental Concern	Maintain designation of 53 existing ACECs containing 325k of occupied sage-grouse habitat.	Same as Alternative A.	Designate 39 new ACECs encompassing approximately 4.2 million acres of occupied sage-grouse habitat.	Same as Alternative A.	Same as Alternative A.	Designate 17 new ACECs encompassing 11.5 million acres of occupied sage-grouse habitat; or designate 18 new ACECs encompassing 3.01 million acres of occupied sage-grouse habitat..

We understand BLM is interested in whether ICF could support the development of documents that would provide informationabout non-market values related to EISs to support sage grouse habitat conservation. The specifications, as we understand them, are as follows:
>
> - Use the framework we created for other sage-grouse EISs (e.g. NW Colorado) to assess non-market values associated with recreation, also documenting the scientific/economic principles of non-market valuation generally
>
> - The geographic scope would include all of the Rocky Mountain EISs (WY, ND, SD, and the remainder of MT not covered by the ID / SWMT EIS).
>
> - Because the analysis would focus on recreational value, and there are few or no quantitative predictions of changes in recreational activity across the alternatives for those EISs, the analysis would focus primarily or perhapsexclusively on baseline assessment (within a defined recent time period, e.g., 2008-2012)
>
> - For each EIS, deliverables would comprise a Word document of a few pages, plus the summary excel tables (to facilitate BLM doing additional manipulations it deems necessary)
>
> - BLM would need draft deliverables completed by approximately April 6, and there would be round of review and revision between approximately April 6 and approximately April 30.
>
> Note that ICF would need BLM to provide recreation data for the desired years from the BLM RMIS system (Report 26, I believe). We would also use data from the FS NVUM system, which is publicly available online (in addition to data on non-marketvaluation from the work of John Loomis, and others).

> We think this would fit within the scope of the current Task Order (it is closely related to the cumulative analysis), but would require a contract modification.

Alex, Julie,

Sounds good – the net benefits discussion could be of particular importance, if there are increases in adverse impacts to any of the particular sectors under proposed plans.

Let me know when requests are finalized, and I'll send them out.

Thanks,
Chris

Thanks, Chris. I will bring up your examples, as we move forward in discussions with resource specialists. I would also like to discuss your thoughts on language for net benefits, maybe after ICF has had a chance to see the proposed plans as well (we haven't seen them yet, but I expect to see the Utah one tomorrow).

If you could forward the data requests to FS staff and copy me and Laura Johnson (copied here), I would appreciate it.

Thanks,

Alex

Subject: RE: BLM SGSE - Proposed Plan Socioeconomic Data Requests

Alex,

If you feel specialists need more details regarding the question about 'how impacts from the proposed plan differ from …remaining alternatives', then you could add:

> "For example, could changes in habitat designations (e.g., specification of sagebrush focus areas), seasonal habitat desired conditions, compensatory mitigation, or adaptive management trigger responses under the proposed plan have impacts on current/future permit holders that differ substantially from other alternatives?"

Not related to the information requests – but given that we included a section in the DEIS about the efficiency of the overall decision in providing net sage grouse benefits – there may be a need to include new language about how the proposed plans provide for greater efficiency (hopefully?) and potential for net sage grouse benefits. This type of discussion would not need to be quantitative or highly complex – however, it still seems we need to add some qualitative language that differentiates the proposed plan from other alternatives. I don't have an immediate suggestion about who would be the best specialists/leads to engage on this.

I have a list of FS folks to send requests to - I can provide that to you, or let me know if you want me to send it out. BTW – recreation is not much of a perceived issue, so FS no longer has a rec specialist on the GRSG team.

Chris

Subject: RE: BLM SGSE - Proposed Plan Socioeconomic Data Requests

Lauren,

I attached revised data requests for NVCA, removing references to an Alternative G. This was the only sub-region where we were making such reference. The data requests for the remaining sub-regions remain the same. Please feel free to distribute to the resource specialists as soon as you find appropriate. I would also appreciate if you could let us know by when we can expect to receive input from the resource specialists. Ideally, we would have at least a week after receiving input from the resource specialists to clarify any questions we may have, insert the analysis in our own write-ups, QC and deliver to you. If this is not possible, at least a few days would be appreciated.

Julie, I understand you will be forwarding the data requests for Utah to Quincy Bahr and for ID/MT to Jonathan Beck, is that correct? Would you also let me know by when we can expect input from the resource specialists?

Stewart, would you be able to forward the data requests for Oregon to Joan Suther? If you could also let me know by when we could expect to receive input from the resource specialists, I would appreciate.

Thanks,

Alex

Subject: RE: BLM SGSE - Proposed Plan Socioeconomic Data Requests

Thanks for sending this Alex – may I make one request for all plans in the Great Basin Region. None of the four plans refer to the Proposed Plan as Alternative G.....it is just the "Proposed Plan". I think that sending out a request for Alternative G will be confusing, so if you could change your data requests at the bottom of each write-up to refer to only the Proposed Plan before we distribute, that would be great.
Thank you and Happy Weekend.
Lauren

Subject: BLM SGSE - Proposed Plan Socioeconomic Data Requests

Julie, Stewart, Chris,

Please find attached requests for input from resource specialists for the socioeconomic analysis of potential impacts from the proposed plans for the four sub-regional EISs of the Great Basin region. The data requests are in four folders, one for each sub-region.

I would appreciate if you could take a quick look and let me know if you have any comments or suggestions for modifications. Per Lauren's suggestion, I will then forward these requests to the sub-regional leads, copying you:

Lauren Mermejo and Randy Sharp for NV/CA
Jonathan Beck for ID/MT
Quincy Bahr for Utah
Joan Suther for Oregon

Chris, please let me know if there is anyone else you think I should forward these to at the FS.

Josh, I will be sending you similar data requests for NWCO early next week. If you take a look at the attached data requests and feel we need to change the way they are presented, please do let me know.

Lauren, as promised, I am sending these data requests today to you as well, but I would appreciate if we would wait until early next week to distribute to the resource specialist, in case Julie, Stewart, Josh or Chris suggest changes.

Please note the following:

- We included in each data request the names of those who previously provided input for the socioeconomic analysis of the remaining alternatives.
- In addition, the data requests for NV/CA, ID/MT and Utah are also directed to Julie Suhr Pierce and the data requests for Oregon are also directed to Stewart Allen, under the understanding that Julie and Stewart will be able to help communicate our data needs with the various resource specialists, if needed. I am also available to interact directly with the resources specialists, as needed.
- We have also directed all the grazing data requests to Chris Miller and Dustin Bambrough for their input. Chris, please feel free look at the other data requests for NV/CA, ID/MT and Utah, in case you feel FS input is needed (e.g, recreation, wind energy).
- Because of the short time we will have to coordinate with resource specialists, we included as much information possible on the current socioeconomic impact analysis of the remaining alternatives to give resource specialists as much background as possible on how the requested data will be used, relative to the other alternatives analyzed
- We have not yet seen the proposed plans. We may have additional questions to resource specialists when the proposed plans become available to us.

Thank you. Please feel free to contact me if you have any questions or concerns,

Alex

Subject: Re: BLM SGSE - Questions for resources specialists in Idaho and Nevada
Attachments: Impacts from Management of Locatable Minerals (DEIS socioecon).docx

Hi Alex,

I have emailed these questions to the appropriate specialists with the exception of the mineral questions for NV. I'm concerned that the first question repeated below is not totally accurate and, most importantly, does not provide enough context or ask a specific enough question for the specialists to respond to.

- *The DEIS socioeconomics section states that production of gold, silver and copper would remain the same across alternatives despite increased withdrawals in GRSG habitat and restrictions and design features imposed by action alternatives. Comments to the Nevada/California GRSG DEIS request further detail be provided on how this conclusion was reached. We would appreciate your help in developing the reasoning behind this conclusion or in revising it.*

The socioeconomics section states, "BLM specialists generally expect that the production of gold, silver, and copper would remain the same across all alternatives (BLM 2013g), **at least in the first three to five years** after any withdrawal from locatable mineral entry is implemented." This is the case for only those alternatives that are proposing withdraws. The first sentence in the summary of comments in the comment analysis report for locatables says, "Economic impacts analysis under Alt B, C, D, E, and F is inadequate and misleading - no quantitative or "even semi-quantitative analysis" was completed. Description of management alternatives reveals "substantial" differences with respect to locatable minerals across alternatives."

I think the comments on the socioeconomics impact analysis related to locatable minerals were some of the more substantive comments, and I really want to ensure we adequately address them. My recommendation is start by attaching the current, revised language included in the socioeconomics impact section for locatable minerals (I've attached it here). Then revise the question as follows:

- *Comments to the Nevada/California GRSG DEIS request further detail on the economic impacts from management of locatable minerals. Generally the comments on the current analysis can be summarized as follows:* ***Economic impacts analysis under Alt B, C, D, E, and F is inadequate and misleading - no quantitative or "even semi-quantitative analysis" was completed. Description of management alternatives reveals "substantial" differences with respect to locatable minerals across alternatives."*** *For your reference, attached is the current impact discussion that we developed for the EIS. As you are aware, a quantitative analysis is not possible because neither an RFD or minerals potential report were developed for locatable minerals for this planning*

> *effort. We would appreciate your help in developing a more defensible rationale/justification for the current qualitative economic analysis or help revising it by provide more specific information (quantitative or other) on potential impacts to locatable minerals under the different alternatives.*

What do you think? Thanks.

Josh

>
> Comments to the Idaho GRSG DEIS request discussion of socioeconomic impacts of the of alternatives on phosphate mining. Our understanding from the DEIS minerals section is that:
>
> - Of the 86 federal phosphate leases that BLM administers in Idaho, only ten are located in GRSG habitat. None of these leases have had active mining operations on them, nor is any mining planned on the leases in the next 5 to 10 years;
>
> - Demand for phosphate remains high, and the companies that mine in southeast Idaho continue to develop new mines as old ones are reclaimed and remediated.

- Tables 4-64 through 4-67 show considerable acreage of unleased areas closed to future or subject to NSO, CSU or TL stipulations, particularly under Alternatives B, C and D.

Is there any way to estimate the potential impact of alternatives on future phosphate based on the impacts to both leased and unleased areas? If no quantitative estimate is possible, are there relative magnitudes (comparing one alternative to another) of the impacts of alternatives on production that can be discussed?

2. Question for Nevada grazing specialist, Mike Tietmeyer

Comments to the Nevada/California GRSG DEIS state that the DEIS erroneously assumed the difference between active and billed (actual) AUMs is controlled by the permittee. They argue that reasons for the difference between active an billed AUMs include "regulations, grazing restrictions, fire and drought closures, vacant allotments, economic market conditions, etc." We would appreciate assistance in better understanding the reasons behind observed differences in active and billed AUMs and the extent to which permittees may adjust billed AUMs in response to restrictions on active AUMS.

3. Question for Nevada lands and realty specialist, Dan Ryan.

Comments to the Nevada/California GRSG DEIS express concern with the requirement for burying new and existing power lines and the impact of associated costs on energy consumers. Please clarify whether the management action recommending burying new and existing power lines: a) applies to transmission or distribution lines; b) applies to all action alternatives. Please also clarify what share of new and existing lines would this requirement be expected to apply to under each alternative, if possible.

4. Question for Nevada recreation and travel management specialists, Barbara Keleher and Leo Drumm

Comments to the Nevada/California GRSG DEIS dispute the DEIS statements in the socioeconomics section that suggest restrictions to OHV use would not alter overall recreational use of BLM and FS lands in the affected area. The statements in the DEIS socioeconomics section point to input from BLM recreation specialists as support to this conclusion. How can we better support this statement? If this statement is not correct, do we have enough information to provide an approximate estimate of potential reductions in recreational use of BLM and FS lands?

5. Questions for Nevada minerals specialists, Scott Murrelwright, Stuart Grange and John Menghini

a) The DEIS socioeconomics section states that production of gold, silver and copper would remain the same across alternatives despite increased withdrawals in GRSG habitat and restrictions and design features imposed by action alternatives. Comments to the Nevada/California GRSG DEIS request further detail be provided on how this conclusion was reached. We would appreciate your help in developing the reasoning behind this conclusion or in revising it.

b) To what extent are the impacts on the production of locatable minerals largely in the counties of Elko, Lander, Eureka and White Pine? Could you provide information on the cities and counties, within Nevada, where companies that provide inputs and services to the mining industry are typically located?

c) Comments to the Nevada/California DEIS question whether the impacts to fluid minerals will be the same under Alternatives A, C, D and E, given the existence of differences among the alternatives with respect to leasing and winter habitat NSOs. We would appreciate your assistance in further supporting this conclusion of revising it.

d) Could you provide information on the cities and counties, within Nevada, where that provide inputs and services to the oil and gas sector are typically located? Are the impacts of management alternatives on oil and gas production largely restricted to the counties of Elko, Eureka, White Pine, Nye and Lincoln?

6. Question for Nevada wind energy specialist

Comments to the Nevada/California GRSG DEIS request further analysis of the local, regional and national socioeconomic impact of effects of GRSG management alternatives on wind energy. The current DEIS analysis states that future installation of wind energy capacity would be expected to be reduced under all alternatives compared to Alternative A but that no quantification of impacts is currently possible. Is there more detail that we can provide regarding relative magnitude of impacts or rationale behind the current conclusion?

7. Question for Nevada fuels specialist

Comments to the Nevada/California GRSG DEIS suggest removal of livestock grazing would expand fire fuels and promote larger and more costly fires with impacts to local economies. We would appreciate your input on:

> a) Whether removal of livestock grazing could in fact expand the risk of fires;
>
> b) Independent of your answer to item “a” above, what can we expect would be the impacts alternatives on the risk of wildfires and their relative magnitude, and what is the rationale and evidence behind the expected impacts.
>
> **ALEX URIARTE** | Technical Specialist | 703.218.2587 | alex.uriarte@icfi.com | icfi.com

Impacts from Management of Locatable Minerals

As described in **Chapter 3**, the study area produces several locatable minerals, including gold, silver and copper. GRSG habitat management alternatives would impose restrictions on development of mineral production, particularly under Alternatives B, C and F, under which some lands would be petitioned for withdrawal from locatable mineral entry (see **Section 4.13**, Minerals – Locatable).

Any entity that holds valid existing rights to locatable mineral development would not be affected by a withdrawal of lands from locatable mineral entry because the valid existing right would supersede a withdrawal if it occurs. **Section 4.13**, Minerals – Locatable, provides more information about valid existing rights; also, see the definition of valid existing rights in **Chapter 8**, Acronyms and Glossary. For areas without a valid existing right, if an area is withdrawn for locatable mineral entry, an applicant wishing to stake a claim would be required to pay for a mineral examination to determine if the claim is valid, based on geological potential and expected economic viability. The applicant would pay the cost of the mineral examination. This would hinder exploration or claim activity for some operators and some claims, depending on the size of the claim, expected return on investment, and the operator's ability to invest capital upfront in the process. However, because all of this information is site-specific, it is not possible to determine the specific economic impacts of the petition for withdrawal under Alternatives B and F.

Commented [JBS1]: Should this include Alt C?

BLM specialists generally expect that the production of gold, silver, and copper would remain the same across all alternatives (BLM 2013g), at least in the first three to five years after any withdrawal from locatable mineral entry is implemented. In the long run, production of locatable minerals would be affected only to the degree that the cost of conducting a mineral examination would affect individual operators' decisions to pursue claim, which would depend on site-specific and operator-specific conditions.

Overall, economic activity associated with management of locatable minerals would be the same for Alternatives A, D, and E, and may be lower under Alternatives B, C and F depending on site-specific and operator-specific conditions.

Yes, you can contact Jessica for Wyoming and Dakotas. Please cc me on any email. Thanks,

Josh

> Josh, you had mentioned I work with Julie if I needed any additional information from resource specialists. I think all I need right now is some help getting oil and gas production estimates by alternatives in the Wyoming, Montana and Dakota sage grouse EISs. I assume I should contact Jessica Montag for that. Is that correct? Please let me know, I am happy to do so.

Subject: Re: BLM SGSE - Touching base

Hey Alex,

Thank you for touching base.

While it did not result in a major change in the results, I do think the revised cumulative oil & gas impact method makes more sense. Our next step will be to check in with NW CO.

I have received some unofficial information on schedule that indicates that it might be pushed back significantly. Below is what I have heard

February 2015 - Draft Proposed Plans/FEISs come to the Washington Office for review
May 2015 - Publish Proposed Plans/FEIS
June 2015 - End of 30 day Protest Period
August 2015 - RODs signed

Again, this is unofficial and it is confidential. In light of this information, I have really slowed down. I don't want to burn through your budget any more at this point, and I don't want to gather information from specialists that might change.

With that in mind, I'll communicate updates with you as it gets communicated to me.

I have finished commenting and editing on the ID revisions based on public comments (I made some substantial changes to the phosphate discussion and added some language to the powerline discussion). I am still waiting to get feedback on recreation. Also, as noted in a previous email thread, there is a chance that the AUM numbers might change. I'm hesitant to send the comments along because of these pending issues. What do you think? Would it be efficient for you have our comments to date and start addressing those now? Let me know.

Thanks again for your patience Alex!

Josh

> Hi, Josh,

> We haven't communicated in a couple of weeks. I calculated the cumulative oil and gas of the GRSG management alternatives across the 10 state sage-grouse range as a share of projected oil and gas production for the 10 states, as we had discussed. I used EIA projections for the lower 48 states as a whole, since projections were not available by state. The results are only slightly lower than what we had before (see first tab of attached spreadsheet). If production were expected to grow much more in the 10 states than in the 48 as a whole, the result could be different, but I don't think we have those projections (at least I couldn't find any on the websites of the WOGCC and the COGCC).
>
> Let me know if you want to touch base. Any news on schedule? Any news on the information we were seeking on the proposed plans? Do you think it would be useful for me to try to pursue some of the information we need on the proposed plans directly with other resource specialists, maybe copying you?

Do you have a revised file similar to the one attached (the attached file contains the old RFD data)?

Assumptions:
All wells drilled in Sand Wash Basin
Decline rate of 5% a year
Wells are considered to start production on Jan 1 of each year.
Initial Potential 200 bbls/month and 10 MMscf/month (per RFD)
Drilled wells in 20-year RFD projection - 1255 Fee, 1776 Federal, 3031 Total
80% successful completion rate
Completed for production - 1004 Fee, 1420 Federal, 2424 Total
Completed for production per year - Fed 71/year, Total 121/year
High Potential areas will have 96% of potential wells drilled (per RFD)
Medium potential areas will have 3% of potential wells drilled (per RFD)
Low potential areas will have 1% of potential wells drilled
No down hole access from off lease acerage
Wells drilled at a uniform rate during 20 year RFD projection

Alex,

I did get a chance to look over the impacts table.For our field office, I don't feel that we need to have a reduction for any of the alternatives.

On Wed, Mar 13, 2013 at 8:15 AM, Uriarte, Alex<Alex.Uriarte@icfi.com>wrote:

Hi, Greg,

Thanks for getting back to me. As discussed on the phone, see attached what we received from other field offices, just as a reference. Feel free to providewhatever you think is appropriate for your FO.

Best regards,

Alex

Hi, Kimberly and Gregory,

I just left a voice mail for each of you. I am working on the socioeconomic impact sections for the Sage Grouse EIS for NW Colorado and would like to talk abit about the recreation data you provided to us (see emails below). We are on the hook to provide our impact analysis by March 15 so I would appreciate it if we could discuss at your earliest convenience, since your data feeds into our analysis. Please feelfree to call my cell phone (703-439-9812), call me at my office (number below), or let me know when you would be available to discuss and I will call you.

I look forward to hearing from you,

Alex

Hi Rob and Alex -

See attached data request for recreation for the CRVFO (thank you Kim and David!).

Please take a look at the data provided and the explanation of the data and let us know if you have any questions at all.

Thanks so much!

Erin,

Attached are our socioeconomic numbers.We don't have much information to make these assumptions, so we used the White River National Forest Visitor Use information (which David Epstein has provided to me) for all of our activities.So,our assumptions are that our percentages should be close to White River NF because of our proximity to the forest location, and that all activities share similar percentages.We had to make those assumptions because we don't have any more specific data.

Please let me know if you have any further questions.

Kim,

Here is what I found for all activity types for White River NF:

Non-Local Day 11.0%

Non-Local Overnight 53%

Local Day 23.0%

Local Overnight 4.0%

Non-Primary 9.0%

Total: 100.0%

Let me know what you find out from Erin.

Alex,

I got some revised numbers yesterday that included SFA, and revised that on the table. It increased the percent affected a little bit for the proposed plan.

Attached is my Excel file that includes all the calculations.

Subject: RE: Great Basin GRSG - NEPA PM Call Tuesday

Thanks, Julie,

I was on the Great Basin call yesterday and I agreed to provide Lauren Mermejo (who led the call) with data requests for the various resource areas by the end of the week. I would also participate on the call next week where I understand we would establish deadlines for the various resource areas to get us their input on the effects of the proposed plan for their resource areas.

I think the main message needs to be that that resource specialists need to keep in mind that a) the economic analysis depends on their input; b) the socioeconomic section must be consistent with what they write in their sections. This means that they need provide us input in a timely fashion and they need to communicate to us any last minute modifications to their sections. Furthermore, it seems like the Great Basin will give us only about three and a half weeks to analyze the proposed plan, so that BLM regional offices can do their internal reviews before forwarding the documents. We previously had the opportunity to look at draft sections of other resource areas, so that we could bring into the socioeconomic sections any relevant information. It seems like we will not have the opportunity to do so this time around, so we will need to work closely to remain consistent in what we are saying.

I have not seen the proposed plans yet, so I cannot formulate specific questions with regards to anything that is in there (Lauren said she would provide the proposed plans). NV/CA had previously provided a draft proposed plan that we analyzed as “Alternative G,” but I suspect the actual proposed plan is quite different.

We will be asking input from the resources specialists on grazing (Mike Tietmeyer), oil and gas (John Menghini), geothermal (David Davis), wind energy (Wendy Seley), recreation (Dan Ryan, Leo Drumm), locatable and salable minerals (Scott Murrellwright), lands and realty and travel management (Dan Ryan, Leo Drumm). The names in brackets are those of people who I believe previously provided information. We will be asking for quantitative information from grazing (AUMs open and closed), oil and gas (numbers of wells drilled and completed), geothermal (MW installed), wind (MW installed) and for all resources areas we will request qualitative description of costs or restrictions to operators/investors/users.

I hope this helps. If you need to talk to me, I will be in my office all day.

Thanks,

Alex

Alex, I'm in the NV/CA SG IDT meeting today and will also be here tomorrow. Is there anything specific that you'd like me to convey to the resource specialists for them to keep in mind or to which to explicitly pay special attention as they make the revisions necessary due to the changes in boundaries, the addition of Sagebrush Focal Areas, and any other expected changes in management and the new proposed action?

Thanks,
Julie

Thanks, Josh. That is totally up to you. I feel comfortable explaining the type of input we will be looking for, that we will be sending data requests to each resource specialist and that we will need to stay coordinated until the sections are done to avoid inconsistencies. I am working under the assumption that there will be no changes of schedule at this point.

When we actually need to interact with the specialists, any help you all can provide in actually obtaining their input would be appreciated. We can initiate all the contacts and request the input (keeping you copied in emails), but your help in ensuring we do get the input we need in a timely fashion would be very much appreciated. I counted 37 resource areas that we discuss in the economic sections (among the 5 EISs) and for which we looked at resource specialists for their input (not always for input to IMPLAN, sometimes borrowing from their draft sections). So we will need to keep close track of this process.

Thanks, again,

Alex

Reminder - Great Basin GRSG PM conference call Tuesday (2/17) at 10AM Pacific Time / 11AM Mountain Time. Call in info and draft agenda below.

877-928-4213
participants: 9009662#

Agenda

1. WO review updates

    - Any additional questions for WO on guidance

2. Coordination and incorporation of socioeconomic analysis

3. Schedule – immediate critical paths:

    - Submit data to NOC (due 2/13) – Complete (verify)

    - Comment response team – Carol-Anne pulling together the team and approach

    - Update Chapter 2 (due 2/20)

    - Direct and Indirect impact analysis (3/27)

4. Other topics?

5. Action Items from past calls

<u>WO, Sub regional PMs, and Forest Service</u>

- National comment response team to reconvene and review national responses in light of the new guidance.

<u>EMPSi</u>

- Review comment response reports to determine which responses may change based on new guidance.

Subject: Re: GRSG NVCA - wind estimates

Just to follow up, I'm not entirely sure if I'm prior assessment it right. However, based on the multipliers in the methods appendix it just seems that way. For example, total jobs = 1.646/MW for construction and = 0.205 per MW for operations. Maybe it has something to do with total construction period verses operational period. Anyway, any clarity would be appreciated. Thanks.

Josh

Subject:Q re: estimated production

Alex,

Thanks for providing the worksheets and revised RFD – lots of help. And geez – the OG impact calculations are indeed complicated – lots of details and tweeksneed to be tracked!

I have three questions about specific calculations for OG (more pressing):

- In table W-5, I get about half of the estimated production numbers. To calculate an average number of new producing wells per year over a 15 yearperiod, I assumed that there would be no production in year one (when only drilling and completion would be occurring), and then each subsequent year would be the accumulation of wells completed in prior years until you reach year 15. If you assume an averagenumber of producing wells to be the number of completed wells in year 7.5 and multiply that by 15yr production per well – then that should give you total production over a 15 year period? Same question applies to the spreadsheets.Yes. My numbers account for impacts beyond the 15 year period. I will adjust.

- For the “input” worksheet – should the total completed wells for existing (line 18) and new leases (line 26) add up to equal the total number of completedwells in line 11?Yes, I had made an assumption regarding share of completion of wells on new leases being the same as that on old leases to get the completion numbers for newleases but what you suggest is clearly the right way to do this. Thanks.

- Should the multiplier adjustments apply equally to drilling and completion for wells on pph inexisting leasesas it would to wells on pph innew leases,across all action alternatives (i.e., do the same drilling and design feature cost impacts apply to new wells in both lease areas, consistently across all alternatives)? Right now, itseems we apply the same 1.38 adjustment across Alternatives B, C, and D when in fact the requirements/conditions might differ for those alternatives.When we estimated the number of wells on existing leases under each alternative based on the increase in drilling and completion costs for wells in PPH (cost spreadsheet we developedfor Tyler), the assumption was that the conditions required are the same for any wells in PPH, whether in existing or new leases and across alternatives. I think we need to stick to this, even though it may not be exact (the RDF, for example, says that “ alternativesB, C,and to a lesser extent, D,include management decisions (i.e. management actions MA-MIN-21 through MA-MIN-31 in Table 2.1 of the EIS) that would be applied to new development on existing leases.”).**Canwe specify this simplifying assumption in App W?

It would also be good to get clarification about the following (less pressing):

- Appendix W could really use a table that shows cost per well and percentage of total wells, by type of well (e.g., vert, hor, directional), by alternative.Ok, I will include

- For Appendix W on pg W-8, I think we need a more complete explanation of how costs per well compare between Alternative A/E and the Alts BCD – andthen explain how those differences in costs were used to adjust Tex’s original multipliers. It might help if we walked through the multiplier adjustments in the spreadsheets.Ok

- For wells on existing leases, I thought we were assuming that drilling/completion expenditures for new wells remain constant across the alternatives,implying that job impacts for new wells on existing leases would also be equal across alternatives? Unless the distribution of expenses changes across the industry sectors for different alternatives – and this might be the case if increased allocations ofexpenses for design features are assigned to a different industry sector (you might be diverting $ from drill rigs to fence builders?). Production and production jobs would indeed drop under the action alternatives because fewer wells are developed (basedon Alex’s prior calculations/worksheets). The calculation sheets do not break out impacts according to existing vs new leases – so its hard to tell if calculations are consistent with the assumption that expenditure and labor impacts remain constant for existingleases.Drilling/completion expenditures for new wells in existing leases remains the same across alternatives for those wells in PPH. The share of wells in PPH is differentin each alternative. Also, the assumption for existing leases is that the number of wells drops in inverse proportion to the increase in costs so that the expenditures remain the same (the idea of a fixe budget by operators).**Not sure if you are confirming or denying that expenditures (and job impacts) for drilling and completion of new wells on existing leases is the same across alternatives?I thought drilling/completion expenditures forallnew wells in existing lease areas, that overlap the analysis area, remains the same across alternatives, regardless of whether wells are in pph or not (because there is no pph in Alternative A).

- Its not clear why adjustments are applied to multipliers for Alternative A (as implied in the “all drill compl Impact” worksheet). It was my impressionthat, after talking with Tex (and Mike Retzlaff) that Tex’s multipliers already account for the current drilling conditions (i.e., Tex’s mulitpliers accounted for directional/horizontal drilling (55%/2%), plus fracking)? An adjustment of 1.03 is pretty minoreither way though….You might be right,but we started the cost estimates of wells in PPH for Tyler under the assumption that $3,250,000 is the average cost of a vertical well.This number actually came from the mid-point of a range (between $1,500,000 and $5,000,000) that includes more expensive horizontal and directional drilling but also cheaper CBNG wells. I think we need to stick to this assumption**and “this assumption” is the assumption that average actual drill/completion costs for Alt A is something slightly greater than $3,250,000? Again – please clarify withtext or table footnotes in app W.)at his point.

- Can you clarify the source for numbers of wells within and outside Fed PPH in worksheet “All drill compl Impact” – I couldn’t find those numbers inthe RFD tables. Maybe they are the result of your interpretations of the information in the text for the RFD – as reflected in the many comment bubbles in the “input” worksheet?Yes, but I believe the numbers in that tab are actually explicitly in the RFD. You need to look at table R1 of the RFD and in the last sentences of each section of the RFD textwhere some breakdown of the wells is described.**add this clarification to footnote to “all drill compl impact” worksheet.

- With the substantial increase in multipliers for Fed pph wells – is there a chance that we might be calculating increased numbers of jobs for developmentwithinnew leasesunder an action alternative (i.e., number of wells drilled goes down, but number of jobs per well goes up to offset reduced number of wells in new lease areas)?Not sure I totally understand your question but the number of jobs per well definitely goes up with the increase in costs. This is the issue we discussed on the phone where ameasure assumed to be restrictive would actually increase the local economic impact due to the increase in local expenditures. Again, not sure if this was what you were asking.**Itis indeed my question. Fortunately for us, the total reduction in number of wells on new leases under Alt D and the proposed alternative (in your “Input” spreadsheet) is just large enough to offset the 1.38 factor increase in costs per well, such that we appearto be calculating a decrease in OG jobs for new leases under Alt D (and proposed alt), relative to A. But the decrease is pretty small – and if there had been just a few more fed wells in pph under Alt D – we might have had the unfortunate result that jobsactually increase under Alt D for new leases. These types of results further reinforce my distrust of the use of input output analysis (what we should be looking at is net benefits and net benefits per well – rather than changes in OG employment)!

Thanks again,
Chris

Subject:UT GRSG - O&G econ analysis files

Hi Alex,

As we discussed earlier this week, please send Chris and me the files used to calculate the econ impacts associated with O&G as soon as possible. Given the magnitude of the potential impact, it is important for us to understand and followthe calculations; especially since it is not possible to replicate the results based on the information in the document (both Chap 4 and the method appendix).

Thanks.

Josh

My assessment is that there is no a priori identifiable economic impact due to the nature of the permit renewal process.

What are your thoughts, Quincy?

> Hi, all,
> If SFAs add acres under restrictions, the language suggested by Chris would seem appropriate to me, but please note that we did not ignore the SFAs when looking at potential economic impacts of the Proposed Plan,although we were under the impression that SFAs were a subset of PHMAs. We included mention when we were able to identify an economic impact. For example, for grazing under the Proposed Plan our understanding is that the main effect of the SFAs is that theassessment of rangeland health standards and desired conditions will start in allotments in SFAs, then go on to PHMA and then to GHMA, while under current management it is done as grazing permits expire. Other than the order, it is not clear to me whetherthis will have an increased economic impact but we do describe the possibilities of impacts from assessment of rangeland health standards and desired conditions. On the other hand, the Proposed Plan in Utah does recommend withdrawal of mineral developmentin SFA and we mention this.

Subject:SFAs comment

Madelyn,

In one of your comments for lands you as how we are incorporating sagebrush focal areas into our lands econ discussion, as well as other subsections in the econ section. Currently, we are not really bringing that up at all. It was my impressionthat SFAs were sub-areas within PHMAs that would receive special attention and might tend toward more protective end of the spectrum for RDFs and conservation measure guidelines, as well as prioritization for treatments/restoration. The existence of SFAs wouldnot necessarily be increasing areas of exclusion or avoidance for ROWs etc. (though I guess there is some possibility for small areas of non-habitat or GHMA to be included within SFAs that could jack up requirements and costs on land users that would not haveoccurred in absence of the SFA)?

Can you let me know of some specific examples we might want to be noting in the econ sections to capture inceases in economc impacts associated with SFAs under the proposed plan (Im assuming SFAs don’t exist under other alts)? Happy toadd language to the econ sections.

Thanks,
Chris

Sure – sounds good. I talked to Madelyn further, and its not clear that we will be getting much from FS staff, as there is no formal request to FS to provide input to effects section to the FEIS. More to come on that I guess.

Thanks, for forwarding, Chris. I appreciate your suggestions to Madelyn as well, I think they will help. When we receive her final input, I might need to follow-up with a call to her to make sure we are interpreting correctly, if that is ok with you.

Thanks,

Alex

Thanks Madelyn!

When you say “impacts to the public” – could you say whether its adverse or positive impacts (I think I can interpret whats positive or negative – but I was a little uncertain about some of the undesignated/designated language) to consumers of the utilities?

If there will be any quantitative language about miles of corridor effects in your own effects section – could you make a note of that (so ICF can look for those at later date in case needed)?

ICF might alter some of the language to make it consistent with final draft EIS language – I’m ccing Alex and Laura at ICF in case they with to weigh in.

Chris

Hi Chris – Before a start on the either ID or NV, would you please take a look at the attached, and let me know if the response is sufficient?

Thanks.

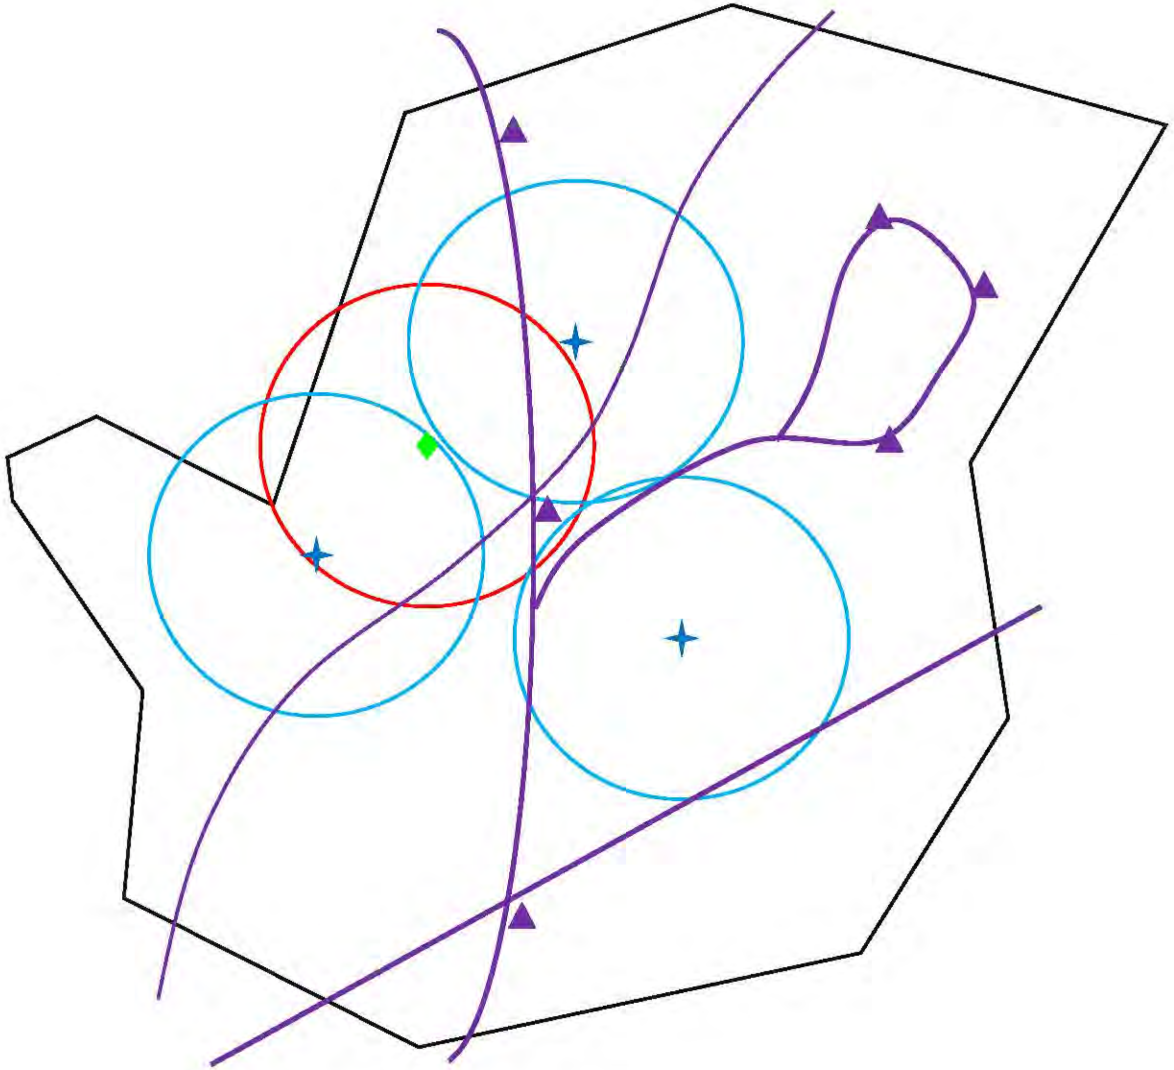
Subject: UTSG Proposed Plan Analysis Kickoff
When: Thursday, February 26, 2015 1:00 PM-2:30 PM (UTC-07:00) Mountain Time (US & Canada).
Where:

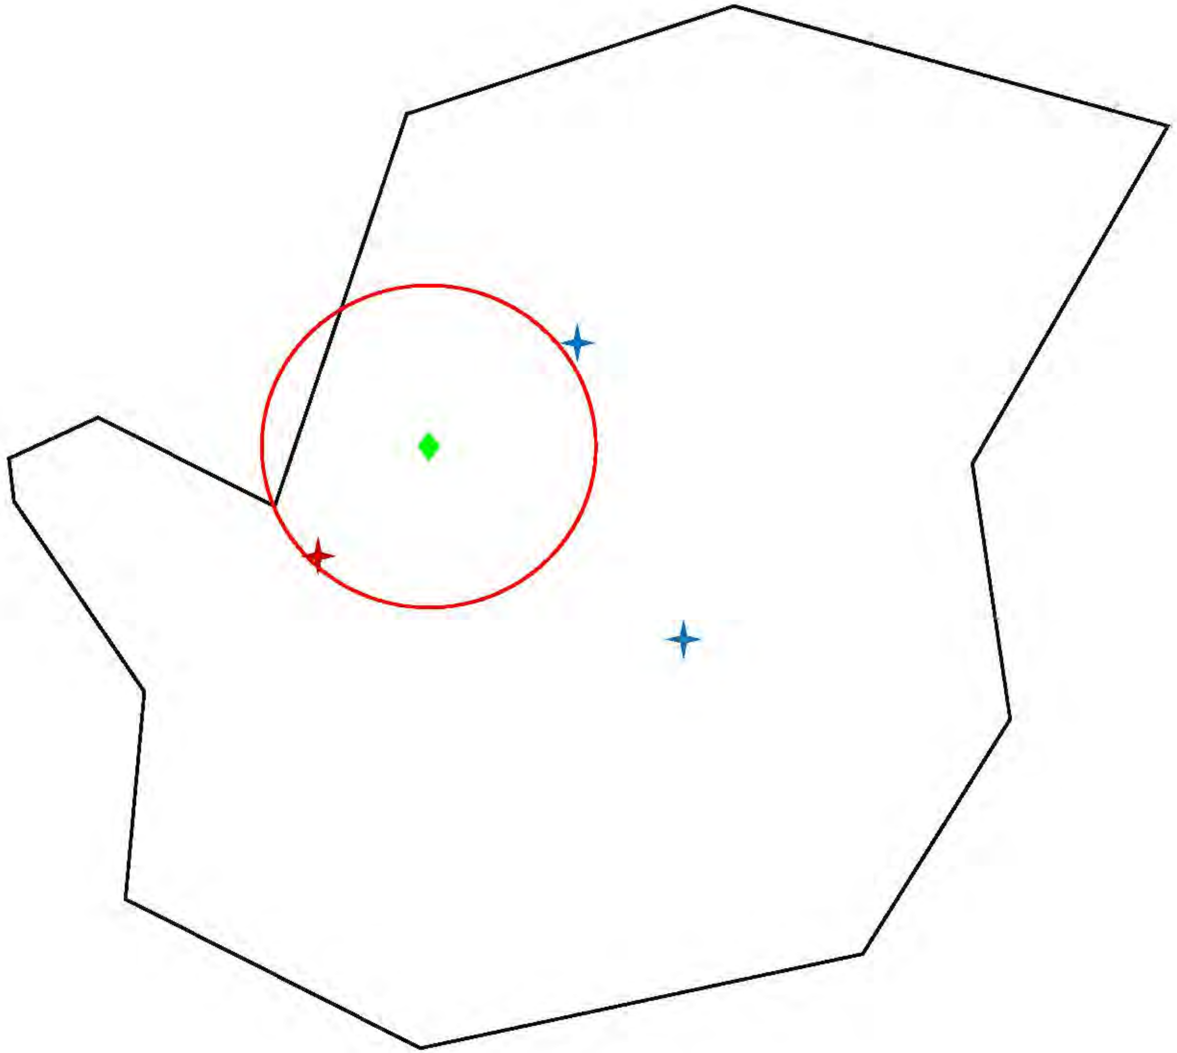
You are invited to the kickoff meeting for the UTSG Proposed Plan impacts analysis. Quincy will review the major changes between draft and final, particularly as they relate to the Utah Subregion. We will send out some materials for your review in advance of the meeting. As a heads-up, we WILL be asking for GIS requests before the meeting in order to stick with the schedule. Let Chad or me know if you have any questions between now and then. Thank you.

[redacted]

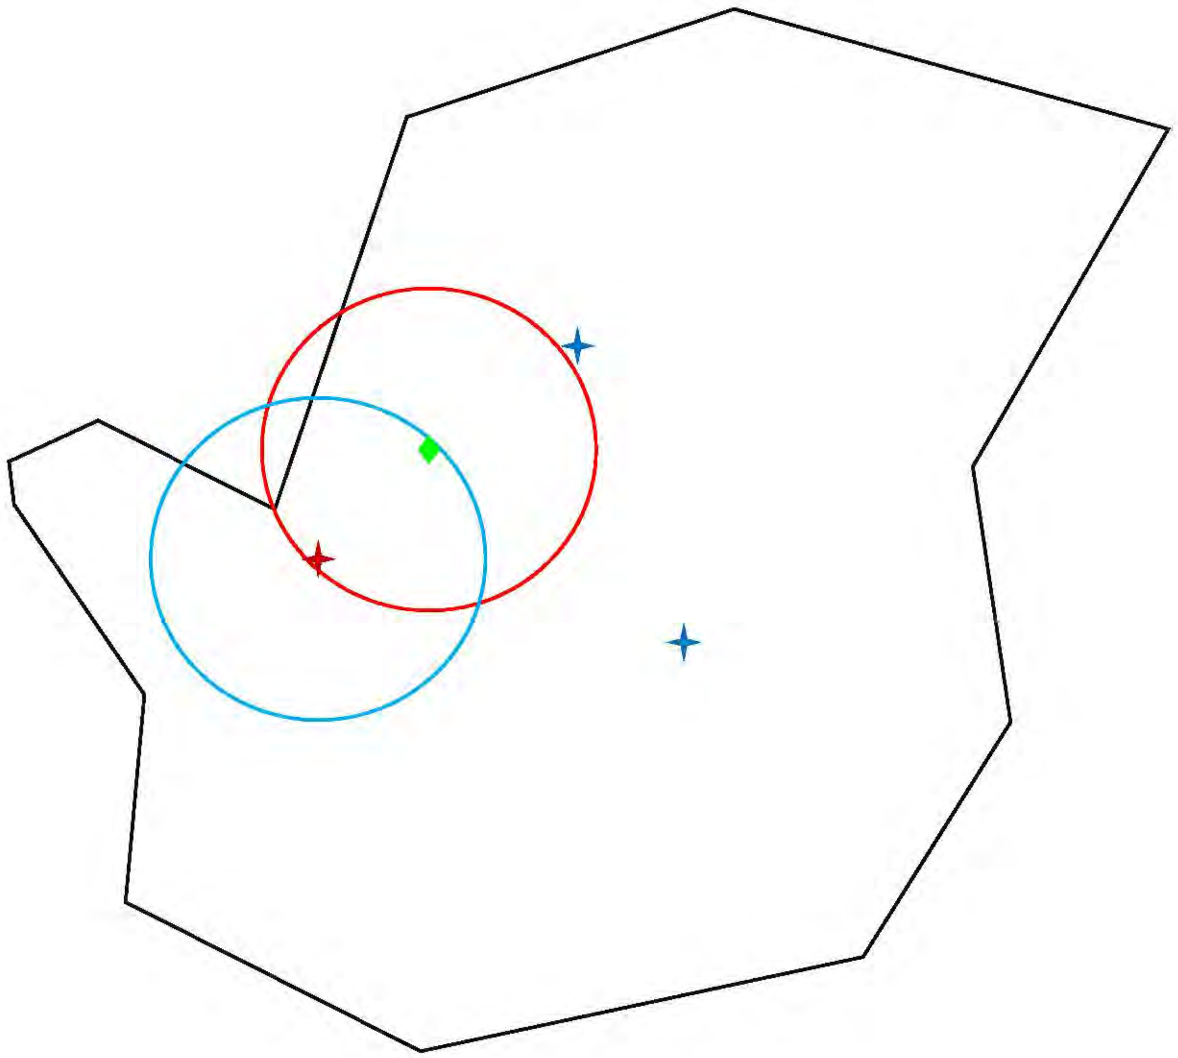


Disturbance Calculation Scenario:

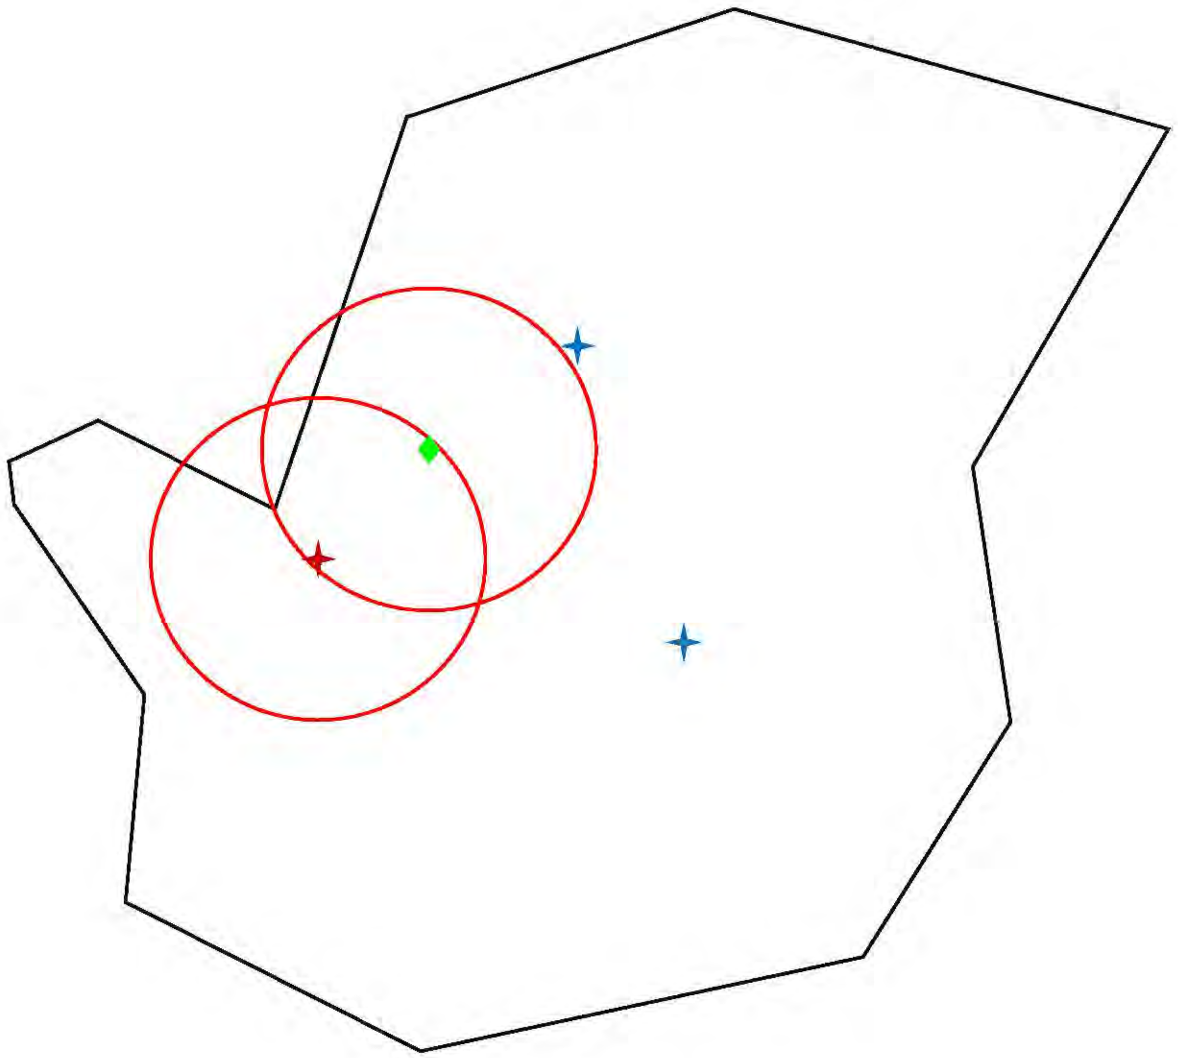
- Black Outline: PHMA associated with a PAC (for Utah, this is our “Biologically Significant Area”). For the purposes of this exercise, we’ll assume it is 250,000 acres.
- Green Diamond: Proposed area of physical disturbance related to the project.
- Blue Stars: Occupied Greater Sage-Grouse Leks
- Purple “stuff”: Existing disturbance from the 12 degradation threats.
- Red Circle: Four-mile project boundary
- Blue Circles: Four-mile lek boundaries



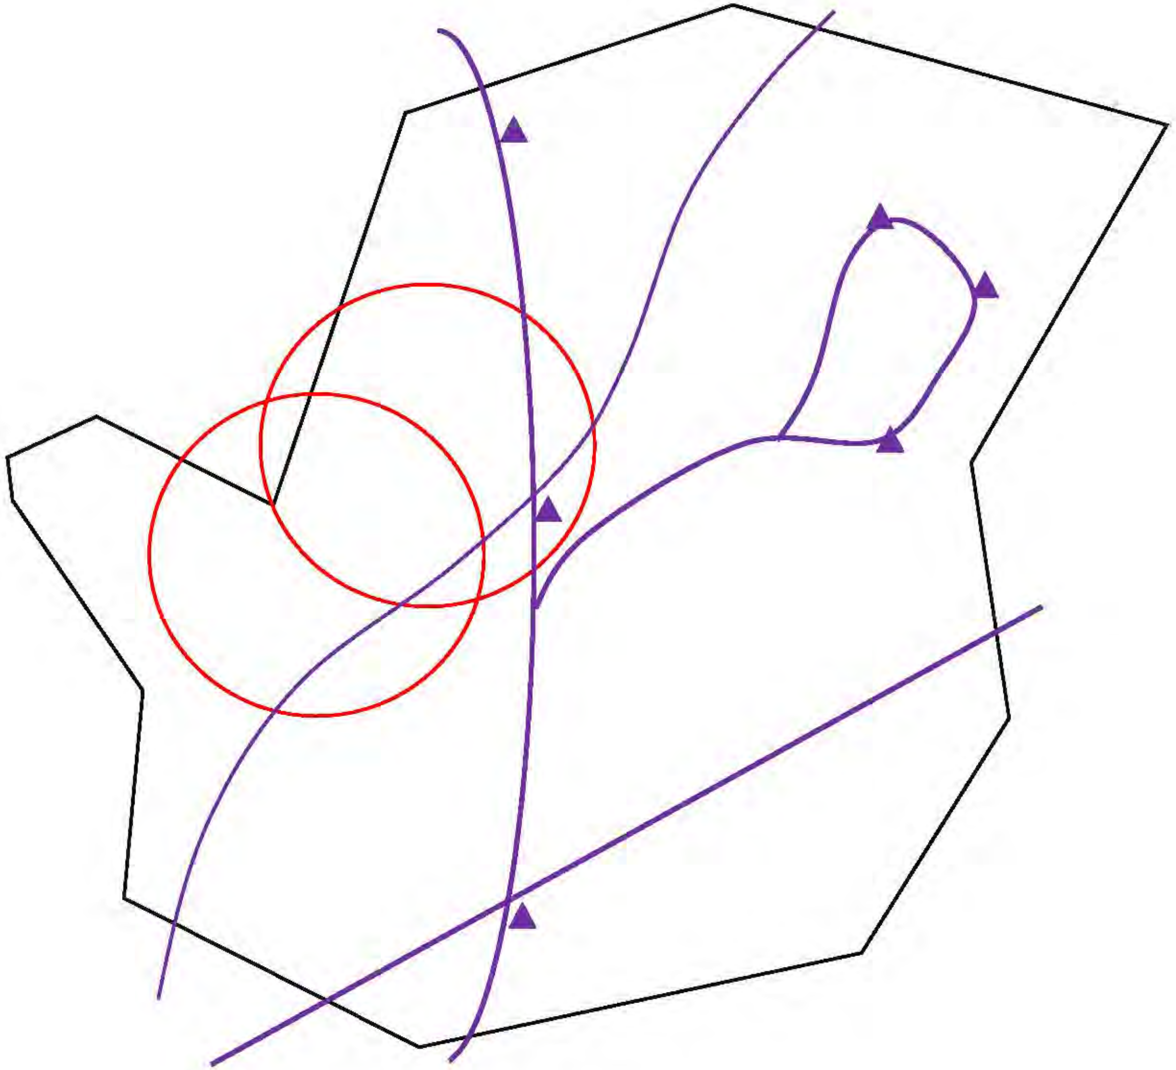
1) Determine potentially affected occupied leks by placing a four mile boundary around the proposed area of physical disturbance related to the project. All occupied leks located within the four mile project boundary and within PHMA will be considered affected by the project.



2) Next, place a four mile boundary around each of the affected occupied leks.



3) The PHMA within the four mile lek boundary and the four mile project boundary creates the project analysis area for each individual project. If there are no occupied leks within the four-mile project boundary, the project analysis area will be that portion of the four-mile project boundary within the Priority Habitat Management Area. For the purposes of this scenario, we'll assume that there are approximately 51,500 acres within the two circles. Approximately 6,500 acres of these circles fall outside the PHMA (black line), leaving us with 45,000 acres in our project analysis area.



4) Map disturbances or use locally available data. Use of NAIP imagery is recommended.

For the purposes of this scenario, we'll assume the following existing disturbances in the biological significant unit:

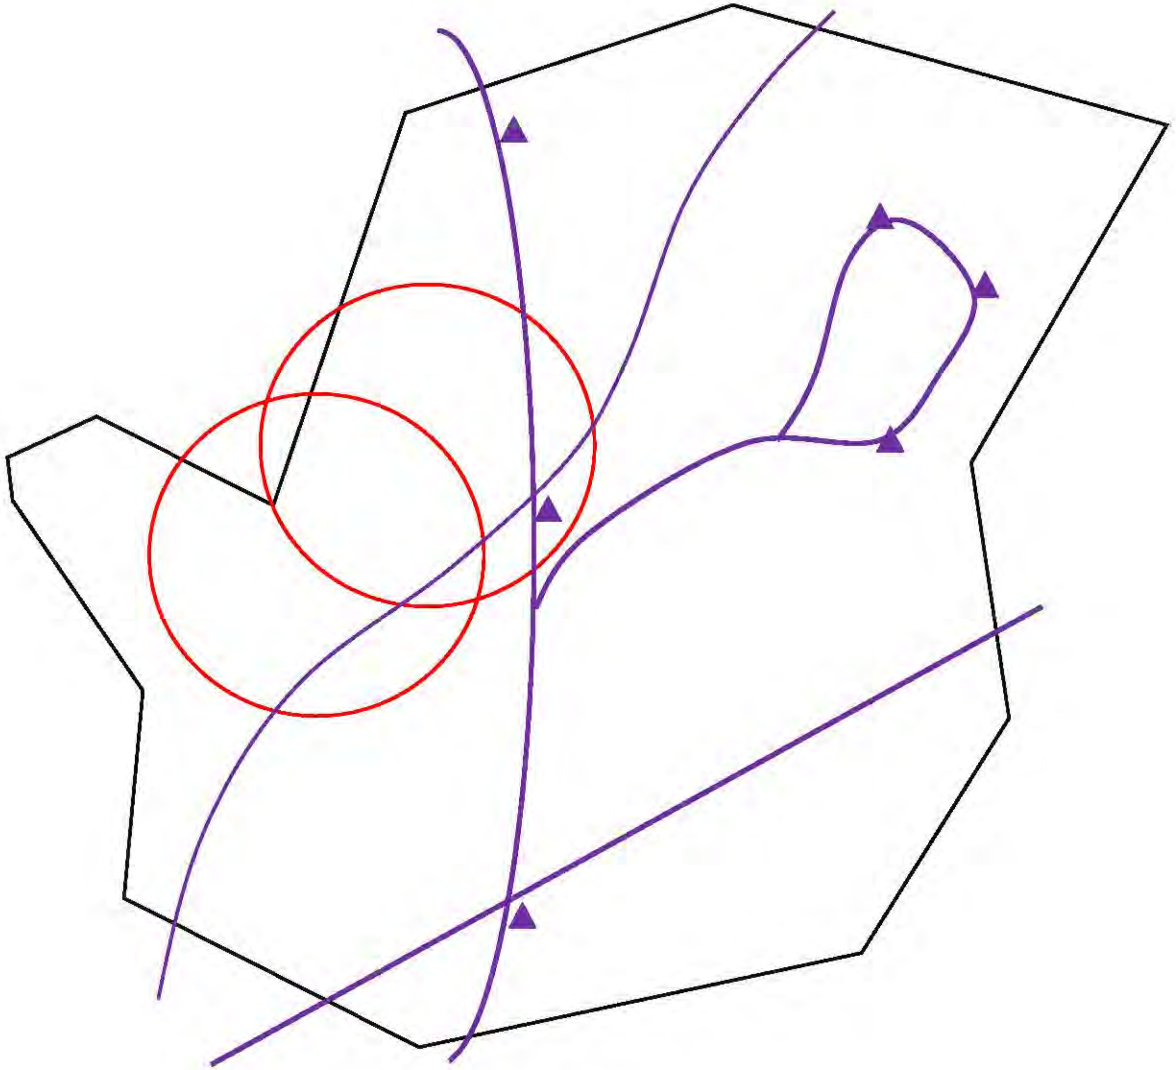
- 10 miles of railroad = 40 acres
- 14 miles of class B county road = 136 acres
- 18 miles of 2 collocated powerlines = 400 acres
- 15 miles of a 1.5 lane dirt road = 33 acres
- 3 wellpads = 20 acres
- 2 large mineral material pits = 600 acres
- 1 hardrock mine = 1,000 acres

Total disturbance = 2,229 acres

Within the project analysis area, assumed disturbance is as follows:

- 3 miles of class B county road = 30 acres
- 3 miles of 2 collocated powerlines = 65 acres
- 1 hardrock mine = 1,000 acres

Total disturbance = 1,095 acres



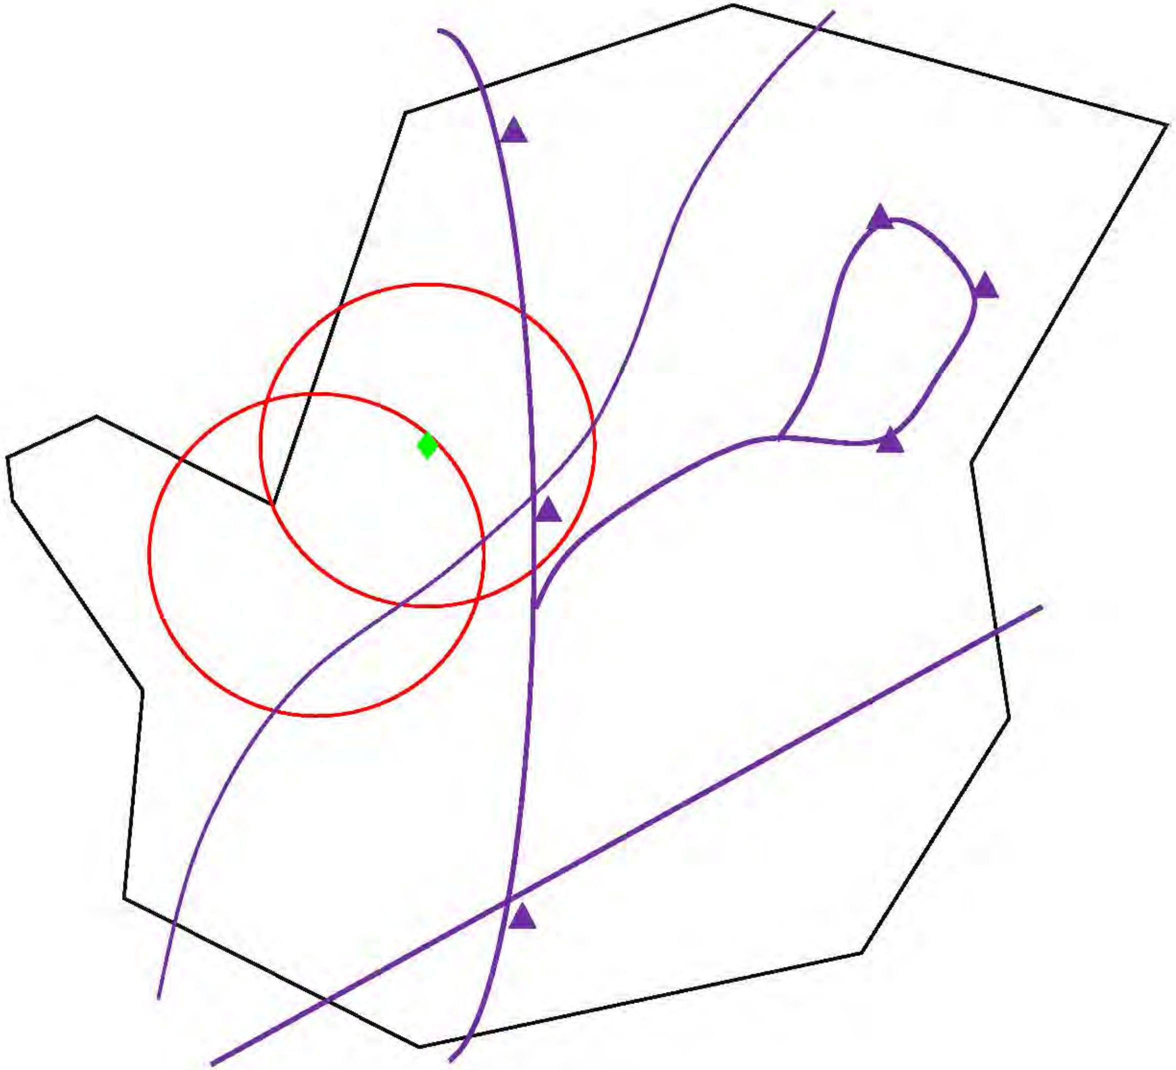
5) Calculate percent existing disturbance using the disturbance calculation formula. If existing disturbance is less than 3%, proceed to next step. If existing disturbance is greater than 3%, defer the project.

For the BSU:
% Degradation Disturbance = (combined acres of the 12 degradation threats*) ÷ (acres of all lands within the PHMAs in a BSU) x 100.

2,229 ÷ 250,000 x 100 = 0.89%

For the project analysis area:
% Degradation Disturbance = (combined acres of the 12 degradation threats[1] plus the 7 site scale threats[2]) ÷ (acres of all lands within the project analysis area in the PHMA) x 100.

1,095 ÷ 45,000 x 100 = 2.43%



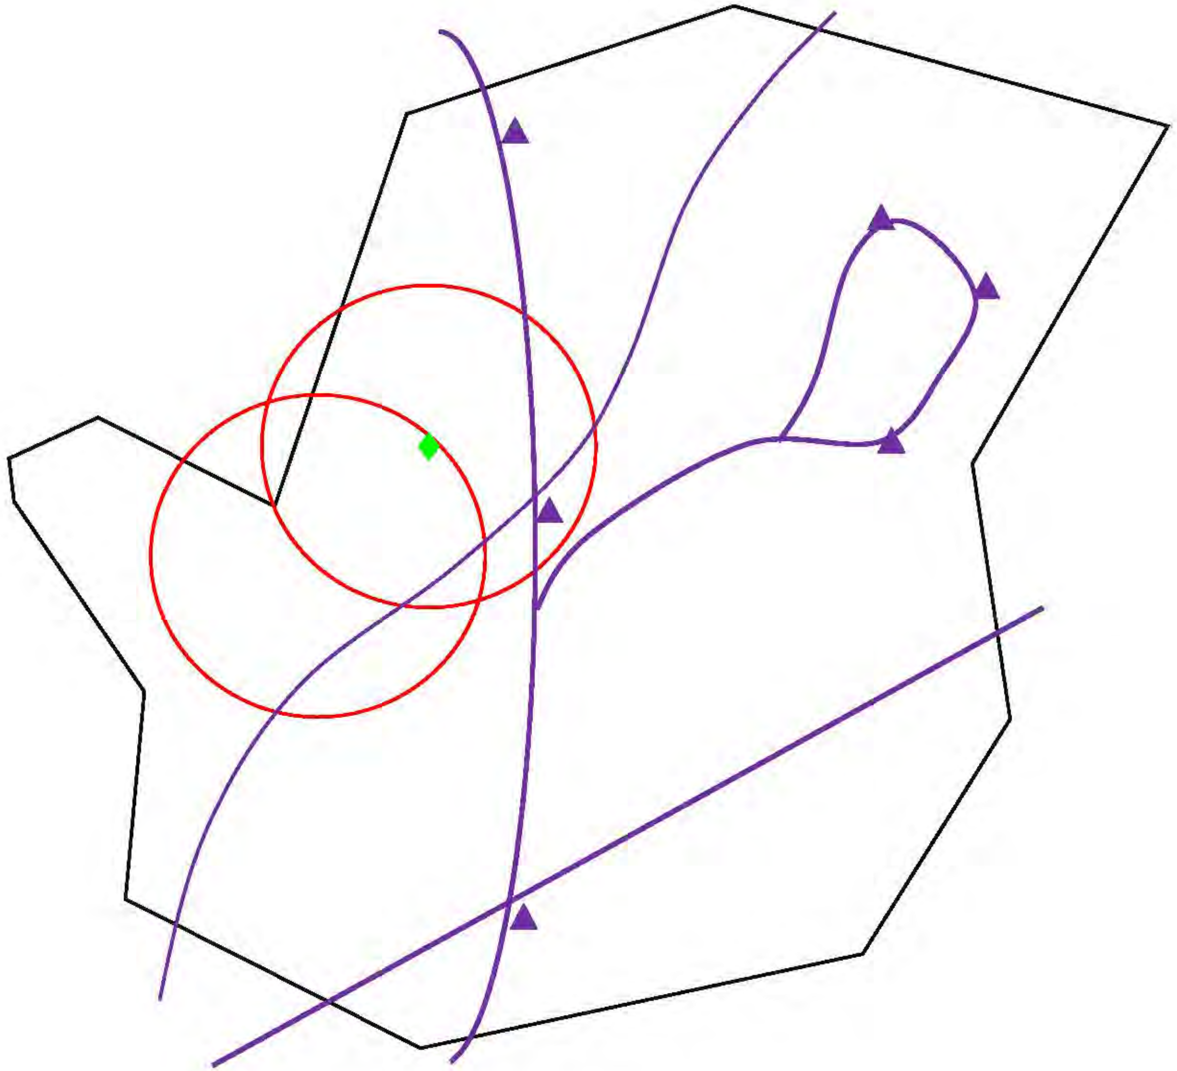
6) Add proposed project disturbance footprint area and recalculate the percent disturbance. If disturbance is less than 3%, proceed to next step. If disturbance is greater than 3%, defer project.

For the purposes of this scenario, we'll assume the project will result in the following additional disturbance:

- New development complex with communication sites complex, mineral material site, and staging area (100 acres).

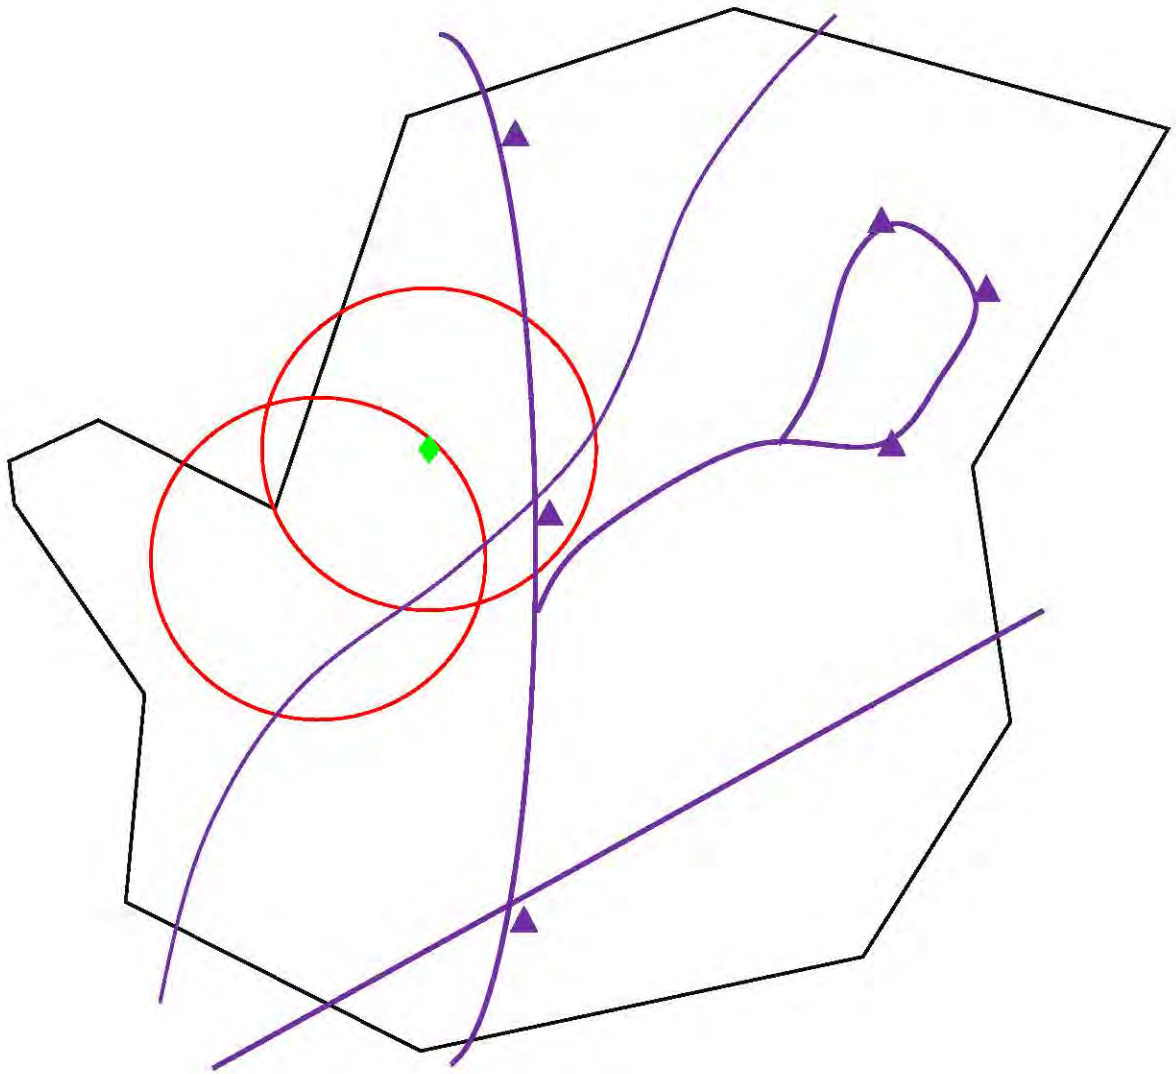
For the BSU:
(2,229 + 100) ÷ 250,000 x 100 = 0.93%

For the project analysis area:
(1,095 + 100) ÷ 45,000 x 100 = 2.66%

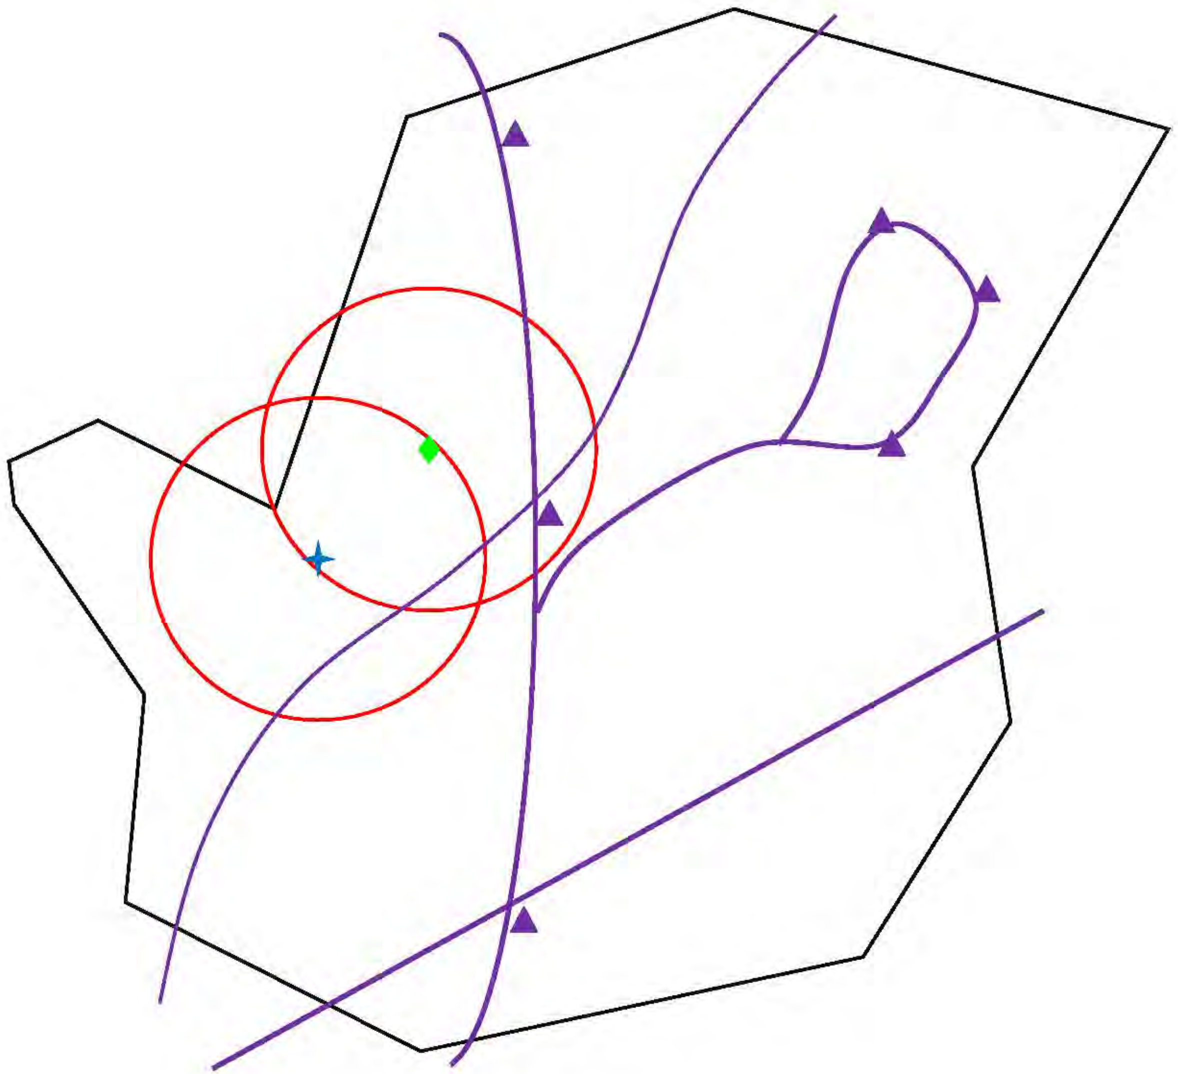


7) Calculate the disturbance density of energy and mining facilities. If the disturbance density is less than 1 facility per 640 acres, averaged across project analysis area, proceed to the NEPA analysis incorporating mitigation measures into an alternative. If the disturbance density is greater than 1 facility per 640 acres, averaged across the project analysis area, either defer the proposed project or co-locate it into existing disturbed area.

For this scenario, I don't have this. We'll assume we're good to go for this criteria.



8) If a project that would exceed the degradation cap or density cap cannot be deferred due to valid existing rights or other existing laws and regulations, fully disclose the local and regional impacts of the proposed action in the associated NEPA.



Key points to remember:

- The disturbance cap applies ONLY to PHMA. If a portion of the project analysis area is outside PHMA, the denominator will decrease.
- The disturbance cap is calculated regardless of land ownership. While the BLM/FS can only make decisions on the lands which we administer, we do take into account impacts from adjacent lands.
- The disturbance cap does not differentiate between habitat and non-habitat within the biologically significant unit or project analysis area. It applies equally to all types of vegetation.

BLM-UTAH

Greater Sage-Grouse Planning Issues for the BLM Planning Teams to Insert and Analyze in Administrative Draft Proposed Plan (ADPP)

January 30, 2015

The March 4, 2010 decision by the U.S. Fish and Wildlife Service that the greater sage-grouse warranted listing but was precluded [Endangered and Threatened Wildlife and Plants; 12-Month Findings for Petitions to list the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered] *set in motion the most comprehensive land-use planning initiative in the BLM's history.*

In 2011, the BLM began updating land-use plans across the West so as to ensure not only the long-term viability of the greater sage-grouse on public lands and the continued economic vitality of the West. This has been a complex and demanding process involving collaboration with an unprecedented number of stakeholders, including Governors, State Fish and Game agencies, the U.S. Fish and Wildlife Service and many others. The BLM's mandate of multiple use and sustained yield has required us to balance the full range of resource uses on public lands, including the conservation of crucial wildlife habitat. As we have worked through this process, public land managers throughout the BLM have made difficult resource management decisions.

These documents provide key guidance that will enable the BLM to finalize land use plans that will contribute to the conservation of the Greater Sage-Grouse and other sagebrush associated species across the West. The guidance outlines a suite of tools, such as disturbance limits in key habitats and mitigation approaches, which will help us to reach this goal. These mechanisms will work in concert to conserve sage-grouse habitat so that we can achieve our twin goals of thriving Greater Sage-Grouse populations and robust Western economies.

Issue: **Development in Highly Important Landscapes**

Direction: As more specifically provided in this guidance, the ADPP will include Sagebrush Focal Areas (SFA), consisting of the BLM-managed lands within the area depicted in the October 27, 2014 USFWS memo, *Greater Sage-Grouse: Additional Recommendation to Refine Land Use Allocations in Highly Important Landscapes*. In the Special Status Species Section of Chapter 2, include the following management action drop in language (for the Proposed Plan only):

"Designate Sagebrush Focal Areas (SFA) as shown on Map X (x acres). SFAs will be managed as PHMA, with the following additional management:

1) *Recommended for withdrawal from the General Mining Act of 1872, subject to valid existing rights.*
2) *Managed as NSO, without waiver, exception, or modification, for fluid mineral leasing.*

3) *Prioritized for management and conservation actions in these areas, including, but not limited to review of livestock grazing permits/leases (see livestock grazing section for additional actions)."*

The ADPPs will also reiterate the relevant SFA decisions in the locatable minerals, fluid minerals, and livestock grazing sections of Chapter 2.

<u>The NOC will provide updated shapefiles that delineate the SFAs.</u>

Except as otherwise provided below, the ADPP will provide that all BLM- and FS-managed lands (including subsurface) within SFAs will be allocated and managed as PHMA and include the management actions above.

- *Do Not Include the following in SFA Management:*
    - Wilderness Study Areas (WSAs) in non-habitat within the SFAs have current management which is generally protective of GRSG. These will continue to be managed so as not to impair their suitability for preservation as wilderness.
        - To the extent that these areas were analyzed for contingent management as general or priority habitat, the ADPP will include contingent allocations and management direction that would apply in the event that Congress releases the areas from WSA status.
- *Do Not Include Other Agency Land in SFA Management* –while lands managed by other agencies will be shown on the SFA maps, BLM ADPP decisions will not be applied to them.
- *Northern Monte Cristo Range (FS-UT)* – this area will be treated as PHMA, with the SFA management actions for this FS-land.
- *Do Not Include Private/State Lands in SFA Management* – while private/state lands may be within the SFA boundaries, ADPP decisions will not be applied to them, but may apply to federal subsurface underlying such lands as provided below.
- *Subsurface Estate:*
    - Under private/state lands: subsurface estate identified as PHMA or GHMA in the DEIS should be treated as PHMA with SFA management actions. The subsurface estate located within the Northern Monte Cristo Range (FS-UT) will be managed as PHMA, with the SFA management actions.
    - Under other Federal lands: subsurface estate should be treated as PHMA with SFA management actions if it is not already withdrawn (such as in Refuges or Parks) and PHMA or GHMA management was analyzed in the DEIS.

Additional direction/drop in language for the ADPPs regarding SFAs will be forthcoming.

Issue: **Mitigation**

Direction: The ADPP will include the updated Mitigation Framework (Attachment I) and drop-in Chapter 2 language to reflect the following language:

"In all sage-grouse habitat, in undertaking BLM management actions, and, consistent with valid existing rights and applicable law, in authorizing third-party actions that result in habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions."

Issue: **Mapping**

Direction: BLM-UT will not manage non-habitat (Opportunity Areas) as PHMA, as this was not analyzed in the DEIS and would require NEPA supplementation. In these areas, BLM-UT will apply the most restrictive management analyzed in their DEIS. Concerning the West Tavaputs area, a 3.1-mile area around the leks will be managed as PHMA, with the remainder of the area managed as GHMA.

Issue: **Disturbance**

Direction: Per the original April 2014 NPT guidance on disturbance, the ADPP will use the 3% disturbance cap at the Biologically Significant Unit (BSU) and project scale. The density calculation (an average of 1 facility per 640 acres) applies to energy and mining facilities. The disturbance cap will not be applied to foreclose development of locatable minerals on unpatented claims located under the 1872 Mining Law; the disturbance from locatable mining will be accounted for in determining the percent disturbance and whether the cap has been exceeded. See Attachment II for appropriate scales and methodology for calculating disturbance and recommended drop-in language. Planning units will include the following land use plan actions within their ADPPs that states:

a. *If the 3% anthropogenic disturbance cap is exceeded on lands (regardless of land ownership) within GRSG Priority Habitat Management Areas in any given Biologically Significant Unit, then no further discrete anthropogenic disturbances (subject to applicable laws and regulations, such as the 1872 hard rock mining law, valid existing rights, etc.) will be permitted by BLM within GRSG Priority*

Habitat Management Areas in any given Biologically Significant Unit until the disturbance has been reduced to less than the cap.

b. *If the 3% disturbance cap is exceeded on all lands (regardless of land ownership) within a proposed project analysis area in a Priority Habitat Management Areas, then no further anthropogenic disturbance will be permitted by BLM until disturbance in the proposed project analysis area has been reduced to maintain the area under the cap (subject to applicable laws and regulations, such as the 1872 hard rock mining law, valid existing rights, etc.).*

Issue: **Vegetation Objectives**

Direction: The ADPP will establish and incorporate vegetation and GRSG habitat objectives (see Attachment III for specific guidance and a GRSG Habitat Objectives Table template that follows the Sage-Grouse Habitat Assessment Framework Technical Reference-6710-1). The vegetation and GRSG habitat objectives guidance states that the values for the desired conditions in the GRSG Habitat Objectives Table are to be used, at a minimum, to meet the applicable land health standard in sage-grouse habitats. Planning units may include additional indicators and desired condition values as appropriate. The desired condition value for each indicator can be a range of values rather than a single value (e.g., the value for the desired condition for sagebrush canopy cover in breeding and nesting habitat could be 15-25%).

The GRSG Habitat Objectives table is to be placed in the Special Status Species section of the ADPP. The vegetation objective should be placed in the Vegetation section of the ADPP. Planning units will include the following land use plan vegetation objective within the Vegetation section of their ADPPs:
In all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain a minimum of 70% of lands capable of producing sagebrush with 10 to 30% sagebrush canopy cover. The attributes necessary to sustain these habitats are described in Interpreting Indicators of Rangeland Health (BLM Tech Ref 1734-6).

Issue: **Livestock Grazing**

Direction: The following management actions will be included in the Livestock Grazing section of the ADPP.

- *The BLM will prioritize (1) the review of grazing permits/leases, in particular to determine if modification is necessary prior to renewal, and (2) the processing of grazing permits/leases in Sagebrush Focal Areas (SFAs) followed by PHMAs outside of the SFAs. In setting workload priorities, precedence will be given to existing permits/leases in these areas not meeting Land Health Standards, with focus on those containing riparian areas,* *including wet meadows. The BLM may use other criteria for prioritization to respond to urgent natural resource concerns (ex., fire) and legal obligations.*

- *The NEPA analysis for renewals and modifications of livestock grazing permits/leases that include lands within SFAs and PHMAs will include specific management thresholds based on GRSG Habitat Objectives Table and/or Land Health Standards (43 CFR 4180.2) and defined responses that will allow the authorizing officer to make adjustments to livestock grazing without conducting additional NEPA.*
- *Allotments within SFAs, followed by those within PHMAs, and focusing on those containing riparian areas, including wet meadows, will be prioritized for field checks to help ensure compliance with the terms and conditions of the grazing permits. Field checks could include monitoring for actual use, utilization, and use supervision.*
- *At the time a permittee or lessee voluntarily relinquishes a permit or lease, the BLM will consider whether the public lands where that permitted use was authorized should remain available for livestock grazing or be used for other resource management objectives.*

Attachment IV provides guidance as to how the BLM will incorporate GRGS decisions from the Sage-Grouse RMP/Amendments into grazing permits/leases.

Issue: **Mineral Materials (Salable Minerals)**

Direction: As directed in the NPT guidance, all Priority Habitat Management Areas will be closed to new mineral materials development.

The following management action will be applied to the ADPP:
"PHMAs are closed to new mineral material sales. However, these areas remain "open" to free use permits and the expansion of existing active pits, only if the following criteria are met:

- *the activity is within the Biologically Significant Unit (BSU) and project area disturbance cap;*
- *the activity is subject to the provisions set forth in the mitigation framework [Appendix X];*
- *all applicable required design features are applied; and [if applicable] the activity is permissible under the specific sub-regional screening criteria [site location in ADPP where this screening process is present]."*

Issue: **High-voltage Transmission and Major Pipeline ROWs and Corridors**

Direction: 1) Apply the recommended NPT allocation guidance for PHMA of avoidance.

2) GHMA will remain open because of the limited number of birds in General Habitat Management Areas.

3) For sub-regions that have planned priority transmission lines that traverse their planning area (Gateway West, Boardman to Hemingway, and TransWest Express, including those portions of Gateway South that are co-located), apply the following language as a management action in the ADPP:
"Priority Habitat Management Areas (PHMAs) are designated as avoidance areas for high voltage transmission line ROWs. All authorizations in these areas, other than the excepted projects, must comply with the conservation measures outlined in this proposed plan, including the RDFs and avoidance criteria presented in [insert citation here] of this document. The BLM is currently processing an application for [Insert name of transmission project] and the NEPA review for this project is well underway. The BLM is analyzing GRSG mitigation measures through the project's NEPA review process."

Issue: **Coal Suitability**

Direction: Sub-regions will include the following management action:
"At the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. PHMA is essential habitat for maintaining GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1)."

Issue: **Fluid Mineral Resources (Including Geothermal)**

Direction: The ADPP will include the following as a conservation objective:

"Priority will be given to leasing and development of fluid mineral resources, including geothermal, outside of PHMA and GHMA. When analyzing leasing and authorizing development of fluid mineral resources, including geothermal, in PHMA and GHMA, and subject to applicable stipulations for the conservation of Greater Sage-Grouse, priority will be given to development in non-habitat areas first and then in the least suitable habitat for Greater Sage-Grouse. The implementation of these priorities will be subject to valid existing rights and any applicable law or regulation, including, but not limited to, 30 U.S.C. 226(p) and 43 C.F.R. 3162.3-1(h)."

"Where a proposed fluid mineral development project on an existing lease could adversely affect GRSG populations or habitat, the BLM will work with the lessees, operators, or other project proponents to avoid, reduce and mitigate adverse impacts to the extent compatible with lessees' rights to drill and produce fluid mineral resources. The BLM will work with the lessee, operator, or project proponent in developing an APD for the lease to avoid and minimize impacts to sage-grouse or its habitat and will ensure that the best information about the GRSG and its habitat informs and helps to guide development of such Federal leases."

Issue: **No Surface Occupancy (NSO) Exception Language**

Direction: Follow NPT guidance for Priority Habitat Management Areas. No-surface-occupancy stipulations will be included in new fluid mineral leases at the time of leasing only and may not be applied to existing fluid mineral leases that did not include no-surface-occupancy stipulation at the time of leasing. Include the following language into the ADPP:

No waivers or modifications to a fluid mineral lease no-surface-occupancy stipulation will be granted. The Authorized Officer may grant an exception to a fluid mineral lease no-surface-occupancy stipulation only where the proposed action:

(i) Would not have direct, indirect, or cumulative effects on GRSG or its habitat; or,
(ii) Is proposed to be undertaken as an alternative to a similar action occurring on a nearby parcel, and would provide a clear conservation gain to GRSG.

Exceptions based on conservation gain (ii) may only be considered in (a) PHMAs of mixed ownership where federal minerals underlie less than fifty percent of the total surface, or (b) areas of the public lands where the proposed exception is an alternative to an action occurring on a nearby parcel subject to a valid Federal fluid mineral lease existing as of the date of this RMP [revision or amendment]. Exceptions based on conservation gain must also include measures, such as enforceable institutional controls and buffers, sufficient to allow the BLM to conclude that such benefits will endure for the duration of the proposed action's impacts.

Any exceptions to this lease stipulation may be approved by the Authorized Officer only with the concurrence of the State Director. The Authorized Officer may not grant an exception unless the applicable state wildlife agency, the USFWS, and the BLM unanimously find that the proposed action satisfies (i) or (ii). Such finding shall initially be made by a team of one field biologist or other GRSG expert from each respective agency. In the event the initial finding is not unanimous, the finding may *be elevated to the appropriate BLM State Director, USFWS State Ecological Services Director, and state wildlife agency head for final resolution. In the event their finding is not unanimous, the exception will not be granted. Approved exceptions will be made publically available at least quarterly."*

Issue: **Adaptive Management**

Direction: Follow the NPT Adaptive Management Guidance and Sideboards. When a hard trigger is hit in a BSU, the designated response will be put in place in that BSU. Triggers and responses have been developed with local state and FWS experts.

When a hard trigger is hit in a BSU within a PAC that has multiple BSUs, including those that cross state lines, the WAFWA Management Zone Greater Sage-Grouse Conservation Team will convene to determine the causal factor, put project level responses in place, as appropriate and discuss further appropriate actions to be applied. The team will also investigate the status of the hard triggers in other BSUs within the PAC and will invoke the appropriate plan response. Adoption of any further actions at the plan level may require initiating a plan amendment process.

Issue: **Application of Lek Buffers**

Direction: The ADPP will require the use of lek buffer-distances for all new BLM-managed and BLM-authorized anthropogenic disturbances in both GHMA and PHMA (see Attachment V) through this drop-in Chapter 2 language:

"In undertaking BLM management actions, and consistent with valid and existing rights and applicable law in authorizing third-party actions, the BLM will apply the lek buffer-distances identified in the USGS Report Conservation Buffer Distance Estimates for Greater Sage-Grouse – A Review (Open File Report 2014-1239*) in accordance with Appendix X."*

Mineral Materials – General	Open

Attachment I

GREATER SAGE-GROUSE RMPA/FEIS
TEMPLATE LANGUAGE FOR ADDRESSING
MITIGATION

[🟩] = Instructions
[🟨] = Fill in the blank

[This mitigation language addresses greater sage-grouse. However, if you are working on a plan revision, you may need to add additional language to be more inclusive of other resource and value objectives (e.g. cultural resources, national historic trails, recreation values, other special status species) that may need to be mitigated.]

Chapter 1 - Introduction

[Nothing new to add to EIS]

Chapter 2 – Alternatives – [Proposed Plan/Proposed Plan Amendment]

- Add these two new sections (below) to the **Chapter 2 Alternatives** section.
- Replace the Regional Mitigation placeholder language that was included in the draft EIS with the new "Mitigation" section, below.
- Ensure a degree of consistency between this nationally standardized language and that found in the rest of the EIS.
- Fine tune this language, if necessary, but maintain consistency with the other BLM/USFS plan amendments.
- Remove references to USFS for plans that do not address US Forest Service lands

Consistent with the proposed plan's goal outlined in [Table 2-X – Description of Alternatives], the intent of the [Proposed Plan/Proposed Plan Amendment] is to provide a net conservation gain to the species. To do so, in undertaking BLM/USFS management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM will require and assure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. This is also consistent with BLM Manual 6840 – Special Status Species Management, Section .02B, which states "to initiate protective conservation measures that reduce or eliminate threats to Bureau sensitive species to minimize the likelihood of the need for listing of these species under the ESA."

Mitigation

Mitigation Standards. In undertaking BLM/USFS management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM will require and assure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. Mitigation will follow the regulations from the White House Council on Environmental Quality (CEQ) (40 CFR 1508.20; e.g. avoid, minimize, and compensate), hereafter referred to as the mitigation hierarchy. If impacts from BLM/USFS management actions and authorized third party actions that result in habitat loss and degradation remain after applying avoidance and minimization measures (i.e. residual impacts), then compensatory mitigation projects will be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation (see the concepts of durability, timeliness, and additionality as described further in Appendix X).

Greater Sage-Grouse Conservation Team. The BLM/USFS will establish a WAFWA Management Zone Greater Sage-Grouse Conservation Team (hereafter, Team) to help guide the conservation of greater sage-grouse, within 90 days of the issuance of the Record of Decision. This Team will develop a WAFWA Management Zone Regional Mitigation Strategy (hereafter, Regional Mitigation Strategy). The Team will also compile and report on monitoring data (including data on habitat condition, population trends, and mitigation effectiveness) from States across the WAFWA Management Zone (see Monitoring section). Subsequently, the Team will use these data to either modify the appropriate Regional Mitigation Strategy or recommend adaptive management actions (see Adaptive Management section).

The BLM/USFS will invite governmental and Tribal partners to participate in this Team, including the State Wildlife Agency and U.S. Fish and Wildlife Service, in compliance with the exemptions provided for committees defined in the Federal Advisory Committee Act and the regulations that implement that act. The BLM/USFS will strive for a collaborative and unified approach between Federal agencies (e.g. FWS, BLM, and USFS), Tribal governments, state and local government(s), and other stakeholders for greater sage-grouse conservation. The Team will provide advice, and will not make any decisions that impact Federal lands. The BLM/USFS will remain responsible for making decisions that affect Federal lands.

Developing a Regional Mitigation Strategy. The Team will develop a Regional Mitigation Strategy to inform the mitigation components of NEPA analyses for BLM/USFS management actions and third party actions that result in habitat loss and degradation. The Strategy will be developed within one year of the issuance of the Record of Decision. The BLM's Regional Mitigation Manual MS-1794 will serve as a framework for developing the Regional Mitigation Strategy. The Regional Mitigation Strategy will be applicable to the States/Field Offices/Forests within the WAFWA Management Zone's boundaries.

Regional mitigation is a landscape-scale approach to mitigating impacts to resources. This involves anticipating future mitigation needs and strategically identifying mitigation sites and measures that can provide a net conservation gain to the species. The Regional Mitigation Strategy developed by the Team will elaborate on the components identified above (i.e.

avoidance, minimization, and compensation; additionality, timeliness, and durability) and further explained in Appendix [X].

In the time period before the Strategy is developed, BLM will consider regional conditions, trends, and sites, to the greatest extent possible, when applying the mitigation hierarchy and will ensure that mitigation is consistent with the standards set forth in the first paragraph of this section.

Incorporating the Regional Mitigation Strategy into NEPA Analyses. The BLM/USFS will include the avoidance, minimization, and compensatory recommendations from the Regional Mitigation Strategy in one or more of the NEPA analysis' alternatives for BLM/USFS management actions and third party actions that result in habitat loss and degradation and the appropriate mitigation actions will be carried forward into the decision.

Implementing a Compensatory Mitigation Program. Consistent with the principles identified above, the BLM/USFS need to ensure that compensatory mitigation is strategically implemented to provide a net conservation gain to the species, as identified in the Regional Mitigation Strategy. In order to align with existing compensatory mitigation efforts, this compensatory mitigation program will be implemented at a State-level (as opposed to a WAFWA Management Zone, a Field Office, or a Forest), in collaboration with our partners (e.g. Federal, Tribal, and State agencies).

To ensure transparent and effective management of the compensatory mitigation funds, the BLM/USFS will enter into a contract or agreement with a third-party to help manage the State-level compensatory mitigation funds, within one year of the issuance of the Record of Decision. The selection of the third-party compensatory mitigation administrator will conform to all relevant laws, regulations, and policies. The BLM/USFS will remain responsible for making decisions that affect Federal lands.

Chapter 3 – Affected Environment

[Nothing to add]

Chapter 4 – Environmental Consequences – [Proposed Plan/Proposed Plan Amendment]

Mitigation

This Chapter describes the environmental consequences associated with the impacts to greater sage-grouse and its habitat from activities carried out in conformance with this plan, in addition to BLM/USFS management actions. In undertaking BLM/USFS management actions, and consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM/USFS will require mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. In addition, to help implement this [Proposed Plan / Proposed Plan Amendment], a WAFWA Management Zone Regional Mitigation Strategy (per Appendix [X]) will be developed within one year of the issuance of the Record of Decision. The Strategy will elaborate on the components identified in Chapter 2 (avoidance, minimization, compensation, additionality, timeliness, and durability), and will be considered by the BLM/USFS for BLM/USFS management actions and third party actions that result in habitat loss and degradation. The implementation of a Regional Mitigation Strategy will benefit greater sage-grouse, the public, and land-users by providing a reduction in threats, increased public transparency and confidence, and a predictable permit process for land-use authorization applicants.

Appendix [X]

- Add this new **Appendix.**
- Ensure a degree of consistency between this nationally standardized language and that found in the rest of the EIS.
- Fine tune this language, if necessary, but maintain consistency with the other BLM/USFS plan amendments.
- Remove references to USFS for plans that do not address US Forest Service lands

Appendix (X) – Mitigation – [Proposed Plan/Proposed Plan Amendment]

General

In undertaking BLM/USFS management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM/USFS will require and assure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. Mitigation will follow the regulations from the White House Council on Environmental Quality (CEQ) (40 CFR 1508.20; e.g. avoid, minimize, and compensate), hereafter referred to as the mitigation hierarchy. If impacts from BLM/USFS management actions and authorized third party actions that result in habitat loss and degradation remain after applying avoidance and minimization measures (i.e. residual impacts), then compensatory mitigation projects will be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation (see glossary).

The BLM/USFS, via the WAFWA Management Zone Greater Sage-Grouse Conservation Team, will develop a WAFWA Management Zone Regional Mitigation Strategy that will inform the NEPA decision making process including the application of the mitigation hierarchy for BLM/USFS management actions and third party actions that result in habitat loss and degradation. A robust and transparent Regional Mitigation Strategy will contribute to greater sage-grouse habitat conservation by reducing, eliminating, or minimizing threats and compensating for residual impacts to greater sage-grouse and its habitat.

The BLM's Regional Mitigation Manual MS-1794 serves as a framework for developing and implementing a Regional Mitigation Strategy. The following sections provide additional guidance specific to the development and implementation of a WAFWA Management Zone Regional Mitigation Strategy.

Developing a WAFWA Management Zone Regional Mitigation Strategy

The BLM/USFS, via the WAFWA Management Zone Greater Sage-Grouse Conservation Team, will develop a WAFWA Management Zone Regional Mitigation Strategy to guide the application of the mitigation hierarchy for BLM/USFS management actions and third party actions that result in habitat loss and degradation. The Strategy should consider any State-level greater sage-grouse mitigation guidance that is consistent with the requirements identified in this Appendix. The Regional Mitigation Strategy should be developed in a transparent manner, based on the best science available and standardized metrics.

As described in Chapter 2, the BLM/USFS will establish a WAFWA Management Zone Greater Sage-Grouse Conservation Team (hereafter, Team) to help guide the conservation of greater sage-grouse, within 90 days of the issuance of the Record of Decision. The Strategy will be developed within one year of the issuance of the Record of Decision.

The Regional Mitigation Strategy should include mitigation guidance on avoidance, minimization, and compensation, as follows:

- Avoidance
  - Include avoidance areas (e.g. right-of-way avoidance/exclusion areas, no surface occupancy areas) already included in laws, regulations, policies, and/or land use plans (e.g. Resource Management Plans, Forest Plans, State Plans); and,
  - Include any potential, additional avoidance actions (e.g. additional avoidance best management practices) with regard to greater sage-grouse conservation.
- Minimization
  - Include minimization actions (e.g. required design features, best management practices) already included in laws, regulations, policies, land use plans, and/or land-use authorizations; and,
  - Include any potential, additional minimization actions (e.g. additional minimization best management practices) with regard to greater sage-grouse conservation.
- Compensation
  - Include discussion of impact/project valuation, compensatory mitigation options, siting, compensatory project types and costs, monitoring, reporting, and program administration. Each of these topics is discussed in more detail below.
    - Residual Impact and Compensatory Mitigation Project Valuation Guidance
      - A common standardized method should be identified for estimating the value of the residual impacts and value of the compensatory mitigation projects, including accounting for any uncertainty associated with the effectiveness of the projects.

    - This method should consider the quality of habitat, scarcity of the habitat, and the size of the impact/project.
    - For compensatory mitigation projects, consideration of durability (see glossary), timeliness (see glossary), and the potential for failure (e.g. uncertainty associated with effectiveness) may require an upward adjustment of the valuation.
    - The resultant compensatory mitigation project will, after application of the above guidance, result in proactive conservation measures for Greater Sage-grouse (consistent with BLM Manual 6840 – Special Status Species Management, section .02).
- Compensatory Mitigation Options
    - Options for implementing compensatory mitigation should be identified, such as:
        - Utilizing certified mitigation/conservation bank or credit exchanges.
        - Contributing to an existing mitigation/conservation fund.
        - Authorized-user conducted mitigation projects.
    - For any compensatory mitigation project, the investment must be additional (i.e. additionality: the conservation benefits of compensatory mitigation are demonstrably new and would not have resulted without the compensatory mitigation project).
- Compensatory Mitigation Siting
    - Sites should be in areas that have the potential to yield a net conservation gain to the greater sage-grouse, regardless of land ownership.
    - Sites should be durable (see glossary).
    - Sites identified by existing plans and strategies (e.g. fire restoration plans, invasive species strategies, healthy land focal areas) should be considered, if those sites have the potential to yield a net conservation gain to greater sage-grouse and are durable.
- Compensatory Mitigation Project Types and Costs
    - Project types should be identified that help reduce threats to greater sage-grouse (e.g. protection, conservation, and restoration projects).
    - Each project type should have a goal and measurable objectives.
    - Each project type should have associated monitoring and maintenance requirements, for the duration of the impact.
    - To inform contributions to a mitigation/conservation fund, expected costs for these project types (and their monitoring and maintenance), within the WAFWA Management Zone, should be identified.
- Compensatory Mitigation Compliance and Monitoring
    - Mitigation projects should be inspected to ensure they are implemented as designed, and if not, there should be methods to enforce compliance.
    - Mitigation projects should be monitored to ensure that the goals and objectives are met and that the benefits are effective for the duration of the impact.

- Compensatory Mitigation Reporting
    - Standardized, transparent, scalable, and scientifically-defensible reporting requirements should be identified for mitigation projects.
    - Reports should be compiled, summarized, and reviewed in the WAFWA Management Zone in order to determine if greater sage-grouse conservation has been achieved and/or to support adaptive management recommendations.
- Compensatory Mitigation Program Implementation Guidelines
    - Guidelines for implementing the State-level compensatory mitigation program should include holding and applying compensatory mitigation funds, operating a transparent and credible accounting system, certifying mitigation credits, and managing reporting requirements.

Incorporating the Regional Mitigation Strategy into NEPA Analyses

The BLM/USFS will include the avoidance, minimization, and compensatory recommendations from the Regional Mitigation Strategy in one or more of the NEPA analysis' alternatives for BLM/USFS management actions and third party actions that result in habitat loss and degradation and the appropriate mitigation actions will be carried forward into the decision.

Implementing a Compensatory Mitigation Program

The BLM/USFS need to ensure that compensatory mitigation is strategically implemented to provide a net conservation gain to the species, as identified in the Regional Mitigation Strategy. In order to align with existing compensatory mitigation efforts, this compensatory mitigation program will be managed at a State-level (as opposed to a WAFWA Management Zone, a Field Office, or a Forest), in collaboration with our partners (e.g. Federal, Tribal, and State agencies).

To ensure transparent and effective management of the compensatory mitigation funds, the BLM/USFS will enter into a contract or agreement with a third-party to help manage the State-level compensatory mitigation funds, within one year of the issuance of the Record of Decision. The selection of the third-party compensatory mitigation administrator will conform to all relevant laws, regulations, and policies. The BLM/USFS will remain responsible for making decisions that affect Federal lands.

Glossary Terms

Additionality: The conservation benefits of compensatory mitigation are demonstrably new and would not have resulted without the compensatory mitigation project. (adopted and modified from BLM Manual Section 1794).

Avoidance mitigation: Avoiding the impact altogether by not taking a certain action or parts of an action. (40 CFR 1508.20(a)) (e.g. may also include avoiding the impact by moving the proposed action to a different time or location.)

Compensatory mitigation: Compensating for the (residual) impact by replacing or providing substitute resources or environments. (40 CFR 1508.20)

Compensatory mitigation projects: The restoration, creation, enhancement, and/or preservation of impacted resources (adopted and modified from 33 CFR 332), such as on-the-ground actions to improve and/or protect habitats (e.g. chemical vegetation treatments, land acquisitions, conservation easements). (adopted and modified from BLM Manual Section 1794).

Compensatory mitigation sites: The durable areas where compensatory mitigation projects will occur. (adopted and modified from BLM Manual Section 1794).

Durability (protective and ecological): the maintenance of the effectiveness of a mitigation site and project for the duration of the associated impacts, which includes resource, administrative/legal, and financial considerations. (adopted and modified from BLM Manual Section 1794).

Minimization mitigation: Minimizing impacts by limiting the degree or magnitude of the action and its implementation. (40 CFR 1508.20 (b))

Residual impacts: Impacts that remain after applying avoidance and minimization mitigation; also referred to as unavoidable impacts.

Timeliness: The lack of a time lag between impacts and the achievement of compensatory mitigation goals and objectives (BLM Manual Section 1794).

Attachment II

Greater Sage-Grouse (GRSG) Land Use Plans
Disturbance Caps Guidance

Purpose

I. Provide the planning units with land use planning actions that need to be incorporated into the administrative draft proposed plans to respond to the 3% disturbance cap once it is exceeded in either the Biologically Significant Units (BSU) or at the project scale.
II. Provide guidance on the use of the west-wide habitat degradation (disturbance) data layers as well as the use of locally collected disturbance data for BSUs to determine if the disturbance cap has been exceeded as the land use plans (LUP) are being implemented.
III. Provide guidance on the use of locally collected disturbance data for project authorizations to determine if the disturbance cap has been exceeded as the LUPs are being implemented.
IV. Provide guidance on the inclusion of fire in disturbance calculations.
V. Provide guidance on the use of the density of energy and mining facilities during authorizations
VI. Provide guidance on the use of the BER analysis in the land use plans (Chapter 2, Affected Environment) and the use of the "west-wide" sagebrush availability and habitat degradation data/estimates for the Priority Habitat Management Areas in each population for monitoring and management purposes as the LUPs are being implemented.
VII. Provide guidance on what is considered in the disturbance calculations versus what is considered for the disturbance cap.

Guidance

I. Planning units will include the following land use plan actions within their administrative draft proposed land use plans (ADPPs) that states:
    a. *If the 3% anthropogenic disturbance cap is exceeded on lands (regardless of land ownership) within GRSG Priority Habitat Management Areas in any given Biologically Significant Unit, then no further discrete anthropogenic disturbances (subject to applicable laws and regulations, such as the 1872 hard rock mining law, valid existing rights, etc.) will be permitted by BLM within GRSG Priority Habitat Management Areas in any given Biologically Significant Unit until the disturbance has been reduced to less than the cap.*
    b. *If the 3% disturbance cap is exceeded on all lands (regardless of land ownership) within a proposed project analysis area in a Priority Habitat Management Areas, then no further anthropogenic disturbance will be permitted by BLM until disturbance in the proposed project analysis area has been reduced to maintain*

the area under the cap (subject to applicable laws and regulations, such as the 1872 hard rock mining law, valid existing rights, etc.).

II. Use of west-wide habitat degradation data as well as the use of locally collected disturbance data to determine the level of existing disturbance:

   a) In the GRSG Priority Habitat Management Areas in any given Biologically Significant Unit, use the west-wide data at a minimum and/or locally collected disturbance data as available (e.g., DDCT) for the anthropogenic disturbance types listed in Table 1.

III. Use of locally collected disturbance data for project authorizations:

   a) In a proposed project analysis area, digitize all existing anthropogenic disturbances identified in the GRSG Monitoring Framework and the 7 additional features that are considered threats to sage-grouse (Table 2). Using 1 meter resolution NAIP imagery is recommended. Use local data if available.

IV. Fire-burned and habitat treatment areas will not be included in the project scale degradation disturbance calculation for managing sage-grouse habitat under a disturbance cap. These areas will be considered part of a sagebrush availability when rangewide, consistent, interagency fine- and site-scale monitoring has been completed and the areas have been determined to meet sage-grouse habitat requirements. These and other disturbances identified in Table 3 will be part of a sagebrush availability evaluation and will be considered along with other local conditions that may affect sage-grouse during the analysis of the proposed project area.

V. Planning units are directed to use a density cap related to the density of energy and mining facilities (listed below) during project scale authorizations. If the disturbance density in a proposed project area is on average less than 1/ 640 acres, proceed to the NEPA analysis incorporating mitigation measures into an alternative. If the disturbance density is greater than an average of 1/ 640 acres, either defer the proposed project or co-locate it into existing disturbed area *(subject to applicable laws and regulations, such as the 1872 Mining Law, valid existing rights, etc.).*

   - Energy (oil and gas wells and development facilities)
   - Energy (coal mines)
   - Energy (wind towers)
   - Energy (solar fields)
   - Energy (geothermal)
   - Mining (active locatable, leasable, and saleable developments)

VI. Planning units are directed to continue using the baseline data from the 2013 USGS Baseline Environmental Report (BER) in the Affected Environment section of the proposed plans/ FEISs. West-wide sagebrush availability and habitat degradation data layers will be used for the Priority Habitat Management Areas in each population for monitoring (see the GRSG Monitoring Framework in the Monitoring Appendix of the EIS) and management purposes as the LUPs are being implemented. The BER reported on individual threats across the range of sage-grouse while the west-wide disturbance calculation consolidated the anthropogenic disturbance data into a single measure using formulas from the GRSG Monitoring Framework. These calculations will be completed on an annual basis by the BLM's National Operation Center. Planning units will be provided the 2014 baseline disturbance calculation derived from the west-wide data once the RODs are signed that describe the Priority Habitat Management Areas.

VII. Planning units are directed to use the three measures (sagebrush availability, habitat degradation, density of energy and mining) in conjunction with other information during the NEPA process to most effectively site project locations, such as by clustering disturbances and/or locating facilities in already disturbed areas. Although locatable mine sites are included in the degradation calculation, mining activities under the 1872 mining law may not be subject to the 3% disturbance cap. Details about locatable mining activities should be fully disclosed and analyzed in the NEPA process to assess impacts to sage-grouse and their habitat as well as to BLM goals and objectives, and other BLM programs and activities.

Additional Information/Formulas

Disturbance Calculations for the BSUs and for the Project Analysis Areas:

- For the BSUs: **% Degradation Disturbance = (combined acres of the 12 degradation threats*) ÷ (acres of all lands within the PHMAs in a BSU) x 100.**
- For the Project Analysis Area: **% Degradation Disturbance = (combined acres of the 12 degradation threats[1] plus the 7 site scale threats[2]) ÷ (acres of all lands within the project analysis area in the PHMA) x 100.**

[1] see Table 3. [2] see Table 2

Project analysis area method for permitting surface disturbance activities:

- Determine potentially affected occupied leks by placing a four mile boundary around the proposed area of physical disturbance related to the project. All occupied leks located within the four mile project boundary and within PHMA will be considered affected by the project.

- Next, place a four mile boundary around each of the affected occupied leks.
- The PHMA within the four mile lek boundary and the four mile project boundary creates the project analysis area for each individual project. If there are no occupied leks within the four-mile project boundary, the project analysis area will be that portion of the four-mile project boundary within the Priority Habitat Management Area.
- Map disturbances or use locally available data. Use of NAIP imagery is recommended.
- Calculate percent existing disturbance using the formula above. If existing disturbance is less than 3%, proceed to next step. If existing disturbance is greater than 3%, defer the project.
- Add proposed project disturbance footprint area and recalculate the percent disturbance. If disturbance is less than 3%, proceed to next step. If disturbance is greater than 3%, defer project.
- Calculate the disturbance density of energy and mining facilities (listed above). If the disturbance density is less than 1 facility per 640 acres, averaged across project analysis area, proceed to the NEPA analysis incorporating mitigation measures into an alternative. If the disturbance density is greater than 1 facility per 640 acres, averaged across the project analysis area, either defer the proposed project or co-locate it into existing disturbed area.
- If a project that would exceed the degradation cap or density cap cannot be deferred due to valid existing rights or other existing laws and regulations, fully disclose the local and regional impacts of the proposed action in the associated NEPA.

Table 1. Anthropogenic disturbance types for disturbance calculations. Data sources are described for the west-wide habitat degradation estimates (Table copied from the GRSG Monitoring Framework)

Degradation Type	Subcategory	Data Source	Direct Area of Influence	Area Source
Energy (oil & gas)	Wells	IHS; BLM (AFMSS)	5.0ac (2.0ha)	BLM WO-300

Background

In the USFWS's 2010 listing decision for sage-grouse, the USFWS identified 18 threats contributing to the destruction, modification, or curtailment of the sage-grouse's habitat or range (75 FR 13910 2010). In April 2014, the Interagency GRSG Disturbance and Monitoring Sub-Team finalized the Greater Sage-Grouse Monitoring Framework (hereafter, framework) to track these threats. The 18 threats have been aggregated into three measures to account for whether the threat predominantly removes sagebrush or degrades habitat. The three measures are:

Measure 1: Sagebrush Availability (percent of sagebrush per unit area)
Measure 2: Habitat Degradation (percent of human activity per unit area)
Measure 3: Density of Energy and Mining (facilities and locations per unit area)

The BLM is committed to monitoring the three disturbance measures and reporting them to the FWS on an annual basis. However, for the purposes of calculating the amount of disturbance to provide information for management decisions and inform the success of the sage-grouse planning effort, the data depicting the location and extent of the 12 anthropogenic types of threats will be used at a minimum in the BSUs and those same 12 anthropogenic and the additional 7 types of features that are threats to sage-grouse will be used in the project analysis areas.

		Scales		
		Broad/Mid (Populations)	**Intermediate (BSU)**	**Local/Project (Seas. Hab.)**

ACRONYMS

PHMA = Priority Habitat Management Area	*BSU = Biologically Significant Unit*
EVT = Existing Vegetation Type	*BpS = Areas of Biotic Potential*

[1] *Only mines with a Plan of Operation (>5 acres of disturbance) will be included.*

[2] *Westwide data will be used only if state or local data are not available.*

[3] *This footnot was removed from the table. January 2015.*

[4] *This may be one of several variables used to inform Adaptive Management. The BSU is the scale at which Adaptive Management will be applied.*

[5] *A moving window analysis will be conducted at this scale by the NOC using westwide data. If available, state and local data/analysis should be used for Adaptive Management*

[6] *The project analysis area will be based on a 4-mile radius project boundary combined with a 4-mile lek boundary for leks within the 4mi project boundary in PHMA (DDCT methodology).*

[7] *See Table 2*

Attachment III

Greater Sage-Grouse (GRSG) Land Use Plans Vegetation Objectives Guidance

Purpose

I. Provide the planning units with land use planning vegetation objectives that need to be incorporated into the administrative draft proposed plans.

II. Provide guidance on the use of a template for GRSG habitat objectives in the Special Status Species section of the ADPPs.

III. Provide guidance on prioritizing land health assessments in sage-grouse habitats and conducting assessments at the watershed scale using the sage-grouse habitat objectives.

Guidance

I. Planning units will include the following land use plan vegetation objective within the Vegetation section of their administrative draft proposed land use plans (ADPPs) that states:

> *In all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain a minimum of 70% of lands capable of producing sagebrush with 10 to 30% sagebrush canopy cover. The attributes necessary to sustain these habitats are described in Interpreting Indicators of Rangeland Health (BLM Tech Ref 1734-6).*

II. Planning units will populate the GRSG Habitat Objectives table template to provide vegetation objectives for sage-grouse life history stages based on the ecology in your region to be used to meet the applicable land health standard in GRSG habitats. Planning units are encouraged to work across boundaries when developing the objectives to ensure regional continuity and will provide appropriate peer-reviewed science to support the habitat values for the indicators. These desired condition value can be a range of values rather than a single value (e.g., the value for the desired condition for sagebrush canopy cover in breeding and nesting habitat could be 15-25%). Planning units may include additional indicators and desired condition values as appropriate (see the Sage-Grouse Habitat Assessment Framework (HAF, *Technical Reference 6710-1*) for appropriate indicators). The HAF contains values for habitat suitability indicators in sage-grouse seasonal habitats from the Connelly et al. (2000) sage-grouse guidelines and has incorporated many of the core indicators in the AIM strategy (Toevs et al. 2011) as well. Planning units may use the indicator values from Connelly et al. (2000) while developing the land use plan Sage-Grouse Habitat Objectives table.

When using the indicators to guide management actions or during land health assessments, consider that the indicators are sensitive to the ecological processes operating at the scale of interest and that a single habitat indicator does not necessarily define habitat suitability for an area or particular scale. Indicators must be collectively reviewed, assessed based on the site potential, and put into spatial and temporal context to correctly determine habitat suitability which will include more than one scale and multiple indicators. Assessment and evaluation of these objectives will follow the steps described in the HAF.

The GRSG Habitat Objectives table is to be placed in the Special Status Species section of the ADPP and is to be used as a minimum to meet the applicable land health standard in sage-grouse habitats.

Greater Sage-Grouse Habitat Objectives

ATTRIBUTE	INDICATORS	DESIRED CONDITION	Reference
BREEDING AND NESTING (Seasonal Use Period March 1-June 15)			
Lek Security	Proximity of trees		
	Proximity of sagebrush to leks		
Cover	% of seasonal habitat meeting desired conditions		
	Sagebrush canopy cover		
	Sagebrush height Arid sites Mesic sites		
	Predominant sagebrush shape		
	Perennial grass cover Arid sites Mesic sites		
	Perennial grass and forb height		
	Perennial forb canopy cover Arid sites Mesic sites		
BROOD-REARING/SUMMER[1] (Seasonal Use Period June 16-October 31)			
Cover	% of Seasonal habitat meeting desired condition		
	Sagebrush canopy cover		
	Sagebrush height		
	Perennial grass canopy cover and forbs		
	Riparian areas/mesic meadows		
	Upland and riparian perennial forb availability		
WINTER[1] (Seasonal Use Period November 1-February 28)			
Cover and Food	% of seasonal habitat meeting desired conditions		
	Sagebrush canopy cover above snow		
	Sagebrush height above snow		

III. The BLM will prioritize land health assessments in Sagebrush Focal Areas (SFAs) followed by PHMAs outside of the SFAs. Field offices are to conduct land health assessments at the watershed scale and use the GRSG habitat objectives when assessing the applicable standard in GRSG habitats.

When conducting land heath assessments, the BLM should follow, at a minimum, "Interpreting Indicators of Rangeland Health" (Pellant et. al. 2005) and the "BLM Core Terrestrial Indicators and Methods" (MacKinnon et al. 2011). For assessments being conducted in GRSG designated management areas, the BLM should collect additional data to inform the HAF indicators that have not been collected using the above methods. Implementation of the principles outlined in the AIM strategy will allow the data to be used to generate unbiased estimates of condition across the area of interest; facilitate consistent data collection and rollup analysis among management units; help provide consistent data to inform the classification and interpretation of imagery; and provide condition and trend of the indicators describing sagebrush characteristics important to sage-grouse habitat.

Attachment IV

Incorporating GSGR RMP Decisions into Grazing Authorizations

Purpose

The purpose is to provide recommended ADPP language; outline the process for prioritizing the review and processing of grazing permits/leases to determine if modification is necessary (prior to renewal and in accordance with prioritization criteria); provide direction for including specific management thresholds and defined responses that will allow adjustments to livestock grazing within the terms and conditions of permits; and provide a process for prioritizing compliance monitoring within Sagebrush Focal Areas (SFAs) and Priority Habitat Management Areas (PHMAs).

Background

The BLM manages approximately 18,000 livestock grazing permits and leases on the public lands. Livestock grazing is an integral part of the BLM multiple-use mission and is authorized by the Taylor Grazing Act (1934), the Federal Land Policy Management Act (1976) and the Public Rangeland Improvement Act (1978). By statute and regulation, grazing leases and permits are normally issued for 10-year periods. Annually, a range of 1,200 to 3,200 grazing permits expire and the BLM receives 500 to 1,500 grazing permit/lease transfer requests.

The BLM currently issues permits/leases in accordance with:

- All applicable law, regulation, policy (NEPA, consultation, proposed/final grazing decision-also known as a fully processed permit); or
- Various appropriation authorities enacted between 1999 and 2014 extending terms and conditions of expiring or transferred permits/leases that the BLM is unable to fully process before their expiration; or
- Section 402(c)(2) of FLPMA (as amended by Public Law 113-291, enacted December 19, 2014).

Congress has acted to ensure that grazing permittees could continue to graze if the BLM is unable to complete the environmental analysis mandated by the NEPA and other applicable laws. Since 1999, a provision ("the rider") has been included in the Interior Appropriations bill that, in various forms, generally authorizes the BLM to renew grazing permits and leases under their same terms and conditions until it fully processes the permit renewal in compliance with NEPA, ESA, and other legal or regulatory requirements. The most recent rider is contained in Section 411, Public Law 113-76.[1] The FLPMA amendment to Section 402 (c) allows BLM to renew

---

[1] The Consolidated Appropriations Act, 2014 includes the provision Section 411 which states: "Section 415 of division E of Public Law 112–74 is amended by striking ''and 2013'' and inserting ''through 2015.'' The terms and conditions of section 325 of Public Law 108-108 (117 stat. 1307), regarding permits at the Department of the Interior and the Forest Service, shall remain in effect through fiscal year 2015. A grazing permit or lease issued by the Secretary of the Interior for lands administered by the Bureau of Land Management that is the subject of a request for a grazing preference transfer shall be issued, without further processing, for the remaining time period in

grazing permits and leases under the same terms and conditions. This relieves the BLM's renewal processing workload, allowing the BLM to prioritize permit processing based on sensitivity of the resources at issue.[2]

The BLM may modify terms and conditions of a permit or lease at any time following completion of appropriate analysis and consultation, cooperation, and coordination with the affected lessees or permittees, the State having lands or responsible for managing resources within the area, and the interested public.[3] Under 43 C.F.R. 4160.1, the BLM must serve a proposed decision on any affected applicant, permittee or lessee, any agent and lien holder of record. Copies of the decisions are provided to the interested publics.

Recommended Language to be incorporated as Livestock Grazing Management Actions within the GRSG ADPPs:

- The BLM will prioritize the review of grazing permits/leases, including those prior to renewal to determine if modification is necessary, and processing of grazing permits and leases, in Sagebrush Focal Areas (SFAs) followed by PHMAs outside of the SFAs. In setting workload priorities, precedence will be given to existing permits/leases in areas not meeting Land Health Standards, with focus on those containing riparian areas, including wet meadows. The BLM may use other criteria for prioritization to respond to urgent natural resource conditions (ex., fire) and legal obligations.
- The NEPA analysis for renewals and modifications of livestock grazing permits/leases that include lands within SFAs and PHMAs will include specific management thresholds based on GRSG Habitat Objectives Table and/or Land Health Standards (43 CFR 4180.2) and defined responses that will allow the authorizing officer to make adjustments to livestock grazing without conducting additional NEPA.
- Allotments within SFAs, followed by those within PHMAs, and focusing on those containing riparian areas, including wet meadows, will be prioritized for field checks to

---

the existing permit or lease using the same mandatory terms and conditions. If the authorized officer determines a change in the mandatory terms and conditions is required, the new permit must be processed as directed in section 325 of Public Law 108-108." Where a FO is unable to fully process a permit renewal in compliance with all applicable laws prior to the permit expiration, Section 411 extends the authority to renew the grazing permit with the same terms and conditions as the expiring permit. Section 325 provides the process for authorizing grazing until a permit or lease is issued in compliance with all applicable law and regulatory processes.

[2] The newly amended section 402(c) of FLPMA provides permanent authority to BLM to renew expiring permits. That section states, "The terms and conditions in a grazing permit or lease that has expired, or was terminated due to a grazing preference transfer, shall be continued under a new permit or lease until the date on which the Secretary concerned completes any environmental analysis and documentation for the permit or lease required under the National Environmental Policy Act of 1969 (42 U.S.C. 4321 et seq.) and other applicable laws."

[3] 43 CFR 4130.3-3 states: Following consultation, cooperation and coordination with the affected lessees or permittees, the State having lands or responsible for managing resources within the area, and the interested public, the authorized officer may modify terms and conditions of the permit or lease when the active grazing use or related management practices are not meeting the land use plan, allotment management plan or other activity plan, or management objectives, or is not in conformance with the provisions of subpart 4180 (Fundamentals of Rangeland Health and Standards and Guidelines for Grazing Administration).

help ensure compliance with the terms and conditions within the grazing permits. Field checks could include monitoring for actual use, utilization, and use supervision.

- At the time a permittee or lessee voluntarily relinquishes a permit or lease, the BLM will consider whether the public lands where that permitted use was authorized should remain available for livestock grazing or be used for other resource management objectives.

Addressing GRSG RMP Amendments/Revisions Objectives in Grazing Permits/Leases

BLM will develop criteria to prioritize the workload to process permits/leases (either fully processed or reauthorized based on the Appropriations rider, or issued under Section 402(c)(2) of FLPMA) and determine whether modification is necessary prior to renewal within PHMAs, beginning with those in SFAs. In setting priorities, those containing riparian areas and areas not meeting Land Health Standards (43 C.F.R. 4180) will take precedence. Potential criteria for prioritizing permit modifications could include:

- Are there riparian areas or wet meadows in the permit/lease area?
- Was current livestock grazing identified as a causal factor for not meeting Land Health Standards?
- Since the last allotment/watershed evaluation, is there current monitoring information to determine that the watershed/allotment is currently achieving or making significant progress towards achieving land health standards?
- Does the permit have terms and conditions adequate to ensure proper grazing practices to meet GRSG habitat objectives found in the Special Status Species section of the land use plan?
- Is there data that indicates that the GRSG habitat objectives, including the Habitat Objectives table, found in the Special Status Species section of the land use plan are being met?
- Is there a request from the permittee to modify the terms and conditions of his/her permit?

Additionally, if an existing permit/lease within PHMAs requires modification because current grazing is a significant causal factor for not meeting the Land Health Standards, the BLM will prepare the appropriate NEPA analysis and issue the proposed/final grazing decision under 43 C.F.R. Subpart 4160, subject to administrative appeal and potential judicial challenge.

The NEPA analysis for renewals and modifications of livestock grazing permits/leases that include lands within SFAs and PHMAs will include specific management thresholds based on GRSG Habitat Objectives Table and/or Land Health Standards (43 CFR 4180.2) and defined responses that will allow the authorizing officer to make adjustments to livestock grazing without conducting additional NEPA. Adjustments to meet seasonal Sage-Grouse habitat requirements could include:

- Season or timing of use;
- Numbers of livestock (includes temporary non-use or livestock removal);
- Distribution of livestock use;
- Intensity of use; and
- Type of livestock (e.g., cattle, sheep, horses, llamas, alpacas and goats).

Compliance Monitoring

The BLM will monitor grazing permits/leases renewed or modified in accordance with the direction contained in this guidance as follows: Allotments within SFAs, followed by those in other PHMA, and focusing on those with riparian areas, will be prioritized for monitoring to ensure compliance with the terms and conditions in the permits. The BLM will collect, at a minimum, the following monitoring data:

- Vegetation Condition
- Actual Use
- Utilization
- Use Supervision

Concerning Voluntary Relinquishments

All ADPPs will include the following language:

At the time a permittee or lessee voluntarily relinquishes a permit or lease, the BLM will consider whether the public lands where that permitted use was authorized should remain available for livestock grazing or be used for other resource management objectives.

For completing this, BLM offices should use WO IM 2013-184 Relinquishment of Grazing Permitted Use or the most recent policy guidance.

Attachment V

Applying Lek Buffer-Distances When Approving Actions

- *Buffer Distances and Evaluation of Impacts to Leks*
  Evaluate impacts to leks from actions requiring NEPA analysis. In addition to any other relevant information determined to be appropriate (e.g. State wildlife agency plans), the BLM will assess and address impacts from the following activities using the lek buffer-distances as identified in the USGS Report *Conservation Buffer Distance Estimates for Greater Sage-Grouse – A Review* (Open File Report 2014-1239). The BLM will apply the lek buffer-distances specified as the lower end of the interpreted range in the report unless justifiable departures are determined to be appropriate (see below). The lower end of the interpreted range of the lek buffer-distances is as follows:
    - linear features (roads) within 3.1 miles of leks
    - infrastructure related to energy development within 3.1 miles of leks.
    - tall structures (e.g., communication or transmission towers, transmission lines) within 2 miles of leks.
    - low structures (e.g., fences, rangeland structures) within1.2 miles of leks.
    - surface disturbance (continuing human activities that alter or remove the natural vegetation) within 3.1 miles of leks.
    - noise and related disruptive activities including those that do not result in habitat loss (e.g., motorized recreational events) at least 0.25 miles from leks.

  Justifiable departures to decrease or increase from these distances, based on local data, best available science, landscape features, and other existing protections (e.g., land use allocations, state regulations) may be appropriate for determining activity impacts. The USGS report recognized "that because of variation in populations, habitats, development patterns, social context, and other factors, for a particular disturbance type, there is no single distance that is an appropriate buffer for all populations and habitats across the sage-grouse range". The USGS report also states that "various protection measures have been developed and implemented… [which have] the ability (alone or in concert with others) to protect important habitats, sustain populations, and support multiple-use demands for public lands". All variations in lek buffer-distances will require appropriate analysis and disclosure as part of activity authorization.

  In determining lek locations, the BLM will use the most recent active or occupied lek data available from the state wildlife agency.

- *For Actions in GHMA*
  The BLM will apply the lek buffer-distances identified above as required conservation measures to fully address the impacts to leks as identified in the NEPA analysis.
    - Impacts should first be avoided by locating the action outside of the applicable lek buffer-distance(s) identified above.
    - If it is not possible to relocate the project outside of the applicable lek buffer-distance(s) identified above, the BLM may approve the project only if:
        - Based on best available science, landscape features, and other existing protections, (e.g., land use allocations, state regulations), the BLM determines that a lek buffer-distance other than the applicable distance identified above offers the same or a greater

    level of protection to GRSG and its habitat, including conservation of seasonal habitat outside of the analyzed buffer area; or
    - The BLM determines that impacts to GRSG and its habitat are minimized such that the project will cause minor or no new disturbance (ex. co-location with existing authorizations); and
    - Any residual impacts within the lek buffer-distances are addressed through compensatory mitigation measures sufficient to ensure a net conservation gain, as outlined in the Mitigation Strategy (Appendix X).

- *For Actions in PHMA*
  The BLM will apply the lek buffer-distances identified above as mandatory conservation measures to fully address the impacts to leks as identified in the NEPA analysis. Impacts should be avoided by locating the action outside of the applicable lek buffer-distance(s) identified above.

  The BLM may approve actions in PHMA that are within the applicable lek buffer distance identified above only if:
    - The BLM, with input from the state fish and wildlife agency, determines, based on best available science, landscape features, and other existing protections, that a buffer distance other than the distance identified above offers the same or greater level of protection to GRSG and its habitat, including conservation of seasonal habitat outside of the analyzed buffer area.

- The BLM will explain its justification for determining the approved buffer distances meet these conditions in its project decision.

Vernon. 2015. Fire and Fuels Management Contributions to Sage-Grouse Conservation: A Status Report. Western Association of Fish and Wildlife Agencies. Unpublished Report. Cheyenne, Wyoming. 73 pp.

Executive Overview

Within big sagebrush (*Artemisia tridentata*) communities, expansion of invasive plants and changes in wildfire patterns have emerged as the greatest threat to sage-grouse habitats, particularly in the western part of its range. Feedback cycles between invasive species and large intense wildfires effectively fragment habitats, reduce sagebrush cover, and create fire-prone landscape conditions detrimental to sage-grouse. In response to this threat, numerous efforts to respond to wildland fires and manage vegetation are underway, with an overarching intent of conserving sage-grouse and their habitats. This report, developed by the Western Association of Fish and Wildlife Agencies (WAFWA), Wildfire and Invasive Species Initiative Working Group (Working Group), summarizes the current state of Fire Operations and Fuels management functions. While other status reports have been completed, there has been no synthesis of the fire and fuels management programs at the private, local, state, and federal agency scales. The intent of this report is to illustrate the type and responsiveness of efforts being made. Finally, the report concludes by presenting future options and a series of recommendations that may inform future policy and allocation decisions.

Drivers of Report

This report is driven by the need among wildlife management and regulatory agencies for an explanation of the decision-making and allocation processes in wildland fire management, including hazardous fuels management programs. Specifically, the WAFWA Working Group was requested by the U.S. Fish and Wildlife Service (USFWS) to evaluate and explain how sage-grouse and their habitats are included in fire management prioritization, real-time resource allocations, and project development.

Organization of Report

This report is divided into seven sections. The introduction provides the background of the issue and scope of the document. The second and third sections describe the current state of the Federal and State programs, respectively. The fourth section describes efforts taking place at local scales, often involving partnerships between local agencies and private landowners. The fifth section concludes with practices that hold promise, opportunities, barriers, and additional considerations that may be useful in future policy and infrastructure decisions. The sixth section presents recommendations related to policy, funding, and science and technology. The final section contains appendices.

Acknowledgements

Many people and organizations have contributed to the development of this report. We would like to acknowledge the USFWS, BLM, USFS, NRCS, for their financial support and providing the staff time for their employees to serve on the WAFWA Working Group. We also want to thank the Great Basin state fish and wildlife agencies (NDOW, ODFW, IDFG, WYGF, UDWR) for supporting their biologist to serve on the Working Group. Special thanks must be given to Steve Lewis with University of Nevada Reno, Cooperative Extension and Lara Neil with NDOW for their support of the Work Group efforts. And finally we want to extend a special thank you to Dr. David Pyke (USGS) and Theodore Stein (USFWS) for their editorial support and San Stiver (WAFWA) for assistance in developing the final publication.

I Introduction

Wildland fire management, as it pertains to sage-grouse conservation, is a collaborative effort that involves agencies and participants at all levels of government. Because fire knows no political boundaries, its management in the United States is a coordinated effort among federal, state, tribal and local agencies through the National Interagency Fire Center (NIFC), National Interagency Coordination Center (NICC), and the National Wildfire Coordinating Group (NWCG). While land management and fire management objectives vary among agencies and across governmental levels, there are consistent standards, coordination, and agreements that enable all agencies to work together to provide the most effective and efficient response to wildfire regardless of location and land ownership. Federal agencies play a lead role in the coordination of these practices, while state and local agencies are key cooperators and play a coordinated role across the range of sage-grouse. For this document, wildland fire management is referred to as **fire management**, and meant to include preparedness activities, fire operations, and all related logistical coordination. **Fuels management** is defined as those practices intended to modify fire behavior, improve ecological condition, or augment fire suppression efforts. Examples of fuels management practices include prescribed burning, mechanical, chemical, and biological treatments. The explanation of federal, state, and local fire/fuels management programs will be necessarily broad to convey the many interconnected components. Federal programs are specific to the Bureau of Land Management (BLM), U.S. Forest Service (USFS), USFWS, Bureau of Indian Affairs (BIA), and National Park Service (NPS). While emergency stabilization and rehabilitation (ESR) and burned area emergency rehabilitation (BAER) are key elements of habitat restoration, they are not covered in this report.

Recent Wildfire Trends and Occurrence

As identified in the 2013 COT report, large fires in sagebrush habitats pose a daunting challenge to land managers. In the past 15 years, the interplay of annual invasive plants, multiple fire ignitions, and climatic extremes have resulted in large-scale habitat losses. Arranged in descending order based on acreage, the largest fires in sage-grouse habitat in the past decade are illustrated below and further described in Murphy et al. (2013). Fire seasons in the west vary greatly year to year, strongly influenced by trends in weather patterns. Large fires typically occur during strong winds (often associated with cold front passage) coinciding with high, flashy fuel loading, multiple fire starts from lightning, and where topography or remoteness slows initial attack (source: John Glenn, BLM Fire Operations Division Chief). Between 1992 and 2012, 33,782 fires occurred in sage-grouse habitat (defined as priority and general habitats). During this time, 97% (32,601) of fires were less than 1,000 acres and 242 (less than 1%) were greater than 10,000 acres. Within the last decade (2005 through 2014), 8,028 fires burned on priority and general habitats.

Of these, 5,760 were lightning caused (72%), and 2,268 were human caused (28%). Fires caused by power lines, vehicles, and equipment use (welding, cutting torches, chainsaws, etc.) were the most common human ignition sources, followed by railroad fires, warming/cooking fires, agricultural/debris burning, and fireworks.

Fire Name	Acres	Fire Year	State
Murphy Complex	590,808	2007	Idaho
Long Draw	582,707	2012	Oregon

During this time, 97% (32,601) of fires were less than 1,000 acres and 242 (less than 1%) were greater than 10,000 acres. Within the last decade (2005 through 2014), 8,028 fires burned on priority and general habitats. Of these, 5,760 were lightning caused (72%), and 2,268 were human caused (28%). Fires caused by power lines, vehicles, and equipment use (welding, cutting torches, chainsaws, etc.) were the most common human ignition sources, followed by railroad fires, warming/cooking fires, agricultural/debris burning, and fireworks.

The table below illustrates the distribution of fire size classes in sage-grouse habitat (1992-2012).

Fire Occurrence in Sage-Grouse Habitat (all causes)							
Fire Size (Acres)	< 1 acre	< 10 acres	< 100 acres	< 1K acres	<10 K acres	>10 K acres	All Fires
# of fires	17,838	26,580	30,399	32,601	33,540	242	33,782
% of all fires	53%	79%	90%	97%	99%	.7%	100%

Table 2 Fire occurrence in greater sage-grouse habitats, 2006-2014 (source: USGS GeoMac fire perimeter database).

*Sage-Grouse habitat data source: Data submitted by states with sage-grouse habitat and compiled by National Interagency Fire Center.

*Fire occurrence data source: Short, Karen C. 2014. Spatial wildfire occurrence data for the United States, 1992-2012 FPA_FOD_20140428]. 2nd Edition. Fort Collins, CO: U.S. Department of Agriculture, Forest Service, Rocky Mountain Research Station. http://dx.doi.org/10.2737/RDS-2013-0009.2

Today's Situation: What does this fire trend mean?

Several conclusions can be drawn from the raw data. First, effective initial attack keeps over 99% of wildfires at less than 10,000 acres. Given the extreme burning conditions which fire managers face, this is a commendable achievement. At the same time, any management actions done before the fire which can eliminate even one "mega-fire" is a valuable investment. While there is little room to further improve the initial attack effectiveness, certain pro-active measures may compliment suppression efforts and potentially result in fewer large fires.

II. Federal Fire and Fuels Management Programs

Federal land management agencies are responsible for all aspects of fire on federal lands as well as for leading the coordination of response to all wildfires in the country that require resources beyond local and regional capabilities, regardless of land ownership. Additionally, the federal government can draw upon or support international fire management resources. To support the goal of managing fire at the lowest jurisdictional level, yet ensure adequate resources are available, fire management is organized in a tiered structure from the local unit to the Geographic Area Coordination Centers (GACC), to the National Interagency Coordination Center (NICC). Federal agencies assess fire potential in relation to values at risk, such as homes, communities, and natural resources, to determine how to initially position assets across the country to reduce risk and to be prepared for response. As conditions change, these assets can be repositioned to where fire potential is greatest.

Wildfire management has leveraged science and technology to develop a broad suite of fire behavior, fire risk, and fire potential models. These tools are applied by fire managers to inform actions before, during and after wildfire. All federal agencies have land management plans describing management objectives or desired conditions for a defined area. Fire and fuels program goals tier off of land management objectives. Before the fire season, climatology data is updated, seasonal outlooks are generated, and pre-season training is completed, which includes fire management considerations in sage-grouse habitat (see best management practices, Appendix B). Once a wildfire starts on a unit, the response reflects pre-identified values such as GRSG habitats, infrastructure, or wildland-urban interface. If a unit is unable to meet their objectives with their assets, they can request assistance from other units, agencies, or through the Geographic Area Coordination Center. If sufficient assets are unavailable, they are requested through the National Interagency Coordination Center. In the few instances when fire management needs outstrip resources nationally, resources are allocated based on the values at risk and probability of success. In summary, sage-grouse habitat is but one of myriad values considered in these decisions.

The National Cohesive Wildland Fire Management Strategy (Cohesive Strategy)

This initiative, finalized in 2014, lays the broad framework for fire and fuels management in the years ahead. The Strategy establishes key goals and regional action plans which are specific to the area of interest. All greater sage-grouse habitat falls within the "western" region identified in the strategy. Key cohesive strategy goals include:

- **Restore and maintain landscapes**: Landscapes across all jurisdictions will be managed for resilience to fire-related disturbances in accordance with management objectives. Corresponding resource functions include fuels management, forestry, restoration/ rehabilitation, and other vegetation management programs.
- **Fire-adapted communities**: Human populations and infrastructure are prepared to withstand a wildfire without loss of life and property. (Communities here are defined as human population locations rather than vegetative communities). Corresponding resource functions include preparedness, mitigation, education, and fire prevention.
- **Wildfire response**: All jurisdictions actively participate in making and implementing safe, effective, efficient risk-based wildfire management decisions.

Further information on the Cohesive Strategy is available at: www.forestsandrangelands.gov.

Land Use and Fire Management Plans

Fire management response among Federal agencies is pre-planned, coordinated, and guided by Land Use Plans (LUPs), Fire Management Plans (FMPs), and local operational plans. Land Use Plans provide overarching goals and objectives for federal agencies. This guidance may include subdividing a jurisdiction into smaller landscapes, such as management areas, management prescription categories, or other polygons. Unique fire and fuels management guidance within these polygons is further refined in agency Fire Management Plans. The *2009 Guidance for Implementation of Federal Wildland Fire Management Policy* directs all federal units with burnable vegetation to develop Fire Management Plans that refine broad land use plan guidance into specific management actions for the Fire Operations and Fuels Management functions. FMPs identify areas having unique management guidance related to habitat protection, equipment use, appropriate suppression tactics, planned fuels accomplishments, and desired conditions. An example of guidance might include protection measures for highly valued habitats, heavy equipment constraints, guidance for burning out during fire operations, mitigation efforts to protect leks, or other measures specific to that area. Increasingly, agencies are moving to spatial fire management plans that rely on geospatial data and fewer text documents to convey fire and fuels management guidance. FMP guidance is further refined into operational plans at the local unit level. Information from FMPs is translated to specific, operational guidance to fire suppression resources, dispatch centers, and related support staff. Examples of local operational guidance would include dispatch procedures during multiple-start days, staffing of outstations, local best management practices, lek locations, and duty officer assignments.

Process for Fire Operations Coordination and Prioritization

At all times, firefighter and public safety is the overriding tenet for fire operations. Beyond that absolute, the decision framework driving fire operations is highly complex, and driven by values at risk, budget, availability of firefighting resources, and numerous political factors. This complexity is amplified when firefighting resources are scarce, values are threatened, and significant risk to human life or property is involved. The entities described in this section each play a role in real-time decision-making related to the deployment and management of wildfires. Where applicable, the relevance of these entities related to sage-grouse is noted at the end of each section in a text box.

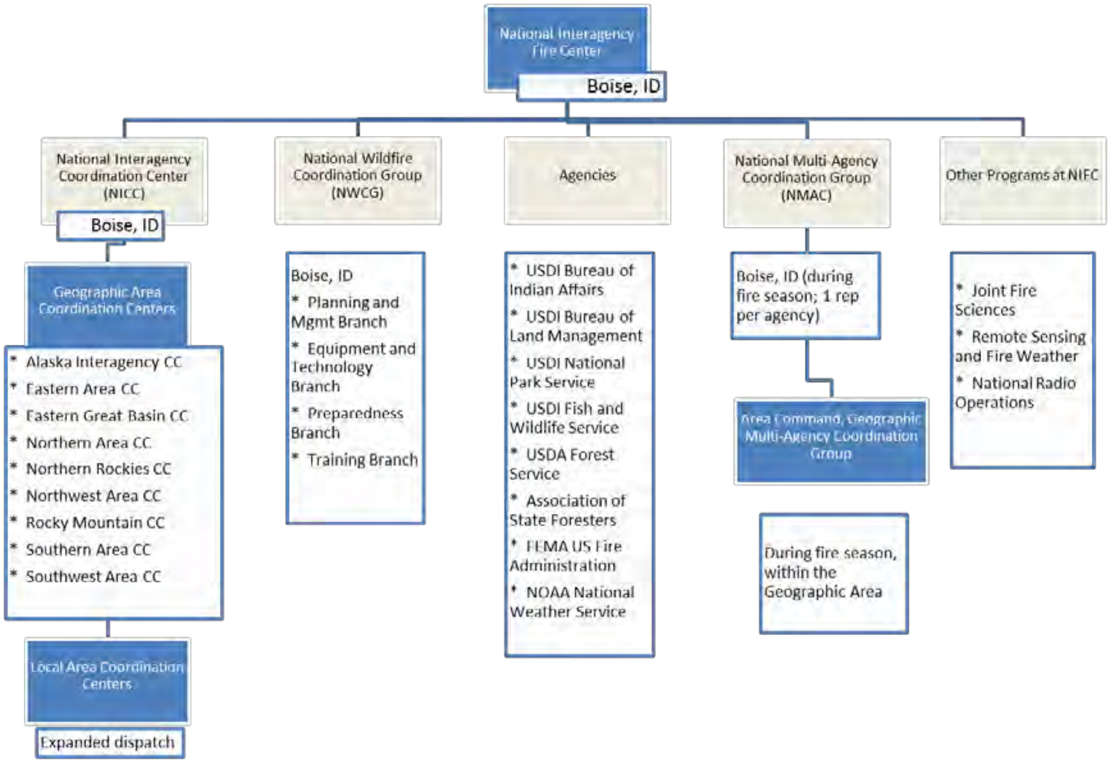

Figure 1 Structure of the National Interagency Fires Center, Boise, Idaho and related fire operations groups.

National Interagency Fire Center

The National Interagency Fire Center, located in Boise, Idaho, serves as the centralized location for coordination of wildland fire management across the United States (see http://www.nifc.gov/).

Eight different agencies are represented at NIFC. All facets of fire management such as budget, policy, operations, fuels, training, decision support, resource allocation, supply, logistics, and communication are represented at the fire center.

How does NIFC affect sage-grouse?

As the focal point for coordinating the national mobilization of resource for incidents throughout the United States, NIFC plays a key role in ensuring resources are moved to locations of highest need based on values at risk (e.g., life/property, infrastructure, communities, natural resources). Additionally, the center maintains equipment and supplies that can be easily dispatched to support fire management. Since all agencies are represented at the center, it promotes coordination of fire policy development, implementation, and fire planning.

National Wildfire Coordinating Group

The purpose of the National Wildfire Coordinating Group (NWCG) is to provide national leadership to develop, maintain, and communicate interagency standards, guidelines, qualifications, training, and other capabilities that enable interoperable operations among federal and non-federal entities (see www.nwcg.gov). Core membership includes representatives from the USFS, all DOI agencies, Federal Emergency Management Agency, U.S. Fire Administration, and non-federal entities such as the Intertribal Timber Council and the National Association of State Foresters. The NWCG involves a series of committees including Fire Planning, Fuels Management, Equipment Technology, Training, and Risk Management. Collectively, these committees provide overarching guidance for Fire and Fuels Management. The functions of NWCG are to:

- Develop and propose standards, guidelines, training, and certification for interagency wildland fire operations.
- Establish qualifications for all wildfire positions, including required training, experience, and competencies in order to perform wildfire support tasks.
- Maintain approved standards, guidelines, training, and certification for interagency wildland fire operations.
- Participate in the development of operational standards and procedures for non-fire incident and emergency management to ensure consistency and interoperability.

How does NWCG affect sage-grouse?

The overarching charge of NWCG is to facilitate efficient fire management through training, logistical, budgetary, and standards development. Consistent standards for operations, training, and qualifications of fire personnel enable movement of resources across the country and across agencies. Use of sage-grouse examples in training curricula is one opportunity to expand awareness.

National Interagency Coordination Center

The NICC, located at NIFC, is the focal point for overseeing all interagency coordination activities throughout the United States. Wildfire suppression is built on a three-tiered system of support - the local area, one of the 11 geographic areas, and finally, the national level. When a fire is reported, the local agency and its firefighting partners respond. If the fire continues to grow, the agency can ask for help from its geographic area. When a geographic area has exhausted all its resources, it can turn to NICC at the National NIFC for help in locating what is needed, from air tankers to radios to firefighting crews to incident management teams. Additional information on NICC can be found at: http://www.nifc.gov/nicc/index.htm.

Figure 2 Map of Geographic Area Coordinating Centers.

How does NICC affect sage-grouse?

NICC serves as a logistical coordination center and facilitates the efficient ordering and dispatch of all fire management resources across geographic areas. NICC does not make allocation decisions.

Geographic Area Coordination Centers

GACCs coordinate resource ordering and showcase fire activity in their area. GACCs participate in meetings and calls used to establish national drawdown and preparedness levels. It should be noted that the Eastern Great Basin and Western Great Basin Coordination Centers will be combined in 2015, and located in Salt Lake City, Utah.

Western Great Basin Geographic Area Coordination Center (WGBCC) is the interagency focal point for coordinating the mobilization of resources for wildland fire, wildland fire use, prescribed fire and other all-hazard incidents throughout the Western Great Basin Area and, when necessary, for assignment throughout the United States. Located in Reno, Nevada the Center also provides Intelligence and Predictive Services related-products to support wildland fire managers and firefighters in the decision making process throughout the Great Basin

Figure 3. Each geographic area coordination center hosts a website showcasing resource availability and fire activity in their region.

How do Geographic Area Coordination Centers affect sage-grouse?

The primary charge of GACCs is to implement resource assignment decisions made by the Geographic Multi-Agency Coordination group. GACCs which implement GMAC decisions in sage-grouse habitats include Eastern Great Basin (http://gacc.nifc.gov/egbc/index.php), Western Great Basin (http://gacc.nifc.gov/wgbc/), Northwest (http://www.nwccweb.us/index.aspx), and Rocky Mountain (http://gacc.nifc.gov/rmcc/).

National Multi-Agency Coordination Group

The National Multi-Agency Coordination Group (NMAC), located at NIFC, is comprised of representatives from the BLM, BIA, NPS, USFS, USFWS, Federal Emergency Management Administration (FEMA), and the National Association of State Foresters. The NMAC group prioritizes and allocates resources when there are critical shortages of national resources such as smokejumpers, air tankers, or Type 1 Incident Management Teams IMTs). The NMAC provides an essential management mechanism for national level strategic coordination to ensure that firefighting resources are efficiently and appropriately managed in a cost effective manner. The NMAC is responsible for establishing National and Geographic Area MAC business practices; ensuring timely national level incident information and firefighting resource status; setting national priorities among Geographic Areas; directing, allocating and reallocating firefighting resources among Geographic Areas to meet NMAC priorities; anticipating and identifying future firefighting resource requirements; and coordinating and resolving firefighting resource policy issues. The NMAC delegation specifically provides the authority to manage resource prioritization and allocation between Geographic Areas. Management of resources within a Geographic Area is the responsibility of the GMAC. Further information on NMAC can be found at: http://www.nifc.gov/nicc/administrative/nmac/index.html.

Roles and responsibilities of NMAC include:

- Establishing national priorities among the Geographic Areas (GAs)
- Directing and allocating resources among or between GAs to meet national priorities
- Providing oversight of general business practices between NMAC and the Geographic Multi-Agency Coordination (GMAC) groups
- Distributing and archiving NMAC:
    - Decisions
    - Direction
    - Best management practices
- Determining National Preparedness Levels (PLs)
- Determining national fire resource availability to support non-fire/all hazard operations (Reference Support to the National Response Framework)
- Managing Area Command Teams

How does the National Multi-Agency Coordination Group affect sage-grouse?

NMAC affects sage-grouse as a result of allocation decisions made across geographic areas. NMAC establishes the priority order among GACCs, and where scarce resources are placed across the country. NMAC decisions are necessarily broad, and consequently do not address species-specific topics.

Note: Further information on the Objectives, Policy, and Scope for wildland fire operations and supporting groups can be found in the National Interagency Mobilization Guide (http://www.nifc.gov/nicc/mobguide).

Area Command, Geographic Multi-Agency Coordination (GMAC) Groups

Area Command teams manage multiple fire incidents in a geographic area, under delegation from local Agency Administrators. They are comprised of an area commander, and leadership for planning, logistics, and aviation. At a slightly larger scale, each geographic area is represented by a GMAC group, which establishes priorities for resource allocation for all fires within the geographic area. Membership of GMAC groups includes fire management designees, who report to Agency Administrators for affected jurisdictions. GMAC groups review Incident

Status Summaries (ICS form 209) and identified values at risk to assign incident management teams, set priorities, and make key allocation decisions. These priorities include the type and number of resources which manage fires. For example, GMACs direct the placement of scarce resources such as Hotshot Crews and overhead.

How do Area Command Teams and Geographic Multi-Agency Groups affect sage-grouse?

Area Command teams and GMAC groups make key decisions related to the staffing and prioritization of fires at multiple scales within geographic areas. Their decisions have direct consequences for sage-grouse habitats. Membership of these groups is largely represented by fire operations employees who may not be informed on sage-grouse habitats, populations, and threats. Based upon identified values at risk fire complexity, and information from local dispatch centers, priorities for staffing and support are established. Consequently, decisions made by Area Command Teams and GMAC groups have a strong and direct influence on sage-grouse habitats.

Predictive Services

Predictive Service staff units are located at the NICC and at the GACCs across the country. These units were developed to provide decision support prior to expected fire activity and help determine resource allocation needs. Predictive Services provides information and products for three functional areas; fire weather, fire danger/fuels, and intelligence/resource status. It functions under the guidance of the National Predictive Services Subcommittee (NPSS), which is chartered under NWCG to provide leadership and direction for the program. Predictive Services products include:

(1) 7-Day Fire Potential Outlooks are designed to determine when and where regionally and nationally shared resources will be in demand across the U.S. for the subsequent week. This daily report assesses large fire potential and provides a weather synopsis for a seven-day period. It combines forecasted fuel dryness with significant weather triggers to identify high-risk areas. A national map is under development to display fire potential across the country for each day of the forecast period.

(2) Monthly Outlooks and Seasonal Trend Forecasts are normally posted on the first workday of each month and produced with input from all of the Geographic Area Predictive Service units using the most recent weather and fuels data available. These outlooks include general reports with maps intended to provide fire management personnel with an area-wide outlook and prediction of where the greatest fire potential will exist during the following month. They also provide a trend forecast for the following three-month period.

How does Predictive Services affect sage-grouse?

Predictive Services indirectly influence sage-grouse by defining patterns of fire occurrence, large fire potential, and fire weather. This information is used at geographic and local scales to position resources and other pre-suppression activities.

Local Dispatch Centers

Fire Operations resources are coordinated at the unit level by local dispatch centers. Although the assignment of fire resources may appear random, pre-planned dispatch procedures reflect direction from Land Use Plans and Fire Management Plans. Dispatch centers convey daily fire weather forecasts, provide daily resource tracking, and assign resources to fire incidents. The assignment of fire operations resources such as engines, dozers, and water tenders is largely pre-planned. These pre-planned decisions are delivered through automated computer dispatching systems, such as Wildfire Computer Aided Dispatch (WildCAD) that provide specific directions for responding to individual rural properties, including a description of the property, water sources available, and any special information pertinent to fire suppression and rescue operations In these applications, the type and number of resources dispatched to an incident is pre-identified based upon fire danger rating factors, potential for growth, number of on-going fires, and guidance contained in fire management plans. Finally, local duty officers (typically Fire Management Officers) further refine the prioritization of resources during multiple fire situations or as conditions warrant.

How do local dispatch centers affect sage-grouse?

Local dispatch centers are the conduit for mission-critical information between fire suppression resources and fire managers. Dispatch centers implement staffing assignments according to pre-established factors. Local dispatch centers affect sage-grouse by making decisions that allocate suppression resources based on changing fire conditions.

Predictive Services indirectly influence sage-grouse by defining patterns of fire occurrence, large fire potential, and fire weather. This information is used at geographic and local scales to position resources and other pre-suppression activities.

Duty Officer

During the fire season, most federal agencies are required to designate a duty officer who is the responsible official for tactical coordination of multiple wildfires within a unit. Duty Officers are typically qualified as a Type III incident commander and serve as the connection to local line officers during fires. Duty Officers ensure an adequate span of control for operational resources, and apply broad oversight to local fire management programs. Duty Officers are commonly drawn from a pool of Fire Management Officers, Assistant Fire Management Officers, Fire Operations Specialists, Fuels Management Specialists, or other managers meeting minimum IQCS qualifications.

How do duty officers affect sage-grouse?

Duty officers influence sage-grouse as a result of staffing decisions that consider safety, values at risk, and myriad operational details. Their decisions are informed by a number of competing factors in a dynamic environment. For example, duty officers must make real-time decisions which balance considerations such as habitat loss, probability of success, and multiple fires, typically with incomplete information.

Incident Commander

All wildfires are managed by an on-site Incident Commander (IC), regardless of fire size or complexity. IC's are responsible for: ensuring safety; proper transfer of command as fire complexity changes; developing objectives, strategies, and tactics; building the organizational structure as conditions change; assigning resources; and completing documentation. Incident commanders and their subordinates interact with resource advisors for protection or conservation of natural and cultural features. In sage-grouse habitats, these considerations could relate to lek locations, seasonal habitats, and other information relevant to fire management decisions. Incident commanders or their subordinates make real-time decisions related to fire line location, heavy equipment use, or burning out.

How do incident commanders affect sage-grouse?

Incident commanders affect sage-grouse by making tactical decisions in real time. These include fire line locations, direct or indirect attack methods, burnouts/blacklining, and others that affect the scale and location of firefighting impacts and effectiveness. This is the scale at which conservation of locally relevant sage-grouse habitats can occur. Thus, incident commanders are key in the chain of command.

Resource Advisors

Resource Advisors are responsible for anticipating fire impacts on natural and cultural resources, and for advising the Incident Commander. Resource advisors are typically federal agency employees, but may include qualified state-employees. It should be noted that there are opportunities for non-federal biologists to contribute to fire management by serving as resource advisors. Because of their expert knowledge of local conditions, resource advisors play a critical role in ensuring compliance with Land Use and Fire Management Plans related to location of fire lines, acceptable heavy equipment use, location and concerns related to critical wildlife habitat or populations archaeological sites, management in wilderness areas and other resource conflicts. Resource advisors are currently identified in BLM’s Best Management Practices as an important asset in mitigating certain negative effects of fire operations in and around sage-grouse habitats.

How do resource advisors affect sage-grouse?

Resource advisors provide biological expertise to inform tactical decisions, such as fire line locations, direct or indirect attack methods, or heavy equipment use. Resource advisors provide information but do not make tactical decisions. Resource advisors thus indirectly influence populations and habitats through this information exchange with on-the-ground fire managers.

Fire Operations Policy Guidance

Operational federal wildland fire policy is embedded in a document called the "*Interagency Standards for Fire and Fire Aviation Operations*" (also known as the Redbook, reflecting the color of its front and back covers). The Redbook provides fire and fire aviation program management direction for BLM, USFS, USFWS, and NPS managers. Employees engaged in fire management activities are required to comply with all agency-specific health and safety policies. Other resources, such as the NWCG Incident Response Pocket Guide (PMS 461, NFES 1077) and the NWCG Wildland Fire Incident Management Field Guide (PMS 210), provide operational guidance. BLM-specific guidance on sage-grouse conservation is provided in the Redbook in a section titled *"Sage-Grouse Conservation Related to Wildland Fire and Fuels Management."* Excerpts from Chapter 2 of the Redbook include:

- Utilize available maps and spatial data depicted sage-grouse habitats during suppression activities;
- Use predictive services to prioritize and preposition firefighting resources in critical habitat areas.

Table 4. USFS suppression capacity in 2014

* includes seasonal workforce

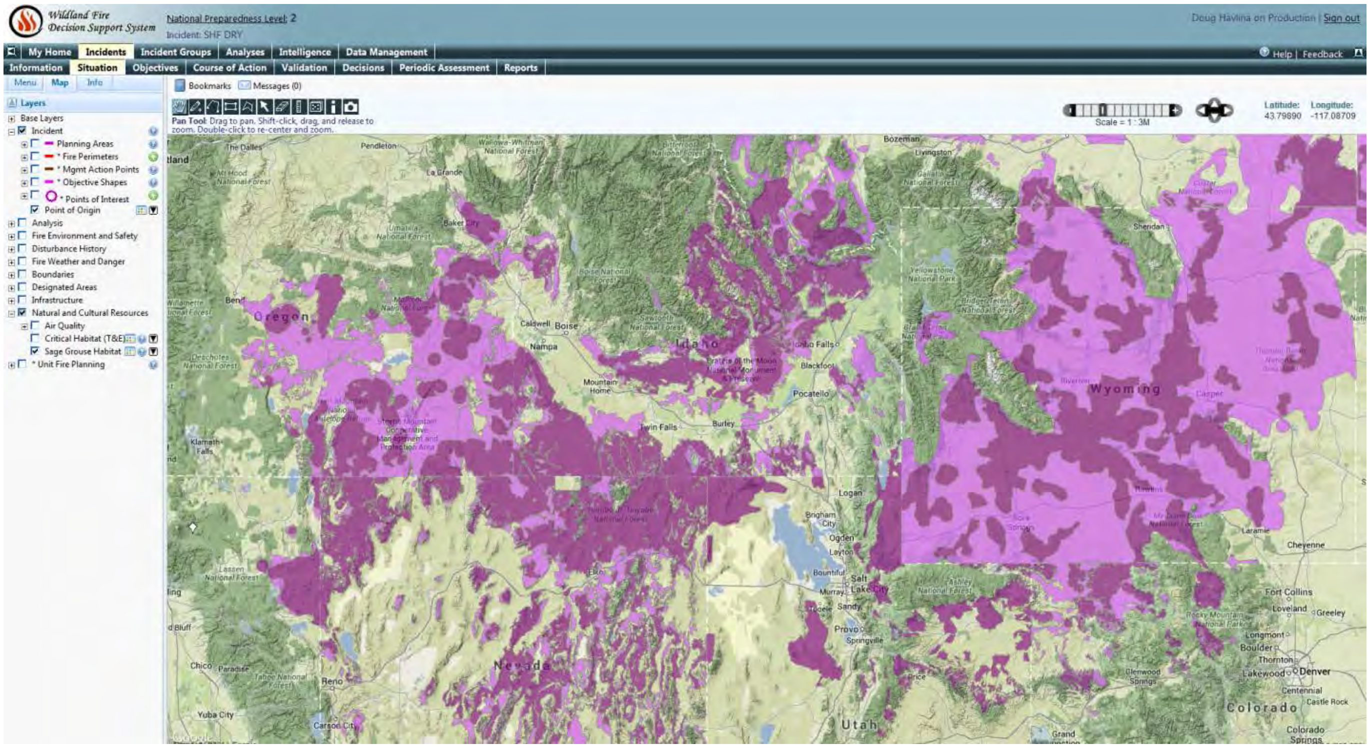
Fire Personnel and Equipment

Federal agencies maintain a diverse cadre of seasonal and full-time fire personnel and equipment dedicated to fire preparedness, fire response, and fuels management. Additionally, many personnel in resource, maintenance, administration, and emergency response positions are trained and actively participate in fire management, greatly increasing the overall response capacity. With personnel stationed in sage-grouse habitat as well as throughout the country, federal agencies have the capability to conduct long-term management of fuels management, fire preparedness and response as well as provide surge capacity as necessary.

Decision Support

The Wildland Fire Decision Support System (WFDSS) is a web-based application used by all federal agencies and select state agencies to evaluate wildfire risks and document decisions. Land use and fire management plan information, as well as geospatial layers, are pre-loaded in WFDSS for consideration when determining the response to a fire. This land and fire management plan information, as well as the geospatial display of values and key resources, predicted fire spread through fire behavior modeling and the risk and benefits assessment are utilized in the system to make risk informed decisions on fires.

WFDSS contains geospatial displays of preliminary priority habitat (PPH) and preliminary general habitat (PGH) for both greater and Gunnison sage-grouse which are annually updated as the information is revised at the State scale. These layers are used during wildfire situations to support management decisions related to resource placement, suppression strategies, and other considerations influenced by the presence of sage-grouse habitat. Opportunities exist to incorporate additional sage-grouse habitat features into WFDSS in the future if it provides value to decision makers.



Pan Tool: Drag to pan. Shift-click, drag, and release to zoom. Double-click to re-center and zoom.

Figure 4. Displays of PPH and PGH in the Wildland Fire Decision Support System

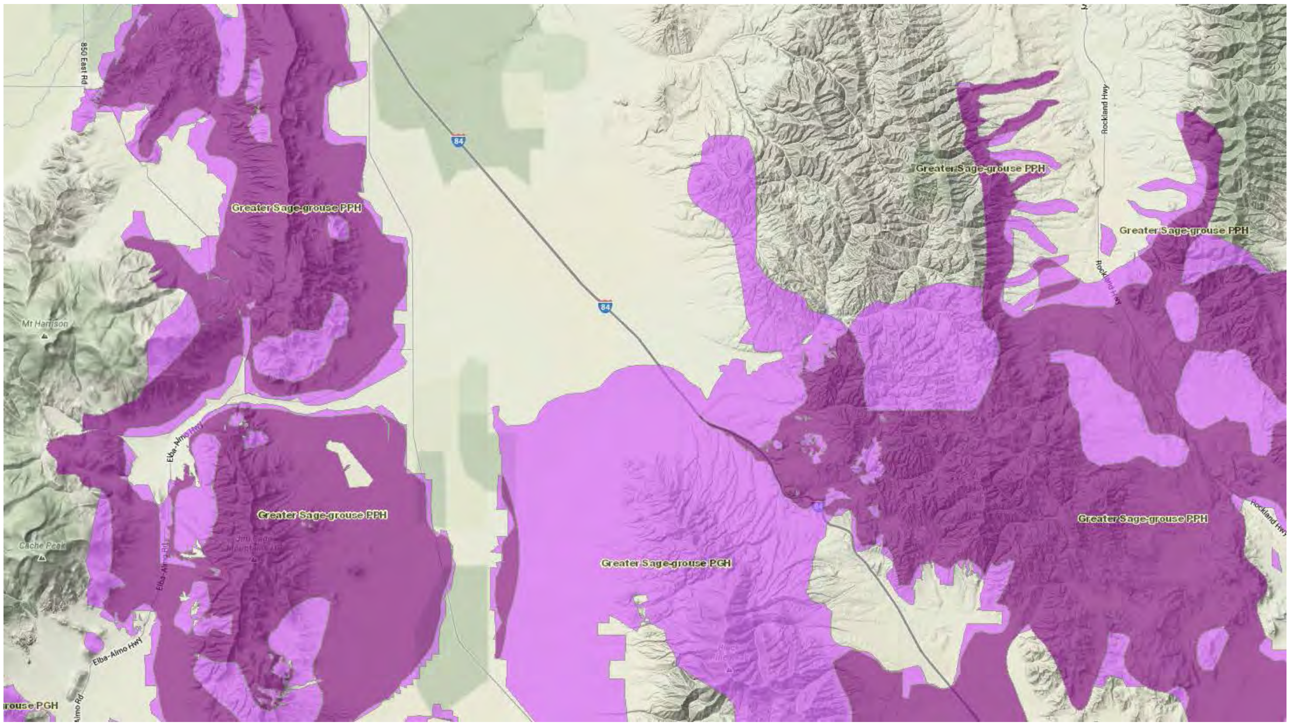


Figure 5. Displays of PPH and PGH in the Wildland Fire Decision Support System (Zoomed)

How does WFDSS affect sage-grouse?

WFDSS provides spatial displays of PPH and PGH across the range of sage-grouse. These data inform real-time fire decisions related to suppression strategies and prioritization. This display allows managers to see the spatial relationship between habitats and on-going fires. A summary of acres of at-risk habitat is included in the WFDSS values inventory page.

Federal Prevention and Fuels Management Accomplishments

The federal fuels management program is led by the NWCG Fuels Management Committee (FMC), which "… has primary responsibility for developing, implementing and providing oversight for an effective and coordinated National interagency wildland fuels management program. The program is designed to help mitigate risks from wildland fires to the wildland/urban interface and its infrastructure and to maintain and restore healthy vegetative communities in other wildland areas." Furthermore, the FMC "…provides national interagency program oversight to: reduce wildland fire risk to communities, restore and maintain land health, ensure that Hazardous Fuels Reduction program funding is targeted to the highest national fuels project priorities, ensure program accountability, effectiveness and efficiency, develop standards and policy for prescribed fire, promote efficient biomass use, promote economic opportunities for rural communities, emphasize landscape scale cross-boundary projects."

From 2002 to present, the FMC has directed $140 million to $210 million annually to federal agencies for fuels projects. This work includes management actions such as prescribed burning and mechanical treatments, as well as practical research such as The Sage-Steppe project and the Fire Effects Information System. For further information on the FMC, see http://www.nwcg.gov/branches/ppm/fmc/index.htm

Change in BLM Fuels Funding Allocation

As recently as FY 2012, the funding for BLM's fuels management programs was strongly skewed to treatments in the Wildland-Urban Interface (WUI). At that time, approximately 90% of BLM's fuels budget was allocated to projects which reduced risks to communities and infrastructure in and around urban areas. In three years, the emphasis of the fuels program has changed dramatically to emphasize treatments which benefit sage-grouse. Beginning in fiscal year 2015, BLM is allocating a significant proportion of project dollars ($25 million) to projects which benefit sage-grouse, following guidance in the Wildfire and Invasive Annual Grass Assessment (FIAT) Step 1. These funds are for projects which address threat factors and include conifer removal, seeding, chemical treatment of invasive species, strategically placed fuel breaks, and other measures which change fire behavior, augment suppression effectiveness, or maintain/restore habitat. BLM's fuels management funding is now skewed to States having the five priority FIAT landscapes which have been identified as most at risk due to fire and invasives. Specifically, BLM's fuels funding is earmarked for projects near or within the focal habitats identified in the FIAT process. Many projects resulting from FIAT assessments will be fuels treatments designed to improve initial attack effectiveness.

In a continued effort to reduce wildfire impacts to sage-grouse habitat, in 2014 BLM treated approximately 239,000 acres. Treatments were mainly focused on building and maintaining fuel breaks (14,000 acres) to conserve existing sage-grouse habitat, reducing conifer encroachment (112,000 acres), and treating invasive species (112,000 acres) to reduce wildfire hazard.

FY14 BLM Fuels Program Summary _Sage Grouse Conservation Work								
State	Invasive Species Work		Conifer Encroachment Work		Fuel Break Work		Total Acres in SG	
	Acres Treated	Cost	Acres Treated	Cost	Acres Treated	Cost	Acres Treated	Cost

Table 5 continued

The National Fire Plan Operations Reporting System

The National Fire Plan Operations and Reporting System (NFPORS) is a Department of Interior automated data management and reporting system. NFPORS was established in 2001 to provide accountability for hazardous fuels reduction, burned area rehabilitation projects, and community assistance activities. The system has tabs used to track projects that benefit candidate, sensitive, and TES species. A latitude and longitude is entered for each planned project, and a shapefile is uploaded when projects are completed. Consequently, specific queries about federal projects that have been implemented for sage-grouse can be obtained from the system.

The effectiveness of federal fuels management projects is documented in local monitoring records and also the Fuels Treatment Effectiveness Monitoring (FTEM) database. Federal agencies are required to enter the following observations into this system whenever a wildfire intersects a federally implemented fuels treatment:

(1) "Did the treatment modify fire behavior?" (Y/N)

(2) "Did the treatment help control the wildfire?" (Y/N)

Based upon these and other qualitative observations, some conclusions may be drawn related to fuels treatment effectiveness which can be used to improve the treatment prescriptions.

Federal Prevention, Education, and Outreach Efforts

While treatments that augment suppression efforts or restore habitats are important, public awareness of fire prevention goals is also a component in habitat conservation. The BLM and its partners are working to prevent human-caused fires that burn sage-grouse habitat and educate the public about the need and strategy for reducing the spread of invasive species such as cheatgrass and medusa-head. A recent 10 year *statistical analysis revealed that 28% of all fires that burn sage-grouse habitat are human-caused. During the 2014 fire season, teams of fire prevention and education specialists were ordered in Idaho, Oregon and Washington during periods of high fire activity. These teams incorporated sagebrush habitat preservation and invasive species messaging into public education and outreach efforts. The use of sage-grouse as an icon of sagebrush importance is in its infancy, but is a concept which should be carried forward and strengthened. The graphic below is an example of using sage-grouse in fire prevention messaging.

Figure 6. Fire prevention message from Idaho's "One Less Spark" initiative.

Challenges and Barriers

Impediments to federal fire operations and fuels management efforts include:

- Emerging science which synthesizes our knowledge of ecological resilience and potential for success has not been fully integrated into the design and implementation of fuels management projects and fire operations planning.
- The capacity of federal agencies is constrained in terms of positions, funding streams, and planning.
- Real-time information-sharing between sage-grouse biologists and fire managers is sometimes lacking during periods of high fire activity across the Great Basin. This deficiency is found within Incident Management Teams, Area Command Teams, and Geographic Multi-Agency Coordination Groups.
- Competing priorities that exist across program areas impair integration across these functional areas.
- Federal land management agencies planning processes are often delayed or modified as a result of litigation, appeals, and protests of potential treatments.
- The current fire suppression funding process needs to be revised to allow fire operation budget to function more like a "natural disaster" (dedicated dollars available for firefighting) and not fiscally overburden existing program budgets of the federal fire agencies. Currently, there is no single fire budget that covers the entire yearly firefighting effort. Thus, dollars are redirected from other program budgets to make up the difference, which often negatively affects those programs.

III. State Fire and Fuels Management Programs

Western states vary significantly in their approach to managing wildland fire due to variables including the amount and location of private lands, existing land uses, landscape condition, state statutes, codes, regulations, and available resources. Because of the diversity among states and the need for consistent approaches to managing wildland fire a variety of efforts have been undertaken over the last 20 years including the National Fire Plan, the Healthy Forest Restoration Act, the Quadrennial Fire Review process and most recently the National Cohesive Wildland Fire Management Strategy (Cohesive Strategy). Federal, state and local land and wildfire management agencies developed the Cohesive Strategy together to maintain specific individuality while coming together through consensus on common goals and objectives.

Through the implementation of the Cohesive Strategy, the nation as a whole is poised to manage wildland fire in a more unified and efficient manner. The Western Governors Association (WGA) has also taken a leadership role striving for consistent and effective response to wildland fire through active management programs, data and information collection and educational outreach that reduces the threat of catastrophic wildland fire and associated impacts to sagebrush ecosystems. Wildland fire programs operate in those states that are managing sage-grouse and their associated sagebrush ecosystems. To be effective, landscape-scale management of sagebrush ecosystems requires an interagency approach through local level planning processes for projects and activities. State "Action Plans" have, and are being developed to address the coordinated management of wildfire and sage-grouse habitat in specific geographical areas. Specific projects are detailed in the Action Plans to reduce fuels, improve preparedness and initial attack response, identify equipment and training needs, and ensure safe, rapid and aggressive response to wildfire ignitions; and address rehabilitation of wildfire damaged lands to mitigate the spread of invasive plant species.

State wildland fire management responsibilities typically reside in state forestry agencies and are integrated with state natural resource departments and Universities. Partnerships also exist with numerous federal land and natural resource management agencies, that bring the latest technology, research and management tools to the forefront for reducing landscape level, catastrophic wildfires and the spread of invasive plant species. State forestry agencies are delivering a wide variety of wildfire management programs in conjunction with their local and federal cooperators (e.g., prevention, fuels management, preparedness, suppression & rehabilitation).

Process for Fire Suppression Coordination Prioritization

The organic development of wildland fire management capacity and administrative organization across Western states means that there is no one standard model for state fire management. The wildfire management function can be housed in state Departments of Forestry, Natural Resources, Parks and Recreation, and Lands, each having slightly different missions. Some states have comprehensive operational programs while others have only certain components focused more on technical assistance and support of local governmental or other suppression resources. State wildland fire management agencies, despite distinct administrative organization and capacities, have adopted national wildland fire coordination and operational standards, policies, guidance documents and participate in NICC, NMAC, GACCs and local interagency dispatch centers through National Association of State Foresters representatives. State wildland fire management agencies participate through agency specific representatives on state MAC groups and a variety of interagency Boards or Groups focused on coordination decisions. The result is a process which produces consensus for communication, notification and coordination from a statewide perspective including the local level. The interagency integrated approach to wildfire management has proven successful throughout the country and provides for the rapid movement of suppression resources state-to-state or agency-to-agency efficiently.

Fire Operations Programs

Those state wildland fire management agencies with operational capacities operate on an “interagency” basis that includes federal land managers and local governmental entities given wildfire activity, landownership patterns and applicable laws, state statutes and operational agreements. State wildland fire management agencies operations have developed in response to specific jurisdictional responsibilities, such as state lands (e.g., state forests, state parks & wildlife refuges, etc.), while others have assumed (through agreement and/or state statutes) wildland fire management responsibilities for “some” specific non-federal lands (e.g., private lands, city & county lands, etc.) within their state, up to and including “all” non-federal lands on a statewide basis.

So while it is difficult to generalize state wildland fire operational programs, it is possible to identify common operational practices in place with interagency partners. For example, utilization of “closest forces” is an adopted concept shared throughout western states in an effort to keep wildfires small. State and local fire management agencies view all wildfires as “full suppression” incidents and every effort is made to suppress them safely and quickly with a strong initial attack. Many states have agreements with their neighboring states to facilitate a rapid initial attack, regardless of topographical challenges or political boundaries. States, local jurisdictions and interagency partners may manage a wildfire utilizing “unified command” concepts, where impacted jurisdictions participate together in operational decisions providing direction to the designated Incident Commander. For extended attack incidents, states will join with their interagency partners as detailed in the federal agency section in executing a WFDSS for an incident as well as “Delegations of Authority” to an Incident Management Team that takes management responsibilities for a given wildfire. Through all of these documents and protocols sagebrush ecosystems may be prioritized for suppression actions.

Fuels Management Programs

Not all states have the capacity to staff and manage statewide fuels management programs, but a majority of states do support and participate in specific fuels reduction projects on state lands, private lands and federally managed lands to varying degrees depending on capacity and available funding. State forestry agencies focus on non-federal lands, working with private landowners, counties and communities in both the Wildland Urban Interface (WUI) and rural ranching settings.

Projects and activities designed to protect sage-grouse and their sagebrush ecosystems across the west are diverse. Fuels reduction and vegetative management projects are the most common, both at the scale of the individual properties and across multiple ownerships. Fuels reduction in existing highway rights-of-way, utility corridors and designated fuel breaks are ongoing. Areas where pinyon pine and juniper have encroached into sagebrush ecosystems are being treated by mechanical removal on Federal, State, local, and private lands. Hand cutting, pile burning, broadcast burning and utilization of mechanized equipment such as masticators are all techniques being employed by state fire programs in conjunction with federal and local cooperators.

- **State-Specific Challenges and Barriers** Sufficient funding for preparedness activities including training, heavy equipment/engines, PPE, radios, and facilities is often lacking.
- There is inadequate time and funding to comply with expanding NWCG qualification requirements.
- Dedicated year-round work force & associated funding is needed.
- Periods of high wildfire activity with multiple ignitions in short time periods can result in shortages of suppression resources that limit effectiveness.
- Clear delineation of the highest priority sage-grouse habitat designated for protection from wildfire is needed at all levels and should be updated appropriately.
- Active and timely land management, especially on federal lands, suffers from limited funding, permitting requirements, and litigation.
- Extensive delays in processing State-submitted fire bills by the federal agencies can create significant cash flow problems and impacts fuel treatment programs.

IV. Local Fire and Fuels Management Programs

Local programs that contribute to fire and fuels management over the range of sage-grouse include Rural Fire Departments (RFDs), Rangeland Fire Protection Associations, and private landowners through their participation with sanctioned entities. Similar to state-level programs, there is a diversity of local government capabilities specific to emergency services including wildfire suppression. On one hand, some larger urban communities and/or counties with WUI areas have developed state-of-the art capabilities, with 24-hour staffing, and ready availability of engines, tenders, aviation assets and hand crews. Many rural communities and/or counties may be forced to rely on aging federal surplus equipment and an all-volunteer firefighting staff working with limited training and high turnover.

One positive development is the advent of community-based organizations such as Fire Adapted Communities, Fire Safe Councils, Fire Wise and Living With Fire programs that are now established in most western states, counties and communities. These entities facilitate fire prevention activities, pursue grant funding and implement local and landscape-level fuels-reduction projects across multiple ownerships. The combined efforts of these interagency efforts and initiatives have greatly improved wildfire management in counties, cities and communities. They are achieving the associated goals of reducing the occurrence and impacts of large wildfires and reducing loss of sage grouse habitat.

Fire Suppression Coordination/Prioritization

Local governments, urban and rural, are the first responders to all emergency incidents including wildfires within their specific jurisdictions, which are typically delineated by geographic boundaries as a fire district or an agreed-upon response area. Response capability is measured by "level of service" typically desired and funded by the landowners within the fire district. Rural communities typically field a volunteer fire department with varying levels of qualified members, equipment and training. In almost all cases though, local and rural fire departments have adopted NFPA and NWCG standards and qualifications and train their members to those national standards.

Whether an emergency incident is a structure fire, vehicle accident, medical or a wildfire ignition, the first notification is to the local area dispatch center through their 911 system. In the case of a wildland fire incident, once the first responders are on scene and the incident assessed, the coordination and management of the wildfire incident may or may not be transferred to an interagency dispatch center operated jointly by federal and state agencies specifically for wildfire coordination and prioritization. Time of year, level of ongoing emergency activity and size/location/fuel conditions all influence how a wildfire response is managed at the local level. In some areas of the country wildfire ignitions never go any further than the local dispatch center. Interagency dispatch centers are likely to be called on if the ignition occur during "wildfire season" (e.g., May-August) and if it has the potential to threaten public safety, structures and adjacent lands. These incidents are then incorporated into the interagency process for wildfire coordination and prioritization.

Fire Operations Program

Significant differences also exist across the western landscape for the management of wildland fire at the local level. Land ownership, vegetation, topography and urban development patterns typically drive wildland fire response capacities. Community capacity varies greatly and may range from a well- staffed, trained and equipped "all-risk" fire department to a volunteer fire department with limited resources or individual ranch owners with a single piece of equipment. Several states now have added "Rangeland Fire Protection Associations" (RFPA) as a component to their volunteer and paid fire services in those rural areas not served by any other means. RFPA's vary in scope, but can be described as non-profit, non-governmental entities primarily comprised of individual ranchers and landowners. Their ability to provide improved initial attack response to wildfire ignitions is reducing the threat of catastrophic wildfires in rural areas of the west. Local governments, volunteers and RFPA's are often the first responders across western states to wildfire ignitions in sagebrush ecosystems, particularly outside of an average wildfire season. It may be hours before additional federal and/or state resources reach an incident in rural areas, thus it is important to sustain local response capabilities.

Most federal and state wildland fire programs are designed and managed around their respective fire seasons, rather than staffed year-round. Several western states are expanding year-round wildfire management capabilities in concert with local governments, given the lengthening of fire seasons beyond historic norms. During those periods when state and federal resources are reduced or may not be available, (fall, winter & early spring) response to wildfire ignitions falls to local government, volunteers and RFPA organizations.

As mentioned previously, the interagency wildfire partnership, structured now within the Cohesive Strategy, includes local government, volunteers and RFPA organizations. At the local level, training and equipping firefighters is achieved in a variety of ways, but an interagency approach is most common. Annual refresher training and required firefighter courses are open to all entities and typically held annually in numerous locations. Federal excess fire equipment is often acquired by state forestry agencies and rebuilt for distribution on a local level. Federal land managers allocate excess fire equipment directly to local governments for their use.

Fuels Management Program

A wide variety of habitat improvement and fuels reduction projects are being implemented on the ground throughout the west, including critical implementation elements at the local level. Water resources, riparian areas and meadows, key to healthy sage-grouse habitat are often in private landownership due to settlement patterns in the west. Private landowners are utilizing both state and federal cost-share programs to improve and protect habitat for sage-grouse in conjunction with their specific land management activities. Designing fuel treatment projects with connectivity across ownerships is increasing, although complications related to NEPA compliance when projects involve federal lands is an issue.

In the WUI areas of the west, communities and local governments are taking responsibility for their jurisdictional lands, educating landowners, designing fuels treatments, pursuing grants and implementing fuels reduction projects. While there is an increasing effort to integrate non-federal land treatments with adjacent federal lands projects, fuels treatment projects often do not line up due to timing and funding challenges. A landscape treatment approach is increasingly viewed as the desired strategy, but navigating project permit processes, including the public review requirements of NEPA, securing sufficient funding and finding qualified contractors remain challenges.

Local Challenges and Barriers

Local Government challenges include:

- Firefighter retention and the loss of institutional knowledge of managing wildfire;
- There is insufficient funding for preparedness and response capacity including training, heavy equipment/ engines, PPE, radios, and facilities.
- Shortages of qualified wildfire management trainers, programs and inadequate delivery systems in rural areas create operational constraints.
- Inconsistent federal land management policies are negatively impacting the sustainability of multiple land uses on public lands.
- There is a significant need for developing and utilization of integrated and dynamic livestock grazing plans that assist with fuels reduction through targeted grazing and consistent monitoring.
- It is difficult to implement a landscape approach to fuels management because of challenges posed by environmental regulations, the availability of sufficient funding, the lack of qualified contractors and the complicated NEPA permit process.

V. Positioning For the Future

The scope of future sage-grouse conservation is enormous. In order to make meaningful progress, collaborative efforts that tie proven technology with strategic placement of management activities will be required. Existing fire programs that provide opportunities for sage-grouse conservation at meaningful scales are identified below. Examples of practices and partnerships making a positive difference for sage-grouse are also identified and discussed. The section concludes with a synthesis of future needs in the fire and fuels management functions.

Example 1: Rangeland Fire Protection Associations

Rangeland Fire Protection Associations (RFPAs) are non-profit corporations established to prevent and suppress rangeland fires, and are governed and directed by its members. These associations require State legislation, status as non-profit entities, and operate under a Cooperative Rangeland Fire Protection Agreement. Creation of RFPAs is a collaborative effort between local ranchers, State Government, and the Federal Government (typically the BLM or USFS). Local boards and grants generate funding. Federal and State agencies provide equipment and training for RFPAs. Day-to-day operations of RFPAs are spelled out in annual operating plans and memorandums of understanding that are annually updated. The benefits of RFPAs include: (1) faster initial response to small fires; (2) allowing ranchers the ability to protect forage resources important to their livelihood; (3) ensuring firefighting safety through adoption of standardized firefighting practices, equipment, and communication; (4) where sage-grouse are represented on the local landscape, better awareness of sage-grouse habitat by the ranching community.

Figure 7. Engaging ranchers and rural communities in fire management through RFPAs taps local knowledge and expertise in further protecting resource values. (Photo courtesy: Jeremy Maestas, NRCS).

In 2014, Oregon has 17 operational RFPAs and Idaho has five. Nevada does not have RFPAs, but is introducing legislation that would authorize their formation in future years. See Appendix 6 for the RFPA formation checklist.

How do RFPAs affect sage-grouse conservation?

While retention of grazing opportunities is a key incentive for RFPAs, sage-grouse conservation can also be a direct beneficiary of their services. Because federal agencies interface with RFPAs regarding values to be protected, the locations and extent of sage-grouse habitats are directly applied by RFPAs in how they manage wildland fires. RFPAs can also contribute to sage-grouse conservation with other local interests through promoting awareness of habitat location and importance.

Example 2: Cooperative Landscape Approaches

South Warner Juniper Removal Project

Warner Mountains, Oregon (2010-2020)

Partners: BLM-Lakeview Resource Area, Private Landowners/Permittees, NRCS Sage Grouse Initiative, Oregon Department of Fish and Wildlife, University of Idaho, Oregon State University, Lake County Watershed Council, Intermountain West Joint Venture, Point Blue Conservation Science

The South Warner Project is a landscape-scale partnership working seamlessly across public and private and public lands to remove encroaching conifers in and around the Western Great Basin PAC of south-central Oregon. Expansion and infill of western juniper into sagebrush communities affects large portions of the western range, fortunately, many areas are still in the early stages of woodland succession, which affords

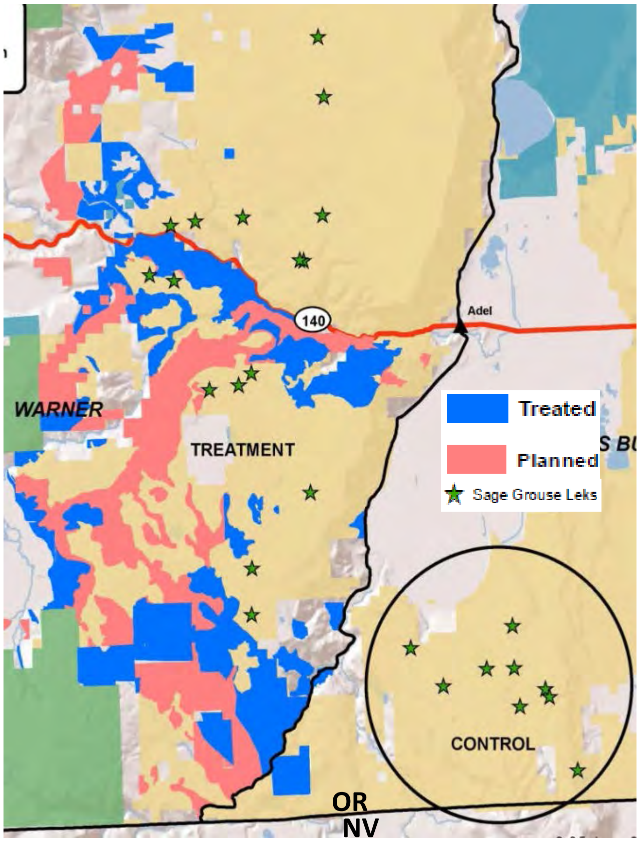

Figure 8 South Warner project area, Oregon. Polygons depict juniper removal treatments as of 2013.

opportunities to proactively remove trees before sage-grouse are displaced by habitat conversion.

BLM and private landowners, with support from the NRCS Sage Grouse Initiative and other partners, are working side-by-side to remove encroaching conifers trees and reconnect large, intact sagebrush rangelands. Over 47,000 acres are being treated which encompasses most of the post-settlement trees in this 100,000-acre area. BLM treatments total 25,000 acres, while private landowner treatments exceed 22,000 acres. Roughly half of planned treatments have already been completed. Junipers are removed primarily through hand cutting with chainsaws. Slash is reduced through a variety of techniques including lop-and-scatter, single tree burning, and pile burning to reduce fuels and vertical structure. All treatments are designed to maximize retention of sagebrush and other native vegetation. Long-term, outcome-based evaluations are also underway in this landscape to assess sage-grouse and sagebrush-obligate songbird response to conifer encroachment and removal. University of Idaho researchers are in the final field season of a five-year management study to assess the effects of conifer encroachment and subsequent removal on sage-grouse and their habitats, with a second phase of research beginning this fall for another five years. The non-profit group Point Blue Conservation Science is also assessing songbird responses to conifer treatments to provide a more holistic understanding of treatment effects. These science evaluations are helping

Figure 9 Chainsaw tree removal allows retention of sagebrush

Figure 10 Before (top) and after (bottom) treatment. Photos by: BLM

inform conservation delivery and adaptive management range-wide.

Burley Landscape Sage-Grouse Habitat Restoration Project

Cassia County, Idaho (2012-2017)

Partners: BLM-Burley Field Office, Private Landowners/Permittees, NRCS Sage Grouse Initiative, Pheasants Forever, Idaho Department of Fish and Game, Mule Deer Foundation, U.S. Fish & Wildlife Service, West Cassia Soil and Water Conservation District, South Magic Valley Sage-Grouse Local Working Group

The Burley Project is an innovative collaboration across public and private lands reducing the threat of conifer encroachment to sage-grouse and sagebrush ecosystems in the Northern Great Basin PAC of southern Idaho. Encroachment of Utah juniper in this area threatens persistence of sage-grouse and other sagebrush obligate species, as well as, increases the risk of catastrophic wildfire due to heavy and continuous fuel loads.

The project's overall objective is to remove juniper across about 38,000 acres of BLM land by 2017; over 11,000 acres have already been completed. Additional treatments are also being implemented on adjacent state and private lands to enhance connectivity. Treatments are prioritized in and around priority grouse habitats, such as, breeding areas near leks. Mechanical treatment techniques, including chainsaws and masticators, are employed to carefully remove juniper while retaining understory sagebrush, grasses, and forbs to the maximum extent possible. The vast majority of treatment areas are still in early stages of juniper expansion.

Figure 11. Days after treatment, sage-grouse take advantage of habitat recently reclaimed from dense juniper invasion. Photo by: BLM.

Project partners are combining technical and financial resources to overcome barriers to get the job done on the ground. BLM resource experts completed initial planning and NEPA, but limited fuels budgets necessitated a partnership to implement the project. The NRCS Sage Grouse Initiative now provides most of the needed funding for treatments through the Farm Bill's Environmental Quality Incentives Program, with

How does cooperative landscape planning affect sage-grouse conservation?

Cooperative landscape planning leverages the diverse resources, skills, and knowledge of multiple partners for the benefit of sage-grouse. Many working groups involve private, state, and federal cooperators, which illustrates the benefits that come from multiple contributors working at landscape scales. The Sage-Grouse Initiative led by the NRCS is one example of a cooperative landscape approach.

matching funds provided by Idaho Department of Fish and Game and others. NRCS coordinates conservation plans and contracts with local permit-holding ranchers on public lands to enable the work. Pheasants Forever facilitates project implementation across land ownerships through a Stewardship Agreement with BLM. PF hires contractors for implementation, administers contracts, and jointly conducts project inspection on contractor work with BLM project representatives. This project serves as a model for how partners can combine resources to accelerate implementation across private and public lands throughout the West.

Example 3: Application of Resistance and Resilience Concepts

The recently completed General Technical Report describing resistance and resilience concepts (Chambers et al. 2014) is a fundamental synthesis of scientific knowledge with great promise to land managers. This report is intended for broad application in the development of ecologically based management strategies and practices for fuels management, fire operations, habitat restoration, and rehabilitation efforts. Many land management units, such as BLM Districts or National Forests, have applied these concepts in the past with success. The following photos highlight a project which successfully established Wyoming big sagebrush following the 2006 Esmeralda Fire in northeast Nevada, by evaluating site specifics and incorporating resistance and resilience concepts in developing the type and timing of treatments.

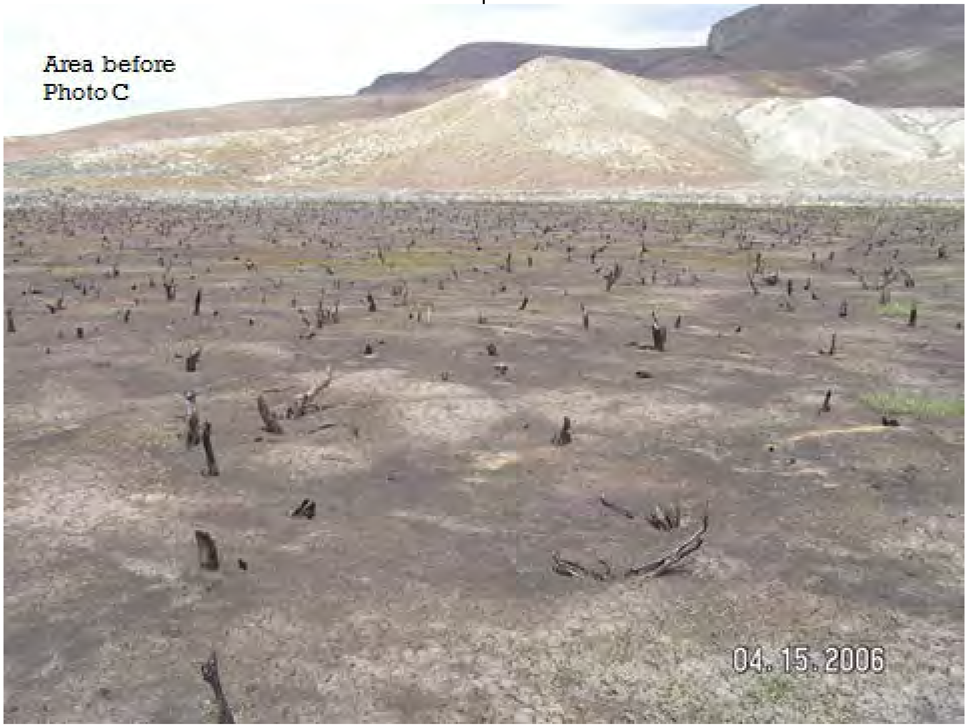

Photo 1. Post-fire landscape following 2006 Esmeralda Fire, Elko BLM District (photo courtesy Tom Warren, Elko BLM.

Photo 3. Rehabilitation results five years following the 2006 Esmeralda Fire, Elko BLM District (photo courtesy Tom Warren, Elko BLM.

Example 4: Linear Fuel Breaks

In the spring of 2012, the BLM's Upper Snake Field Office implemented its first phase of the Big Desert Fuel Breaks Project, as planned in the March 2012 Environmental Assessment of the Big Desert Roads Fuel Breaks Project. The intent of the project was to modify potential fire behavior characteristics (e.g., rate of spread, flame length) adjacent to road corridors in order to protect the remaining intact sagebrush habitat within the field office, and to improve firefighter safety. The initial treatment phase of this plan consisted of mowing approximately 30 miles (1,130 acres) of vegetation adjacent to strategic road corridors. Work was initiated on April 30, 2012 and consisted of roto-mowing the existing vegetation to a height of 8 inches at a distance between 100-150 feet from the centerline, creating fuel breaks 200-300 feet in width. Additionally, the new plan allowed for areas previously treated to be retreated mechanically or with approved herbicides to reduce shrub densities and reduce fuel continuity by removing annual grasses from within the interspaces. To date, approximately 230 acres have been retreated using the chemical method.

The Cox's Well Fire ignited on the afternoon of July 10, 2012 within the NPS Craters of the Moon National Monument and Preserve. Daytime temperatures during the fire ranged between 85-98°F and fire danger indices were extreme. Due to the passage of numerous thunderstorms, fire activity was erratic, resulting in the fire actively burning on multiple flanks. Strong, gusty winds and hot dry conditions allowed the fire to quickly reach 4,575 acres of public lands administered by the BLM's Upper Snake Field Office and 3,225 acres of BLM Monument lands located within the Craters of the Moon National Monument.

Suppression operations of the Cox's Well Fire began around 13:30 with initial attack crews attempting to anchor and tie the fire into the Great Rift within the BLM Monument Lands. When direct attack was unsuccessful, crews backed out to the Arco/Minidoka Road and started improving the road grade and back burning off the road. Recently completed fuel breaks (spring 2012) along the Arco/Minidoka Road served to augment suppression operations. Treated fuels exhibited flame lengths of approximately two feet, providing an area for suppression crews to safely and effectively manage the fire.

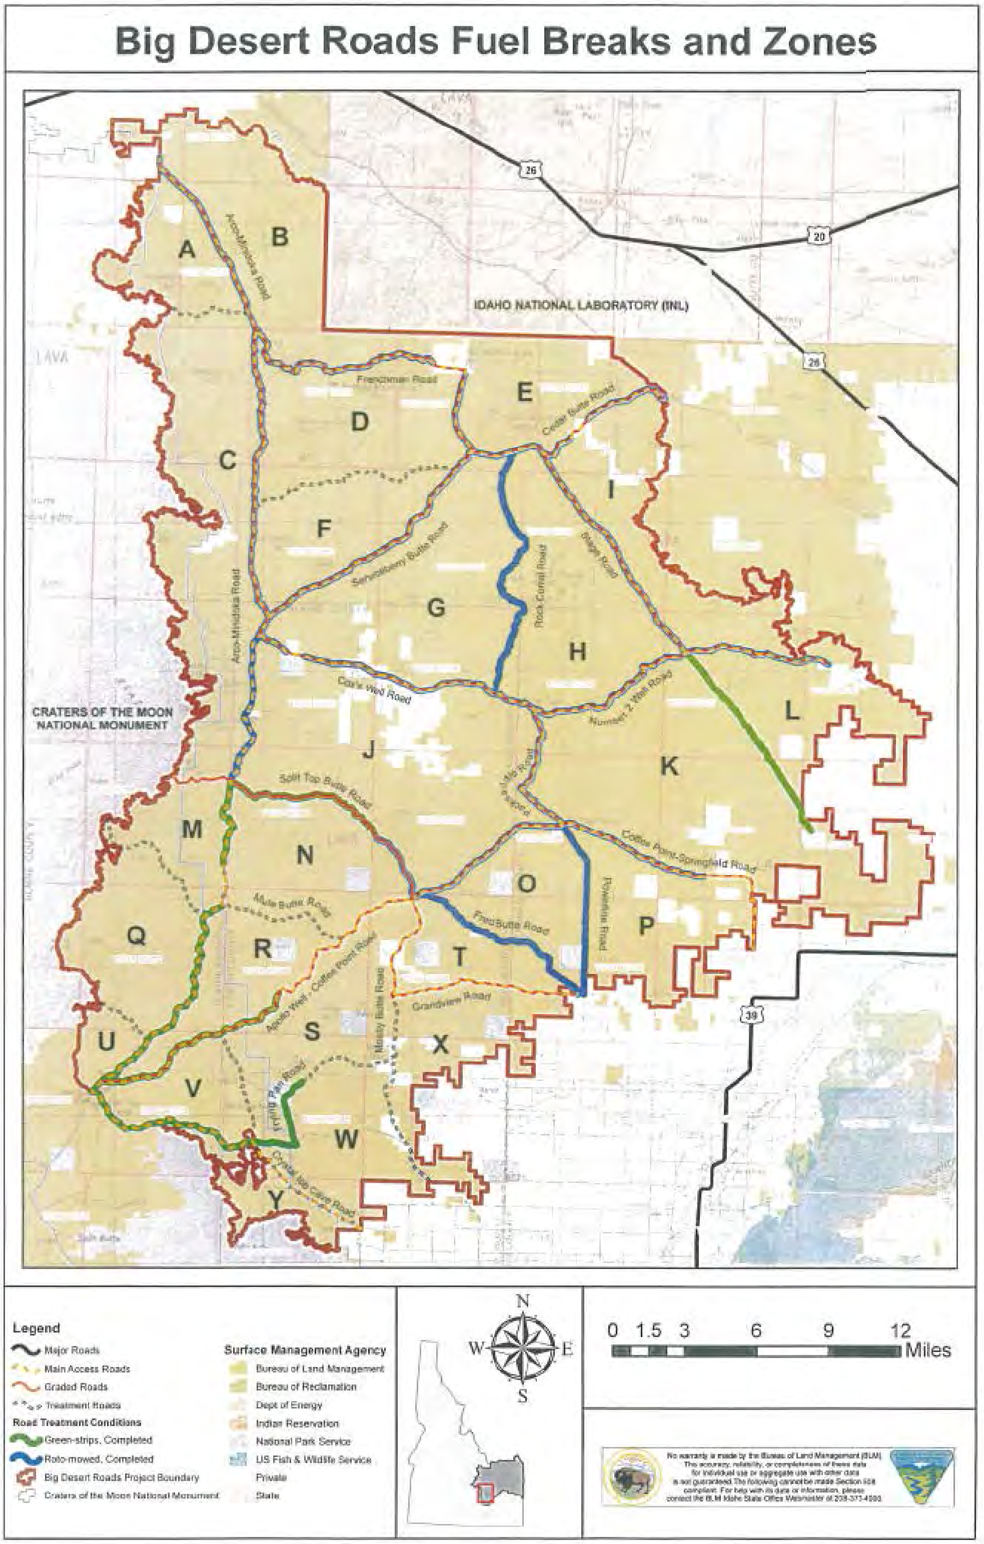

Figure 12. Map of Big Desert fuel break and landscape compartments.

Figure 13. Overview of the fuel breaks size and vegetative height and distribution

Figure 14. Overview of the burned and unburned portions of the fuel breaks following the Cox's Well Fire (photos courtesy Ben Dyer, BLM Fire Ecologist)

VI. Summary and Recommendations

Proactive measures in the fire operations and fuels management arenas are crucial to long-term sage-grouse conservation. Approximately 97% of initial attack efforts are successful at keeping fires under 1,000 acres. Site-appropriate measures before and after the fire represent the greatest opportunities to interrupt the invasive plant and wildfire cycle, and potentially augment initial attack effectiveness. At the same time, the body of knowledge related to "what works" should be bolstered through research and testing.

It is critical to note that there are common themes that are repeated in on-going science assessments dealing with wildland fire and sage-grouse. In the USGS Sage-Grouse Science Needs Assessment, the BLM's Fire and Rangelands symposium report, and in this document, there is glaring overlap in the identified science, policy, and funding needs. Given the wide range of the scientists contributing to these reports, this overlap should be acknowledged as significant.

In the suite of recommendations which follow, some can be readily addressed in the short term. Others will require long-term institutional change through the development of new policy. In any case, disrupting the feedback loop between wildfire and the loss of sagebrush is daunting. The biological barriers to sage-grouse conservation are well understood (Knick et al. 2011), though extraordinary in scope and complexity. Policy and funding barriers have been recently clarified through this and other reports. Surmounting these barriers will require collaboration, persistence and creativity. Our recommendations represent areas where meaningful change can result in the policy, research, and applied management arenas. To aid the reader in better understanding the genesis of these recommendations, we have restated the challenges and barriers identified in Sections II through IV of this report below.

From Section II: Federal Challenges and Barriers

- Emerging science that synthesizes our knowledge of ecological resilience and potential for success has not been fully integrated into the design and implementation of fuels management projects and fire operations planning.
- The capacity of federal agencies in terms of positions, funding streams, and planning is limited.
- Real-time information sharing between sage-grouse biologists and fire managers is sometime lacking during periods of high fire activity across the Great Basin. This deficiency is found within Incident Management Teams, Area Command Teams, and Geographic Multi-Agency Coordination Groups.
- Competing priorities exist across program areas. Integration across these functional areas needs improvement.
- Required public review processes, including litigation, appeals, and protests of potential treatments, impede the finalization of land-use plans.
- The current fire suppression funding process needs to be modified to allow fire operations to function more like a "natural disaster" and not fiscally overburden existing program budgets of the federal fire agencies. Currently, there is no single fire budget that covers the entire yearly firefighting effort. Thus, dollars are

redirected from other program budgets to make up the difference, which often negatively affects those programs.

From Section III: State Challenges and Barriers

- There is insufficient funding for wildfire preparedness activities, including training, heavy equipment/engines, Personal Protective Equipment, radios, and facilities.
- Expanding National Wildfire Coordinating Group (NWCG) qualification requirements and associated time required results in shortages of qualified personnel in many positions;
- The historic seasonal approach to wildfire suppression and management is inadequate given the complexities of natural resource management. A dedicated year round work force and associated funding is needed to address the expanding wildfire management challenges;
- Periods of high wildfire activity with multiple ignitions in short time periods, which results in shortages of suppression resources can limit response effectiveness;
- Clear delineation of the highest priority sage-grouse habitat designated for protection from wildfire is needed at all wildfire response levels and mapping updated appropriately;
- There is a lack of active and timely land management actions, especially on federal lands, due to limited funding, permitting requirements, and litigation;
- Extensive delays in processing fire bills by the federal agencies can create significant cash flow problems and impacts state and local fuel treatment programs;
- Wildfire rehabilitation funding is limited, which perpetuates the invasive plant species problems and increases fire return intervals on all ownerships.

From Section IV: Local Challenges and Barriers

- Firefighter retention and the loss of institutional knowledge of managing wildfire;
- There is insufficient funding for preparedness and response capacity including training, heavy equipment/engines, PPE, radios, and facilities.
- Shortages of qualified wildfire management trainers, programs and inadequate delivery systems in rural areas create operational constraints.
- Inconsistent federal land management policies are negatively impacting the sustainability of multiple land uses on public lands.
- There is a significant need for developing and utilization of integrated and dynamic livestock grazing plans that assist with fuels reduction through targeted grazing and consistent monitoring.
- It is difficult to implement a landscape approach to fuels management because of challenges posed by environmental regulations, the availability of sufficient funding, the lack of qualified contractors and the complicated NEPA permit process.
-

Recommendation #1: Utilize Emerging Science

Incorporate emerging science and analysis (Resistance and Resilience concepts, FIAT Fire and Invasives Assessments) to place management strategies and treatments in the locations with the highest probability of success. While many administrative units have applied knowledge of ecological sites and resilience in past practices, a broader adoption of the resistance/resilience concept is needed and overdue. Emerging science concepts allow managers to prioritize management efforts and scarce resources to achieve successful outcomes. One example would be a broader use of FIAT assessments to apply “the right treatments in the right place”.

Recommendation #2: Fuel Breaks

Conduct research that quantifies fuels treatment effectiveness in terms of limiting fire growth, final fire size, or aiding suppression effectiveness. Currently, the metrics used to evaluate fuels treatment effectiveness are subjective, qualitative, or lack causal relationship (e.g., observed change in fire behavior, dollars spent, acres treated). Current assumptions regarding linear fuel breaks, green-stripping, and other treatments need to be tested and their outcomes quantified. Studies should evaluate variables that include the timing, sequence, and pattern of treatments.

Once the most effective fuel-break techniques are identified, scale up implementation of strategically placed fuel breaks in priority PACS and FIAT focal habitat areas to proactively address the 3% of fires that escape initial attack. While linear fuel treatments may potentially fragment habitats, “mega-fires” eliminate habitat. Managers should consider application of fuel management strategies that can augment suppression effectiveness and reduce the likelihood of catastrophic fire growth.. While fuel breaks are not intended to stop fires, they can help reduce fire size by providing firefighters with safe anchor points for suppression. Development of effective pre-suppression strategies should be identified through interdisciplinary efforts involving both sage-grouse biologists and fire managers.

Recommendation #3: Involve the Experts

State and federal biologists with sage-grouse expertise and invasive species should inform fire management decisions in Incident Management Teams, Area Command Teams, and Geographic Multi-Agency Coordination groups. This should include increased participation of non-federal Resource Advisors on the line, as well as subject matter experts in real-time decision making with Incident Management Teams. Coordination should also occur before fire season to ensure the real-time participation of key biologists with knowledge of lek locations, populations, and seasonal habitats. All of the above must comply with NWCG qualifications and standards for fireline personnel. A mechanism for overtime compensation for non-federal employees is needed.

Recommendation #4: Promote Awareness

Develop a process whereby sage-grouse and their habitats are highlighted as a high-priority value in the above discussions for the public and. Currently, sage-grouse is viewed as one of myriad natural resource values to consider during fire operations decisions. Sage-grouse sensitivity to fire effects should be highlighted in allocation decisions (e.g., slow recovery of sagebrush ecosystems, bird affinity for lek locations, biological significance of intact sagebrush, etc.). This awareness must highlight the need to minimize fire growth on fires that threaten valued habitat.

Recommendation #5: Incorporate Sage-Grouse Considerations in Pre-Season Activities

Fully incorporate sage-grouse information sharing, planning, and coordination in pre-season meetings. This should include full discussions related to delegations of authority, the process for in-briefings, resource advisor roles, and participation by area wildlife biologists with incident managers when fires occur.

Recommendation #6: Invest now to save later

Develop reliable funding streams focused on pre-fire vegetation management to improve sage-grouse habitat and improving sagebrush ecosystem resilience. This provides continuity for out-year planning and staffing. Prioritize vegetation management opportunities in priority areas identified through the FIAT process where cooperative landscape approaches are being taken across public-private land ownership boundaries. Acknowledge the reality that need for multiple interventions, repeated treatments, and adaptive management will likely exceed agencies' current budgets. Maximize the impact of new funding streams by prioritizing support for collaborative landscape approaches.

Recommendation #7: Streamline Planning Processes

Work with CEQ to explore mechanisms for accelerating NEPA planning for implementation of key vegetation treatments in priority landscapes identified through the FIAT process to provide real-time protection capability. With current planning efforts often spanning years, increasing fire frequency and magnitude are outpacing our ability to keep up with implementation.

Recommendation #8: Update Fire Management Plans

Based upon our knowledge of sage-grouse populations, habitats, and related threats, implement the decisions from the revised land use plan EIS's in order to update fire management plans. Subsequently, agencies should revisit operational plans related to fire prioritization, resource placement, and suppression response procedures. Integrate lek, population, and key habitat data into fire management response protocols for Federal and State agencies.

Recommendation #9: Improve Decision Support Tools

Develop decision support tools that contribute to rangeland fire management decision-making. One specific technical gap is rangeland fire behavior modeling (dynamic fuel modeling). Currently, predicting the dynamics of fire behavior in forested systems is more advanced than that in rangeland ecosystems. This is a technical gap that needs to be closed to improve future treatment planning and fire management decisions.

Recommendation #10: Adopt an "All Lands" Approach

Develop an "all lands" solution to wildfire and fuels management relative to sage-grouse habitat conservation. Rangeland Fire Protection Associations represent a key component of incorporating private and ranching interests. Expand the cooperation between federal agencies, state fire agencies and local governments to establish RFPAs on a broader scale. Develop commitments to provide training and equipment to RFPAs. Expand training opportunities to include volunteer firefighters, RFPA's, and local fire departments. Expand model programs such as “Partners in Conservation and NRCS “Sage Grouse Initiative” to develop innovative funding mechanisms for landscape scale habitat restoration projects across multiple ownerships.

Recommendation #11: Model Fire Funding on Disaster Response

Finalize proposed legislation that allows fire management (suppression) to be funded like natural disasters, as identified in the 2014 WAFWA Gap Report. The current fire suppression funding process should be modified to where fire costs are funded akin to “natural disasters”, thereby easing fiscal competition in federal and state agencies.

Recommendation #12: Evaluate Grazing as a Fuels Management Opportunity

In concert with research needs identified by USGS and the 2014 WAFWA Gap Analysis, conduct research on the efficacy and opportunities related to livestock grazing as a fuels management tool. Given the high degree of overlap between domestic livestock grazing and sage-grouse habitats, evaluate variables associated with grazing intensity, timing, and extent to determine value as a fuels management tool.

VII. Appendices

Appendix 1. Glossary of Terms

Source: NWCG Glossary of Wildland Fire Terminology PMS 205 (2014)

Agency
An administrative division of a government with a specific function, or a non-governmental organization (e.g., private contractor, business, etc.) that offers a particular kind of assistance. A federal, tribal, state or local agency that has direct fire management or land management responsibilities or that has programs and actives that support fire management activities.
see also: Assisting Agency
Cooperating Agency
Supporting Agency

Agency Administrator
The official responsible for the management of a geographic unit or functional area. The managing officer of an agency, division thereof, or jurisdiction having statutory responsibility for incident mitigation and management. Examples: NPS Park Superintendent, BIA Agency Superintendent, USFS Forest Supervisor, BLM District Manager, FWS Refuge Manager, State Forest Officer, Tribal Chairperson, Fire Chief, Police Chief.
see also: Line Officer

Agency/Area Coordination Center
A facility which serves as a central point for one or more agencies to use in processing information and resource requests. It may also serve as a dispatch center for one of the agencies.

Anchor Point
An advantageous location, usually a barrier to fire spread, from which to start constructing a fire line. The anchor point is used to minimize the chance of being flanked by the fire while the line is being constructed.

Area Command
An organization established to: 1) oversee the management of multiple incidents that are each being handled by an incident management team (IMT) organization; or 2) to oversee the management of a very large incident that has multiple IMTs assigned to it. Area Command has the responsibility to set overall strategy and priorities, allocate critical resources based on priorities, ensure that incidents are properly managed, and that objectives are met and strategies followed.

Backfire
A fire set along the inner edge of a fire line to consume the fuel in the path of a wildfire or change the direction of force of the fire's convection column.

Backfiring
A tactic associated with indirect attack, intentionally setting fire to fuels inside the control line to slow, knock down, or contain a rapidly spreading fire. Backfiring provides a wide defense perimeter and may be further employed to change the force of the convection column. Backfiring makes possible a strategy of locating control lines at places where the fire can be fought on the firefighter's terms. Except for rare circumstance meeting specified criteria, backfiring is executed on a command decision made through line channels of authority.

Barrier
Any obstruction to the spread of fire. Typically an area or strip devoid of combustible fuel.

Blackline
Pre-burning of fuels adjacent to a control line before igniting a prescribed burn. Blacklining is usually done in heavy fuels adjacent to a control line during periods of low fire danger to reduce heat on holding crews and lessen chances for spotting across control line. In fire suppression, a blackline denotes a condition where there is no unburned material between the fire line and the fire edge.

Burn Out
Setting fire inside a control line to consume fuel between the edge of the fire and the control line.
see also: Backfire

Contained
The status of a wildfire suppression action signifying that a control line has been completed around the fire, and any associated spot fires, which can reasonably be expected to stop the fire's spread.

Cooperating Agency
An agency supplying assistance including but not limited to direct tactical or support functions or resources to the incident control effort (e.g. Red Cross, law enforcement agency, telephone company, etc.).
see also: Agency
Agency Representative
Assisting Agency
Supporting Agency

Cooperator
A federal, tribal, state, or local agency that participates with another agency(s) in planning and conducting fire or emergency management projects and activities.
see also: Agency
Agency Representative
Assisting Agency
Cooperating Agency
Supporting Agency

Coordination Center
Term used to describe any facility that is used for the coordination of agency or jurisdictional resources in support of one or more incidents.

Direct Attack
Any treatment applied directly to burning fuel such as wetting, smothering, or chemically quenching the fire or by physically separating the burning from unburned fuel.
synonym: Direct Line

Direct Line
Any treatment applied directly to burning fuel such as wetting, smothering, or chemically quenching the fire or by physically separating the burning from unburned fuel.
synonym: Direct Attack

Dispatch Center
A facility from which resources are assigned to an incident.

Dispatcher
A person who receives reports of discovery and status of fires, confirms their locations, takes action promptly to provide people and equipment likely to be needed for control efforts.
see also: Agency Dispatcher

Dry Lightning Storm
Thunderstorm in which negligible precipitation reaches the ground. Also called dry storm.

Emergency Stabilization
Planned actions to stabilize and prevent unacceptable degradation to natural and cultural resource, to minimize threats to life or property resulting from the effects of a fire, or to repair/replace/construct physical improvements necessary to prevent degradation of land or resources.

Extreme Fire Behavior
"Extreme" implies a level of fire behavior characteristics that ordinarily precludes methods of direct control action. One or more of the following is usually involved: high rate of spread, prolific crowning and/or spotting, presence of fire whirls, strong convection column. Predictability is difficult because such fires often exercise some degree of influence on their environment and behave erratically, sometimes dangerously.
see also: Blowup
Fire Storm
Flare-up

Fine Fuels
Fast-drying dead or live fuels, generally characterized by a comparatively high surface area-to-volume ratio, which are less than 1/4-inch in diameter and have a time lag of one hour or less. These fuels (grass, leaves, needles, etc.) ignite readily and are consumed rapidly by fire when dry.

Fire Behavior
The manner in which a fire reacts to the influences of fuel, weather, and topography.

Fire Management Plan (FMP)
A plan that identifies and integrates all wildland fire management and related activities within the context of approved land/resource management plans. A fire management plan defines a program to manage wildland fires (wildfire and prescribed fire). The plan is supplemented by operational plans, including but not limited to preparedness plans, preplanned dispatch plans, prescribed fire burn plans, and prevention plans. Fire management plans assure that wildland fire management goals and components are coordinated.

Fire Management Unit (FMU)
A land area definable by specified management objectives, constraints, topographic features, access, values to be protected, political boundaries, fuel types, major fire regime groups, and other defined elements that set it apart from an adjacent area. The primary purpose of developing Fire Management Units in fire management planning is to assist in organizing information in complex landscapes. A fire management unit may have dominant management objectives and pre-selected strategies assigned to accomplish these objectives.

Fire Presuppression
Activities undertaken in advance of fire occurrence to help ensure more effective fire suppression. Activities includes overall planning, recruitment and training of fire personnel, procurement and maintenance of firefighting equipment and supplies, fuel treatment and creating, maintaining, and improving a system of fuel breaks, roads, water sources, and control lines.

Fire Weather
Weather conditions which influence fire ignition, behavior, and suppression.

Fire Weather Forecast
A weather prediction specially prepared for use in wildland fire operations and prescribed fire.

Firebreak
A natural or constructed barrier used to stop or check fires that may occur, or to provide a control line from which to work.

Fire line
The part of a containment or control line that is scraped or dug to mineral soil.

Fuel Arrangement
1 A general term referring to the spatial distribution and orientation of fuel particles or pieces.

Fuel Bed
An array of fuels usually constructed with specific loading, depth, and particle size to meet experimental requirements; also, commonly used to describe the fuel composition.

Fuel Loading
The amount of fuel present expressed quantitatively in terms of weight of fuel per unit area. This may be available fuel (consumable fuel) or total fuel and is usually dry weight.

Fuel Reduction
Manipulation, including combustion, or removal of fuels to reduce the likelihood of ignition and/or to lessen potential damage and resistance to control.

Fuel Treatment
Manipulation or removal of fuels to reduce the likelihood of ignition and/or to lessen potential damage and resistance to control (e.g., lopping, chipping, crushing, piling and burning).
synonym: Fuel Modification

Fuel break
A natural or manmade change in fuel characteristics which affects fire behavior so that fires burning into them can be more readily controlled.

Geographic Area Coordinating Group (GACG)
An interagency body of fire management representatives from each federal and state land management agency within a nationally recognized regional area that provides leadership and support to facilitate safe and efficient fire management activities. Working collaboratively, a GACG's mission is not only for wildland fire emergencies, but for other emergency incidents, as necessary.

Geographic Area Coordination Center (GACC)
The physical location of an interagency, regional operation center for the effective coordination, mobilization and demobilization of emergency management resources. A coordination center serves federal, state and local wildland fire agencies through logistical coordination of resources throughout the geographic area, and with other geographic areas, as well. Listings of geographic coordination centers and their respective geographic coordinating areas can be found within the National Interagency Mobilization Guide.
see also: Geographic Area
Geographic Coordinating Area

Geographic Multi-Agency Coordination (GMAC) Group
Interagency group within a geographic which convenes during periods of high fire activity to:
(1) determine and set geographic area priorities;
(2) acquire, allocate, and reallocate resources; and
(3) issue coordinated situation assessment statements.

Head of a Fire
The most rapidly spreading portion of a fire's perimeter, usually to the leeward or up slope.

Hotshot Crew
Intensively trained fire crew used primarily in hand line construction (Type-1).

Incident
An occurrence either human-caused or natural phenomenon, that requires action or support by emergency service personnel to prevent or minimize loss of life or damage to property and/or natural resources.

Incident Action Plan (IAP)
Contains objectives reflecting the overall incident strategy and specific tactical actions and supporting information for the next operational period. The plan may be oral or written. When written, the plan may have a number of attachments, including: incident objectives, organization assignment list, division assignment, incident radio communication plan, medical plan, traffic plan, safety plan, and incident map. Formerly called shift plan.

Incident Commander (ICT1, ICT2, ICT3, ICT4, or ICT5)
This ICS position is responsible for overall management of the incident and reports to the Agency Administrator for the agency having incident jurisdiction. This position may have one or more deputies assigned from the same agency or from an assisting agency(s).

Incident Management Team
The incident commander and appropriate general and command staff personnel assigned to an incident.

Incident Meteorologist (IMET)
A specially trained meteorologist who provides site specific weather forecasts and information at an incident. The individual works under the direction of the fire behavior analyst and the planning section chief.

Incident Objectives
Statements of guidance and direction necessary for the selection of appropriate strategy(s), and the tactical direction of resources. Incident objectives are based upon agency administrators direction and constraints. Incident objectives must be achievable and measurable, yet flexible enough to allow for strategic and tactical alternatives.

Initial Attack (IA)
A preplanned response to a wildfire given the wildfire’s potential. Initial attack may include size up, patrolling, monitoring, and holding action or suppression.

Jurisdictional Agency
The agency having land and resource management responsibility for a specific geographical or functional area as provided by federal, state or local law.

Land Use Plan
A set of decisions that establish management direction for land within an administrative area; an assimilation of land-use-plan-level decisions developed through the planning process regardless of the scale at which the decisions were developed.

Land/Resource Management Plan (L/RMP)
A document prepared with public participation and approved by an agency administrator that provides general guidance and direction for land and resource management activities for an administrative area. The L/RMP identifies the need for fire's role in a particular area and for a specific benefit. The objectives in the L/RMP provide the basis for the development of fire management objective and the fire management program in the designated area.

Leader's Intent
A concise statement that outlines what individuals must know in order to be successful for a given assignment. The intent communicates three essential pieces of information:
- Task – What is the goal or objective
- Purpose – Why it is to be done
- End state – How it should look when successfully completed

Lightning Activity Level (LAL)
Part of the National Fire Danger Rating System (NFDRS). A number, on a scale of 1 to 6, which reflects frequency and character of cloud-to-ground lightning (forecasted or observed). The scale for 1 to 5 is exponential, based on powers of 2 (i.e., LAL 3 indicates twice the lightning of LAL 2). LAL 6 is a special category for dry lightning and is closely equivalent to LAL 3 in strike frequency.

Line Officer
Managing officer, or designee, of the agency, division thereof, or jurisdiction having statutory responsibility for incident mitigation and management.
see also: Agency Administrator

Local Agency
Any agency having jurisdictional responsibility for all or part of an incident.

Local Resource
Resources within a dispatch center's area of responsibility.

Mobilization
The process and procedures used by all organizations, federal, state and local, for activating, assembling, and transporting all resources that have been requested to respond to or support an incident.

Mobilization Guide
A written description of procedures used by federal, state, and local organizations for activating, assembling, and transporting resources that have been requested to respond to or support an incident.

Mop Up
Extinguishing or removing burning material near control lines, felling snags, and trenching logs to prevent rolling after an area has burned, to make a fire safe, or to reduce residual smoke.

Multi-Agency Coordinating Group (MAC Group)
A national, regional, or local management group for interagency planning, coordination, and operations leadership for incidents. Provides an essential management mechanism for strategic coordination to ensure incident resources are efficiently and appropriately managed in a cost effective manner.

Multi-Agency Coordination (MAC)
A generalized term which describes the functions and activities of representatives of involved agencies and/or jurisdictions who come together to make decisions regarding the prioritizing of incidents, and the sharing and use of critical resources. The MAC organization is not a part of the on-scene ICS and is not involved in developing incident strategy or tactics.

Multi-Agency Coordination System (MACS)
MACS provides the framework to support coordination for incident prioritization, critical resource allocation, communication systems integration, and information coordination. MACS components include facilities, equipment, emergency operating centers EOCs), specific multiagency coordination entities, personnel, procedures, and communications.

Multiple Fire Situations
High fire frequency over a short period of time in an administrative unit, usually overtaxing the normal initial attack capability of the unit.

National Fire Danger Rating System (NFDRS)
A uniform fire danger rating system that focuses on the environmental factors that control the moisture content of fuels.

National Interagency Coordination Center (NICC)
Coordinates allocation of resources to one or more coordination centers or major fires within the nation. Located in Boise, Idaho.

National Interagency Fire Center (NIFC)
A facility located at Boise, Idaho, jointly operated by several federal agencies, dedicated to coordination, logistical support, and improved weather services in support of fire management operations throughout the United States.

National Multi-Agency Coordination (NMAC) Group

During National Preparedness Levels 4 and 5, the National Multi-Agency Coordinating Group (NMAC) is activated and daily briefings are conducted. This body involves representatives from all federal fire agencies, the National Association of State Foresters, and the Federal Emergency Management Administration (FEMA). This group provides national wildland fire operations direction, coordination, prioritization, allocation and oversight.

National Wildfire Coordinating Group (NWCG)
An intergovernmental body that provides national leadership to develop, maintain and communicate standards, guidelines, qualifications, training, and other capabilities that enable interoperable operations among federal and non-federal entities for wildland fire program management.

Natural Barrier
Any area where lack of flammable material obstructs the spread of wildfires.

Overhead
Personnel assigned to supervisory positions, including incident commander, command staff, general staff, branch directors, supervisors, unit leaders, managers and staff.

Predictive Services
Those Geographic Area and National-level fire weather or fire danger services and products produced by wildland fire agency meteorologists and intelligence staffs in support of resource allocation and prioritization.

Preparedness
1 Activities that lead to a safe, efficient, and cost-effective fire management program in support of land and resource management objectives through appropriate planning and coordination.
2 Mental readiness to recognize changes in fire danger and act promptly when action is appropriate.
3 The range of deliberate, critical tasks, and activities necessary to build, sustain, and improve the capability to protect against, respond to, and recover from domestic incidents.

Preparedness Level
Increments of planning and organization readiness commensurate with increasing fire danger.

Prescribed Fire
Any fire intentionally ignited by management actions in accordance with applicable laws, policies, and regulations to meet specific objectives.

Presuppression
Activities in advance of fire occurrence to ensure effective suppression action. Includes planning the organization, recruiting and training, procuring equipment and supplies, maintaining fire

equipment and fire control improvements, and negotiating cooperative and/or mutual aid agreements.

Prevention

1 Activities directed at reducing the incidence of fires, including public education, law enforcement, personal contact, and reduction of fuel hazards (fuels management).

2 Actions to avoid an incident, to intervene for the purpose of stopping an incident from occurring, or to mitigate an incident's effect to protect life and property. Includes measures designed to mitigate damage by reducing or eliminating risks to persons or property, lessening the potential effects or consequences of an incident.

Rate of Spread

The relative activity of a fire in extending its horizontal dimensions. It is expressed as rate of increase of the total perimeter of the fire, as rate of forward spread of the fire front, or as rate of increase in area, depending on the intended use of the information. Usually it is expressed in chains or acres per hour for a specific period in the fire's history.

Red Flag Warning

Term used by fire weather forecasters to alert forecast users to an ongoing or imminent critical fire weather pattern.

Rehabilitation

Efforts undertaken within three years of a wildland fire to repair or improve fire damaged lands unlikely to recover to a management approved conditions or to repair or replace minor facilities damaged by fire.

Restoration

The continuation of rehabilitation beyond the initial three years or the repair or replacement of major facilities damaged by the fire.

Rural Fire District (RFD)

An organization established to provide fire protection to a designated geographic area outside of areas under municipal fire protection. Usually has some taxing authority and officials may be appointed or elected.

Rural Fire Protection

Fire protection and firefighting problems that are outside of areas under municipal fire prevention and building regulations and that are usually remote from public water supplies.

Situational Awareness (SA)

An on-going process of gathering information by observation and by communication with others. This information is integrated to create an individual's perception of a given situation.

Size Class of Fire
As to size of wildfire:
Class A - one-fourth acre or less;
Class B - more than one-fourth acre, but less than 10 acres;
Class C - 10 acres or more, but less than 100 acres;
Class D - 100 acres or more, but less than 300 acres;
Class E - 300 acres or more, but less than 1,000 acres;
Class F - 1,000 acres or more, but less than 5,000 acres;
Class G - 5,000 acres or more.

Smokejumper
A specifically trained and certified firefighter who travels to wildland fires by aircraft and parachutes to the fire.

Spot Fire
Fire ignited outside the perimeter of the main fire by a firebrand.

Spot Weather Forecast
A special forecast issued to fit the time, topography, and weather of a specific incident. These forecasts are issued upon request of the user agency and are more detailed, timely, and specific than zone forecasts. Usually, on-site weather observations or a close, representative observation is required for a forecast to be issued.

Strategy
The general plan or direction selected to accomplish incident objectives.

Suppression
Management action to extinguish a fire or confine fire spread beginning with its discovery.

Tactics
Deploying and directing resources on an incident to accomplish the objectives designated by strategy.

Uncontrolled Fire
Any fire which threatens to destroy life, property, or natural resources, and (a) is not burning within the confines of firebreaks, or (b) is burning with such intensity that it could not be readily extinguished with ordinary tools commonly available.

Wildland Fire
Any non-structure fire that occurs in vegetation or natural fuels. Wildland fire includes prescribed fire and wildfire.

Wildland Urban Interface (WUI)
The line, area, or zone where structures and other human development meet or intermingle with undeveloped wildland or vegetative fuels. Describes an area within or adjacent to private and public property where mitigation actions can prevent damage or loss from wildfire.

Appendix 2. BLM Best Management Practices for Fire Operations and Fuels Management.

A. Fire Operations Best Management Practices for Sage-Grouse Conservation

1. Compile district-level information into statewide sage-grouse toolboxes. Toolboxes will contain maps, listing of resource advisors, contact information, local guidance, and other relevant information for each district, which will be aggregated into a statewide document.

2. Provide localized maps to dispatch offices and extended attack incident commanders for use in prioritizing wildfire suppression resources and designing suppression tactics.

3. Assign a resource advisor with sage-grouse expertise, or who has access to sage-grouse expertise, to all extended attack fires in or near sage-grouse habitat areas. Prior to the fire season, provide training to sage-grouse resource advisors on wildfire suppression organization, objectives, tactics, and procedures to develop a cadre of qualified individuals.

4. On critical fire weather days, pre-position additional fire suppression resources to optimize a quick and efficient response in sage-grouse habitat areas.

5. As appropriate, utilize existing fuel breaks, such as roads or discrete changes in fuel type, as control lines in order to minimize fire spread.

6. During periods of multiple fires, ensure line officers are involved in setting priorities.

7. To the extent possible, locate wildfire suppression facilities (i.e., base camps, spike camps, drop points, staging areas, heli-bases, etc.) in areas where physical disturbance to sage-grouse habitat can be minimized. These include disturbed areas, grasslands, near roads/trails or in other areas where there is existing disturbance or minimal sagebrush cover.

8. Power-wash all firefighting vehicles, to the extent possible, including engines, water tenders, personnel vehicles, and all-terrain vehicles (ATV) prior to deploying in or near sage-grouse habitat areas to minimize noxious weed spread.

9. Minimize unnecessary cross-country vehicle travel during fire operations in sage-grouse habitat.

10. Minimize burnout operations in key sage-grouse habitat areas by constructing direct fireline whenever safe and practical to do so.

11. Utilize retardant, mechanized equipment, and other available resources to minimize burned acreage during initial attack.

12. As safety allows, conduct mop-up where the black adjoins unburned islands, dog legs, or other habitat features to minimize sagebrush loss.

13. Adequately document fire operation activities in sage-grouse habitat for potential follow-up coordination activities.

B. Fuels Management Best Management Practices for Sage-Grouse Conservation

1. Where applicable, design fuels treatment objectives to protect existing sagebrush ecosystems, modify fire behavior, restore native plants, and create landscape patterns which most benefit sage-grouse habitat.

2. Provide training to fuels treatment personnel on sage-grouse biology, habitat requirements, and identification of areas utilized locally.

3. Use burning prescriptions that minimize undesirable effects on vegetation or soils (e.g., minimize mortality of desirable perennial plant species and reduce risk of annual grass invasion).

4. Ensure proposed sagebrush treatments are planned with full interdisciplinary input pursuant to NEPA and coordination with state fish and wildlife agencies, and that treatment acreage is conservative in the context of surrounding sage-grouse seasonal habitats and landscape.

5. Where appropriate, ensure that treatments are configured in a manner that promotes use by sage-grouse.

6. Where applicable, incorporate roads and natural fuel breaks into fuel break design.

7. Power-wash all vehicles and equipment involved in fuels management activities, prior to entering the area, to minimize the introduction of undesirable and/or invasive plant species.

8. Design vegetation treatments in areas of high fire frequency which facilitate firefighter safety, reduce the potential acres burned, and reduce the fire risk to sage-grouse habitat. Additionally, develop maps for sage-grouse habitat that spatially display current fuels treatment opportunities for suppression resources.

9. Give priority for implementing specific sage-grouse habitat restoration projects in annual grasslands, first to sites which are adjacent to or surrounded by preliminary priority habitat (PPH) or that reestablish continuity between priority habitats. Annual grasslands are a second priority for restoration when the sites are not adjacent to PPH, but within two miles of PPH. The third priority for annual grassland habitat restoration projects are sites beyond two miles of PPH. The intent is to focus restoration outward from existing, intact habitat.

10. As funding and logistics permit, restore annual grasslands to a species composition characterized by perennial grasses, forbs, and shrubs or one of that referenced in land use planning documentation.

11. Emphasize the use of native plant species, recognizing that non-native species may be necessary depending on the availability of native seed and prevailing site conditions.

12. Remove standing and encroaching trees within at least 100 meters of occupied sage-grouse leks and other habitats (e.g., nesting, wintering and brood rearing) to reduce the availability of perch sites for avian predators, as resources permit.

13. Protect wildland areas from wildfire originating on private lands, infrastructure corridors, and recreational areas.

14. Reduce the risk of vehicle- or human-caused wildfires and the spread of invasive species by planting perennial vegetation (e.g., green-strips) paralleling road rights-of-way.

15. Strategically place and maintain pre-treated strips/areas (e.g., mowing, herbicide application, etc.) to aid in controlling wildfire, should wildfire occur near PPH or important restoration areas (such as where investments in restoration have already been made).

RANGELAND FIRE PROTECTION ASSOCIATION FORMATION CHECKLIST

Hi All –

By now, I assume that you have all seen the new Secretarial Order with focused goals on reducing the size, severity, and cost of rangeland fires; addressing the spread of cheatgrass and other invasive species; and positioning wildland fire management resources for more effective rangeland fire response.

But…..I don't think you have seen the Great Basin LCC Science Project Portfolio……its very interesting and I would encourage all of you to take a look at all of the great science projects that the LCC is coordinating for the Great Basin.

Lauren

THE SECRETARY OF THE INTERIOR
WASHINGTON

ORDER NO. 3336

Subject: Rangeland Fire Prevention, Management and Restoration

Sec. 1 **Purpose**. This Order sets forth enhanced policies and strategies for preventing and suppressing rangeland fire and for restoring sagebrush landscapes impacted by fire across the West. These actions are essential for conserving habitat for the Greater sage-grouse as well as other wildlife species and economic activity, such as ranching and recreation, associated with the sagebrush-steppe ecosystem in the Great Basin region. This effort will build upon the experience and success of addressing rangeland fire, and broader wildland fire prevention, suppression and restoration efforts to date, including the National Cohesive Wildland Fire Management Strategy, and ensure improved coordination with local, state, tribal, and regional efforts to address the threat of rangeland fire at a landscape-level.

Sec. 2 **Background**. The Department of the Interior is entrusted with overseeing the management of Federal lands for the benefit of current and future generations as well as the protection and recovery of imperiled species of flora and fauna and the ecosystems upon which they depend. Rangeland fires in the Great Basin of the Western United States have increased in size and intensity in recent years. The accelerated invasion of non-native annual grasses, in particular cheatgrass and medusahead rye, and the spread of pinyon-juniper across the sagebrush-steppe ecosystem, along with drought and the effects of climate change, have created conditions that have led to the increased threat of rangeland fires to the sagebrush landscape and the more than 350 species of plants and animals, such as mule deer and pronghorn antelope, that rely on this critically important ecosystem. As a result, the increasing frequency and intensity of rangeland fire also poses a significant threat to ranchers, livestock managers, sportsmen, and outdoor recreation enthusiasts who use the sagebrush-steppe ecosystem, and puts at risk their associated economic contributions across this landscape that support and maintain the American way of life in the West.

In 2010, the U.S. Fish and Wildlife Service (USFWS) found that the invasion of annual grasses and the loss of habitat from fire in the Great Basin is a significant threat to the Greater sage-grouse in that portion of its remaining range. The USFWS is now considering whether protections under the Endangered Species Act are warranted. In response to this finding, the Bureau of Land Management (BLM) and the U.S. Forest Service are currently undertaking land use plan revisions and amendments to incorporate appropriate conservation measures to conserve, enhance, and restore Greater sage-grouse habitat by reducing, eliminating, or minimizing threats to that habitat. More targeted actions to reduce the likelihood and severity of fire, to stem the spread of invasive species, and to restore the health and resilience of the landscape are necessary to preserve, protect, and restore Greater sage-grouse habitat in the sagebrush-steppe ecosystem, and address important public safety, economic, cultural, and social concerns. This includes enhanced coordination and collaboration with partners and stakeholders, including rangeland fire protection associations.

Sec. 3 **Authorities**. This Order is issued under the authority of Section 2 of Reorganization Plan No. 3 of 1950 (64 Stat.1262), as amended. Other statutory authorities related to this Order include and are not limited to the following:

a. National Environmental Policy Act (NEPA), 42 U.S.C. 4321 *et seq.*

b. The Endangered Species Act (ESA), 16 U.S.C. 1531 *et seq.*

c. The Migratory Bird Conservation Act, 16 U.S.C. 715 *et seq.*

d. The National Fish and Wildlife Foundation Establishment Act, 16 U.S.C. 3701 *et seq.*

e. The Fish and Wildlife Coordination Act, 16 U.S.C. 661 *et seq.*

f. The Federal Land and Policy Management Act (FLPMA), 43 U.S.C. 1701 *et seq.*

g. The Federal Land Assistance Management and Enhancement Act of 2009, Title V of Division A of P.L. 111-88.

Sec. 4 **Policy**. Protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, Greater sage-grouse habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department. Allocation of fire management resources and assets before, during, and after wildland fire incidents will reflect this priority, as will investments related to restoration activities.

Sec. 5 **Developing an Enhanced Fire Prevention, Suppression, and Restoration Strategy**. To accomplish protection, conservation, and restoration of Greater sage-grouse habitat the Department, through the Rangeland Fire Task Force established in accordance with Section 6, will:

a. Work cooperatively and collaboratively with other Federal agencies, states, tribes, local stakeholders, and non-governmental organizations on fire management and habitat restoration activities, including: (i) Enhancing the capability and capacity of state, tribal, and local government, as well as non-governmental, fire management organizations, including rangeland fire protection associations and volunteer fire departments, through improved and expanded education and training; and (ii) Improving coordination among all partners involved in rangeland fire management to further improve safety and effectiveness.

b. Utilize risk-based, landscape-scale approaches to identify and facilitate investments in fuels treatments, fire suppression capabilities, and post-fire stabilization, rehabilitation, and restoration in the Great Basin.

c. Seek to reduce the likelihood, size, and severity of rangeland fires by addressing the spread of cheatgrass and other invasive, non-native species.

d. Commit wildland fire management resources and assets to prepare for and respond to rangeland fires.

e. Advance the development and utilization of technologies for identifying areas of high ecological and habitat value in sagebrush-steppe ecosystems to enhance fire prevention and sage-grouse habitat protection efforts.

f. Apply science and research to improve the identification and protection of resistant and resilient sagebrush-steppe landscapes and the development of biocontrols and other tools for cheatgrass control to improve capability for long-term restoration of sagebrush-steppe ecosystems.

g. To the extent practicable, utilize locally-adapted seeds and native plant materials appropriate to the location, conditions, and management objectives for vegetation management and restoration activities, including strategic sourcing for acquiring, storing, and utilizing genetically-appropriate seeds and other plant materials native to the sagebrush-steppe ecosystem.

h. Encourage efforts to expedite processes, streamline procedures, and promote innovations that can improve overall rangeland fire prevention, suppression and restoration efficiency and effectiveness.

i. Explore opportunities to pilot new strategies to reduce the threat of invasive, non-native plant species and rangeland fire to sagebrush-steppe ecosystems and Greater sage-grouse conservation, including enhanced use of veteran fire crews and youth conservation teams, and efforts to further public-private partnerships to expand capacity for improved fire management.

j. Establish protocols for monitoring the effectiveness of fuels management, post-fire, and long-term restoration treatments and a strategy for adaptive management to modify management practices or improve land treatments when necessary.

Sec. 6 **Rangeland Fire Task Force**. A Rangeland Fire Task Force (Task Force) is hereby established and is chaired by the Deputy Secretary. Members of the Task Force shall include: Assistant Secretary – Policy, Management and Budget, Assistant Secretary – Land and Minerals Management, Assistant Secretary for Fish and Wildlife and Parks, Assistant Secretary – Water and Science, and Assistant Secretary – Indian Affairs. The Task Force will do the following:

a. Develop a science-based strategy to reduce the threat of large-scale rangeland fire to habitat for the Greater sage-grouse and the sagebrush-steppe ecosystem through effective rangeland management (including the appropriate use of livestock), fire prevention, fire suppression, and post-fire restoration efforts at a landscape scale.

b. Conduct a comprehensive review of the existing programs, policies, and practices associated with current efforts to prevent, suppress, and restore rangeland fire-impacted sagebrush-steppe, including the outcomes of the recent rangeland fire conference *The Next Steppe: Sage-grouse and Rangeland Fire in the Great Basin*, and utilize the experience of the conference participants; and the expertise of the practitioners and senior policy groups in this effort.

c. Seek input from the U.S. Geological Survey and individual Bureau Fire Directors in the Department; the U.S. Forest Service and the Natural Resources Conservation Service in the

Department of Agriculture; various state wildland fire agencies and programs; the offices of the governors in the states most threatened by rangeland fire, including California, Oregon, Nevada, Utah, and Idaho, as well as the Western Governors' Association; affected American Indian tribes; scientists; and local, community-based fire organizations such as the rangeland fire protection associations, weed collaboratives, native seed production organizations, soil and water conservation districts, and various stakeholder groups with interest and expertise in rangeland fire prevention, suppression, and rangeland restoration.

Sec. 7 **Implementation Plan, Deliverables and Report**.

a. No later than February 1, 2015, the Task Force will provide a detailed plan for implementing this Order that includes a process for tribal consultation.

b. The Task Force will provide to the Secretary two reports that outline actions that can be accomplished prior to the onset of the 2015 Western fire season, actions that can be accomplished prior to the onset of the 2016 Western fire season, and actions that will require a longer period for implementation. At a minimum, these actions are to include the following:
(i) Design and implement comprehensive, integrated fire response plans for the Fire and Invasives Assessment Tool evaluation areas in the Great Basin subject to fire and invasive species;
(ii) Provide clear direction on the prioritization and allocation of fire management resources and assets; (iii) Expand the focus on fuels reduction opportunities and implementation; (iv) Fully integrate the emerging science of ecological resilience into design of habitat management, fuels management, and restoration projects; (v) Review and update emergency stabilization and burned area rehabilitation policies and programs to integrate with long-term restoration activities;
(vi) Commit to multi-year investments for the restoration of sagebrush-steppe ecosystems, including consistent long-term monitoring protocols and adaptive management for restored areas;
(vii) Implement large-scale experimental activities to remove cheatgrass and other invasive annual grasses through various tools; (viii) Commit to multi-year investments in science and research; and
(ix) Develop a comprehensive strategy for acquisition, storage, and distribution of seeds and other plant materials.

c. No later than March 1, 2015, the Task Force will present its initial report on actions that will be implemented prior to the 2015 Western fire season. Individual bureaus are also encouraged to take immediate action to implement improvements within their respective areas of responsibility before the initial report is issued.

d. No later than May 1, 2015, the Task Force will present its final report on activities that will be implemented prior to the 2016 Western fire season, and longer term actions to implement the policy and strategy set forth in this Order, including to ensure continued implementation of approved actions associated with the strategy.

Sec. 8 **Implementation**. The Deputy Secretary is responsible for implementing all aspects of this Order. This responsibility may be delegated as appropriate. This Order does not alter or affect any existing duty or authority of individual Assistant Secretaries or bureaus.

Sec. 9 **Effect of the Order**. This Order is intended to improve the internal management of the

Department. This Order and any resulting report or recommendations are not intended to, and do not, create any right or benefit, substantive or procedural, enforceable at law or equity by a party against the United States, its departments, agencies, instrumentalities or entities, its officers or employees, or any other person. To the extent there is any inconsistency between the provisions of this Order and any Federal laws or regulations, the laws or regulations will control.

Sec. 10 **Expiration Date**. This Order is effective immediately. It will remain in effect until its provisions are converted to the Departmental Manual, or until it is amended, superseded or revoked, whichever occurs first.

Sally Jewell

Secretary of the Interior

Date: JAN 5 2015

Characterization of montane ecosystems, their microclimates, and wildlife distribution and abundance across the hydrographic Great Basin

This project retrieves four years of data from over 200 temperature sensors nested within 28 sites across ~40 million hectares of the hydrographic Great Basin. The sensors span all major aspects and up to 700 m of elevation within sites, and occur in numerous management jurisdictions in 18 mountain ranges plus other areas not in ranges.

Photo courtesy of Thomas P. Albright

This project:

- Quantifies the variability of climate at micro-, meso-, and macroscales across the Basin, and across diel, seasonal, and interannual periods.
- Informs management and conservation efforts, in terms of helping calibrate and refine the climatic 'stage' upon which all biological 'actors' and efforts hinge (Beier and Brost 2010).
- Feeds into other bioclimatic and wildlife studies seeking to describe climate and biotic responses to it.

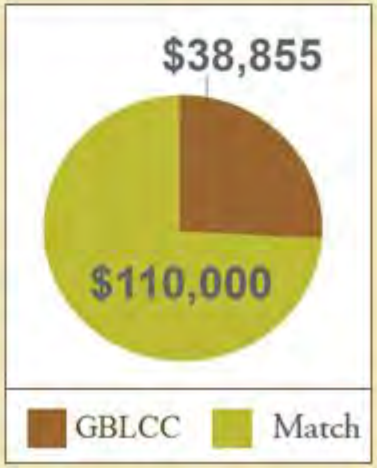
Dr. Erik Beever, US Geological Survey, NOROCK Science Center

Effects of genotype and management treatments of native and invasive herbs on success of sagebrush restoration

The increase in large wildfires at a time when habitat for Greater Sage Grouse and other species dependent on big sagebrush has also increased has led to substantial needs for big sagebrush seeds. Significant decisions on which sagebrush seed to use and on management treatments that affect competing herb layers on the same restoration sites affect the trajectory of habitat.

This project evaluates how seed source, specifically genotype and climate-of-origin, interact with landscape-scale and replicated treatments (fencing, herbicide application, mowing, and seeding).



2013

Dr. Matt Germino, US Geological Survey

Understanding the causes and consequences of cheatgrass die-offs in the Great Basin

Cheatgrass die-offs are unexplained instances of stand failure observed in areas of Nevada and Utah, where cheatgrass fails to grow even though it has been a dominant component of plant communities in the past.

This project:

- Provides information on the size and extent of historic (1985 – 2012) die-offs in the Winnemucca area using satellite imagery.
- Determines if die-offs are restoration opportunities by planting and monitoring local and commercially available native grasses in die-off areas.
- Develops predictive spatial models of die-off from analysis of satellite imagery and GIS models.

Development of tools and technology to improve the success and planning of restoration of big sagebrush ecosystems

Shrub-dominated ecosystems of the Great Basin are being threatened by disturbances, typically wildfire followed by encroachment of invasive plants (e.g., cheat grass). To mitigate these threats and future changes in the climate to big sagebrush (Artemisia tridentata), restorationists require a knowledge base and tools to inform them of the most appropriate seed sources to plant to greatly enhance the success of restoration under contemporary and future climates.

This project develops climate-responsive seed transfer zones based on associating plant quantitative traits and ecophysiological data from common gardens to the climate of the seed source.

2013

Dr. Bryce Richardson, USDA Forest Service, Rocky Mountain Research Station

Desatoya Mountains Project and the Porter Canyon Experimental Watershed

Piñon (Pinus spp.) and juniper (Juniperus spp.) (PJ) currently occupy approximately 19 million hectars in the Intermountain West. Prior to 1860, approximately 66% of what is now woodland occurred as sagebrush plant communities.

This watershed scale project:

- Documents the impact of PJ treatments in formerly sagebrush steppe communities on understory vegetation composition, hydrologic function, and surface runoff and soil erosion at the landscape scale.
- Expands the snow monitoring component to understand snow dynamics and timing of plant phenology in cut and uncut treatments
- Secures expertise to analyze existing datasets.

2013

Dr. Keirith Snyder, USDA Forest Service, Agricultural Research Station

Evaluating Species Management Guidance and Monitoring Programs for the Great Basin in Nevada

The project builds on recent, well-researched species conservation plans for Nevada (GBBO 2010, NWPT 2012) and research on scientifically based disturbance buffer recommendations to evaluate GBBO's statewide landbird monitoring program, the Nevada Bird Count.

This project will create an online open-source compendium document that will provide a scientific review of:

- Current priority species management practices in Nevada
- Status of our combined scientific knowledge of priority species' needs and gaps in that knowledge
- Adequacy of current monitoring programs of priority species.

2013

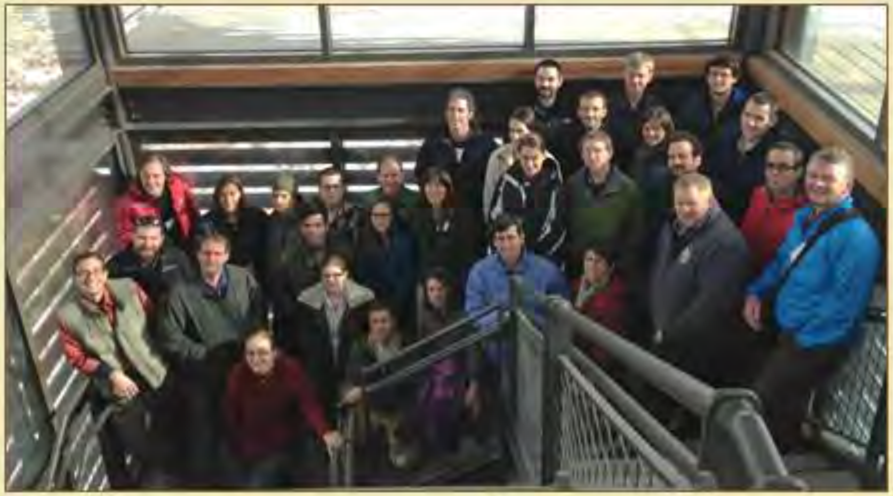
Dr. Elisabeth Ammon, Great Basin Bird Observatory

Forecasting changes in sagebrush distribution and abundance under climate change: integration of spatial, temporal, and mechanistic models

The goal of this project is to forecast the effect of climate change on the distribution and abundance of big sagebrush in order to inform conservation planning, and sage grouse management in particular, across the Intermountain West. The novelty of the work will be the synthesis of models based on spatial, temporal, and mechanistic relationships between climate and sagebrush cover.

The project will:

- Culminate in a working group meeting, bringing together land managers and researchers to draft management recommendations.
- Take advantage of mechanisms already in place to efficiently disseminate this report to management agencies.



2014

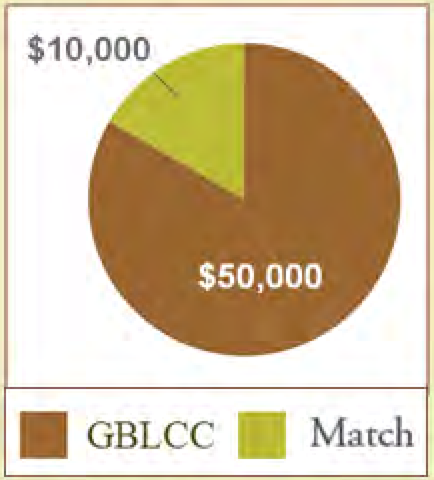
Dr. Peter Adler, Utah State University

Walker River Paiute Tribe TEK project

The Walker River Paiute Tribe has vast Traditional Ecological Knowledge (TEK) of the local area relating to plants, wildlife, fish and water. Due to the rapid rate of climate change and the impacts it has had on the reservation and gathering areas, the Tribe has not been able to keep up with the changes.

To address these challenges, the project team will:

- ➢ Develop a Walker River Vision document which will include TEK of the traditional plants, wildlife, fish and water located on the reservation and traditional hunting/ gathering areas of the Agai Dicutta Numa (Walker River Paiutes) for use in future resource management planning and cultural sustainability.
- ➢ Develop a pilot project along the Walker River on the reservation by planting willows and other traditional plants to determine best practices for re-vegetation.



2014

Marlene Begay, Walker Rive Paiute Tribe

Landscape connectivity of a sagebrush obligate: functional continuity of habitat for the pygmy rabbit

This project quantifies functional landscape connectivity of the pygmy rabbit, a sensitive, sagebrush ecosystem obligate, through integration of landscape genomic data with statistical modeling of habitat quality and connectedness.

The project team will:

- Use models to forecast the distribution and landscape connectivity of this species under various climate change scenarios.
- identify those critical areas with greatest potential to facilitate distributional shifts in response to climate change.
- Further refine the predictive capabilities of these models.

2014

Dr. Marjorie Matocq, University of Nevada Reno

Cheatgrass Stand Failure in the Great Basin: Fungal Pathogens, Carbon Dynamics, and Fungistasis

This project proposes to test the hypothesis that soil fungistasis (suppression of fungal pathogens by soil microbes in carbohydrate-limited soil) and its alleviation through natural carbohydrate augmentation (e.g., cheatgrass litter, leakage from cheatgrass roots) are the principal processes mediating patterns of cheatgrass die-off and recovery in die-off-prone areas.

The project team will use laboratory, greenhouse, and field manipulative experiments to examine the effect of soil carbohydrates on cheatgrass disease incidence.

2014

Dr. Susan Meyer, USFS Rocky Mountain Research Station

Understanding Native cultural dimensions of climate change in the Great Basin

Tribes are disproportionately affected by climate change because their economies, traditions, and even identity are heavily reliant on place-based natural resources. Changes in these resources may result in associated shifts and adaptations in tribal cultural traditions. Observations by tribal elders should lead to better understanding of how the nuances and dimensions of tribal culture in the Great Basin are affected by climate change, what contributes to vulnerability to a changing climate, and the adaptive capacity of these communities to ecological shifts.

To address these challenges, the project team will:

- Explore tribal cultural relationships and practices connected to resources and other aspects of nature that are potentially affected by climate change.
- Interview elders with two tribes in the Great Basin in order to learn how a changing environment has affected aspects of tribal culture.

Using soil climate and geospatial environmental characteristics to determine plant community resilience to fire and fire surrogate treatments

This project associates site-measured soil climate and other soil variables, and geospatially-derived site environmental characteristics with perennial herbaceous and cheatgrass cover in treated and untreated Great Basin wooded shrublands.

The project team will:

- Use vegetation and soil data already collected in SageSTEP and tree shredding studies.
- Develop models to indicate potential vegetation response to tree reduction treatments both for current and projected climate conditions for a wide range of sites.
- Develop ranges of key attributes associated with less to more resilient sites.
- Publish a guide on the SageSTEP website on how to use our models and findings as decision support tools.

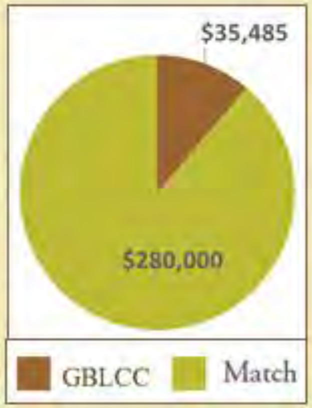
Assessment of Impacts of Feral Horses and Livestock Grazing on Sage-grouse and their Habitats: Long-term trends in sage-grouse demography and habitats on the Sheldon-Hart Mountain National Wildlife Refuge Complex and adjacent lands

This project takes advantage of historical patterns of grazing by both feral horses and livestock and new data to assess sage-grouse population dynamics and habitats under all combinations of grazing by nonnative ungulates.

The project team will:

- Use historical sage-grouse data collected from Hart Mountain before and immediately after livestock were removed in the early 1990s, and historical data from Sheldon before the irruption of feral horses in the mid 2000s.
- Add data from Hart Mountain (no nonnative ungulates for 20 years), Sheldon (no livestock but substantial feral horse impacts), and BLM land south of Sheldon NWR (grazed by both feral horses and livestock).



2014

Dr. James Sedinger - University of Nevada Reno

Using Narrative Stories to Understand Traditional Ecological Knowledge in the Great Basin

This pilot project uses a method of naïve interviewing with tribal youths to gather narrative "micro stories" from elders and key tribal members and then answering a series of carefully constructed questions that allow participants to apply context and meaning to their stories. These questions can then be analyzed quantitatively using correlational statistics to identify key themes and patterns across the narrative dataset.

This approach has several advantages including:

- ➢ It uses tribal members to gather the data.
- ➢ It provides a link between the generations to raise awareness about environmental concerns and TEK.

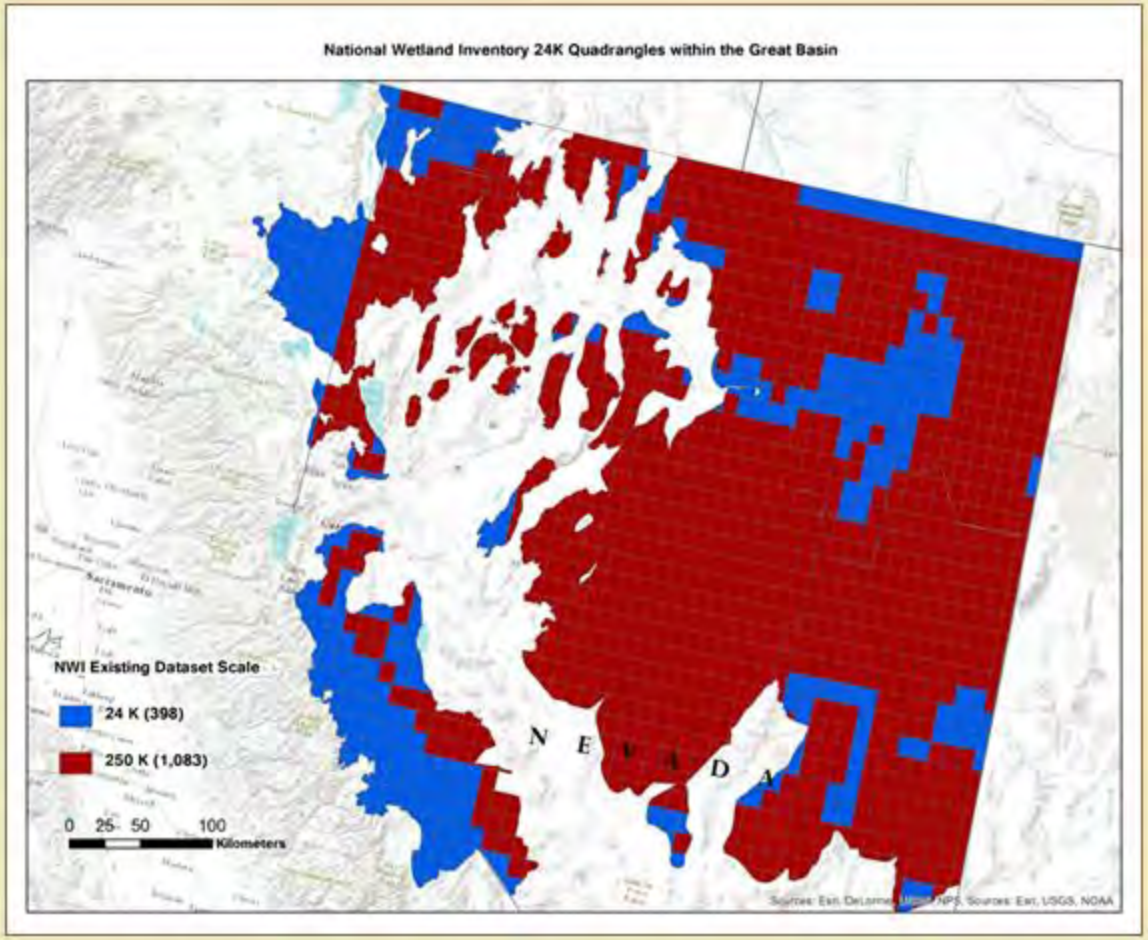
Strategic High-resolution Wetland Mapping in Sage-grouse Biologically Significant Areas of Nevada

This effort is a direct result of the GB LCC led Central Basin & Range Rapid Ecoregional Assessment Challenges and Opportunities Report (draft), which identified a paucity of available wetland and springs data layers for the CBR REA area.

This project will provide wetland mapping at high resolution (1:24,000) for 13 Million acres of sage-grouse Biologically Significant Areas (BSAs) within Nevada.



National Wetland Inventory 24K Quadrangles within the Great Basin

$ 320,000 GBLCC

Target of Opportunity

Elaine Blok, National Wetlands Inventory

Assessment and Inventory of the Great Basin Climatological Monitoring Stations for Climate Adaptation

Almost any map showing weather and climate stations for the United States shows a conspicuous lack of data in the Great Basin compared to surrounding states in all directions.

This project will:

- Create an assessment summarizing the state of climate monitoring
- Identify both areas where observation coverage is acceptable and where there are gaps in monitoring based on present future climates.

Outcomes from this effort will be incorporated into the scenarios for climate change assessment in the Great Basin (SP2 above).

$ 75,000 GBLCC

Target of Opportunity

Dr. Kelly Redmond, Western Regional Climate Center

Great Basin Springs Geospatial Database

This project builds upon the springs and seeps inventory funded by the Desert LCC.

This project will:

- Fill a significant gap in aquatic habitat information for scenario planning.
- Create a publically available geospatial database of approximately 2,000+ known Great Basin springs.
- Create a summary report on the biotic and abiotic conditions of the known springs.

$ 67,700 GBLCC

Target of Opportunity

Dr. Don Sada, Desert Research Institute

Climate Change Adaptation Planning Training for Tribes

This project will conduct two, 3-day workshops on climate change adaptation planning for up to 44 tribal members from the Great Basin.

The trainings will:

- Provide participants with an introduction to the adaptation planning process.
- Deliver templates, resource lists and other material that the tribes can use in developing an adaptation plan.
- Target tribal environmental and natural resource professionals in the Great Basin region (maximum of 22 participants per training).
- Be a mix of presentations, small- and large-group discussions, a field trip and other activities.
- Be lead by staff from the Institute for Tribal Environmental Professionals, GBLCC, tribes, and other agencies or organizations.

$ 90,000 GBLCC

Shrub-Steppe Early Succession Following Juniper Cutting and Prescribed Fire

Jonathan D. Bates · Kirk W. Davies · Robert N. Sharp

Received: 28 January 2010 / Accepted: 24 January 2011 / Published online: 23 February 2011

Abstract *Pinus-Juniperus* L. (Piñon-juniper) woodlands of the western United States have expanded in area nearly 10-fold since the late 1800's. *Juniperus occidentalis* ssp. *occidentalis* Hook. (western juniper) dominance in sagebrush steppe has several negative consequences, including reductions in herbaceous production and diversity, decreased wildlife habitat, and higher erosion and runoff potentials. Prescribed fire and mechanical tree removal are the main methods used to control *J. occidentalis* and restore sagebrush steppe. However, mature woodlands become difficult to prescribe burn because of the lack of understory fuels. We evaluated partial cutting of the woodlands (cutting 25–50% of the trees) to increase surface fuels, followed by prescribed fire treatments in late successional *J. occidentalis* woodlands of southwest Idaho to assess understory recovery. The study was conducted in two different plant associations and evaluated what percentage of the woodland required preparatory cutting to eliminate remaining *J. occidentalis* by prescribed fire, determined the impacts of fire to understory species, and examined early post-fire successional dynamics. The study demonstrated that late successional *J. occidentalis* woodlands can be burned after pre-cutting only a portion of the trees. Early succession in the cut-and-burn treatments were dominated by native annual and perennial forbs, in part due to high mortality of perennial bunchgrasses. By the third year after fire the number of establishing perennial grass seedlings indicated that both associations would achieve full herbaceous recovery. Cutting-prescribed fire combinations are an effective means for controlling encroaching late successional *J. occidentalis* and restoring herbaceous plant communities. However, land managers should recognize that there are potential problems associated with cutting-prescribed fire applications when invasive weeds are present.

Keywords *Bunchgrass* · *Cheatgrass* · *Juniperus occidentalis* · Mountain big sagebrush · Secondary succession · Western snowberry

Introduction

During the past century, woodlands in many areas of the world have undergone rapid and substantial modification as a result of land use demands, alteration of historic fire regimes, invasive species, herbivore impacts, and climate changes. Ecological concerns in several woodland environments involve their loss or degradation, with examples found in South America (Bucher and Huszar 1999; Fuentes and others 1989), Asia (Ciesla and others 1998; Ciesla 2002), Australia (Hobbs and Yates 2000), and Africa (Ciesla and others 1995; Zerihun and Backleus 1991). In these regions, efforts have been focused on restoration of woodland and savanna systems (Bucher and Huszar 1999; Ciesla and others 1998; Yates and Hobbs 1997; Zerihun and Backleus 1991). In North America, Australia, and South Africa, deciduous and coniferous woodlands have expanded into shrublands (Holmes and Cowling 1997; Miller and Rose 1995; Miller and Tausch 2001; Miller and others 2005) and grasslands (Ansley and others 2001;

Archer 1994; Burrows and others 1990; Van Auken 2000), as well as altering savanna systems as tree densities increased (Peterson and others 2007). In these ecosystems, removing or reducing encroaching woodlands is a major focus of restoration efforts to maintain shrublands and grasslands.

Pinus-Juniperus L. (Piñon-juniper) woodlands of the western United States have expanded rapidly since settlement began in the late 1800's (Miller and Tausch 2001). *Juniperus occidentalis* ssp. *occidentalis* Hook. (western juniper) woodlands found in the northern Great Basin and Columbia Plateau and have increased from about 0.3 million ha to nearly 3.5 million ha during the past 130 years in eastern Oregon, southwestern Idaho, and along the northern border of California and Nevada (Miller and others 2000). The main cause of the expansion has been attributed to reductions in fire disturbance as a consequence of grazing induced fine fuel reduction and fire suppression (Burkhardt and Tisdale 1969; Miller and Rose 1995). Prior to Euro-American settlement, mean fire return intervals (MFRI) in sagebrush steppe, sufficient to prevent *J. occidentalis* woodland development, have been estimated at between10 and 50 years (Burkhardt and Tisdale 1976; Miller and Rose 1995; Miller and others 2005; Miller and Heyerdahl 2008; Wright and Bailey 1982).

Encroaching *J. occidentalis* woodlands have been categorized into three successional phases (Miller and others 2005). Phase 1 woodlands occur when shrubs and herbaceous species are the dominant vegetation component with few trees present. In Phase 2 woodlands, *J. occidentalis* co-dominates with shrub and herbaceous layers. Phase 3 woodlands occur when *J. occidentalis* is dominant and is the primary component influencing ecological processes. The negative impacts of *J. occidentalis* invasion include increased soil erosion (Buckhouse and Mattison 1980; Pierson and others 2007), loss of wildlife habitat (Noson and others 2006; Reinkensmeyer and others 2007; Schaefer and others 2003), and reduced plant community diversity and herbaceous productivity (Bates and others 2000; Bates and others 2005; Bates and others 2006; Miller and others 2000; Miller and others 2005).

Prescribed fire, tree cutting, and a combination of these treatments have been the main methods used to control *J. occidentalis* and restore sagebrush steppe, *Populus tremuloides*(quaking aspen) woodlands, and riparian communities (Miller and others 2005). Harvesting of *J. occidentalis* as a bio-fuel for energy production has largely been confined to northeastern California. Elsewhere, commercial use of cut trees has not been economically viable because of transportation costs, inadequate infrastructure, cheaper energy alternatives, and concerns of long-term supply availability.

Fire remains a viable management option for *J. occidentalis* control in woodlands that are in early (Phase 1) to mid successional (Phase 2) stages when sufficient and continuous surface (0–1 m) fuels are present (Miller and others 2005). In late successional (Phase 3) woodlands, surface fuels are typically not adequate to sustain fire and kill trees. Clear-cutting and either removing or retaining cut trees on the ground remains the most common practice for managing late successional woodlands. Cutting treatments using chainsaws and tractor mounted shears has been successful at recovery of shrub-steppe plant communities (Rose and Eddleman 1994; Bates and others 2005; Bates and others 2007a; Miller and others 2005). Cutting and prescribed fire combinations are relatively recent methods for treating Phase 2 and Phase 3 *J. occidentalis* woodlands and have been applied extensively in eastern Oregon and northern California the past decade. These methods entail cutting about 30% of the trees to increase surface fuel levels to carry fire and kill remaining trees (Bates and others 2005; Bates and others 2007b; Miller and others 2005).

We evaluated partial cutting and prescribed fire treatments in Phase 3 *J. occidentalis* woodlands. Two levels of preparatory *J. occidentalis* cutting followed by prescribed fall fire were evaluated. The objectives of the study were to: (1) assess what percentage of woodlands required preparatory cutting to eliminate remaining *J. occidentalis* trees by prescribed fire; (2) determine fire impacts to understory species; and (3) evaluate early post-fire successional dynamics. We hypothesized the fire portion of the treatment would severely impact herbaceous understory, particularly bunchgrasses, by causing high mortality. A previous study indicated that fall burning of *P. tremuloides* woodland after partial cutting (one-third of trees cut) of encroaching *J. occidentalis* (Phase 3 woodland) eliminated the majority of perennial bunchgrasses and suppressed perennial forbs (Bates and others 2007b). Based on successional models developed for post-fire *Pinus-Juniperus* woodlands (Barney and Frischknecht 1974), we hypothesized that early succession would be characterized by high cover and abundance of annual and perennial forbs, with the potential for invasive grasses to increase because *Bromus tectorum* L. (cheatgrass) and *Poa bulbosa* L. (bulbous bluegrass) were present.

Methods

Study Area

The study was near South Mountain, Idaho, about 115 km south-southwest of Boise. Two plant associations were selected for treatment and were designated as Columbiana and Needlegrass. The Columbiana association occurred on north facing aspects, and the Needlegrass association occurred on west and southwest facing aspects. The Columbiana association was characterized by *Artemisia tridentata* Nutt. spp. *vaseyana* (Rydb.) Beetle-*Symphoricarpus oreophilus* Gray/*Achnatherum nelsonii* (Scribn.) Barkworth-*Festuca idahoensis* Elmer (mountain big sagebrush-mountain snowberry/Columbia needlegrass-Idaho fescue) plant communities. The Needlegrass association was comprised of *Artemisia tridentata* spp. *vaseyana*/*Achnatherum lettermanii* (Vasey) Barkworth-*Pseudoroegenaria spicata* (Pursh) A. Löve (Mountain big sagebrush/Letterman's needlegrass-bluebunch wheatgrass) plant communities. Both are representative of plant associations found between 1,525 and 1,800 m that are being invaded by western juniper in southwest Idaho. Elevation at the study sites was about 1,650 m. Both plant associations were dominated by post Euro-American settlement (<130 year old) *J. occidentalis* woodlands (Phase 3 woodlands). *J. occidentalis* encroachment had largely eliminated the shrub layer and depleted the understory. *Poa bulbosa*, a nonnative invasive perennial grass, was the most common herbaceous plant in both associations. *Bromus tectorum*, a nonnative annual grass, was present in trace amounts on the Needlegrass association.

Climate is typical of the northern Great Basin, with the majority of precipitation arriving between November and May, whereas summers are warm and dry. Annual precipitation (October 1–Sept. 30) at the SNOTEL site on South Mountain (12.5 km north of the study area at 1,980 m elevation) has averaged 853 mm the past 25 years (1982–2006) (Natural Resource Conservation Service [NRCS] 2009). Precipitation at the South Mountain SNOTEL, which is 330 m higher in elevation, is likely greater than our study sites, as western juniper typically grows in areas receiving 260–460 mm of annual precipitation (Miller and others 2005). Ecological site descriptions for the study's associations indicate that they were in a 305–406 mm precipitation zone (Natural Resource Conservation Service [NRCS] 2010a). Precipitation was about average during the post-fire (2003–2006) period. Soils were described to the subgroup at each site and were identified as Pachic Argixerolls. The Columbiana sites had a deeper A horizon (A1, 0–10 cm; A2, 10–30 cm) than the Needlegrass sites (A, 0–6 cm). Soil pH of the A horizon was 6.7 on the Columbiana sites and 7.4 in the Needlegrass sites.

Experimental Design and Treatment Application

The experimental design for each association was a randomized complete block design (Peterson 1985). Preparatory tree manipulations involved cutting trees with chainsaws in October 2002. Two levels of cutting were applied and included cutting 25% and 50% of post-settlement trees (based on tree density). For the Needlegrass association, treatments were Needlegrass25 (25% of the trees cut) and Needlegrass50 (50% of the trees cut). Similarly, for the Columbiana association, treatments were Columbiana25 and Columbiana50. Uncut and unburned woodlands (Needlegrass Control, Columbiana Control) were located adjacent to treated plots. Each treatment plot was 1.0 hectare in size and was replicated 5 times (40 plots total) per association. Cut trees dried for one year prior to fire application in fall 2003. Prescribed fires (strip head fire technique) were applied on October 21–22, 2003. All plots, aside from one Needlgrass25 plot, were successfully burned. A control plot in the Columbiana association was lost as a result of fire over-run. Burn conditions were typical for prescribed fire applications for treating encroaching western juniper woodlands (Table 1).

Fire severity was estimated by applying a severity index used by Bates and others (2006) for evaluating *P. tremuloides* community response to fire. The severity categories were light (1–30% mortality of perennial bunchgrasses, needles and small branches of downed *J. occidentalis* consumed, and ≤20% of western juniper killed), moderate (31–70% mortality of perennial bunchgrasses, large branches and trunks remained on downed *J. occidentalis*, and <70% of juniper killed), and high (71–100% mortality of perennial bunchgrasses, only trunks of downed *J. occidentalis* remaining, and >90% of *J. occidentalis* killed).

Table 1 Weather, fuel moisture, and fire conditions for western juniper cutting -prescribed fire treatments in mountain big sagebrush communities, South Mountain, Idaho in October, 2003

	Plant community	
	Needlegrass	Columbiana
Atmospheric conditions		
Air temperature (°C)	15–24	15–24
Relative humidity (%)	18–23	18–23
Wind speed (kph)	5–16	5–16
Soil water content (%, 0–10 cm)	7.6 ± 0.8	9.6 ± 0.5
Fuel moisture (%)		
Herbaceous	4.6 ± 0.2	5.7 ± 0.1
Surface litters	5.4 ± 0.4	5.9 ± 0.2
10 h	5.2 ± 0.4	6.0 ± 0.4
100 h	7.0 ± 0.2	7.3 ± 0.5
1000 h	10.8 ± 0.7	10.5 ± 0.6
Fire conditions		
Soil temp (2 cm below surface)		
Interspace/woodland floor (°C)	<79	79–204
Beneath cut trees (°C)	630–816	704–816
Canopy litter mats (°C)	177–630	204–704
Burn duration (min)	5–43	5–55
Flame length (m)	2–10	2–11

Perennial bunchgrass mortality estimates were derived from pre- and first year post-fire measurements of bunchgrass density.

Gravimetric soil water (0–10 cm) and fuel moisture for herbaceous fine fuels, litter, 1, 10, 100, and 1000-hour fuels were measured the day of fire application (Table 1). Fuel moisture and soil water content were determined by drying samples at 100°C to a constant weight. Weather data (RH, wind speed, temperature) were recorded prior to and during fire applications. Temperature and relative humidity were typical for fall prescribed fire application in the region. Burn duration (active flame) and flame lengths were also estimated.

Soil temperatures during the fires were estimated using Tempilaq[1] paints applied to 25 × 80 × 0.4 mm steel tags. Tempilaq paints melt or discolor at specific temperatures when heat is applied. Five sets of tags were placed 1 cm below the soil surface in each plant community at three locations. Tags were placed in interspaces, beneath live trees, and beneath cut trees. Sets consisted of 20 individual indicator tags and each tag was marked with its own indicator paint. Twenty temperature paints were used from 79°C to 1093°C (intervals between temperatures varied from 14°C at the lower temperatures to about 56°C at the higher temperatures). Temperature values were etched on the metal tags for identification.

Measurements

Pre-treatment vegetation (trees, shrubs, herbaceous) measurements were collected in June 2002. Post-fire measurements were gathered in June, 2004–2006. On each treatment plot, four 50-m transects were permanently established, with transects spaced 20 m apart. Cover of *J. occidentalis* and shrubs were estimated by line intercept (Canfield 1941) along each transect. Density of mature *J. occidentalis* (>2 m height) was estimated by counting all rooted individuals along four, 6 × 50 m belt transects. Density of shrubs and juvenile *J. occidentalis* (<2 m height) were estimated by counting all rooted individuals along four, 2 × 50 m belt transects. Understory canopy cover (by species) and herbaceous perennial density (by species) was sampled inside 0.2 m^2 frames (0.4 × 0.5 m). Frames were placed every 2 m along transect lines. A species list (richness) was compiled for each treatment plot, with scientific nomenclature following the Natural Resource Conservation Service Plant Database (Natural Resource Conservation Service [NRCS] 2010b) and Hitchcock and Cronquist (1987). Herbaceous production was measured by functional group in 2006, using 15, 1-m^2 frames per treatment plot. Herbage was clipped to 4-cm stubble for perennial bunch grasses and to ground level for rhizomatous perennial grasses, annual grasses, and perennial and annual forbs.

Statistical Analysis

Repeated measures analysis of variance (PROC MIXED procedure, SAS Institute, Cary, North Carolina) for a randomized complete block design was used to test for year, treatment, and year by treatment interaction for herbaceous, shrub, and *J. occidentalis* response variables. Plant associations were analyzed separately because of differences in herbaceous composition and soil characteristics. Response variables were *J. occidentalis* cover and density, shrub cover and density, cover (species and life form, bare ground, and surface litter), and herbaceous density (species and life form). Herbaceous life forms were grouped as *Poa secunda* Vasey (Sandberg's bluegrass), *P. bulbosa*, rhizomatous perennial grasses (primarily *Poa pratensis* L. (Kentucky bluegrass)), deep-rooted perennial bunchgrasses (e.g., Idaho fescue, Columbia needlegrass, and Letterman's needlegrass), *B. tectorum*, perennial forbs, and annual forbs. An auto regressive order one covariance structure was used because it provided the best fit for data analysis (Littell and others 1996). Mean separation involved comparison of least squares using the LSMEANS statement (SAS Institute 2002). The models included block (5 blocks; $df = 4$), year ($df = 3$), treatment ($df = 2$), and year by treatment interaction ($df = 6$; with the error term $df = 92$). Because of a strong year effect, years were analyzed separately using a general linearized model (PROC GLM, SAS Institute, 2007) for a randomized complete block to simplify presentation of results and to assist in explaining interactions (model: 5 blocks, $df = 4$; 4 treatments, $df = 3$). Data were tested for normality using the SAS univariate procedure. Data not normally distributed were arcsine square-root transformed to stabilize variance. Back transformed means are reported. Statistical significance for all tests was set at $P < 0.05$.

Results

Juniper Removal and Fire Severity

The burn treatments in both associations eliminated almost all remaining *J. occidentalis* trees, regardless of cutting level. On the Columbiana association, the fires killed 95–99% of the remaining trees, and *J. occidentalis* cover was reduced by 99% (Fig. 1a, b). On the Needlegrass

[1] Tempilaq paints are manufactured by Tempil, South Plainfield, New Jersey, 07080, USA. Mention of trade names does not imply endorsement by USDA-ARS, Eastern Oregon Agricultural Research Center, and Oregon State University.

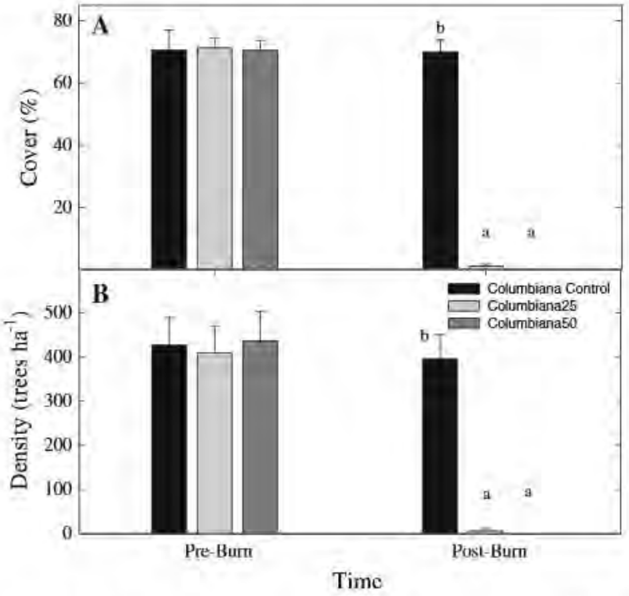

Fig. 1 Pre-fire and post-fire western juniper cover (**a**) and density (**b**) for the Columbiana plant association, South Mountain, Idaho (2002–2006). Treatments are Columbiana Control (untreated control), Columbiana 25 (25% cut and prescribed burn), and Columbiana 50 (50% cut and prescribed burn). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

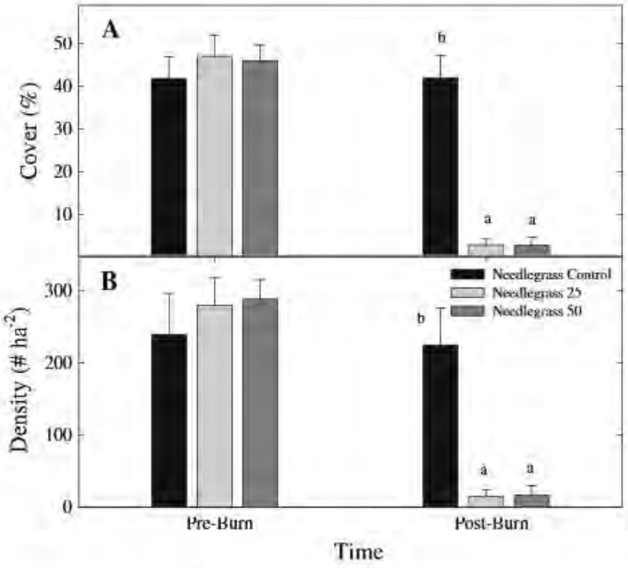

Fig. 2 Pre-fire and post-fire western juniper cover (**a**) and density (**b**) for the Needlegrass plant association, South Mountain, Idaho (2002–2006). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

association, fires killed 90–100% of the remaining trees, and *J. occidentalis* cover was reduced by 90–100% (Fig. 2a, b). In both plant associations, cut trees were either fully consumed or only the trunks remained. Perennial bunchgrass mortality exceeded 80% on the Columbiana plant association and all surface litter was consumed. Fires on the Columbiana association were judged to have been of high severity. Although litter and fuel consumption were largely complete in the Needlegrass association, mortality of perennial bunchgrasses was about 50%, thus, fire severity was concluded to be moderate. Soil temperatures during the fire were greater beneath cut trees and in canopy litter mats around stumps or live trees than the interspace and woodland floor. In the Needlegrass association, interspaces between trees were primarily bare ground, and soil temperature did not exceed 79°C. In both associations, soil temperatures (2 cm depth) beneath cut trees exceeded 704°C.

Columbiana Association: Herbaceous and Shrub Dynamics

Cover of perennial bunchgrasses ($P = 0.839$) and perennial forbs ($P = 0.958$) did not differ among the treatments, although cover increased by 100–130% and 100–180% in 2005 and 2006, respectively (Fig. 3a, b; $P < 0.0001$). Perennial forb species that had greater cover in the Columbiana25 and Columbiana50 treatments after fire than the control were *Astragalus lentiginosus* Dougl. (specklepod milkvetch) (15% greater; $P = 0.040$), *Lupinus arbustus* L. (spur lupine) (20% greater; $P = 0.019$), and *Hydrophyllum capitatum* Dougl. (ballhead waterleaf) (10% greater; $P = 0.005$). Cover of *P. bulbosa* was reduced by about 70% in both cut-burn treatments (Fig. 3c; $P < 0.001$). Annual forb cover was 4–10-fold greater in the cut-and-burn treatments in the second and third year after fire (Fig. 3d; $P < 0.0001$). Total herbaceous cover was 70–100% greater in both cut-and-burn treatments in the second and third year after fire (Fig. 3e; $P < 0.001$). Annual species that had greater cover in both cut-burn treatments than the Columbiana control were *Collinsia parviflora* (Lindl) (blue eyed Mary) (2–7 fold greater; $P = 0.042$), *Collomia linearis* Nutt. (narrow-leaf collomia) (10–150 fold greater; $P = 0.001$), *Claytonia perfoliata.* (miner's lettuce) (2–15 fold greater; $P = 0.001$), *Epilobium minutum* (Lindl. ex Lehm) (willow-weed) (2–15 fold greater; $P = 0.017$), and *Cryptantha* spp. (Lehm.) (>1000 fold greater; $P < 0.001$). Other species and herbaceous functional groups exhibited neither treatment differences nor changes over time. Bare ground was 80–300% greater in the treated plots than the Columbiana control after fire ($P < 0.001$; Fig. 4a). The increase in bare ground resulted from a >90% reduction of *J. occidentalis* litter in the cut-burn treatments ($P < 0.001$; Fig. 4b). Herbaceous litter was 2–2.5 fold higher in the cut-burn treatments than the Columbiana control in 2006 ($P < 0.001$; Fig. 4c).

Perennial bunchgrass density was reduced by 70–85% after fire, thus, the Columbiana25 and Columbiana50

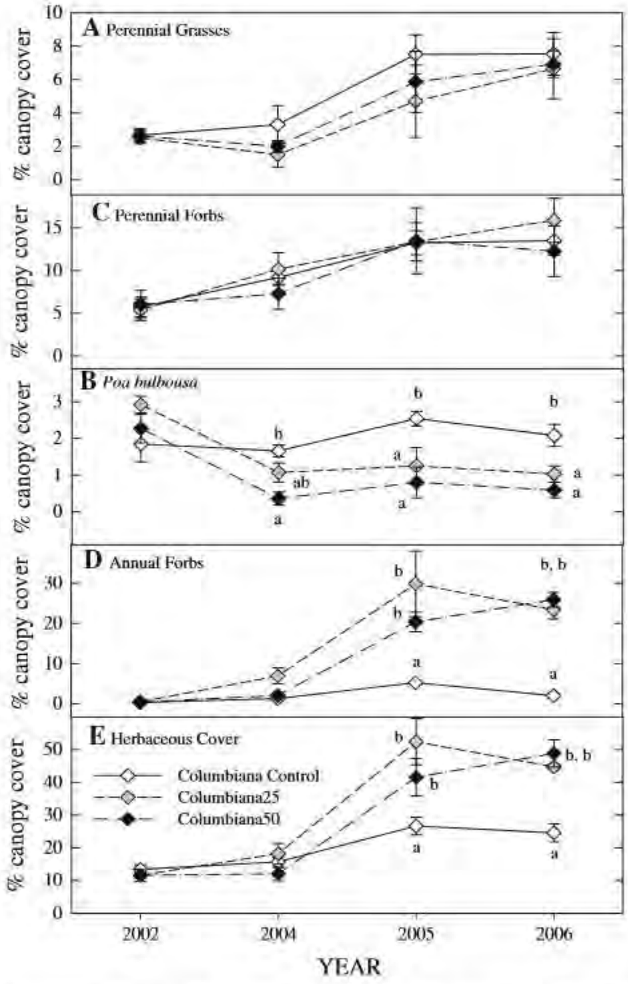

Fig. 3 Functional group cover (%) for the Columbiana plant association, South Mountain, Idaho (2002–2006): **a** perennial grasses; **b** bluegrass spp. (*P. bulbosa* and *P. secunda*); **c** perennial forbs; **d** annual forbs; and (**e**) total herbaceous. Treatments are Columbiana Control (untreated control), Columbiana 25 (25% cut and prescribed burn), and Columbiana 50 (50% cut and prescribed burn). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

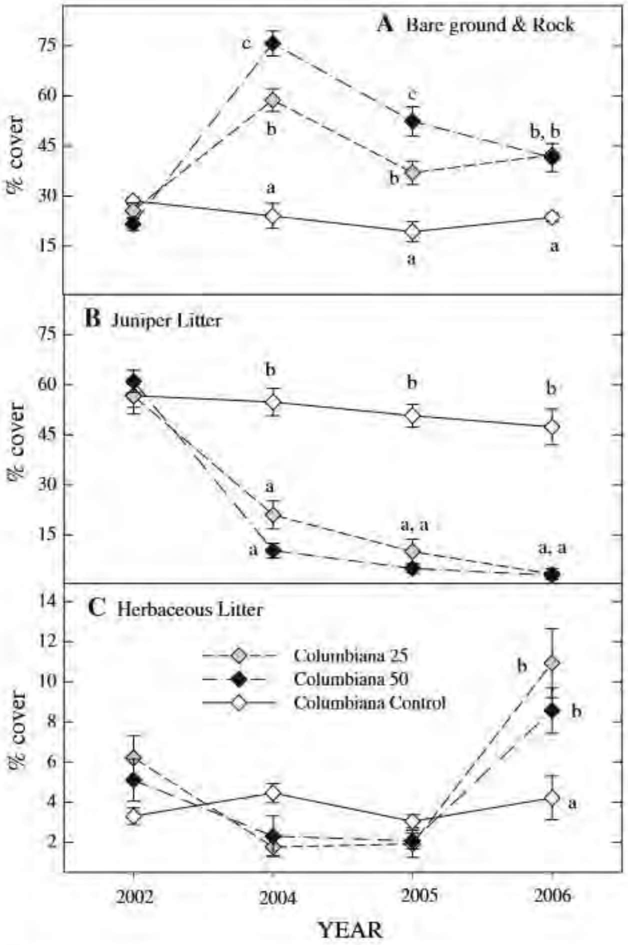

Fig. 4 Bare ground and litter covers (%) for the Columbiana plant association, South Mountain, Idaho (2002–2006): **a** bare ground and rock; **b** juniper litter; and **c** herbaceous litter. Treatments are Columbiana Control (untreated control), Columbiana 25 (25% cut and prescribed burn), and Columbiana 50 (50% cut and prescribed burn). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

treatments were less than the Columbiana control ($P = 0.002$; Fig. 5a). In the third year after fire, bunchgrass grass seedling density was 100–180-fold greater in the cut-and-burn treatments indicating that perennial grasses were recovering rapidly ($P < 0.0001$; Fig. 5b). Perennial forb density was 2-fold greater in the Columbiana control than the Columbiana25 treatment in 2006 ($P = 0.003$; Fig. 5c). *Poa bulbosa* density was reduced by 95% in both cut-and-burn treatments after fire ($P = 0.008$). The number of perennial forb ($P = 0.027$), annual forb ($P < 0.001$), and total herbaceous ($P < 0.001$) species in all treatments increased by 40–60% between 2002 and other measurement years but did not differ among treatments (perennial forb, $P = 0.078$, annual forb, $P = 0.265$, total herbaceous, $P = 0.251$).

Total herbaceous production was about 3-fold greater in the Columbiana25 and Columbiana50 treatments than the Columbiana control in 2006 ($P = 0.020$; Fig. 6). Annual forb biomass was the only functional group that was greater in the cut-burn treatments than the Columbiana control (15–28 fold greater; $P = 0.015$).

A. tridentata spp. *vaseyana* was eliminated by the burn treatments. However, because densities and cover values were low prior to burning, treatments did not differ ($P = 0.526$ and $P = 0.456$, respectively). *S. oreophilus* and *Chrysothamnus nauseous* (Pall) Britt. (gray rabbitbrush) resprouted after fire, however, no treatment differences were detected in density and cover. *Ceanothus*

Treatments are Columbiana Control (untreated control), Columbiana 25 (25% cut and prescribed burn), and Columbiana 50 (50% cut and prescribed burn). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

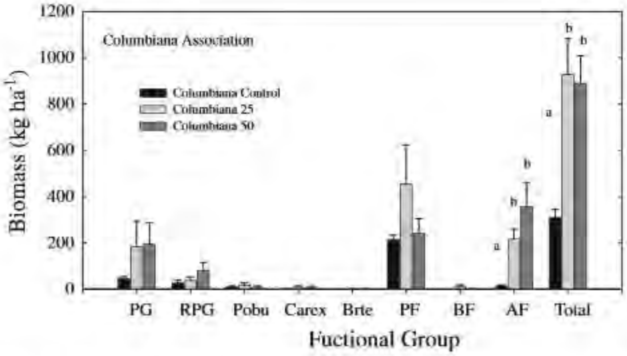

Fig. 6 Biomass (kg ha^{-1}) production in the Columbiana plant association, South mountain, Idaho, 2006. Functional groups are; perennial bunchgrass (PG); rhizomatous grasses (RPG); *P. bulbosa* (Pobu); carex species (Carex); *B. tectorum* (Brte); native perennial forb (PF); non-native biennial forb (BF); annual Forb (AF); and total herbaceous production. Treatments are Columbiana Control (untreated control), Columbiana 25 (25% cut and prescribed burn), and Columbiana 50 (50% cut and prescribed burn). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

velutinus Dougl. (snowbrush), which was not present prior to burning, increased in density in the Columbiana25 and Columbiana50 treatments ($P = 0.0056$).

Needlegrass Association: Herbaceous and Shrub Dynamics

Perennial bunchgrass cover increased about 3 fold in all treatments during the study ($P < 0.001$; Fig. 7a). *Bromus tectorum* cover did not change in response to treatment or across years ($P = 0.082$ and $P = 0.235$, respectively; Fig. 7b). *P. bulbosa* was reduced in cover by 80% in the Needlegrass25 and Needlgrass50 treatments ($P = 0.031$). Cover of perennial forbs was 2–3 fold higher in the cut-burn treatments than the Needlegrass control ($P = 0.018$; Fig. 7c). Annual forbs cover was 4–10-fold greater and total herbaceous cover was 2.5 times greater in the cut-burn treatments than the control in the second and third year after fire ($P < 0.001$ and $P = .005$, respectively; Fig. 7d, e). Bare ground increased about 15% the first year after fire in the cut-burn treatments, however, in subsequent years

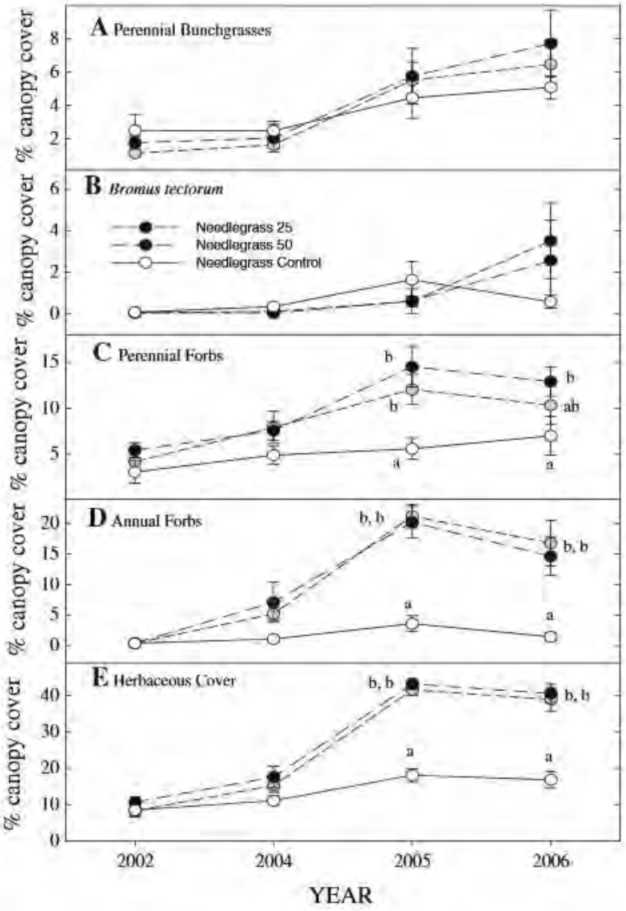

Fig. 7 Functional group cover (%) for the Needlegrass plant association, South Mountain, Idaho (2002–2006): **a** perennial grasses; **b** *B. tectorum*; **c** perennial forbs; **d** annual forbs; and **e** total herbaceous. Treatments are Needlegrass Control (untreated control), Needlegrass 25 (25% cut and prescribed burn), and Needlegrass 50 (50% cut and prescribed burn). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

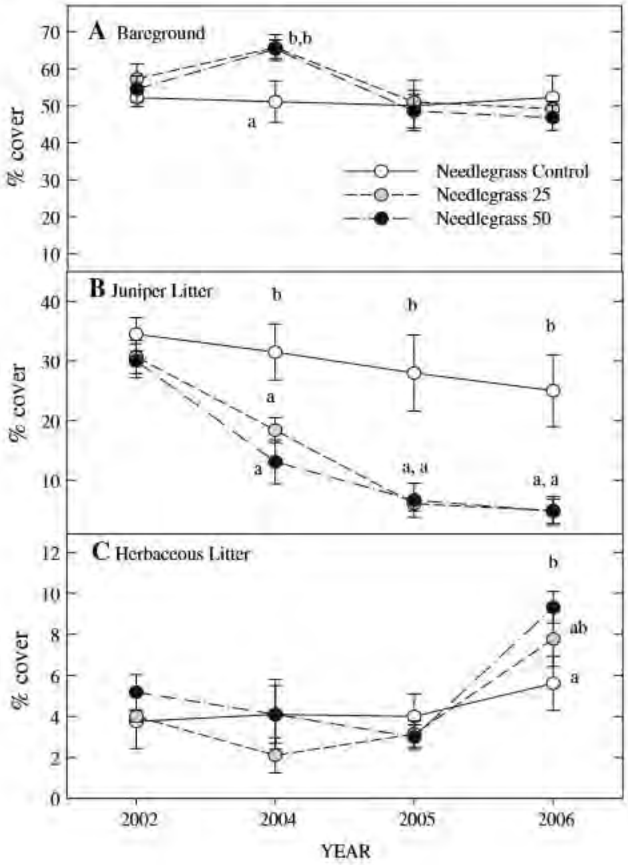

Fig. 8 Bare ground and litter covers (%) for the Needlegrass plant association, South Mountain, Idaho (2002–2006): **a** bare ground and rock; **b** juniper litter; and **c** herbaceous litter. Treatments are Needlegrass Control (untreated control), Needlegrass 25 (25% cut and prescribed burn), and Needlegrass 50 (50% cut and prescribed burn). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

there were no treatment differences ($P = 0.308$; Fig. 8a). *J. occidentalis* litter was reduced about 5-fold after fire in both cut-burn treatments ($P = 0.045$; Fig. 8b). Herbaceous litter increased in all treatments by about 50% and was greatest in the Needlgrass50 treatment the third year after fire ($P = 0.0173$; Fig. 8c). Annual forb species that increased after fire in the cut-burn treatments and were greater than the control were *C. parviflora* (2–5 fold greater, $P = 0.002$), *C. linearis* (2–7 fold greater, $P = 0.001$), *M. gracilis* (3–4 fold greater, $P = 0.005$), *Cyrptantha* spp. (100 to140 fold greater, $P < 0.001$) and *Gayophytum* spp. (4–7 fold greater, $P < 0.001$).

Perennial bunchgrass density decreased 50% after fire ($P = 0.005$) in the Needlegrass25 and Needlgrass50 treatments, and both remained less than the Needlegrass control during the study ($P = 0.0017$; Fig 9a). However, in 2006, the third year after fire, grass seedling density was 30–60 times greater in the cut-and-burn treatments than the Needlegrass control ($P = 0.023$; Fig. 9b). Densities of *P. bulbosa* ($P = 0.031$) and *P. secunda* ($P = 0.0364$) were reduced 75% and 50% respectively in the cut-burn treatments. Perennial forb density increased in all treatments after 2002 ($P < 0.001$); however the increase was greater in the cut-burn treatments than the Needlegrass control ($P = 0.018$; Fig. 9c). The number of perennial ($P < 0.001$) and annual forb species ($P < 0.001$) identified increased by 30% in 2005 and 2006 and were greater in both cut-burn treatments than the control. *A. tridentata* spp. *vaseyana* and *Purshia tridentata* (Pursh) DC. (antelope bitterbrush) remained present in the cut-burn treatments, and there were no treatment differences ($P = 0.336$). *C. velutinus* increased in density in both treatments the first growing season after fire and was greater than the Needlegrass control ($P = 0.027$).

Production of perennial bunchgrass ($P = 0.017$), perennial forbs ($P = 0.028$), annual forbs ($P = 0.022$), and total herbaceous biomass ($P < 0.001$) was greater in the Needlegrass25 and Needlgrass50 treatments in 2006 (Fig. 10). Perennial grass biomass and total herbaceous biomass were about three times greater in the cut-burn treatments than the control.

Treatments are Needlegrass Control (untreated control), Needlegrass 25 (25% cut and prescribed burn), and Needlegrass 50 (50% cut and prescribed burn). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

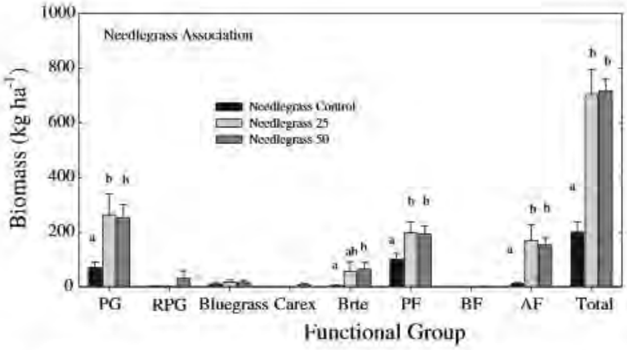

Fig. 10 Biomass (kg ha^{-1}) production in the Needlegrass plant association, South mountain, Idaho, 2006. Functional groups are; perennial bunchgrass (PG); rhizomatous grasses (RPG); *P. bulbosa* and *P. secunda* (Bluegrass); carex species (Carex); *B. tectorum* (Brte); native perennial forb (PF); non-native biennial forb (BF); annual Forb (AF); and total herbaceous production. Treatments are Needlegrass Control (untreated control), Needlegrass 25 (25% cut and prescribed burn), and Needlegrass 50 (50% cut and prescribed burn). Data are in means ± SE. Means sharing a common lower case letter are not significantly different ($P > 0.05$)

Discussion

Treatment Differences

This study demonstrated that late successional (Phase 3) *J. occidentalis* woodlands can be burned successfully after pre-cutting a portion of the trees. After drying for one year, the cut trees carried the fire, which killed most remaining *J. occidentalis*. We had expected a gradient of response in *J. occidentalis* control and understory recovery. However, the levels of *J. occidentalis* control, litter and fuel consumption, mortality of perennial bunchgrasses, and understory response were independent of cutting level because treatments within each association responded similarly to the fires.

In the Columbiana association, the lack of differences between the cut-burn treatments was likely a result of woodland characteristics, fuel conditions, and weather. The woodland floor was largely covered with a mat of *J. occidentalis* leaf litter and, relative to the Needlegrass community, the higher tree cover and density resulted in more material on the ground after cutting. Coupled with very dry conditions and high fuel consumption, the fire treatments had equally severe impacts to the understory. Perennial grass crowns were typically observed to be elevated above the soil in the *J. occidentalis* litter layer, which likely contributed to the high mortality. The impacts of the fires to the understory and early successional stages were similar to those documented for high intensity/severity fires in many forested systems of the western United States and Canada (Brown and Smith 2000). In *Pinus ponderosa* Dougl. (ponderosa pine) forest, perennial grass cover decreased as fire intensity and litter consumption increased (Armour and others 1984). In *P. tremuloides* woodland, pre-cutting one-third of encroaching *J. occidentalis* followed by prescribed fire in the fall resulted in complete consumption of the organic layer, killed almost all perennial grasses, and severely reduced perennial forb recovery (Bates and others 2006).

In the Needlegrass community, the interspace was mostly bare ground. Cutting in similar, open *J. occidentalis* stands reduces the interspace area because of increased coverage by down trees (Bates and others 1998; Bates and Svejcar 2009). Because the Needlegrass50 treatment had twice as many trees on the ground as the Needlegrass25 treatment we had expected to measure greater negative impacts of fire to understory vegetation. Although we did not differentiate among interspaces and areas occupied by cut or standing trees most of the perennial bunchgrass mortality appeared to be beneath down or standing trees, where there was an accumulation of *J. occidentalis* leaf litter. We suspect that cutting 25% of the trees compared to cutting 50% of the trees may not produce that much of a difference (less than 5%) in the amount of interspace covered by trees. This likely explains the lack of differences between the two cut-and-burn treatments in perennial grass mortality and post-fire understory response.

Western Juniper Control

Cutting a minimum of 25% of the mature trees in communities dominated by *J. occidentalis* (cover of 35–70%) was sufficient to remove the majority of remaining live trees during fall prescribed fire application. Cutting more than 25% of the trees was unnecessary when broadcast burning was applied with weather conditions typically encountered with fall prescribed fire. Burning was equally effective on slopes (Columbiana and Needlegrass sites, 10–60% slopes) and on flat ground (Columbiana sites). The 50% pre-fire cutting levels were excessive, particularly in the Columbiana plant community. In *P. tremuloides* woodland, with similar levels of cover and density of *J. occidentalis*, only a third of the trees were cut prior to prescribed fire (Bates and others 2006). Cutting less than 25% (10–20%) of the woodland trees in the Columbiana plant community would likely have been sufficient to kill remaining *J. occidentalis* under the conditions the prescribed fire was applied and may have reduced the adverse effects to the herbaceous layer. If management objectives are to retain some trees on site reducing cutting levels may also reduce fire mortality of remaining *J. occidentalis*, especially in the Needlegrass association which was a more open stand.

The plot size used in our study was small (1 ha), however, the treatments applied are readily scaled up to larger landscape projects in other *Pinus-Juniperus* woodlands. Large scale projects (300–2500 ha) conducted by federal land management agencies, involving the cutting of about 33% of the trees prior to fire, have been used in several shrub-steppe restoration studies in *J. occidentalis* woodlands (Bates and others 2006; Bates and others 2007b). Approximately 30,000 ha of *J. occidentalis* woodlands have been treated using partial cutting and prescribed fire control measures in eastern Oregon. At the larger scales, managers can adjust cutting levels or leave some woodland areas uncut to create a landscape mosaic of burned and unburned areas.

Understory Release

Secondary succession in woodland and forest ecosystems after wild or prescribed fire often varies in composition and recovery rate as a result of varying fire severity, nutrient and water availability, site characteristics, herbivory, and weather (Armour and others 1984; Barney and Frischknecht 1974; Griffis and others 2001; Koniak 1985; Oswald and Covington 1983; Sabo and others 2009). Because of severe fire effects to perennial grasses, early succession in the cut-and-burn treatments in both plant communities was largely dominated by annual and perennial forbs. These results are similar to early successional dynamics following wildfire in *Pinus-Juniperus* woodlands of Nevada (Barney and Frischknecht 1974; Koniak 1985), and ponderosa pine forests in Arizona (Griffis and others 2001; Laughlin and Fulé 2008; Sabo and others 2009). The increase in understory productivity and cover following overstory removal in *J. occidentalis* woodlands has been linked to increased soil water and nitrogen availability (Bates and others 2000; Bates and others 2002).

Both Columbiana and Needlegrass sites remain open to colonization by native and invasive species. However, because there were large numbers of perennial bunchgrass seedlings in 2006, both communities had a high recovery potential. Many perennial grass seedlings appeared to have established (i.e., seedling growth in June 2006 was the 3rd to 4th leaf stage) using criteria developed by Reis and Svejcar (1991). The reduction and lack of recovery of *P. bulbosa* after fire indicate that this species may be effectively controlled by fire treatments when present in *J. occidentalis* woodlands. Although *B. tectorum* was a minor component of herbaceous response in the Needlegrass association, in areas of litter accumulation (litter mats surrounding stumps and beneath cut trees), where perennial grasses were largely eliminated, *B. tectorum* dominated early succession. Despite presence of *B. tectorum* in these locations, perennial grass seedlings were establishing in these zones in 2006 which was likely aided by above average precipitation in late spring (Sheley and Bates 2008). In other *J. occidentalis* control projects, it has not been unusual for perennial grasses to establish and increase despite enhanced densities and biomass of *B. tectorum* (Vaitkus and Eddleman 1987; Miller and others 2005; Bates and others 2005; Bates and others 2007b; Bates and Svejcar 2009). However, there are cases when *B. tectorum* has dominated following *Pinus-Juniperus* treatment including cutting (Vaitkus and Eddleman 1987), chaining (Tausch and Tueller 1977), fire (Barney and Frischknecht 1974; Bates and others 2007b; Quinsey 1984), slash burning (Haskins and Gehring 2004), and herbicide application (Evans and Young 1985).

Differences in *B. tectorum* response and site recovery after treating *J. occidentalis* and other *Pinus-Juniperus* woodlands is likely linked to species composition and herbaceous perennial density. Bates and others (2005) determined that 2–3 bunchgrasses per m^2 were sufficient to restore the native understory after cutting Phase *3 J. occidentalis* woodlands that were susceptible to *B. tectorum* invasion. In our study, where natives dominated post-fire recovery, densities of perennial grasses were greater than 1–2 plants m^2 and perennial forbs greater than 5 plants m^2 the first year after fire. Dominance by *B. tectorum* is most likely to occur where there is little perennial herbaceous vegetation remaining after juniper treatment (Evans and Young 1985; Bates and others 2007b). Where *B. tectorum* has dominated after fire, post-fire densities of perennial grasses were less than 1 plant m^2 and perennial forbs were less than 5 plants m^2 (Bates and others 2006; Bates and others 2007a, b).

Sagebrush-Steppe Restoration

Partial cutting and prescribed fire combinations are a recent management treatment to remove Phase 3 *J. occidentalis* woodlands and restore shrub-steppe plant communities. Previously, treatments using heavy machinery or chainsaws were the most common practice for managing Phase 3 woodlands because applying controlled fires was problematic (Miller and others 2005). However, mechanical treatment of *J. occidentalis* woodlands is often more expensive compared to prescribed fire treatments. Thus, partial cutting and prescribed fire combinations provide land managers with an additional treatment option for managing other Phase 3 *Pinus-Juniperus* woodlands. One difficulty in applying this treatment is predicting plant community response. Shrub and herbaceous recovery after *J. occidentalis* control is generally predictable when the plant communities are still in the early stages (Phase 1 and 2) of woodland development and contain an intact understory of shrubs and native herbaceous species (Miller and others 2005). In fully developed woodlands (Phase 3), predicting community response is difficult because recovery is often slower and these areas are often susceptible to non-native weed invasion and dominance as a result of depleted native understories. In this study, native annual and perennial vegetation has dominated early succession. In other studies, fall burning partially cut Phase 3 woodlands severely impacted herbaceous understory vegetation, resulting in the nearly complete removal of perennial bunchgrasses and a high percentage of the perennial forbs (Bates and others 2006; Bates and others 2007b). The main understory species to respond in these studies were nonnative biennial weeds, *B. tectorum*, and native annual forbs. Haskins and Gehring (2004) measured a fourfold higher abundance of invasive annuals in burned *Pinus-Juniperus* slash areas compared to unburned slash treatments. In *P. ponderosa* forests of Arizona, invasive species tend to increase in areas of greater fire severity (Bataineh and others 2006; Griffis and others 2001; Sabo and others 2009). To augment herbaceous recovery after fire, particularly on sites with high bunchgrass mortality, seeding should be considered. On Columbiana and Needlegrass associations, seeding was successful at establishing high densities of perennial bunch grasses and forbs (Sheley and Bates 2008).

Herbaceous recovery after *J. occidentalis* control requires patience. Delays of several years are typical before understories fully respond to tree removal (Barney and Frischknecht 1974; Bates and others 2000; Bates and others 2005; Bates and others 2007a; Bates and Svejcar 2009; Koniak 1985). Treated *J. occidentalis* sites with depleted understories have taken six years for perennial grass densities to recover and over 10 years for perennial grass cover to be restored (Bates and others 2005). Bunchgrasses require two to three years to produce large amounts of viable seed following fire or tree cutting (Bates 2005; Bates and others 2009). Recruitment of new bunchgrasses tends to occur the third to fifth year following *J. occidentalis* treatment (Bates and others 2005; Bates and Svejcar 2009). In our study, a similar post-fire response occurred in the Columbiana and Needlegrass associations.

Altering season of prescribed fire application in Phase 3 *J. occidentalis* woodlands has been shown to reduce fire impacts on native plant species. Cutting followed by winter or early spring burning when soils were frozen and/or above field capacity lowered mortality of native plants and resulted in faster understory recovery (Bates and others 2006; Bates and Svejcar 2009). Winter and spring applied fires were not as successful at killing remaining *J. occidentalis* trees and juveniles compared to fall burned treatments because of lower fire severities and higher fuel moisture (Bates and others 2006). Thus, managers should be aware that *Pinus-Juniper* trees will likely reoccupy sites treated by winter-spring burning in a shorter time period than fall burned areas. However, if restoration objectives are to retain some *J. occidentalis* or other *Pinus-Juniper* species on site, then winter and spring burning provides managers with additional treatment options.

Recovery periods of shrub species on both community types will likely take longer than reported in the literature because shrub cover and density were already suppressed by *J. occidentalis* dominance and the fire killed non-sprouting species. Recovery of non-sprouting shrubs, particularly *A. t.* ssp. *vaseyana,* may exceed 40 years due to fire-caused mortality of remaining shrubs and a depleted seed bank. Typical recovery periods for *A. t.* ssp. *vaseyana* canopy cover have been reported to be between 20 and 40 years (Harniss and Murray 1973; Lesica and others 2007; Ziegenhagen and Miller 2009). Sprouting shrubs, especially *S. oreophilus* and *C. nauseous,* will likely recover to pre-invasion conditions faster because there was little fire caused mortality and these species typically increase after fire (Anderson and Bailey 1979; Sieg and Wright 1996; Wright and Bailey 1982). The emergence of *C. velutinus* was probably due to its presence in the seed bank. Viable seed of *C. velutinus* can be stored in soils for at least 200 years (Bradley and others 1992; Kramer and Johnson 1987). Browsing by *Odocoileus hemionus* (mule deer) and *Cervus canadensis nelsoni* (Rocky Mountain elk) was restricting further establishment and growth of *C. velutinous*.

Conclusions

Cutting-prescribed fire combinations are an effective means for controlling encroaching Phase 3 *J.* occidentalis woodlands, and could potentially be applied in other *Pinus-Juniperus* woodlands. When burning sites with comparable levels of *J. occidentalis* cover (35–70%) and density (150–475 trees ha^{-1}) a maximum of about one-quarter of the trees should be cut to carry prescribed fire. On similar plant associations, this method of *J. occidentalis* control can initially be expected to stimulate perennial and annual forbs. Perennial grasses will take longer to recover because of reduced densities that are a product of *J. occidentalis* dominance prior to treatment and fire-caused mortality. However, the high mortality sustained by herbaceous perennials, particularly bunchgrasses, increases the potential for cheatgrass or other exotic weeds to dominate areas (Bates and others 2006; Bates and others 2007b). Cutting and burning combinations are not recommended in areas where exotic weeds threaten to dominate after fire. When making site selections for *J. occidentalis* control, managers must carefully consider the potential benefits and problems associated with cutting-prescribed fire applications. If weeds are a threat then winter burning of cut trees or cutting and leaving trees to minimize perennial grass mortality is probably the best option. Because removing Phase 3 woodlands is difficult and expensive and offers less predictable results, managers involved with shrub-steppe restoration should first target *J. occidentalis* control efforts in Phase 1 and Phase 2 successional woodlands. These stages will generally have more intact and complete herbaceous and shrub layers, making restoration efforts more predictable and successful.

Acknowledgments The research was supported by the Agricultural Research Service, private landowners, and the state of Idaho. Many thanks are extended to the Tim and Bill Lowry (Jordan Valley, Oregon) and Idaho Department of State Lands for providing their properties for conducting the study. We recognize the many student summer range technicians who assisted in the field and laboratory for the study: K Adams, J Anderson, J Duchene, E Ersch, K Haile, J Hobbs, R Kessler, K Mumm, J Pyrse, E Rhodes, B Smith, J Svejcar, M Villagrana, C Williams, and L Zeigenhagen. Almost all tree cutting was done by one of the best timber fallers in Oregon, Steve Basey. Dustin Johnson and Claire Poulson were invaluable in fire application and fire control. In addition, we would like to thank Dr. Chad Boyd, Dr. Dave Ganskopp, and three anonymous reviewers for their valuable comments on previous drafts of this manuscript. The Eastern Oregon Agricultural Research Center is jointly funded by the USDA-Agricultural Research Service and Oregon State Agricultural Experiment Station. Mention of a proprietary product does not constitute a guarantee or warranty of the product by USDA-ARS, Oregon State University, or the authors and does not imply approval to the exclusion of other products.

Hi All,

Please see the attached revised Chap 1 drop in language for fire that Kristy wrote. There are now two versions--one for RM, and one for GB. She seems to have addressed our comments. Please take a look and let me know if you have any more comments. We can drop this in next week.

Michael

Ok, not quite this morning but here's what I've come up with. You'll see that there are now two paragraphs - one with a GB flavor and one with a RM flavor.

Hi Kristy,

Thanks so much for drafting something. I shared it with our small group of sage-grouse project managers. Their feedback is below. Take a look and let me know if you can work something up to address the comments. Seems like just a couple tweaks. Thanks again, Michael

- Is it possible to make two of these, one for GB (UT, NV, ID, OR) and one for RM (WY, CO, MT), to highlight the importance of fire management in the GB. Also, please make clear whether the FIAT applies to just the GB or both the GB and RM.
- Is it possible to add more intro and schedule related to FIAT - where did it come from (was it discussed in the drafts?), where is it going, etc.
- I think the Secretarial Order stuff looks good, could add another sentence (such as examples of what activities or how the SO will ensure on-the-ground benefits to habitat)

Hi Folks –

After discussion with the FWS today, some slight changes to the prescribed fire drop-in language were requested in a) and b) below. Please use this language as your new drop in language – verbatim – as is below.

Sorry that this is such a cluster…..but what has to be, has to be!

Thanks for your patience…..I have a sneaking feeling that this won't be our last request.

Lauren

Subject: Prescribed Fire Language

Lauren and Matt -

Please direct the planners to use the following updated drop-in language regarding the use of prescribed fire. Thank you for your patience.

"If prescribed fire is used in Greater Sage-Grouse habitat, the NEPA analysis for the Burn Plan will address:

- *why alternative techniques were not selected as a viable options;*
- *how Greater Sage-Grouse goals and objectives would be met by its use;*

- *how the COT Report objectives would be addressed and met;*
- *a risk assessment to address how potential threats to Greater Sage-Grouse habitat would be minimized.*

a) Prescribed fire as a vegetation or fuels treatment shall only be considered after the NEPA analysis for the Burn Plan has addressed the four bullets outlined above. Prescribed fire could be used to meet specific fuels objectives that would protect Greater Sage-Grouse habitat in PHMAs (e.g., creation of fuel breaks that would disrupt the fuel continuity across the landscape in stands where annual invasive grasses are a minor component in the understory, burning slash piles from conifer reduction treatments, used as a component with other treatment methods to combat annual grasses and restore native plant communities).

b)Prescribed fire in known winter range shall only be considered after the NEPA analysis for the Burn Plan has addressed the four bullets outlined above. Any prescribed fire in winter habitat would need to be designed to strategically reduce wildfire risk around and/or in the winter range and designed to protect winter range habitat quality."

Greater Sage-Grouse Wildfire, Invasive Annual Grasses & Conifer Expansion Assessment

GBR_PUB_0661
7.16

June 2014

Suggested Citation:

Greater Sage-Grouse Wildfire, Invasive Annual Grasses & Conifer Expansion Assessment (Fire and Invasive Assessment Tool (FIAT)). June 2014. Prepared by Fire and Invasive Assessment Team (Appendix 5). 43 pages.

Introduction and Background

The purpose of this assessment is to identify priority habitat areas and management strategies to reduce the threats to Greater Sage-Grouse resulting from impacts of invasive annual grasses, wildfires, and conifer expansion. The Conservation Objectives Team (COT) report (USFWS 2013) and other scientific publications identify wildfire and conversion of sagebrush habitat to invasive annual grass dominated vegetative communities as two of the primary threats to the sustainability of Greater Sage-Grouse (*Centrocercus urophasianus*, hereafter sage-grouse) in the western portion of the species range. For the purposes of this assessment protocol, invasive species are limited to, and hereafter referred to, as **invasive annual grasses** (e.g., primarily cheatgrass [*Bromus tectorum*]). Conifer expansion (also called encroachment) is also addressed in this assessment.

The United States Fish and Wildlife Service (USFWS) will consider the amelioration of impacts, location and extent of treatments, degree of fire risk reduction, locations for suppression priorities, and other proactive measures to conserve sage-grouse in their 2015 listing decision. This determination will be made based in part upon information contained in the United States (US) Department of the Interior, Bureau of Land Management (BLM) resource management plan (RMP) amendments and Forest Service land resource management plan (LRMP) amendments, including this assessment.

This assessment is based in part on National Resources Conservation Service (NRCS) soil surveys that include geospatial information on soil temperature and moisture regimes associated with resistance and resiliency properties (see following section on *Soil Temperature and Moisture Regimes)*. While this assessment is applicable across the range of sage-grouse, the analysis is limited to Western Association of Fish and Wildlife Management Agencies' (WAFWA) Management Zones III, IV, and V (roughly the Great Basin region) because of the significant issues associated with invasive annual grasses and the high level of wildfires in this region. The utility of this assessment process is dependent on incorporating improved information and geospatial data as it becomes available. Although the resistance and resilience concepts have broad applications (e.g., infrastructure development), this assessment is limited to developing strategies to reduce threats to sage-grouse habitat (e.g., invasive annual grasses and wildfires).

Draft Greater Sage-Grouse Environmental Impact Statements (EISs) contain a suggested framework in the appendices ("Draft Greater Sage-Grouse Wildland Fire and Invasive Species Assessment") that provided a consistent approach to conduct these assessments. The current protocol was developed by the Fire and Invasive Species Team (FIAT), a team of wildland fire specialists and other resource specialists and managers, to specifically incorporate resistance to invasive annual grasses and resilience after disturbance principles into the assessment protocol. This protocol is also referred to as the Fire and Invasive Tool. In October 2013, the BLM, Forest Service, and USFWS agreed to incorporate this approach into the final EISs.

The cornerstone of the FIAT protocol is recent scientific research on resistance and resilience of Great Basin ecosystems (Chambers et al. 2014) and the USFWS-sponsored project with the Western Association of Fish and Wildlife Agencies (WAFWA) to assemble an interdisciplinary team to provide additional information on wildland fire and invasive plants and to develop strategies for addressing these issues. This interagency collaboration between rangeland scientists, fire specialists, and sage-grouse biologists resulted in the development of a strategic, multi-scale approach for employing ecosystem resilience and resistance concepts to manage threats to sage-grouse habitats from wildfire and invasive annual grasses (Chambers et al. 2014). This paper has been published as a Forest Service Rocky Mountain Research Station General Technical Report RMRS-GTR-326 and is posted online at http://www.fs.fed.us/rm/pubs/rmrs_gtr326.pdf. It serves as the reference and basis for the protocol described in this assessment.

The assessment process sets the stage for:

- Identifying important sage-grouse occupied habitats and baseline data layers important in defining and prioritizing sage-grouse habitats
- Assessing the resistance to invasive annual grasses and resilience after disturbance and prioritizing focal habitats for conservation and restoration
- Identifying geospatially explicit management strategies to conserve sage-grouse habitats

Management strategies are types of actions or treatments that managers typically implement to resolve resource issues. They can be divided into proactive approaches (e.g., fuels management and habitat recovery/restoration) and reactive approaches (e.g., fire operations and post-fire rehabilitation). Proactive management strategies can favorably modify wildfire behavior and restore or improve desirable habitat with greater resistance to invasive annual grasses and/or resilience after disturbances such as wildfires. Reactive management strategies are employed to reduce the loss of sage-grouse habitat from wildfires or stabilize soils and reduce impacts of invasive annual grasses in sage-grouse habitat after wildfires. Proactive management strategies will result in long-term sage-grouse habitat improvement and stability, while reactive management strategies are essential to reducing current impacts of wildfires on sage-grouse habitat, thus maintaining long-term habitat stability. Management strategies include:

Proactive Strategies-

1. **Fuels Management** includes projects that are designed to change vegetation composition and/or structure to modify fire behavior characteristics for the purpose of aiding in fire suppression and reducing fire extent.

2. **Habitat Restoration/Recovery**
   a. Recovery, referred to as passive restoration (Pyke 2011), is focused on changes in land use (e.g., improved livestock grazing practices) to achieve a desired outcome where the plant community has not crossed a biotic or physical threshold.
   b. Restoration is equivalent to active restoration (Pyke 2011) and is needed when desired species or structural groups are poorly represented in the community and reseeding, often preceded by removal of undesirable species, is required. Note: The Fuels Management program supports recovery/restoration projects through its objective to restore and maintain resilient landscapes.

Reactive Strategies-

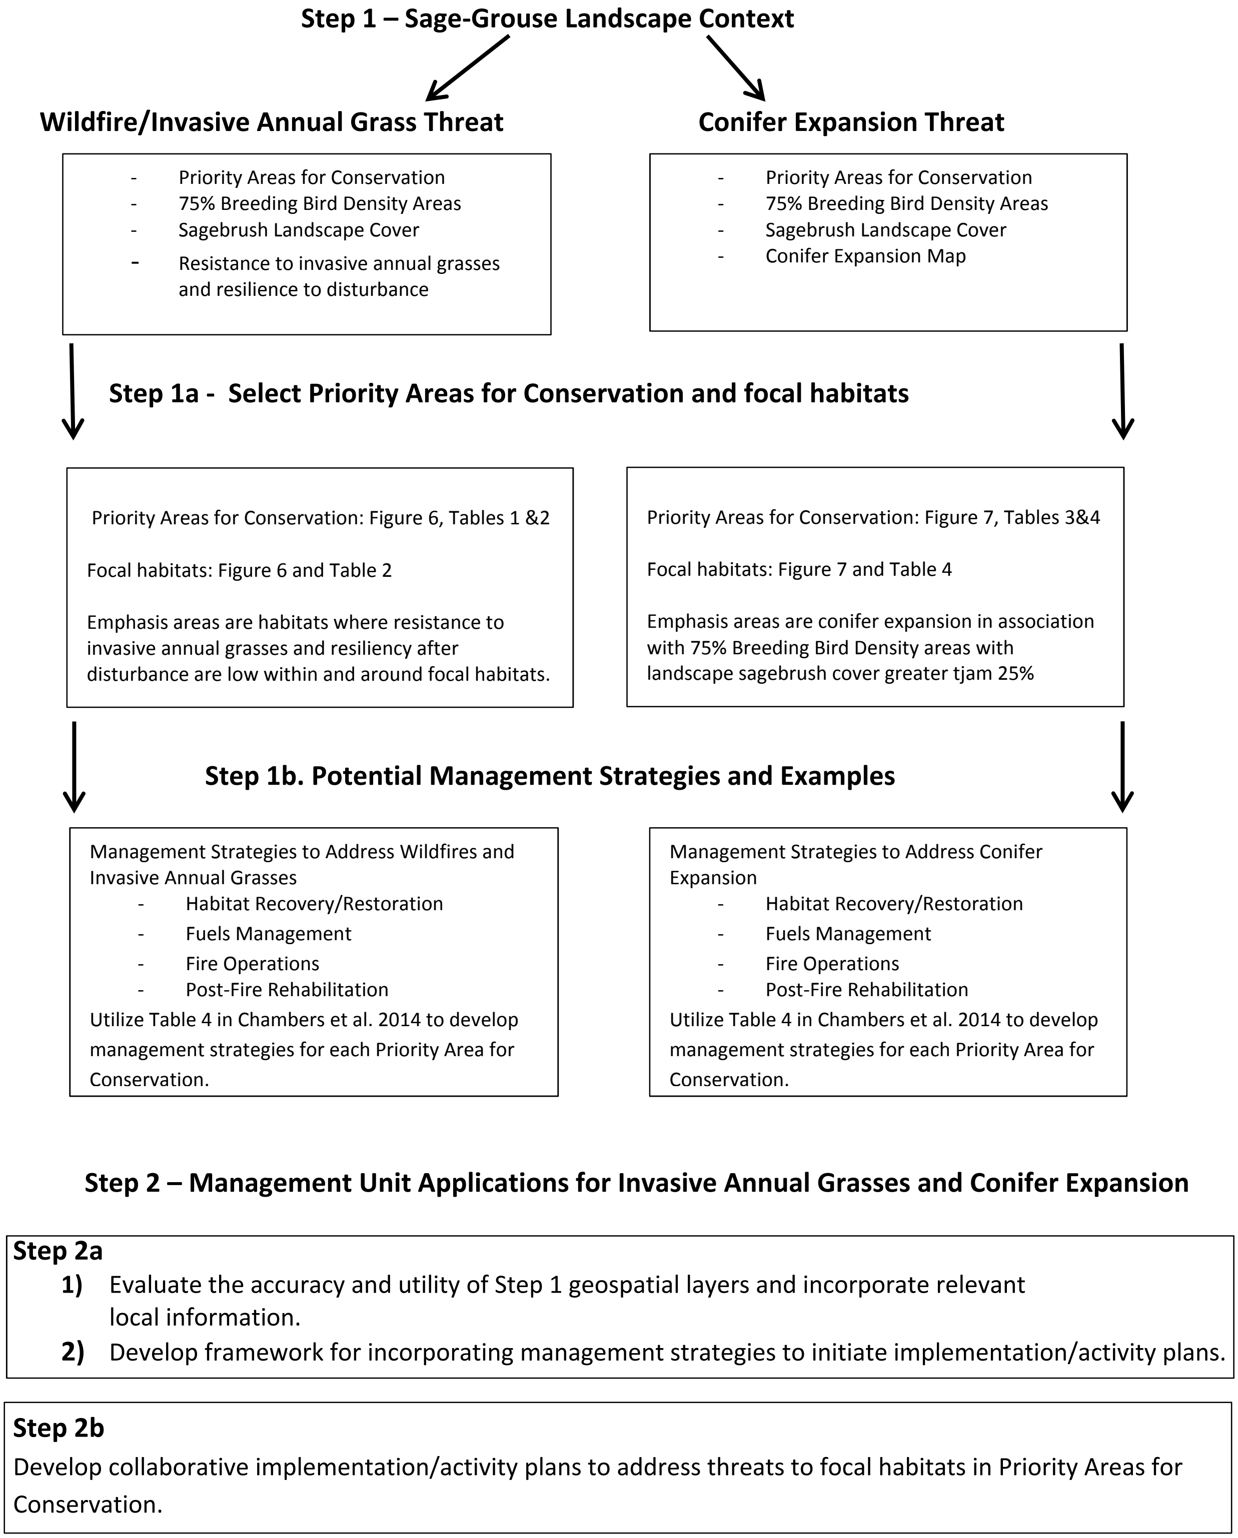
3. **Fire Operations** includes preparedness, prevention, and suppression activities. When discussing specific components of fire operations, the terms fire preparedness, fire prevention and fire suppression are used.

4. **Post-Fire Rehabilitation** includes the BLM's Emergency Stabilization and Rehabilitation (ES&R) Program and the Forest Service's Burned Area Emergency Response (BAER) Program. Policy limits application of funds from 1 to 3 years, thus treatments to restore or enhance habitat after this period of time are considered habitat recovery/restoration.

The assessment process included two steps with sub-elements. First, important Priority Areas for Conservation (PACs) and focal habitats are identified (**Step 1a**). Second, potential management **strategies** (described above) are identified to conserve or restore focal habitats threatened by wildfires, invasive annual grasses, and conifer expansion (primarily pinyon pine and/or juniper species; **Step 1b**). Focal habitats are the portions of a PAC with important habitat characteristics, bird populations, and threats (e.g., wildfires, invasive annual grasses, and conifer expansion) where this assessment will be applied. Areas adjacent to or near the focal habitats can be considered for management treatments such as fire control and fuels management if these locations can reduce wildfire impacts to focal habitats. Soil temperature and moisture regimes are used to characterize capacity for resistance to invasive annual grasses and resilience after disturbance (primarily wildfires) within focal habitats to assist in identifying appropriate management strategies, especially in areas with good habitat characteristics that have low recovery potential following disturbance. Soil moisture and temperature regime relationships have not been quantified to the same degree as for conifer expansion; however, Chambers et al. 2014) discuss preliminary correlations between these two variables.

The results of Steps 1a and 1b, along with associated geospatial data files, are available to local management units to complete Step 2 of the assessment process. Step 2 is conducted by local management units to address wildfire, invasive annual grasses, and conifer expansion in or near focal habitat areas. First, local information and geospatial data are collected and evaluated to apply and improve on Step 1 focal habitat area geospatial data (**Step 2a**). Second, focal habitat activity and implementation plans are developed and include prioritized management **tactics and treatments** to implement effective, fuels management, habitat recovery/restoration, fire operations, and post-fire rehabilitation strategies (**Step 2b**). This assessment will work best if Step 2b is done across management units (internal and externally across BLM and Forest Service administrative units and with other entities). **Figure 1**, Assessment Flow Chart, contains an illustration of the steps in the assessment process.

This analysis does not necessarily address the full suite of actions needed to maintain the current distribution and connectivity of sage-grouse habitats across the Great Basin because resources available to the federal agencies are limited at this time. Future efforts designed to maintain and connect habitats across the range will be needed as current focal areas are addressed and additional resources become available.



Step 1 – Sage-Grouse Landscape Context

Wildfire/Invasive Annual Grass Threat

- Priority Areas for Conservation
- 75% Breeding Bird Density Areas
- Sagebrush Landscape Cover
- Resistance to invasive annual grasses and resilience to disturbance

Conifer Expansion Threat

- Priority Areas for Conservation
- 75% Breeding Bird Density Areas
- Sagebrush Landscape Cover
- Conifer Expansion Map

Step 1a - Select Priority Areas for Conservation and focal habitats

Priority Areas for Conservation: Figure 6, Tables 1 &2

Focal habitats: Figure 6 and Table 2

Emphasis areas are habitats where resistance to invasive annual grasses and resiliency after disturbance are low within and around focal habitats.

Priority Areas for Conservation: Figure 7, Tables 3&4

Focal habitats: Figure 7 and Table 4

Emphasis areas are conifer expansion in association with 75% Breeding Bird Density areas with landscape sagebrush cover greater tjam 25%

Step 1b. Potential Management Strategies and Examples

Management Strategies to Address Wildfires and Invasive Annual Grasses

- Habitat Recovery/Restoration
- Fuels Management
- Fire Operations
- Post-Fire Rehabilitation

Utilize Table 4 in Chambers et al. 2014 to develop management strategies for each Priority Area for Conservation.

Management Strategies to Address Conifer Expansion

- Habitat Recovery/Restoration
- Fuels Management
- Fire Operations
- Post-Fire Rehabilitation

Utilize Table 4 in Chambers et al. 2014 to develop management strategies for each Priority Area for Conservation.

Step 2 – Management Unit Applications for Invasive Annual Grasses and Conifer Expansion

Step 2a

1) Evaluate the accuracy and utility of Step 1 geospatial layers and incorporate relevant local information.
2) Develop framework for incorporating management strategies to initiate implementation/activity plans.

Step 2b

Develop collaborative implementation/activity plans to address threats to focal habitats in Priority Areas for Conservation.

Figure 1, Assessment Flow Chart

Step 1

The first component of the Wildfire and Invasive Annual Grasses Assessment describes the factors that collectively provide the sage-grouse landscape context. Step 1a provides this context by discussing PACs, breeding bird density (BBD), soil temperature and moisture regimes (indicators of resistance to annual grasses and resilience after disturbance), landscape sagebrush cover, and conifer expansion. See Chambers et al. 2014) for a detailed description of Invasive Annual Grass and Wildfire threats to sage-grouse habitat. Priority PACs and focal habitats are derived from the information provided in this sage-grouse landscape context section.

Step 1a- Sage-grouse landscape context

This component of the assessment identifies important PACs and associated focal habitats where wildfire, invasive annual grasses, and conifer expansion pose the most significant threats to sage-grouse.

The primary focus of this assessment is on sage-grouse populations across the WAFWA Management Zones III, IV, and V (**Figure 2**, Current PACs for WAFWA Management Zones III, IV, and V). Sage-grouse are considered a landscape species that require very large areas to meet their annual life history needs. Sage-grouse are highly clumped in their distribution (Doherty et al. 2010), and the amount of landscape cover in sagebrush is an important predictor of sage-grouse persistence in these population centers (Knick et al. 2013). States have used this information combined with local knowledge to identify PACs to help guide long-term conservation efforts. FIAT used data sets that were available across the three management zones as an initial step for prioritizing selected PACs and identifying focal habitats for fire and invasive annual grasses and conifer expansion assessments. These data sets (also described in Chambers et al. 2014) include:

Priority Areas for Conservation (PACs)

PACs have been identified by states as key areas that are necessary to maintain redundant, representative, and resilient sage-grouse populations (USFWS 2013; see Figure 2). A primary objective is to minimize threats within PACs (e.g., wildfire and invasive annual grasses impacts) to ensure the long-term viability of sage-grouse and its habitats. A secondary priority is to conserve sage-grouse habitats outside of PACs since they may also be important for habitat connectivity between PACs (genetic and habitat linkages), habitat restoration and population expansion opportunities, and flexibility for managing habitat changes that may result from climate change. PACs have also been identified by the USFWS as one of the reporting geographic areas that will be considered during listing determinations for sage-grouse.

The combination of PACs with BBD data (described below) assists us in identifying connectivity between populations. PAC boundaries may be modified in the future requiring adjustments in focal habitat areas and management strategy priorities.

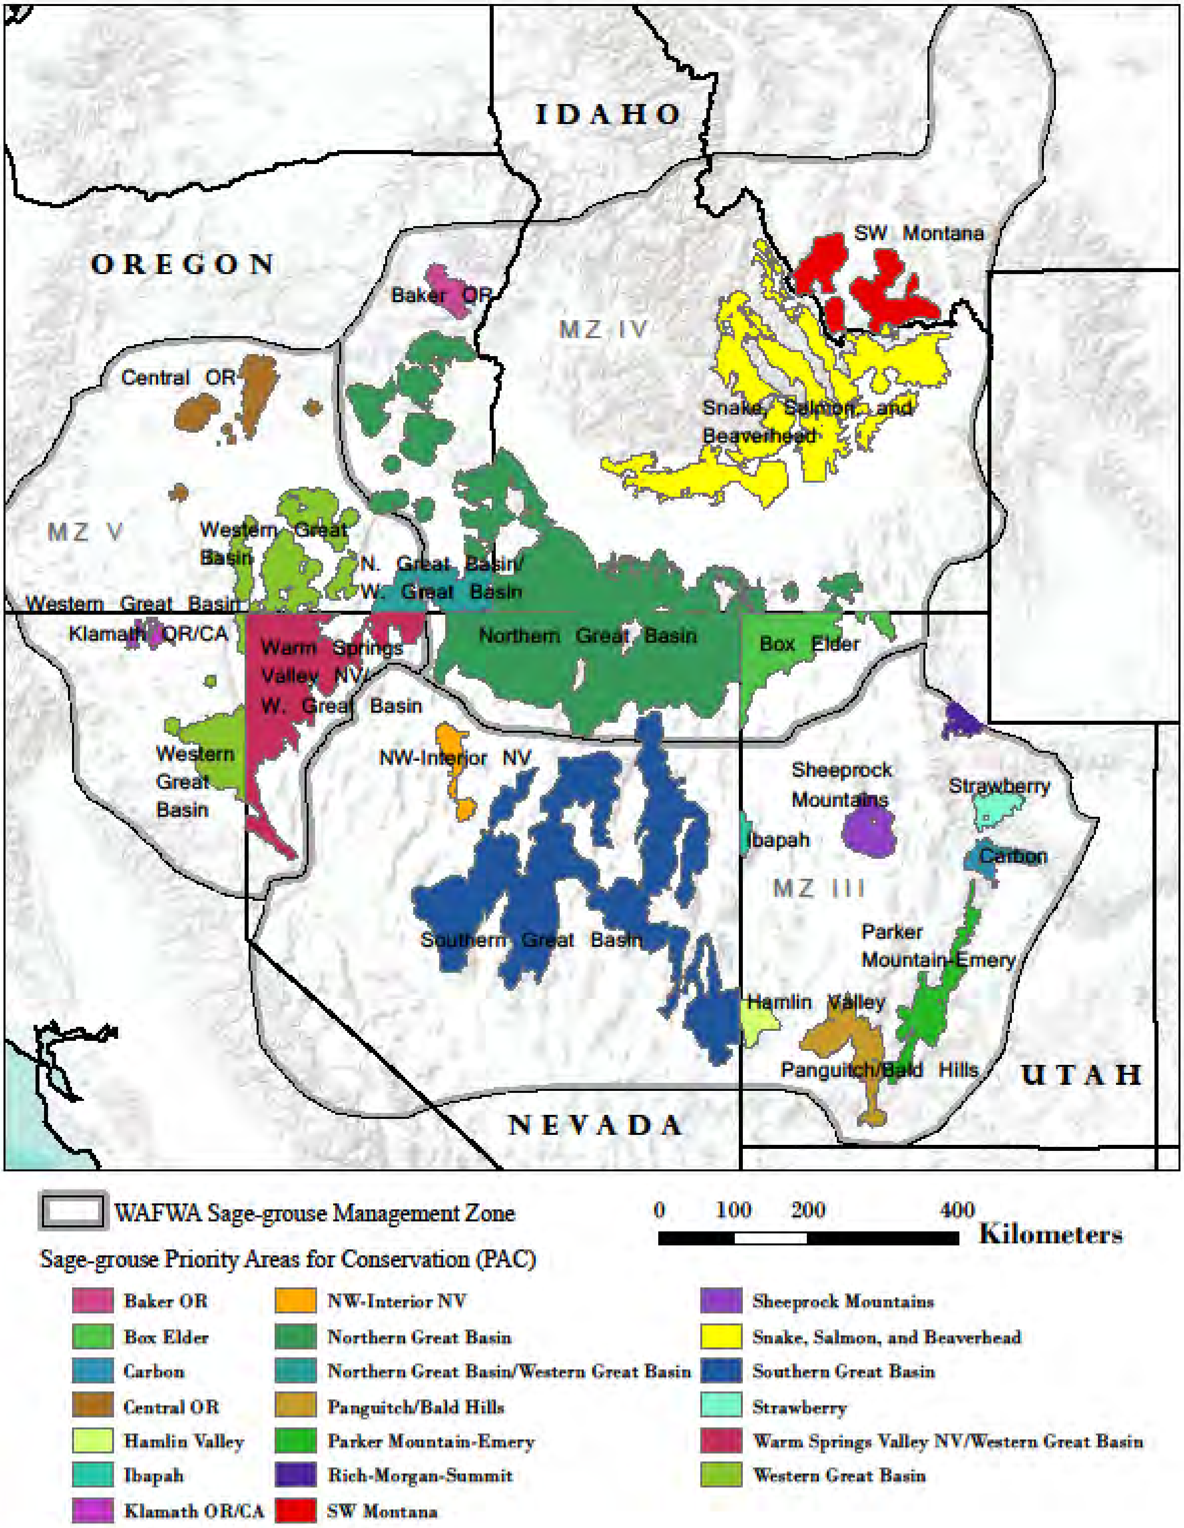


Figure 2, Current PACs for WAFWA Management Zones III, IV, and V. Bi-State sage-grouse populations were not included for this analysis and are being addressed in separate planning efforts.

Breeding Bird Density

Doherty et al. (2010) provided a useful framework for identifying population concentration centers in their range-wide BBD mapping. FIAT used maximum counts of males on leks (4,885 males) to delineate breeding bird density areas that contain 25, 50, 75, and 100 percent of the known breeding population. Leks were then mapped according to abundance values and buffered by 4 to 5.2 miles (6.4 to 8.5 kilometers) to delineate nesting areas. Findings showed that while sage-grouse occupy extremely large landscapes, their breeding distribution is highly aggregated in comparably smaller identifiable population centers; 25 percent of the known population occurs within 3.9 percent (7.2 million acres [2.92 million hectares]) of the species range, and 75 percent of birds are within 27 percent of the species range (50.5 million acres [20.4 million hectares]; Doherty et al. 2010). See **Figures 3**, Sage-Grouse Breeding Bird Density Thresholds.

This analysis places emphasis on breeding habitats because little broad/mid-scale data exists for associated brood-rearing (summer) and winter habitat use areas. Finer scale seasonal habitat use data should be incorporated (or, if not available studies, should be conducted) at local levels to ensure management actions encompass all seasonal habitat requirements. Federal administrative units should consult with state wildlife agencies for additional seasonal habitat information.

For this assessment, FIAT chose to use the 75 percent BBD as an indicator of high bird density areas that informed the approach used by state wildlife agencies to initially identify PACs. Range-wide BBD areas provide a means to further prioritize actions within relatively large PACs to maintain bird distribution and abundance. FIAT used state level BBD data from Doherty et al. (2010) instead of range-wide model results to ensure important breeding areas in Management Zones III, IV, and V were not underweighted due to relatively higher bird densities in the eastern portion of the range. BBD areas of 75 to 100 percent are included in Appendix 1 to provide context for local management units when making decisions concerning connectivity between populations and PACs.

Note that breeding density areas were identified using best available information in 2009, so this range-wide data does not reflect the most current lek count information and changes in conditions since the original analysis. Subsequent analysis should use the most current information available. Also, BBD areas should not be viewed as rigid boundaries but rather as a means to regionally prioritize landscapes where step down assessments and actions should be implemented quickly to conserve the most birds.

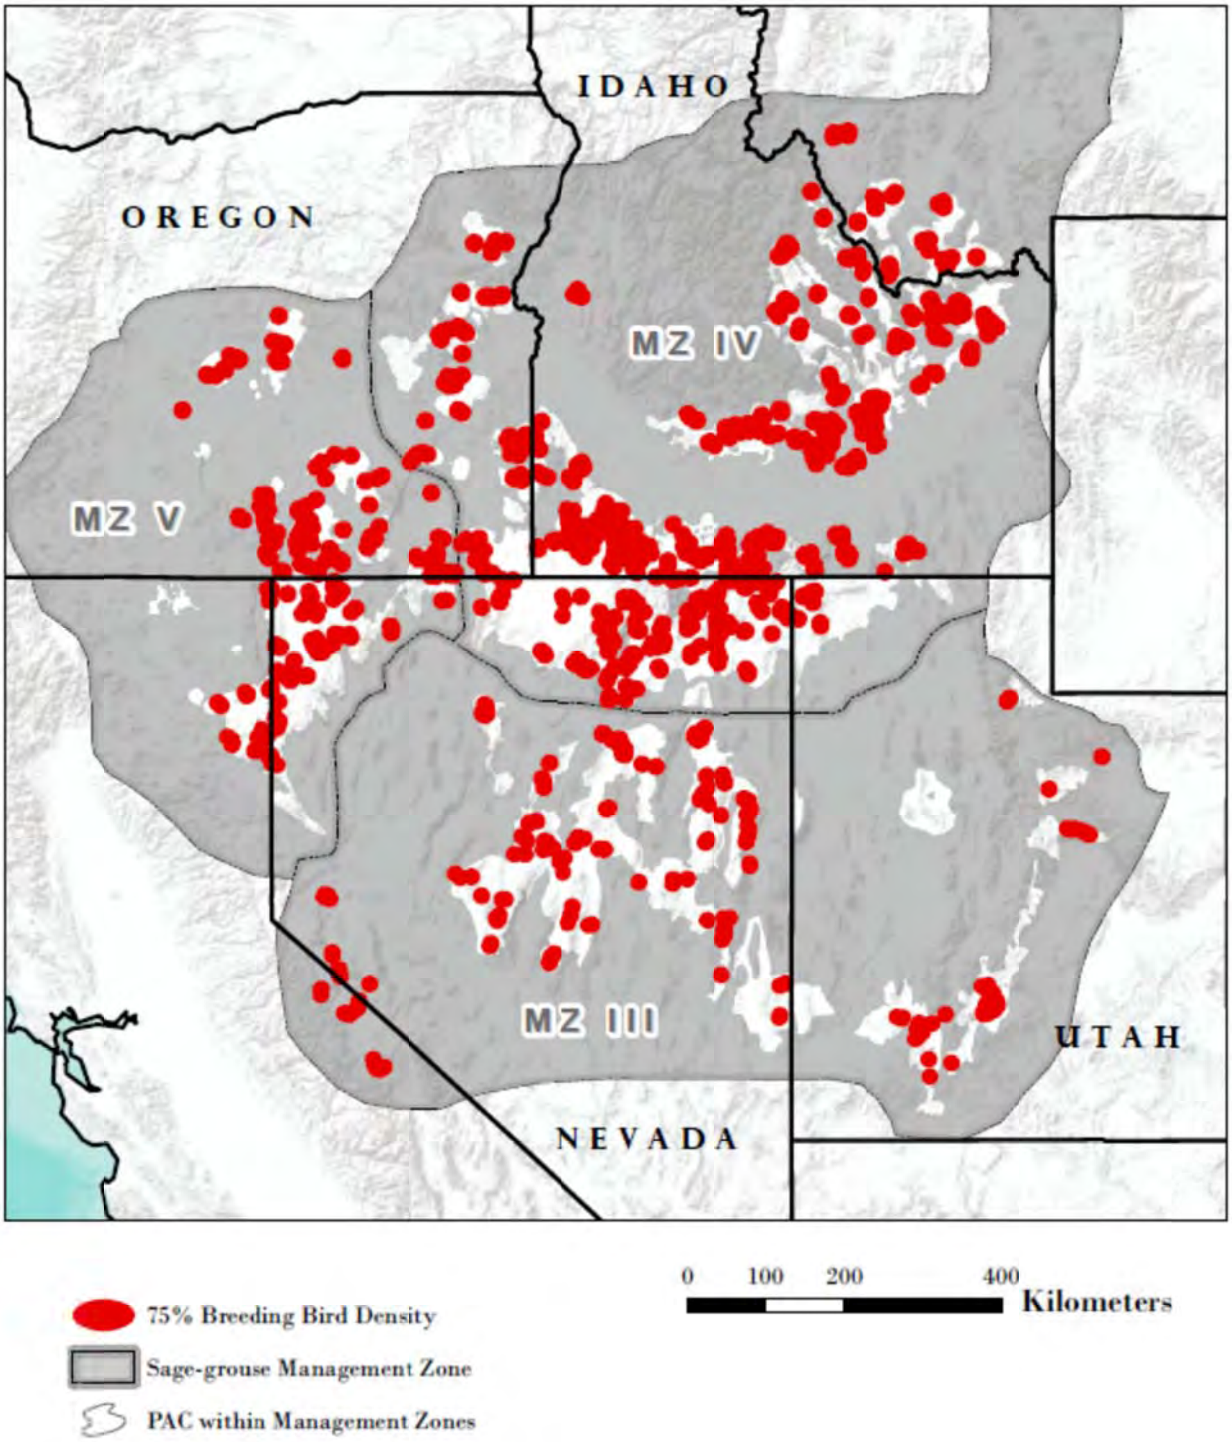

Figure 3, Sage-Grouse Breeding Bird Density Thresholds for 75% of the breeding birds, Management Zones, and PACs. Breeding bird density of 75 to 100% is shown in Appendix 1 to provide context for local management units when making decisions concerning connectivity between populations and PACs.

Soil Temperature and Moisture Regimes

Invasive annual grasses and wildfires can be tied to management strategies through an understanding of resistance and resilience concepts. Invasive annual grasses has significantly reduced sage-grouse habitat throughout large portions of its range (Miller et al. 2011). While abandoned leks were linked to increased nonnative annual grass presence, active leks were associated with less annual grassland cover than in the surrounding landscape (Knick et al. 2013). Invasive annual grasses also increases fire frequency, which directly threatens sage-grouse habitat and further promotes the establishment of invasive annual grasses (Balch et al. 2013). This nonnative annual grass and fire feedback loop can result in conversion from sagebrush shrublands to annual grasslands (Davies 2011).

In cold desert shrublands, vegetation community resistance to invasive annual grasses and resilience following disturbance is strongly influenced by soil temperature and moisture regimes (Chambers et al. 2007; Meyer et al. 2001). Generally, colder soil temperature regimes and moister soil moisture regimes are associated with more resilient and resistant vegetation communities. While vegetation productivity and ability to compete and recover from disturbance increase along a moisture gradient, cooler temperatures limit invasive annual grass growth and reproduction (Chambers et al. 2007; Chambers et al. 2014). Conversely, warm and dry soil temperature and moisture regimes and to a lesser degree cool and dry soil temperature and moisture regimes, are linked to less resistant and resilient communities (see Figure 9 in Chambers et al. 2014). A continuum in resistance and resilience exists between the warm and dry and cool and dry soil temperature and moisture regimes that will need to be considered in Step 2 in developing implementation or activity plans. These relationships can be used to prioritize management actions within sage-grouse habitat using broadly available data.

To capture relative resistance and resilience to disturbance and invasive annual grasses across the landscape, soil temperature and moisture regime information (described in greater detail in Chambers et al. 2014) were obtained from the Natural Resources Conservation Service (NRCS) Soil Survey Geographic Database (SSURGO) data. Where gaps in this coverage existed, the NRCS US General Soil Map (STATSGO2) data was used (Soil Survey Staff 2014; see Appendix 1). The STATSGO2 database includes soils mapped at a 1:250,000-scale; the SSURGO database includes soils mapped at the 1:20,000 scale. Interpretations made from soil temperature and moisture regimes from the STATSGO2 database will not have the same level of accuracy as those made from the SSURGO database.

Areas characterized by warm and dry soil temperature and moisture regimes (low relative resistance and resilience) were intersected with sage-grouse breeding habitat and sagebrush landscape cover to identify candidate areas (emphasis areas) for potential management actions that mitigate threats from invasive annual grasses and wildfire (**Figure 4**, Soil Moisture and Temperature Regimes for Management Zones III, IV, and V, and **Figure 5**, Intersection of High Density (75% BBD) Populations). These data layers provide the baseline information considered important in prioritizing areas where conservation and management actions could be developed to address invasive annual grasses in a scientifically defensible manner (see Table 4 in Chambers et al. 2014).

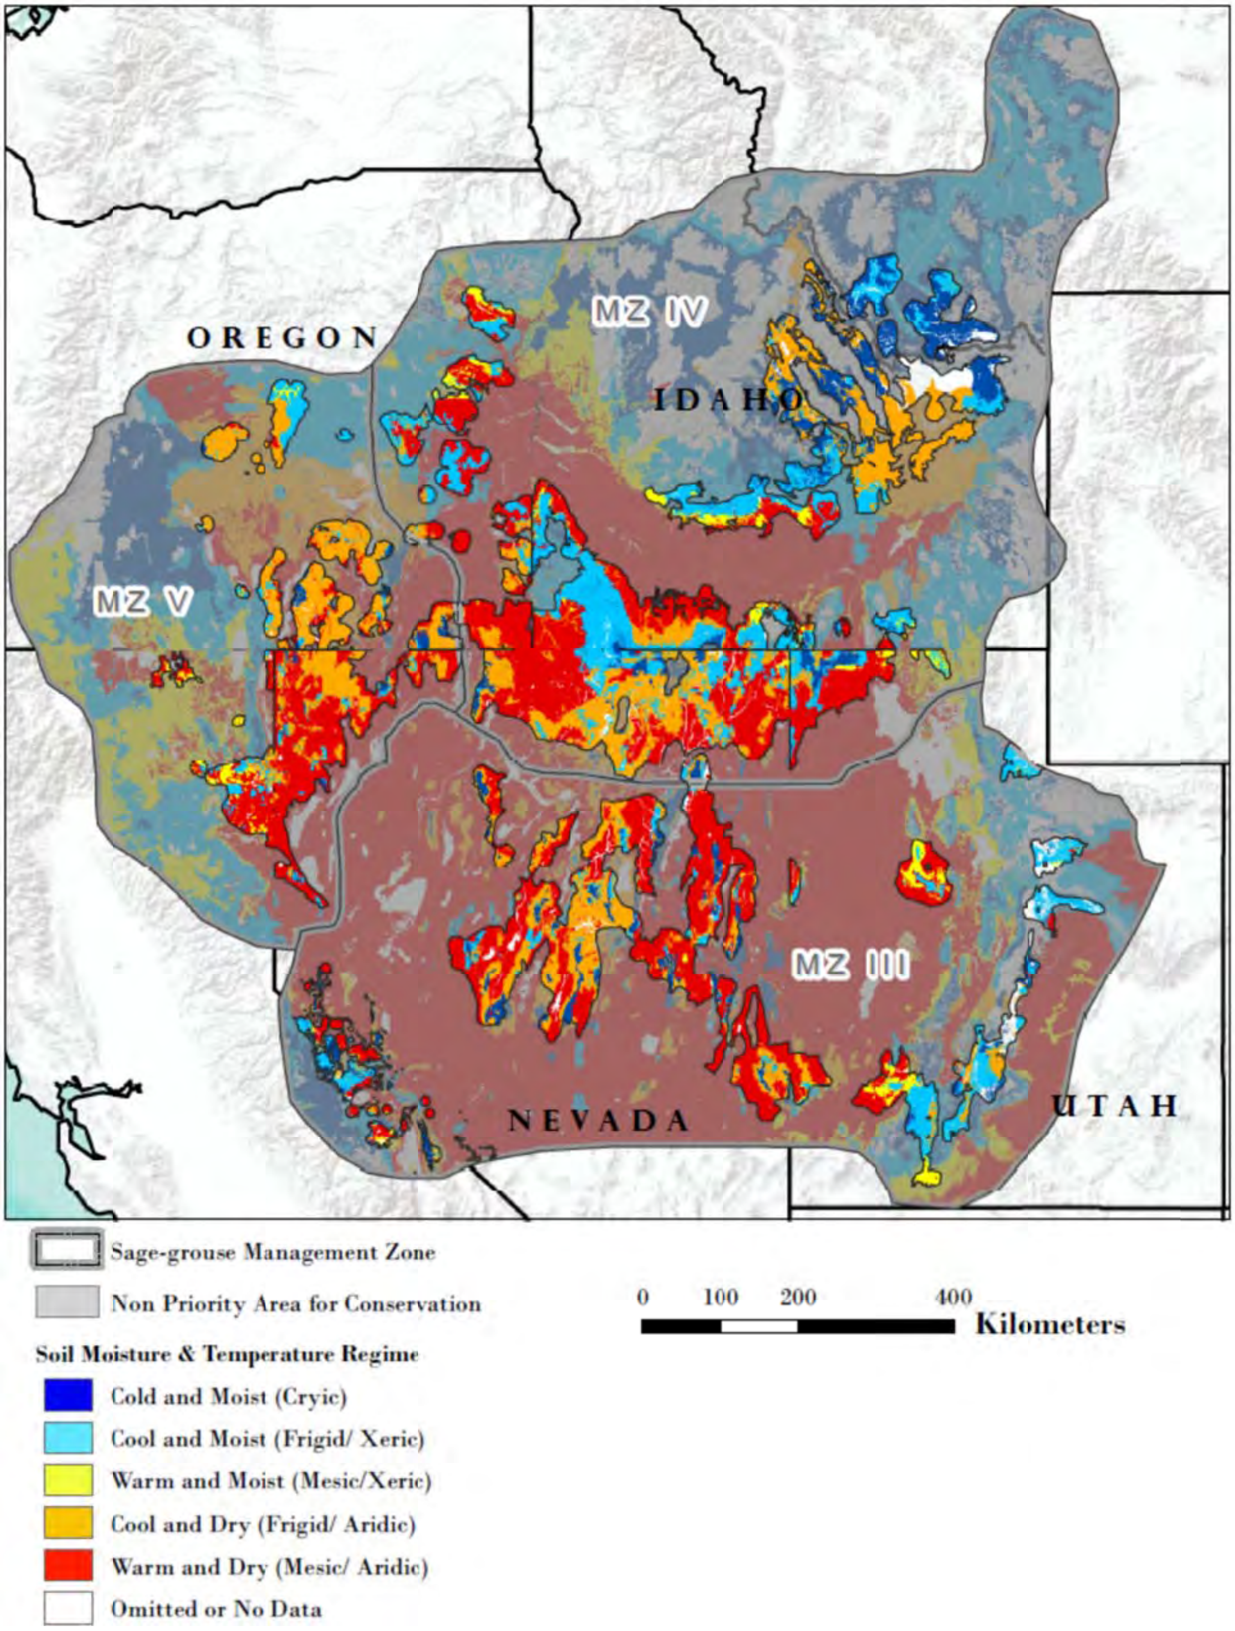

Figure 4, Soil Moisture and Temperature Regimes for Management Zones III, IV, and V

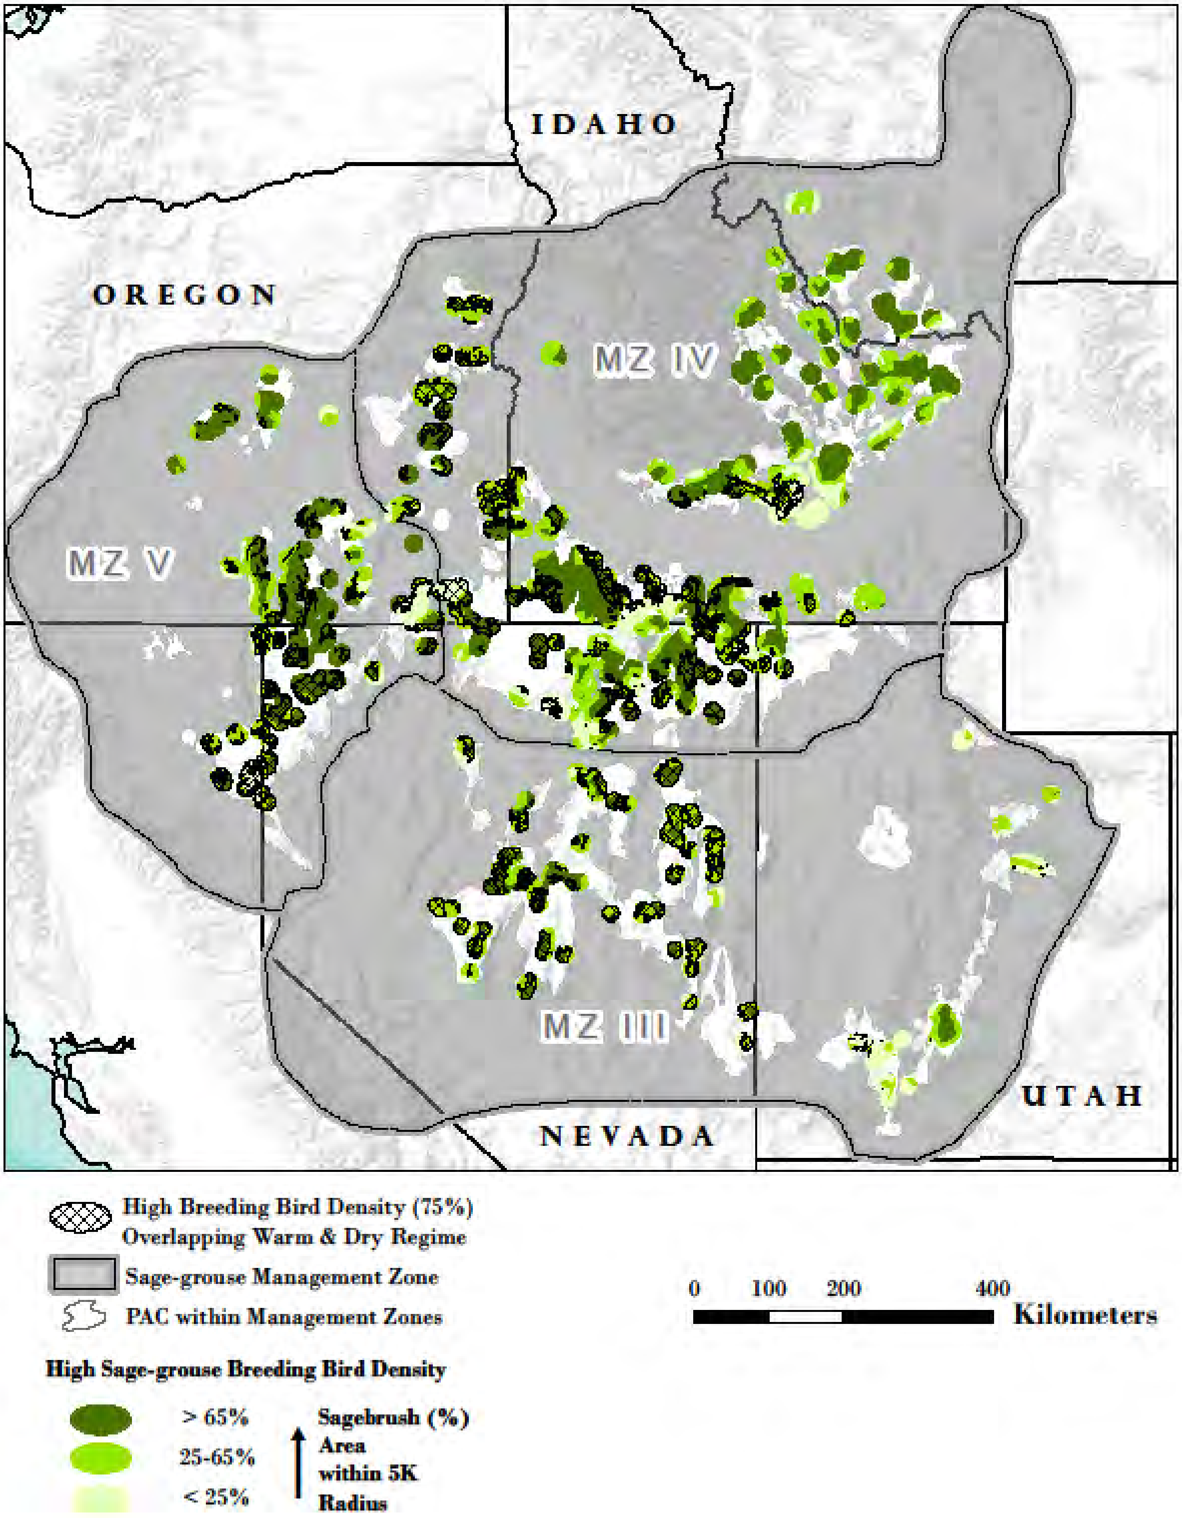

Figure 5, Intersection of High Density (75% BBD) Populations. The warm and dry sites and the proportion of these habitats in the three sagebrush landscape cover classes by management zone, and PACs within the Great Basin.

Sagebrush Landscape Cover

The amount of the landscape in sagebrush cover is closely related to the probability of maintaining active sage-grouse leks, and is used as one of the primary indicators of sage-grouse habitat potential at landscape scales (Aldridge et al. 2008; Wisdom et al. 2011; Knick et al. 2013). For purposes of prioritizing landscapes for sage-grouse habitat management, FIAT used less than or equal to 25 percent sagebrush landscape cover as a level below which there is a low probability of maintaining sage-grouse leks, and greater than or equal to 65 percent as the level above which there is a high probability of sustaining sage-grouse populations with further increases of landscape cover of sagebrush (Aldridge et al. 2008; Wisdom et al. 2011; Knick et al. 2013). Increases in landscape cover of sagebrush have a constant positive relationship with sage-grouse lek probability at between about 25 percent and 65 percent landscape sagebrush cover (Knick et al. 2013). It is important to note that these data and interpretations relate only to persistence (i.e., whether or not a lek remains active), and it is likely that higher proportions of sagebrush cover may be required for population growth.

For the purposes of delineating sagebrush habitat relative to sage-grouse requirements for landscape cover of sagebrush, FIAT calculated the percentage of landscape sagebrush cover (Landfire 2013) within a 3-mile (5-kilometer) radius of each 98-foot by 98-foot (30 meter by 30 meter) pixel in Management Zones III, IV, and V (see Appendix 2 in Chambers et al. 2014) for how landscape sagebrush cover was calculated). FIAT then grouped the percentage of landscape sagebrush cover into each of the selected categories (0 to 25 percent, 25 to 65 percent, 65 to 100 percent; **Figure 6**, Sagebrush Landscape Cover and Fire Perimeters for the Analysis Area). Landfire data was based on 2000 satellite imagery so wildfire perimeters after that date were incorporated into this layer to better reflect landscape sagebrush cover. Burned areas were assumed to fall into the 0 to 25 percent landscape cover class.

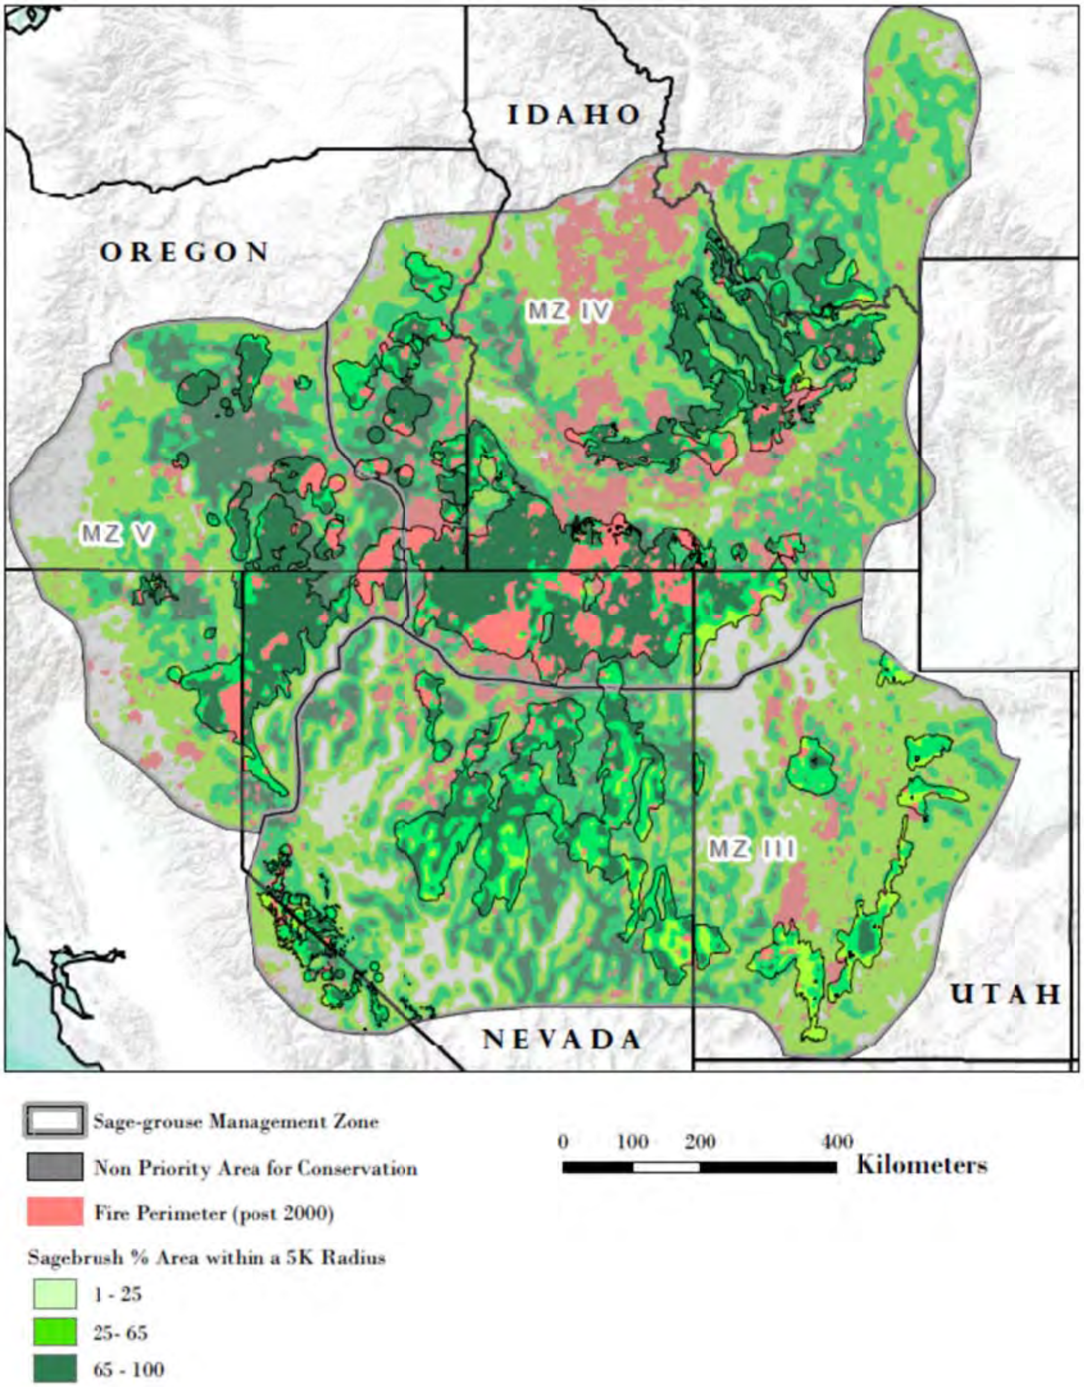

Figure 6, Sagebrush Landscape Cover and Fire Perimeters (post-2000) for the Analysis Area

Conifer Expansion

Conifer expansion into sagebrush landscapes also directly reduces sage-grouse habitat by displacing shrubs and herbaceous understory as well as by providing perches for avian predators. Conifer expansion also leads to larger, more severe fires in sagebrush systems by increasing woody fuel loads (Miller 2013). Sage-grouse populations have been shown to be impacted by even low levels of conifer expansion (Baruch-Mordo et al. 2013). Active sage-grouse leks persist in regions of relatively low conifer woodland and are threatened by conifer expansion (Baruch-Mordo et al. 2013; Knick et al. 2013).

To estimate where sage-grouse breeding habitat faces the largest threat of conifer expansion, FIAT used a risk model developed by Manier et al. (2013) that locates regions where sagebrush landscapes occur within 250 meters of conifer woodland (**Figure 7**, Modeled Conifer Expansion for PACs with Greater Than 25% Sagebrush Landscape Cover In and Around 75% BBD). Although the model is coarse, it is available for the entirety of the three sage-grouse management zones analyzed. FIAT encourages using more accurate conifer expansion data in Step 2.

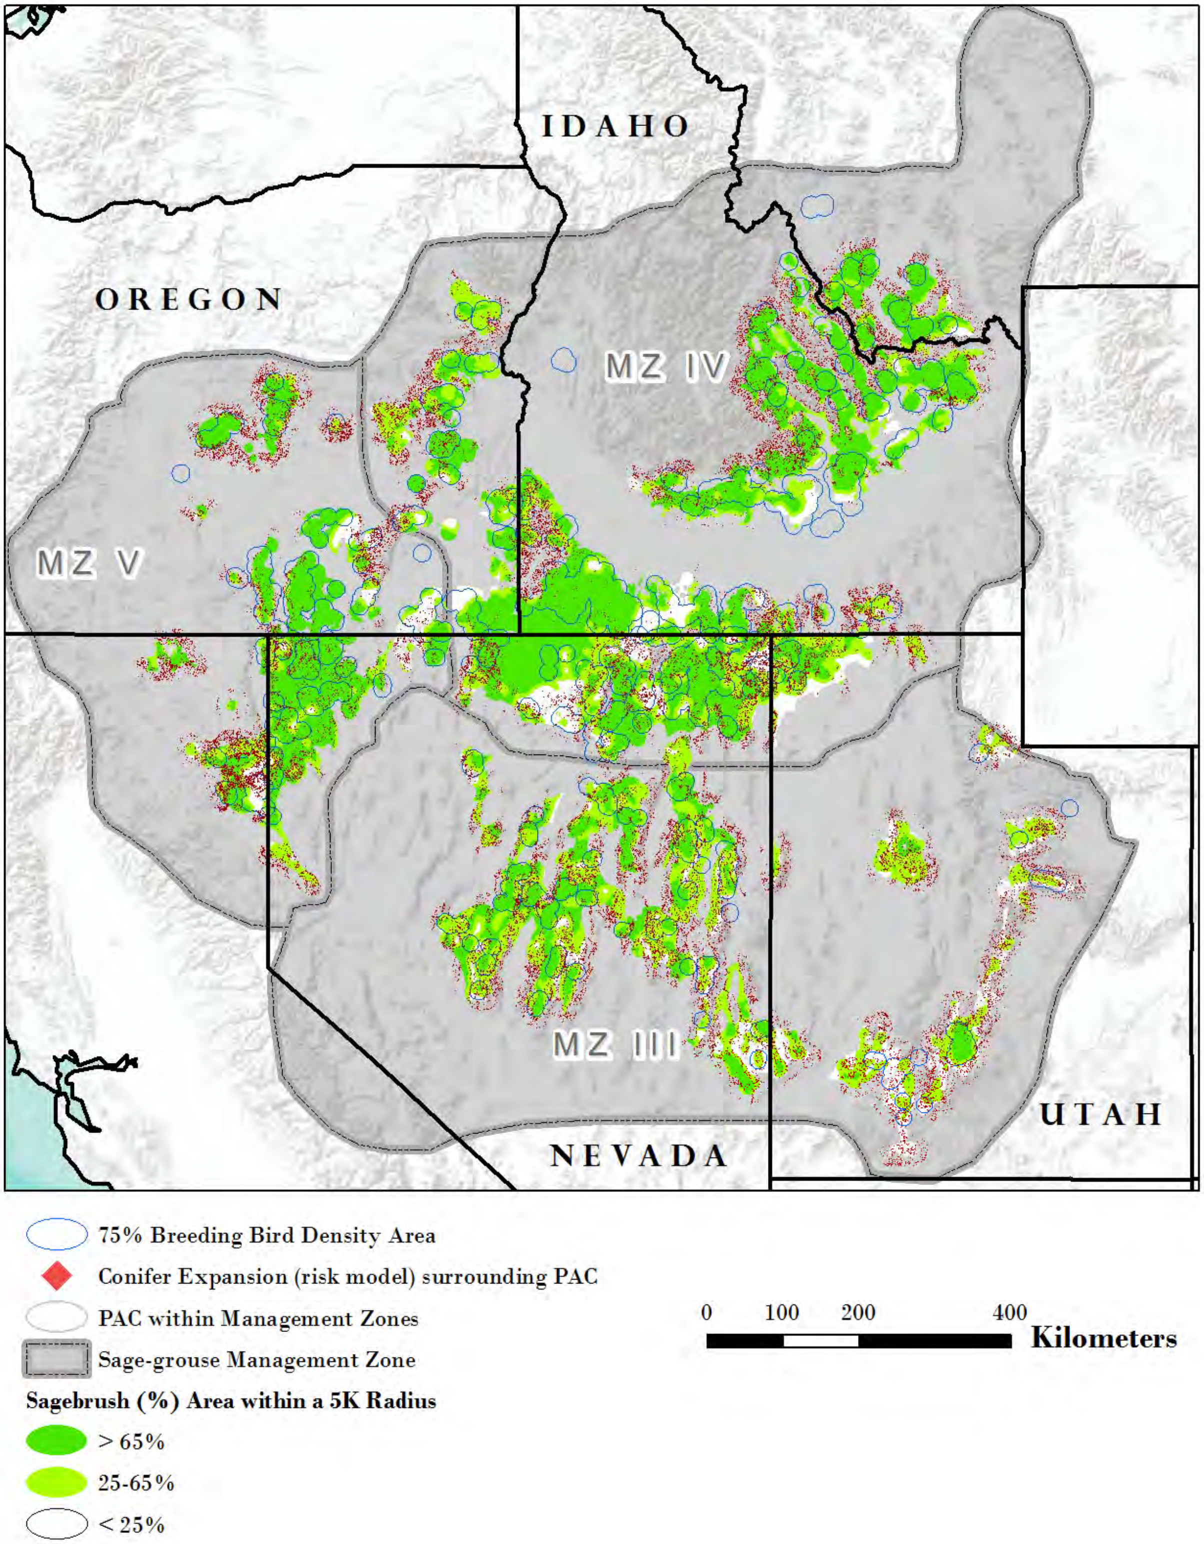

Figure 7, Modeled Conifer Expansion for PACs with Greater Than 25% Sagebrush Landscape Cover In and Around 75% BBD

Step 1a. Identifying PACs and focal habitats

A primary goal for the conservation of sage-grouse populations is the identification of important habitats needed to ensure the persistence and recovery of the species. Loss of habitat, and by inference populations, in these habitats would likely imperil the species in the Great Basin. The first objective is to protect and restore those habitats that provide assurances for retaining large well connected populations.

PACs and the 75 percent BBD maps were used to provide a first-tier stratification (e.g., focal habitats) for prioritizing areas where conservation actions could be especially important for sage-grouse populations. Although these areas are a subset of the larger sage-grouse habitats, they are readily identifiable and include habitats (e.g., breeding and nesting habitats that are considered critical for survival; Connelly et al. 2000; Holloran et al. 2005; Connelly et al. 2011) and necessary for the recovery of the species across its range.

The prioritization of habitats for conservation purposes was based on the several primary threats to remaining sage-grouse populations in the Great Basin including the loss of sagebrush habitats to wildfire and invasive annual grasses, and conifer expansion. The first, and probably the most urgent threat for sage-grouse, is the loss of sagebrush habitat due to wildfire and invasive annual species (e.g., cheatgrass; See Figure 11 in Chambers et al. 2014). Areas of highest concern are those with low resistance to cheatgrass and low resilience after disturbance (warm/dry and some cool/dry temperature and moisture regimes sites) that are either **within or in close proximity** to remaining high density populations of sage-grouse (Figure 5). Sagebrush habitats (greater than 25 percent sagebrush landscape cover) prone to conifer expansion, particularly pinyon pine and/or juniper, are also a management concern when within or adjacent to high density sage-grouse populations (Figure 7).

Because these two threats occur primarily at different points along an elevational gradient and are associated with different soil temperature and moisture regimes, separate approaches are used to select PACs and focal habitats for each.

High Density Populations at Highest Risk from <u>Wildfire and Invasive Annual Grasses</u>

PACs in Management Zones III, IV, and V. were evaluated on the basis of high density (75 percent) BBDs, sagebrush landscape cover, and soil temperature and moisture regimes to identify initial PACs that are a priority for assessments and associated focal habitats. **Figure 8**, High Priority PACs with High Density Sage-Grouse Populations (75% BBD), displays the results of the analysis focusing on the intersection of high density (75 percent BBD) populations, the warm and dry sites, and the proportion of these habitats in the three sagebrush landscape cover classes by management zone, and PACs within the Great Basin. **Table 1**, Relative Ranking of PACs Based on High Density (75% BBD) Populations, Warm/ Dry Sites, and Percentage of Habitat in Sagebrush Landscape Cover Classes, displays quantitative outputs of this analysis. The table allows a comparison of these data, and assists in selecting five PACs that provide the greatest contribution to high density sage-grouse populations, and the amounts (acres and proportion) within those PACs of sagebrush cover classes associated with warm and dry soil temperature and moisture regimes.

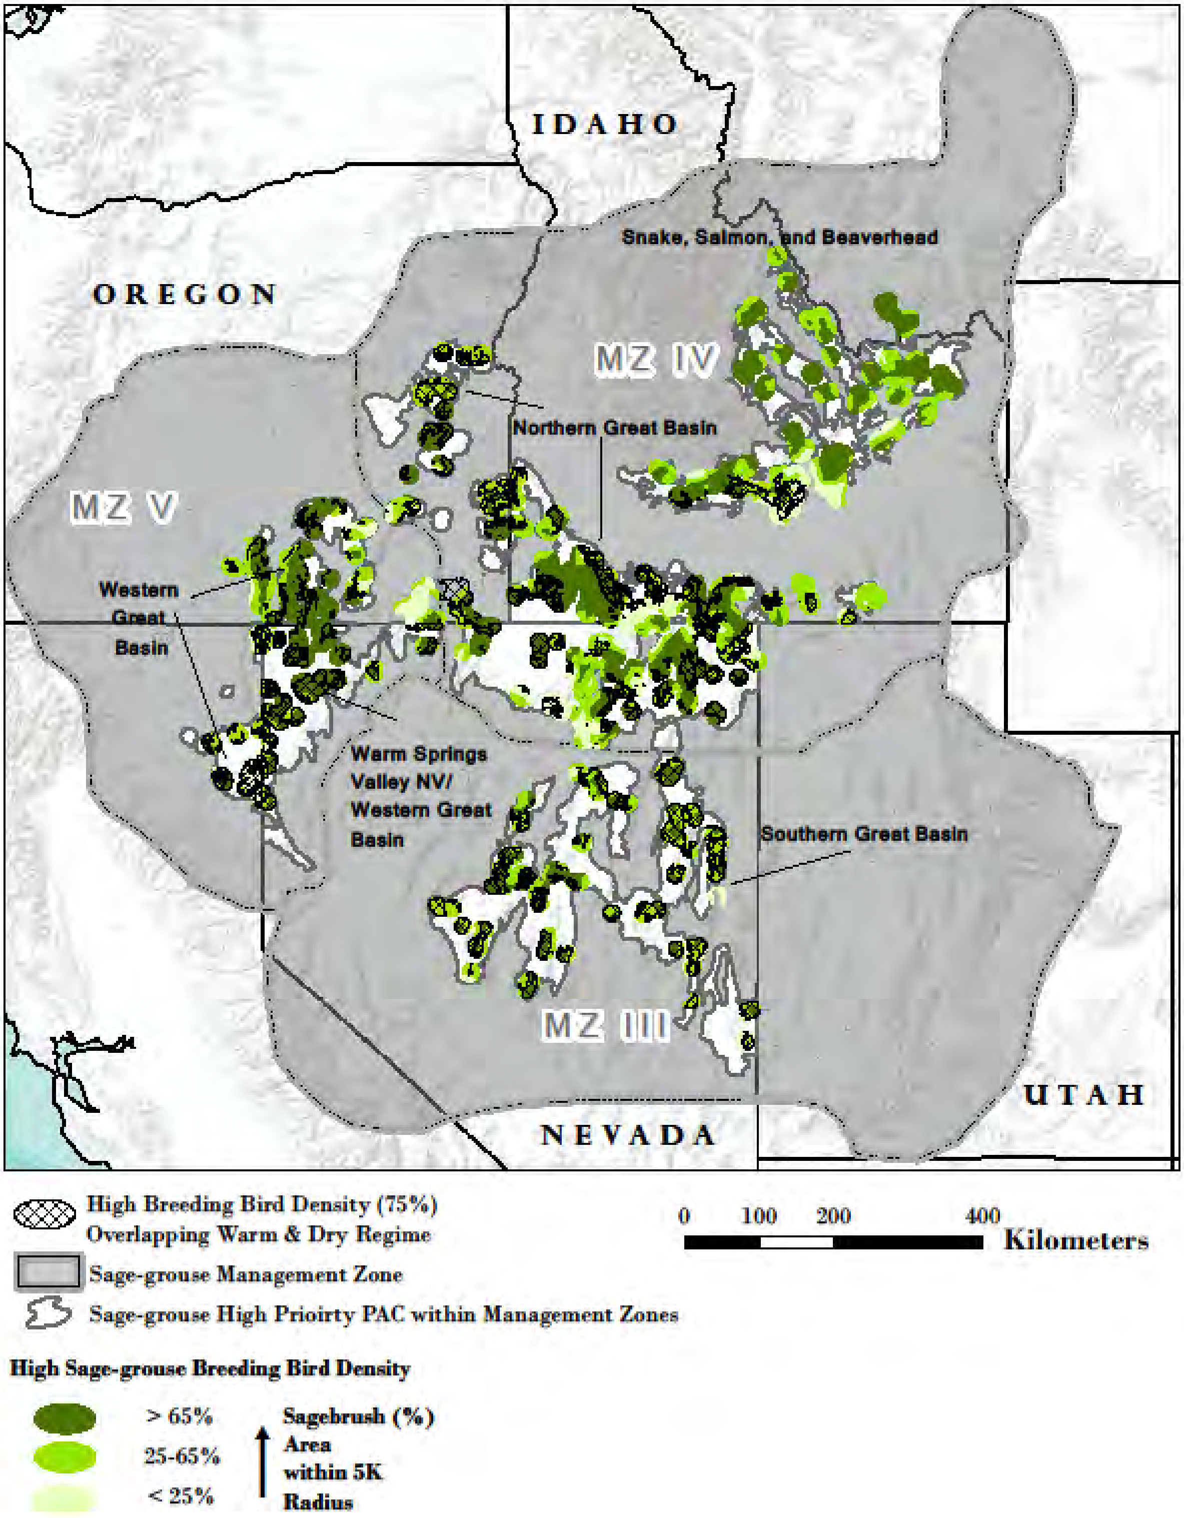

Figure 8, High Priority PACs with High Density Sage-Grouse Populations (75% BBD) sagebrush landscape cover classes, and areas with low resistance and resilience relative to wildfires and invasive annual species.

Table 1, Relative Ranking of PACs Based on High Density (75% BBD) Populations, Warm/ Dry Sites, and Percentage of Habitat in Sagebrush Landscape Cover Classes

Sage-grouse Management Zone	Sage-grouse Priority Area for Conservation (PAC) Name	Total PAC Acres	Breeding Bird Density (75%) Acres	Percent of Breeding Bird Density (75%) Area within PAC	Warm and Dry Soil Moisture & Temperature Regime within Breeding Bird Density (75%) Acres*

* Numbers in parenthesis indicate the percent of acres relative to total acres of breeding bird density (75%)

These five PACs comprise 90 percent and 95 percent of remaining PAC sagebrush landscape cover in the 25 to 65 percent and greater than or equal to 65 percent sagebrush landscape cover classes, respectively, of the 75 percent BBD associated with low resistance/resilience habitats. The 75 percent BBD habitats in the Northern, Southern Great Basin, and Warm Spring PACs appear particularly important for two reasons. They represent a significant part of the remaining habitats for the Great Basin metapopulation, and they have the greatest amount of low resiliency habitat remaining that still functions as sage-grouse habitat.

An examination of the 5 selected PACs shows that the sum of the 75 percent BBD within these PACs is 16,995,496 acres (**Table 2**, PACs with the Highest Acres and Proportions of 75% BBD acres, and Acres and Proportions of 75% BBD Acres within the Warm/Dry Soil Temperature and Moisture Class). These are the **focal habitats**. These five PACs constitute 84 percent of the 75 percent BBD low resiliency habitats for all Management Zones III, IV, and V PACs. Within and immediately around these focal habitats, 5,751,293 acres are in high BBD areas with landscape sagebrush cover in the 25-65 percent and ≥ 65 percent classes and in the warm and dry soil temperature and moisture regimes. These are the habitats in the most danger to loss due to their low resistance to invasive annual grasses and low resilience following wildfire. Within the focal habitats in the high priority PACs, low resistance and resilience areas (cross-hatched areas in Figure 8) are a high priority (emphasis area) for implementing management strategies. Applying management strategies outside the emphasis areas are appropriate if the application of fire operations and fuels management activities will be more effective in addressing wildfire threats.

Table 2, PACs with the Highest Acres and Proportions of 75% BBD acres, and Acres and Proportions of 75% BBD Acres within the Warm/Dry Soil Temperature and Moisture Class (see Figure 8)

PAC	PAC Acres	Acres of 75% BBD in PAC (**focal habitat**)	Proportion of 75% BBD within PACs	Warm & Dry Soils within 75% BBD by Sagebrush Landscape Cover Classes Greater Than 25%*	
				25-65%	>65%

***** This category represents the emphasis areas for applying appropriate management strategies in or near the focal habitats due to the lower probability of recovery after disturbance and higher probability of invasive annual grasses and existing wildfire threats.

High Density Sage-Grouse Habitats at Risk from Conifer Expansion

PACs, sagebrush landscape cover, and the 75 percent BBD data were also used in conjunction with the conifer expansion data (Mainer et al. 2013) to provide an initial stratification to determine PACs where conifer removal would benefit important sagebrush habitats. Conifer expansion threats are primarily western juniper in the northern Great Basin and pinyon pine/Utah juniper in the southern Great Basin.

Figure 7 displays results of the analysis focusing on the intersection of the 75 percent BBD, and modeled conifer expansion areas within two sagebrush landscape cover classes by management zone and PACs within the Great Basin. To identify high density sage-grouse areas affected by conifer expansion, the amount and proportion of acres estimated to be affected were calculated by sagebrush cover class to assist in the identification of the focal habitats (**Table 3)**. **Table 4**, displays quantitative outputs of this analysis using the 25 to 65 percent and greater than 65 percent landscape sagebrush cover classes for the PACs. Thus, **focal habitats** for addressing conifer expansion are the areas within and near conifer expansion in sagebrush landscape cover classes of 25 to 65 percent and greater than 65 percent. Conifer expansion in these two sagebrush landscape cover classes in the 75 percent BBD areas constitutes an emphasis area for treatments to address conifer expansion. Landscapes with less than 25 percent sagebrush cover may require significant additional management actions to restore sagebrush on those landscapes and therefore were considered a lower priority for this analysis. Focal habitats are identified in Table 4 and displayed in **Figure 9**.

Table 3 assists in identifying those PACs that provide the greatest contribution to high density sage-grouse populations, and the amounts (acres and proportion) within those PACs of sagebrush cover classes associated with modelled conifer expansion areas. Although there are uncertainties associated with the model, the results help managers identify specific geographic areas where treatments in conifer (pinyon and/or juniper) could benefit existing important sage-grouse populations.

The results of the screening revealed 5 PACs that contribute substantially to the 75 percent BBD habitats and are currently impacted most by conifer expansion (primarily pinyon pine and/or juniper; Table 4 and Figure 9). Four of the five PACs identified as high priority for conifer expansion treatments were also high priorities for wildfires and invasive annual grass threats. This is likely due to the size of the PACs and the relative importance of these PACs for maintaining the Great Basin sage-grouse meta-populations. As expected, the locations of high density sage-grouse habitats affected by conifer expansion differ spatially from those associated with low resilience habitats within and among the PACs, primarily due to differences in the biophysical settings (e.g., elevation and rainfall) that contribute to threats from invasive annual grasses and wildfires.

Three PACs (Snake/Salmon/Beaverhead, Southwest Montana, and Northern Great Basin/Western Great Basin) ranked high due to their relatively large proportion of high density breeding habitats (Table 3), but were not selected since the threat of conifer expansion was relatively low. One PAC, (Snake/Salmon/Beaverhead, was identified as a potential high priority area but was dismissed because results of the conifer expansion model likely overestimated impacts due to the adjacent conifer forests in this region. The COT Report also identified conifers as a "threat present but localized" in these areas, whereas, the top five PACs prioritized all have conifers identified as a widespread priority threat to address (USFWS 2013).

Table 3, Relative Ranking of PACs Based on High Density (75% BBD) Populations, Modeled Conifer Expansion, and Percentage of Habitats in Sagebrush Landscape Cover Classes

Sage-grouse Management Zone	Sage-grouse Priority Area for Conservation (PAC) Name	PAC acres	Breeding Bird Density (75%) Acres	Relative Proportion of Breeding Bird Density Area within PAC	Conifer Expansion (Modeled) Acres*		
					0-25% Sagebrush Landscape Cover	25%-65% Sagebrush Landscape Cover	65%+ Sagebrush Landscape Cover

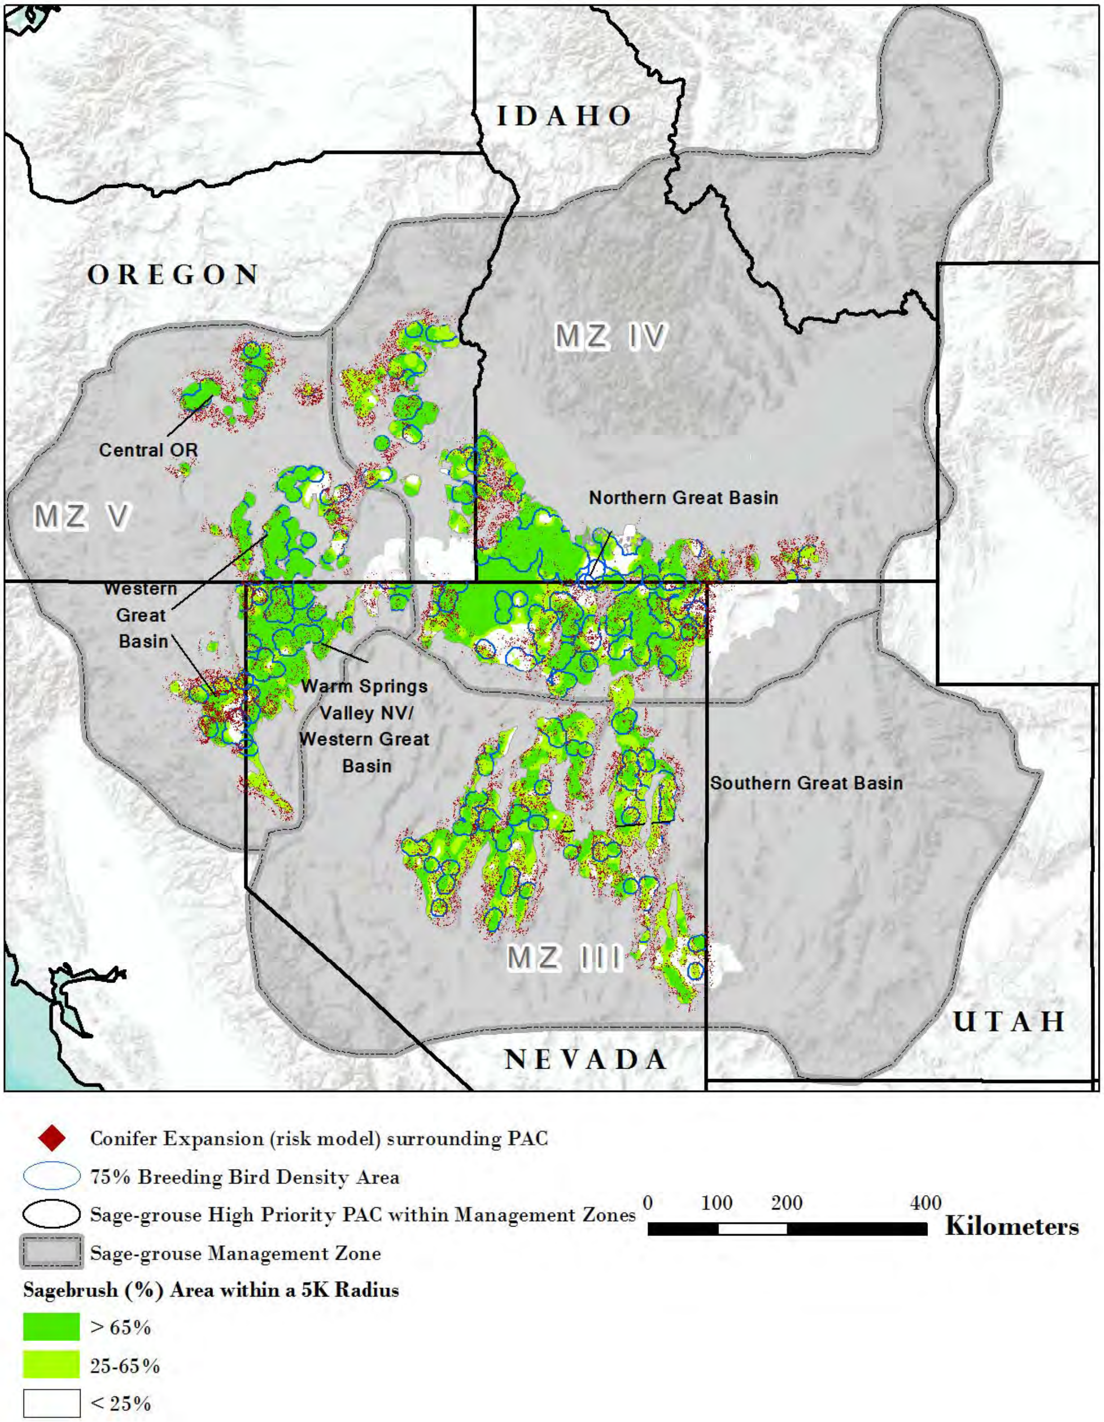

Figure 9, Five PACs Significantly Impacted by Conifer Expansion that contribute substantially to the 75% BBD and that have sagebrush landscape cover greater than 25%.

While the coarse-scale conifer expansion data used in this analysis likely over estimates the extent of the pinyon pine and/or juniper threat, results suggest that far fewer acres are currently affected by conifers than might be at risk from fire and invasive annual grasses impacts. Conifer expansion into sage-grouse habitats occurs at a slower rate, allowing more time for treatment, but early action may be needed to prevent population level impacts on sage-grouse (Baruch-Mordo et al. 2013). Furthermore, conifer expansion is primarily occurring on cooler and moister sites that are more resilient and where restoration is more likely to be effective (Miller et al. 2011), providing managers the opportunity to potentially offset at least some habitat loss expected to continue in less resilient ecosystems. While the available data set used to estimate conifer expansion provides only a coarse assessment of the problem, considerable efforts are currently underway to map conifers across sage-grouse range. These maps are expected to be available in the near future and should be used by land managers to better target project level conifer removal.

FIAT cautions against using the plotted locations of estimated conifer expansion for local management decisions due to the coarse-scale nature of this range-wide data set. Conifer expansion estimates are primarily provided here to aid in judging the relative scope of the threat in each PAC.

Step 1b. Potential Management Strategies

Potential management **strategies** (e.g., fuels management, habitat recovery/restoration, fire operations, post-fire rehabilitation) to conserve or restore Step 1 focal habitats are described below to assist local management units to initiate Step 2. These examples are illustrative and do not contain the full range of management strategies that may be required to address wildfires, invasive annual grasses, and conifer expansion within PACs and associated focal habitats. In general, the priority for applying management strategies is to first maintain or conserve intact habitat and second to strategically restore habitat (after a wildfire or proactively to reconnect habitat). Management strategies will differ when applying the protocol to:

Wildfire and Invasive Annual Grass. (See PACs identified in Table 2 and focal habitats shown in Figure 8). Focal habitats, as they relate to wildfires and invasive annual grasses, are defined as sage-grouse habitat in priority PACs within 75 percent BBD. Within these focal habitats, sagebrush communities with low resilience to disturbance and resistance to invasive annual grasses (warm and dry soil temperature and moisture regimes) are an emphasis area for management actions. Appendix 5 (A) in Chambers et al. 2014) includes a generalized state and transition model with an invasive annual grass component and warm and dry soil temperature and moisture regime associated with 8 to 12 inches of annual precipitation. This state and transition models is useful in developing management strategies to deal with annual grass issues as it contains useful restoration pathways.

Burn Probability is another tool that can be used to assist managers to identify the relative likelihood of large fire occurrence across the landscape within PACs and focal habitats. Burn probability raster data were generated by the Missoula Fire Lab using the large fire simulator - FSim - developed for use in the national Interagency **Fire Program Analysis (FPA)** project. FSim uses historical weather data and LANDFIRE fuel model data to simulate fires burning. Using these simulated fires, an overall burn probability is returned by FSim for each 270m pixel. The burn probability data was overlaid spatially with PACs, soil data, and shrub cover data. The majority of the high and very high burn probability acres lie within the top 5 PACs and are within areas with >25% sagebrush cover. Several of the other PACs have a greater overall percentage of the warm/dry soil regime with high/very high burn probability (northern great basin, baker, and NW interior NV) but the total acres are relatively few. Areas identified with high and very high burn probability are most likely to experience large fires given fire history, fuels, weather and topography. Results are displayed in the table 5 and Figure 10.

Table 5, Percentages of sage-grouse PAC areas with high and very high burn probability, 75% BBD within PAC, 75% BBD and warm dry/temperature regime, and 75% BBD and warm dry/temperature and warm dry/temperature with high and very high burn probability.

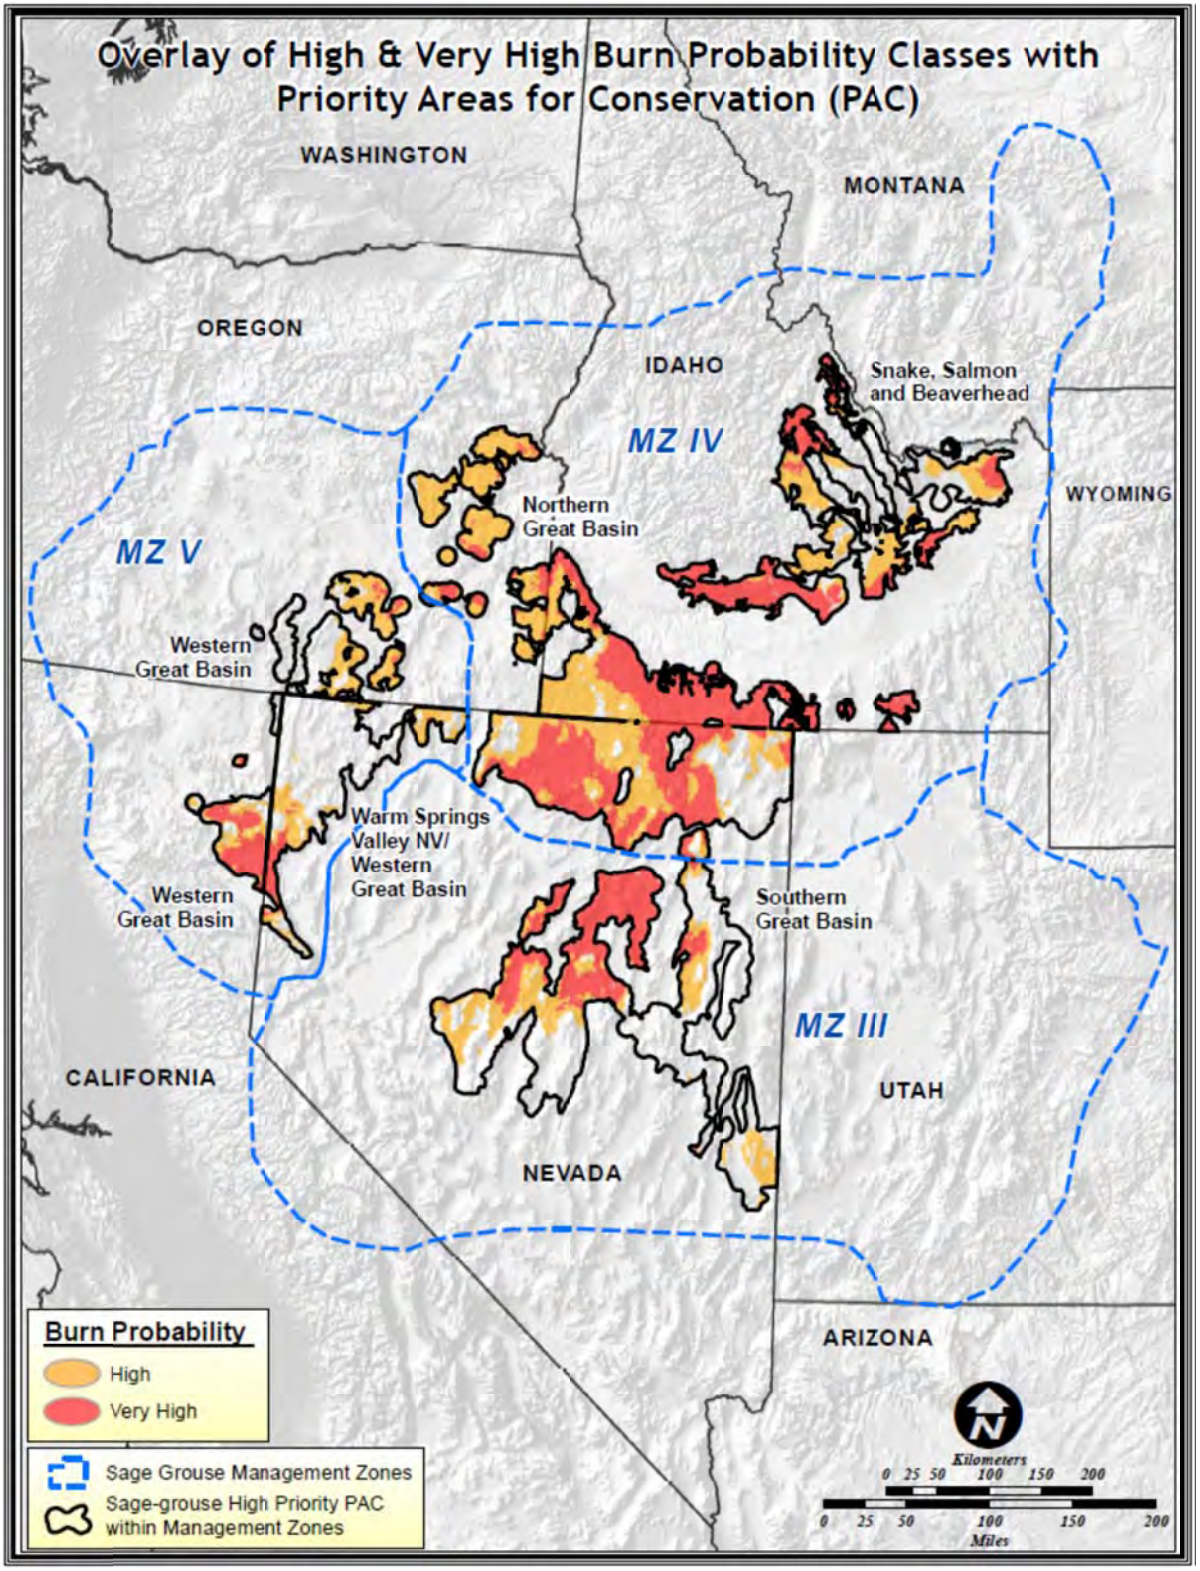

Figure 10, Burn Probability (high and very high) in priority invasive annual grass and wildfire PACs. .

Conifer Expansion. (See priority PACs for assessment identified in Table 4 and focal habitats shown in Figure 9). Focal habitats, as they relate to conifer expansion, are defined as sage-grouse habitat in a priority PAC with sagebrush landscape cover between 25 and 100 percent that is either near or in a conifer expansion area. The relationship between conifer expansion and resilience to disturbance and resistance to expansion is not documented to the same degree as with invasive annual grasses. However, Appendix 5 (D. and E.) in Chambers et al. 2014) includes two generalized state and transition models for conifer expansion with warm to cool and soil temperature regimes associated with precipitation ranges from 12 to 14 or more inches of annual precipitation. These state and transition models are useful in developing management strategies to deal with conifer expansion as they contain useful restoration pathways.

Chambers et al. 2014) is recommended for review at this point for information on applying resistance and resilience concepts along with sage-grouse habitat characteristics to develop management strategies to address wildfires, invasive annual grasses, and conifer expansion. The following tables are recommended for use in developing management strategies in or near focal habitats:

> Table 1. Soil temperature and moisture regimes relationship to vegetation types and resistance and resilience.
> Table 2. Sage-grouse habitat matrix showing the relationship between landscape sagebrush cover and resistance and resilience.
> Table 3. Potential management strategies based on sage-grouse habitat requirements and resistance and resilience.
> Table 4. Management strategies (fire suppression, fuels management, post-fire rehabilitation, and habitat restoration) associated with each cell in the sage-grouse habitat matrix (Table 2).

The "Putting it all together" section of the Chambers et al. 2014) also contains a case study from Northeast Nevada illustrating applications of management strategies to address the conservation, protection, and restoration of sage-grouse habitat.

To further assist in understanding Step 1b, examples of general priorities for management strategies are provided below and illustrated in Appendix 3 and 4:

1. Fuels Management: Projects that are designed to change vegetation composition and/or structure to modify potential fire behavior for the purpose of improving fire suppression effectiveness and limiting fire spread and intensity.
    a. Identify priorities and potential measures to reduce the threats to sage-grouse habitat resulting from changes in invasive annual grasses (primary focus on exotic annual grasses and conifer encroachment) and wildland fires. Place high priority on areas dominated by invasive annual grasses that are near or adjacent to low resistance and resilience habitats that are still intact.
    b. Areas on or near perimeter of successful post-fire rehabilitation and habitat restoration projects where threats of subsequent fire are present are important for consideration.

    c. Fuels management can be a high priority in large tracts of intact sagebrush if impacts on sage-grouse populations are minimal and outweighed by the potential benefits of reduced wildfire impacts in area being protected.

2. Habitat Recovery/Restoration Recovery (passive restoration) is a high priority in intact sagebrush stands to improve resistance and resilience before a disturbance. For example, where understory perennial herbaceous species are limited, improved livestock grazing practices can increase the abundance of these species and promote increased resistance to annual grasses.
    a. Habitat restoration is important where habitat connectivity issues are present within focal habitats.
    b. Pinyon pine and/or juniper removal in Phase I and II stands adjacent to large, contiguous areas of sagebrush (greater than 25 percent sagebrush landscape cover) is a priority.

3. Fire Operations (includes preparedness, prevention and suppression activities).
    a. Higher priority should be placed on areas with greater than 65 percent cover than on areas with 25 to 65 percent cover, followed by 0 to 25 percent cover (these categories are continuums not discrete thresholds).
    b. Higher priority should be placed on lower resistance/resilience habitats compared with higher resistance/resilience habitats.
    c. Fire operations in areas restored or post-fire rehabilitation treatment where subsequent wildfires can have detrimental effect on investment and recovery of habitat are important for consideration.
    d. Fire operations (suppression) are especially important in low elevation winter sagebrush habitat with low resistance and resiliency.
4. Post-Fire Rehabilitation
    a. High priority should be placed on supporting short-term natural recovery and long-term persistence in higher resistance and resiliency habitats (with appropriate management applied).
    b. High priority should be placed on reseeding in moderate to low resistance and resiliency habitats, but only if competition from invasive annual grasses, if present, can be controlled prior to seeding.

Step 2

Step 2 is carried out by local management units using the Step 1 geospatial data, focal habitats, and the associated management strategies. Step 2 includes evaluating the availability and accuracy of local information and geospatial data used to develop local management strategies in or near focal habitats (Step 2a).

It also involves developing focal habitat activity/implementation plans that include prioritized management tactics and treatments to implement effective fuels management, habitat recovery/restoration, fire operations, and post-fire rehabilitation (Step 2b). These activity/implementation plans will serve as the basis for NEPA analysis of site-specific projects.

Step 2a- Review of Step 1 Data and Incorporation of Local Information

Evaluate the accuracy and utility of Step 1 geospatial layers for focal habitats by incorporating more accurate or locally relevant:

- Vegetation maps (especially sagebrush cover)
- Updated or higher resolution conifer expansion layers (if applicable)
- Soil survey and ecological site descriptions
- Weather station, including Remote Automatic Weather Stations, data
- PACs, focal habitats, winter habitats, sage-grouse population distributions (i.e., more recent BBD surveys)
- Maps of cheatgrass and other invasive annual grasses that degrade sage-grouse habitat
- Wildfire polygons including perimeters and unburned islands within burn polygons
- Treatment locations and success (consult US Geological Survey Land Treatment Digital Library at http://ltdl.wr.usgs.gov/). The Land Treatment Digital Library allows the user to search on treatment results on an ecological site basis.
- Models and tools to help inform management strategies. For example, data which characterizes wildfire potential can help identify risk to focal habitats and help plan fire suppression and fuels management strategies to address these risks.
- Rapid Ecoregional Assessments
- Land Use Plans
- Appropriate monitoring or inventory information
- Any other geospatial data or models that could improve the accuracy of the assessment process

It is essential that subregional or local information and geospatial data be subjected to a quality control assessment to ensure that it is appropriate to use in developing Step 2b activity and implementation plans. Since PACs and focal habitats usually transcend multiple administrative boundaries, a collaborative approach is highly recommended for Step 2a.

A series of questions tied to the management strategies described in the Introduction section follows to assist managers in developing the framework to complete Step 2b (development of activity/implementation plans). The questions that follow apply to the focal habitats (and buffer areas around focal areas where management strategies may be more effectively applied) and will help in developing coordinated implementation/activity plans. These questions should not limit the scope of the assessment and additional questions relative to local situations are encouraged. These questions portray the minimum degree of specificity for focal habitats in order for offices to complete Step 2a.

Fuels Management

1. Where are the priority fuels management areas (spatially defined treatment opportunity areas that consider fire risk, fuels conditions, and focal habitats [including areas adjacent to focal habitats])?
2. Based on fire risk to focal habitats, what types of fuels treatments should be implemented to reduce this threat (for example, linear features that can be used as anchors during suppression operations)?
3. Considering resistance/resilience concepts and the landscape context from Step 1, where should treatments be applied in and around focal habitats to:
   a. Constrain fire spread?
   b. Reduce the extent of conifer expansion?
   c. Augment future suppression efforts by creating fuel breaks or anchors for suppression?
4. Based on opportunities for fire to improve/restore focal habitats, what types of fuels treatments should be implemented to compliment managed wildfire by modifying fire behavior and effects?
5. Are there opportunities to utilize a coordinated fuels management approach across jurisdictional boundaries?
6. What fuel reduction techniques will be most effective that are within acceptable impact ranges of local sage-grouse populations, including but not limited to grazing, prescribed fire, chemical, and biological and mechanical treatments? Will combinations of these techniques improve effectiveness (e.g., using livestock to graze fine fuels in a mowed fuel break in sagebrush)?

Habitat Recovery/Restoration

1. Are there opportunities for habitat restoration treatments to protect, enhance or maintain sage-grouse focal habitat especially to restore connectivity of focal area habitat?
2. Considering the resistance and resilience GIS data layer (Figure 4) and the Sage-Grouse Habitat Matrix (Chambers et al. 2014; Table 2), where and why would passive or active restoration treatments be used?
3. What are the risks and opportunities of restoring habitat with low resistance and resilience including the warm/dry and cool/dry soil moisture/temperature regime areas?
4. Are there opportunities to utilize a coordinated approach across jurisdictional boundaries to effectively complete habitat restoration in focal habitats?

Fire Operations

1. Where are priority fire management areas (spatially defined polygons having the highest need for preparedness and suppression action)?

2. Where are the greatest wildfire risks to focal habitats considering trends in fire occurrence and fuel conditions (see Figure 10)?
3. Where do opportunities exist that could enhance or improve suppression capability in and around focal habitats?
    a) For example, increased water availability through installation of helicopter refill wells or water storage tanks.
    b) Decreased response time through pre-positioned resources or staffing remote stations.
4. Should wildfire be managed (per land use plan objectives) for improving focal habitat (e.g., reducing conifer expansion), and if so where, and under what conditions?
5. How can fire management be coordinated across jurisdictional boundaries to reduce risk or to improve focal habitats?

Post-fire Rehabilitation

1. Where are areas that are a high priority for post-fire rehabilitation to improve habitat connectivity if a wildfire occurs?
2. Which areas are more conducive (higher resistance and/or resilience) to recovery and may not need reseeding after a wildfire?
3. What opportunities to build in fire resistant fuel breaks to reduce the likelihood of future wildfires impacts on seeded or recovering areas?
4. Are there opportunities to utilize a coordinated approach across jurisdictional boundaries to implement rehabilitation practices?

The outcome of Step 2a is the assembly of the pertinent information and GIS layers to assist managers in developing implementation or activity plans to address wildfires, invasive annual grasses, and conifer expansion in focal habitats. Activity plans generally refer to plans where management of a resource is changed (livestock grazing plans) whereas implementation plans are generally associated with treatments.

Step 2b- Preparation of Activity/Implementation Plans

Activity/implementation plans are prepared to implement the appropriate management strategies within and adjacent to focal habitats. Since focal habitats cross jurisdictional boundaries, it is especially important that a collaborative approach be used to develop implementation/activity plans. The process of identifying partners and creating collaborative teams to develop these plans is a function of state, regional, and local managers and is not addressed as part of this step.

Implementation/activity plans are required to:

1. Address issues in and around focal habitats related to wildfires, invasive annual grasses, and conifer expansion

2. Use resistance to invasive annual grasses and resilience after disturbance (where appropriate) as part of the selection process for implementing management strategies
3. Emphasize application of management strategies within or near focal habitats with low resistance and resilience (warm/dry and cool/dry soil moisture/temperature regimes) invasive annual grasses and wildfires
4. Use the best available local information to inform the assessment process
5. Encourage collaboration and coordination with focal habitats across jurisdictional boundaries
6. Be adaptive to changing conditions, disturbances, and modifications of PAC boundaries

FIAT recommends considering other factors, such as adaptive management for climate change, local sagebrush mortality due to aroga moth or other pests, and cheatgrass die-off areas in developing activity/implementation plans. The latter two factors could influence where and what kind of management strategies may be needed to address the loss of habitat or changes in fuel characteristics (e.g., load and flammability) associated with these mortality events.

The following recommendations are provided to assist in the preparation of activity/implementation plans:

Fuels Management

1. Spatially delineate priority areas for fuel management treatments per Step 2a information considering:
   a. Linear fuel breaks along roads
   b. Other linear fuel breaks to create anchor points
   c. Prescribed burning which would meet objectives identified in the Fish and Wildlife Service's Conservation Objectives Team (COT) report
   d. Mechanical (e.g., treatment of conifer expansion into sagebrush communities)
   e. Other mechanical, biological, or chemical treatments
   f. If they exist, spatially delineated areas where fuel treatments would increase the ability to use fire to improve/enhance focal habitats.
2. Identify coordination needed between renewable resource, fire management, and fuels management staff to facilitate planning and implementation of fuels treatments.
3. Quantify a projected level of treatment within or near focal habitats.
   a. Identify treatments (projects) to be planned within or near focal habitats.
   b. Include a priority and proposed work plan for proposed treatments.

Habitat Recovery/Restoration

1. Spatially delineate priority areas for restoration, using criteria established in Step 2a. Priority areas for restoration should be delineated by treatment methods:
   a. Seeding priority areas
   b. Invasive annual grasses priority treatment areas (herbicide, mechanical, biological, combination)

    c. Priority areas requiring combinations of treatments (e.g., herbicide followed by seeding).
    d. Include tables, maps or appropriate info.
2. Identify coordination needed between renewable resource, fire management, and fuels management staff to facilitate planning and implementation of restoration treatments.
3. Include a priority or implementation schedule for proposed restoration treatment

Fire Operations

1. Spatially delineate priority areas for fire suppression, based upon criteria established in Step 2a. Priority areas for fire operations should be delineated by type, such as:
    a. Initial attack priority areas
    b. Resource pre-positioning and staging priority areas
2. Spatially delineate areas where opportunities exist to enhance or improve suppression capability.
3. Spatially delineate areas where wildfire can be managed to achieve land use plan and COT objectives.

Post-Fire Rehabilitation

1. Spatially delineate priority areas for post-fire rehabilitation using criteria in Step 2a.
2. Priority areas for post-fire rehabilitation should be based on resistance and resiliency and pre-fire landscape sagebrush cover and include consideration of:
    a. Seeding priority areas
    b. Invasive annual grasses priority treatment areas (herbicide, mechanical, biological (herbivory or seeding),
    c. Priority areas requiring combinations of treatments (e.g., herbicide followed by seeding)
3. Identify coordination needed between renewable resource, fire management, and fuels management staff to facilitate planning and implementation of post-fire rehabilitation treatments.

This completes the assessment process and sets the stage for more detailed project planning and NEPA associated with implementing on-the-ground treatments and management changes.

Members of the FIAT Development and Review teams are listed in Appendix 5.

Abstract

This Report provides a strategic approach for conservation of sagebrush ecosystems and Greater Sage-Grouse (sage-grouse) that focuses specifically on habitat threats caused by invasive annual grasses and altered fire regimes. It uses information on factors that influence (1) sagebrush ecosystem resilience to disturbance and resistance to invasive annual grasses and (2) distribution, relative abundance, and persistence of sage-grouse populations to develop management strategies at both landscape and site scales. A sage-grouse habitat matrix links relative resilience and resistance of sagebrush ecosystems with sage-grouse habitat requirements for landscape cover of sagebrush to help decision makers assess risks and determine appropriate management strategies at landscape scales. Focal areas for management are assessed by overlaying matrix components with sage-grouse Priority Areas for Conservation (PACs), breeding bird densities, and specific habitat threats. Decision tools are discussed for determining the suitability of focal areas for treatment and the most appropriate management treatments.

Keywords: sagebrush habitat, Greater Sage-Grouse, fire effects, invasive annual grasses, management prioritization, conservation, prevention, restoration

Introduction

An unprecedented conservation effort is underway across 11 States in the western United States to reduce threats to Greater Sage-Grouse (*Centrocercus urophasianus*; hereafter, sage-grouse) and the sagebrush ecosystems on which they depend (fig. 1). Recent efforts were accelerated by the March 2010 determination that sage-grouse warrant protection under the Federal Endangered Species Act, and by increased emphasis on broad collaboration among state and Federal partners to proactively identify and implement actions to reverse current trends (USFWS 2010, 2013). Conservation success hinges on being able to achieve "the long-term conservation of sage-grouse and healthy sagebrush shrub and native perennial grass and forb communities by maintaining viable, connected, and well-distributed populations and habitats across their range, through threat amelioration, conservation of key habitats, and restoration activities" (USFWS 2013). While strides are being made to curtail a host of threats across the range, habitat loss and fragmentation due to wildfire and invasive plants remain persistent challenges to

Figure 1. Greater Sage-Grouse (*Centrocercus urophasianus*) (photo by Charlotte Ganskopp).

achieving desired outcomes – particularly in the western portion of the range (Miller et al. 2011; USFWS 2010; 2013). Management responses to date have not been able to match the scale of this problem. Natural resource managers are seeking coordinated approaches that focus appropriate management actions in the right places to maximize conservation effectiveness (Wisdom and Chambers 2009; Murphy et al. 2013).

Improving our ability to manage for resilience to disturbance and resistance to invasive species is fundamental to achieving long-term sage-grouse conservation objectives. Resilient ecosystems have the capacity to ***regain*** their fundamental structure, processes, and functioning when altered by stressors like drought and disturbances like inappropriate livestock grazing and altered fire regimes (Holling 1973; Allen et al. 2005). Species resilience refers to the ability of a species to recover from stressors and disturbances (USFWS 2013), and is closely linked to ecosystem resilience. Resistant ecosystems have the capacity to ***retain*** their fundamental structure, processes, and functioning when exposed to stresses, disturbances, or invasive species (Folke et al. 2004). Resistance to invasion by nonnative plants is increasingly important in sagebrush ecosystems; it is a function of the abiotic and biotic attributes and ecological processes of an ecosystem that limit the population growth of an invading species (D'Antonio and Thomsen 2004**)**. A detailed explanation of the factors that influence resilience and resistance in sagebrush ecosystems is found in Chambers et al. 2014.

In general, species are likely to be more resilient if large populations exist in large blocks of high quality habitat across the full breadth of environmental variability to which the species is adapted (Redford et al. 2011). Because sage-grouse are a broadly distributed and often wide-ranging species that may move long-distances between seasonal habitats (Connelly et al. 2011a,b), a strategic approach that integrates both landscape prioritization and site-scale decision tools is needed. This document develops such an approach for the conservation of sagebrush habitats across the range of sage-grouse with an emphasis on the western portion of the range. In recent years, information and tools have been developed that significantly increase our understanding of factors that influence the resilience of sagebrush ecosystems and the distribution of sage-grouse populations, and that allow us to strategically prioritize management activities where they are most likely to be effective and to benefit the species. Although the emphasis of this Report is on the western portion of the sage-grouse range, the approach has management applicability to other sagebrush ecosystems.

In this report, we briefly review causes and effects of invasive annual grasses and altered fire regimes, and then discuss factors that determine resilience to disturbances like wildfire and resistance to invasive annual grasses in sagebrush ecosystems. We illustrate how an understanding of resilience and resistance, sagebrush habitat requirements for sage-grouse, and consequences that invasive annual grasses and wildfire have on sage-grouse populations can be used to develop management strategies at both landscape and site scales. A sage-grouse habitat matrix is provided that links relative resilience and resistance with habitat requirements for landscape cover of sagebrush to both identify priority areas for management and determine effective management strategies at landscape scales. An approach for assessing focal areas for sage-grouse habitat management is described that overlays Priority Areas for Conservation (PACs) and breeding bird densities with resilience and resistance and habitat suitability to spatially link sage-grouse populations with habitat conditions and risks. The use of this approach is illustrated for the western portion of the range and for a diverse area in the northeast corner of Nevada. It concludes with a discussion of the tools available for determining the suitability of focal areas for treatment and the most appropriate management treatments. Throughout the document, the emphasis is on using this approach to guide and assist fire operations, fuels management, post-fire rehabilitation, and habitat restoration activities to maintain or enhance sage-grouse habitat.

Threats of Invasive Annual Grasses and Altered Fire Regimes to Sagebrush Ecosystems and Sage-Grouse

Effects on Sagebrush Ecosystems

Sage-grouse habitat loss and fragmentation due to wildfire and invasive plants are widely recognized as two of the most significant challenges to conservation of the species, particularly in the western portion of the range (Miller et al. 2011; USFWS 2010, 2013). During pre-settlement times, sagebrush-dominated ecosystems had highly variable fire return intervals that ranged from decades to centuries (Frost 1998; Brown and Smith 2000; Miller et al. 2011). At coarse regional scales, fire return intervals in sagebrush ecological types were determined largely by climate and its effects on fuel abundance and continuity. Consequently, fire frequency was higher in sagebrush types with greater productivity at higher elevations and following periods of increased precipitation than in lower elevation and less productive ecosystems (West 1983b; Mensing et al. 2006). At local scales within sagebrush types, fire return intervals likely were determined by topographic and soil effects on productivity and fuels and exhibited high spatial and temporal variability (Miller and Heyerdahl 2008).

Euro-American arrival in sagebrush ecosystems began in the mid-1800s and initiated a series of changes in vegetation composition and structure that altered fire regimes and resulted in major changes in sagebrush habitats. The first major change in fire regimes occurred when inappropriate grazing by livestock led to a decrease in native perennial grasses and forbs and effectively reduced the abundance of fine fuels (Knapp 1996; Miller and Eddleman 2001; Miller et al. 2011). Decreased competition from perennial herbaceous species, in combination with ongoing climate change and favorable conditions for woody species establishment at the turn of the twentieth century, resulted in increased abundance of shrubs (primarily *Artemisia* species) and trees, including juniper (*Juniperus occidentalis*, *J. osteosperma*) and piñon pine (*Pinus monophylla*), at mid to high elevations (Miller and Eddleman 2001; Miller et al. 2011). The initial effect of these changes in fuel structure was a reduction in fire frequency and size. The second major change in fire regimes occurred when non-native annual grasses (e.g., *Bromus tectorum, Taeniatherum caput-medusa*) were introduced from Eurasia in the late 1800s and spread rapidly into low to mid-elevation ecosystems with depleted understories (Knapp 1996). The invasive annual grasses increased the amount and continuity of fine fuels in many lower elevation sagebrush habitats and initiated annual grass/fire cycles characterized by shortened fire return intervals and larger, more contiguous fires (fig. 2; D'Antonio and Vitousek 1992; Brooks et al. 2004). Since settlement of the region, cheatgrass came to dominate as much as 4 million hectares (9.9 million acres) in the states of Nevada and Utah alone (fig. 3; Bradley and Mustard 2005). The final change in fire regimes occurred as a result of expansion of juniper and piñon pine trees into sagebrush types at mid to high elevations and a reduction of the grass, forb, and shrub species associated with these types. Ongoing infilling of trees is increasing woody fuels, but reducing fine fuels and resulting in less frequent fires (fig. 4; Miller et al. 2013). Extreme burning conditions (high winds, high temperatures, and low relative humidity) in high density (Phase III) stands are resulting in large and severe fires that result in significant losses of above- and below-ground organic matter (sensu Keeley 2009) and have detrimental ecosystem effects (Miller et al. 2013). Based on tree-ring analyses at several Great Basin sites, it is estimated that the extent of piñon and/or juniper woodland increased two to six fold since settlement, and most of that area will exhibit canopy closure within the next 50 years (Miller et al. 2008).

Figure 3. A wildfire that started in invasive annual grass adjacent to a railroad track and burned upslope into a mountain big sagebrush and Jeffrey pine ecosystem in northeast Nevada (top). A big sagebrush ecosystem that has been converted to invasive annual grass in north central Nevada (bottom) (photos by Nolan E. Preece).

Figure 4. Expansion of Utah juniper trees into a mountain big sagebrush ecosystem in east central Utah (top) that is resulting in progressive infilling of the trees and exclusion of native understory species (bottom) (photos by Bruce A. Roundy).

Effects on Sage-Grouse Habitat Selection and Population Dynamics

Understanding the effects of landscape changes on sage-grouse habitat selection and population dynamics can help managers apply more strategic and targeted conservation actions to reduce risks. Two key land cover shifts resulting from invasive annual grasses and altered fire regimes are affecting the ability to achieve the range-wide goal of stable-to-increasing population trends − large-scale reduction of sagebrush cover and conversion of sagebrush ecosystems to annual grasslands.

Sage-grouse are true sagebrush obligates that require large and intact sagebrush landscapes. Consequently, wildfires occurring at the extremes of the natural range of variability that remove sagebrush, even temporarily, over large areas and over short time periods often have negative consequences for sage-grouse. Several range-wide studies have identified the proportion of sagebrush-dominated land cover as a key indicator of sage-grouse population persistence and, importantly, have revealed critical levels of sagebrush landscape cover required by sage-grouse (see Appendix 2 for a description of landscape cover and how it is derived). Knick et al. (2013) found that 90% of active leks in the western portion of the range had more than 40% landscape cover of sagebrush within a 5-km (3.1-mi) radius of leks. Another range-wide analysis documented a high risk of extirpation with <27% sagebrush landscape cover and high probability of persistence with >50% sagebrush landscape cover within 18-km (11.2-mi) of leks (Wisdom et al. 2011). Similarly, Aldridge et al. (2008) found long-term sage-grouse persistence required a minimum of 25%, and preferably at least 65%, sagebrush landscape cover at the 30-km (18.6-mi) scale. Considered collectively, cumulative disturbances that reduce the cover of sagebrush to less than a quarter of the landscape have a high likelihood of resulting in local population extirpation, while the probability of maintaining persistent populations goes up considerably as the proportion of sagebrush cover exceeds two-thirds or more of the landscape. Reduction of sagebrush cover is most critical in low to mid elevations where natural recovery of sagebrush can be very limited within timeframes important to sage-grouse population dynamics (Davies et al. 2011).

Nonnative annual grasses and forbs have invaded vast portions of the sage-grouse range, reducing both habitat quantity and quality (Beck and Mitchell 2000; Rowland et al. 2006; Miller et al. 2011; Balch et al. 2013). Due to repeated fires, some low- to mid-elevation native sagebrush communities are shifting to novel annual grassland states resulting in habitat loss that may be irreversible with current technologies (Davies et al. 2011; Miller et al. 2011; Chambers et al. 2014). At the broadest scales, the presence of non-native annual grasslands on the landscape may be influencing both sage-grouse distribution and abundance. In their analysis of active leks, Knick et al. (2013) found that most leks had very little annual grassland cover (2.2%) within a 5-km (3.1-mi) radius of the leks; leks that were no longer used had almost five times as much annual grassland cover as active leks. Johnson et al. (2011) found that lek use became progressively less as the cover of invasive annual species increased at both the 5-km (3.1-mi) and 18-km (11.2-mi) scales. Also, few leks had >8% invasive annual vegetation cover within both buffer distances.

Patterns of nest site selection also suggest local impacts of invasive annual grasses on birds. In western Nevada, Lockyer (2012) found that sage-grouse selected large expanses of sagebrush-dominated areas and, within those areas, sage-grouse selected microsites with higher shrub canopy cover and lower cheatgrass cover. Average cheatgrass cover at selected locations was 7.1% compared to 13.3% at available locations. Sage-grouse hens essentially avoided nesting in areas with higher cheatgrass cover. Kirol et al. (2012) also found nest-site selection was negatively correlated with the presence of cheatgrass in south-central Wyoming.

Sage-grouse population demographic studies in northern Nevada show that recruitment and annual survival also are affected by presence of annual grasslands at larger scales. Blomberg et al. (2012) analyzed land cover within a 5-km (3.1-mi) radius of leks and found that leks impacted by annual grasslands experienced lower recruitment than non-impacted leks, even following years of high precipitation. Leks that were not affected by invasive annual grasslands exhibited recruitment rates nearly twice as high as the population average and nearly six times greater than affected leks during years of high precipitation.

Piñon and juniper expansion at mid to upper elevations into sagebrush ecosystems also has altered fire regimes and reduced sage-grouse habitat availability and suitability over large areas with population-level consequences (Miller et al. 2011; Baruch-Mordo et al. 2013; Knick et al. 2013). Conifer expansion results in non-linear declines in sagebrush cover and reductions in perennial native grasses and forbs as conifer canopy cover increases (Miller et al. 2000) and this has direct effects on the amount of available habitat for sagebrush-obligate species. Sites in the late stage of piñon and juniper expansion and infilling (Phase III from Miller et al. 2005) have reduced fire frequency (due to decreased fine fuels), but are prone to higher severity fires (due to increased woody fuels) which significantly reduces the likelihood of sagebrush habitat recovery (fig. 5) (Bates et al. 2013). Even before direct habitat loss occurs, sage-grouse avoid or are negatively associated with conifer cover during all life stages (i.e., nesting, brood-rearing, and wintering; Doherty et al. 2008, 2010a; Atamian et al. 2010; Casazza et al. 2011). Also, sage-grouse incur population-level impacts at a very low level of conifer encroachment. The ability to maintain active leks is severely compromised when conifer canopy exceeds 4% in the immediate vicinity of the lek (Baruch-Mordo et al. 2013), and most active leks average less than 1% conifer cover at landscape scales (Knick et al. 2013).

Figure 5. A post-burn, Phase III, singleleaf piñon and Utah juniper dominated sagebrush ecosystem in which soils are highly erosive and few understory plants remain (photo by Jeanne C. Chambers).

Resilience to Disturbance and Resistance to Invasive Annual Grasses in Sagebrush Ecosystems

Our ability to address the changes occurring in sagebrush habitats can be greatly enhanced by understanding the effects of environmental conditions on resilience to stress and disturbance, and resistance to invasion (Wisdom and Chambers 2009; Brooks and Chambers 2011; Chambers et al. 2014). In cold desert ecosystems, resilience of native ecosystems to stress and disturbance changes along climatic and topographic gradients. In these ecosystems, Wyoming big sagebrush (*Artemisia tridentata* spp. *wyomingensis*), mountain big sagebrush (*A. t.* spp. *vaseyana*), and mountain brush types (e.g., mountain big sagebrush, snowberry [*Symphorocarpus* spp.], bitterbrush [*Purshia tridentata*]) occur at progressively higher elevations and are associated with decreasing temperatures and increasing amounts of precipitation, productivity, and fuels (fig. 6; West and Young 2000). Piñon pine and juniper woodlands are typically associated with mountain big sagebrush types, but can occur with relatively cool and moist Wyoming big sagebrush types and warm and moist mountain brush types (Miller et al. 2013). Resilience to disturbance, including wildfire, has been shown to increase along these elevation gradients (fig. 7A) (Condon et al. 2011; Davies et al. 2012; Chambers et al. 2014; Chambers et al. *in press*). Higher precipitation and cooler temperatures, coupled with greater soil development and plant productivity at mid to high elevations, can result in greater resources and more favorable environmental conditions for plant growth and reproduction (Alexander et al. 1993; Dahlgren et al. 1997). In contrast, minimal precipitation and high temperatures at low elevations result in lower resource availability for plant growth (West 1983a,b;

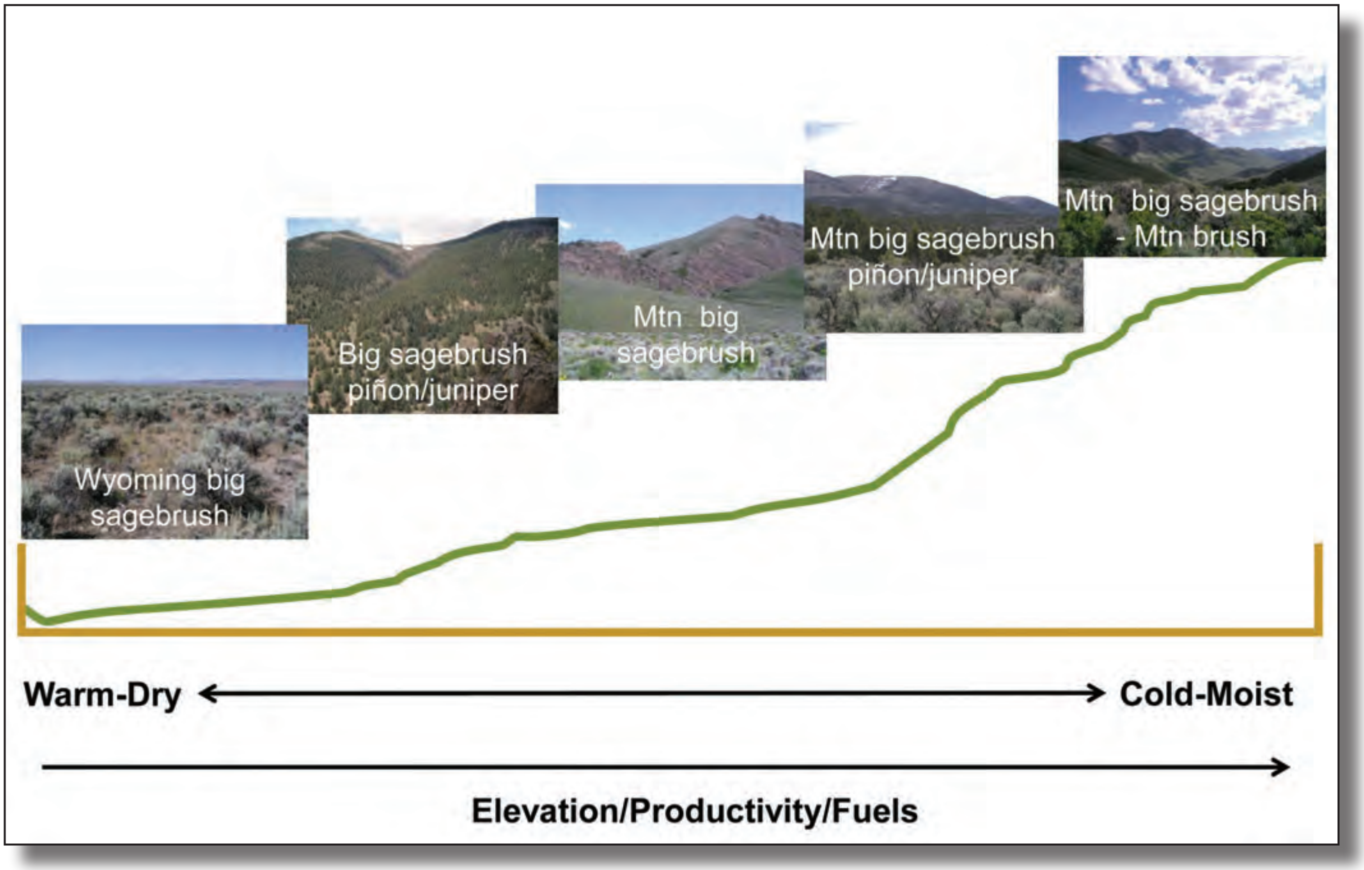

Figure 6. The dominant sagebrush ecological types that occur along environmental gradients in the western United States. As elevation increases, soil temperature and moisture regimes transition from warm and dry to cold and moist and vegetation productivity and fuels become higher.

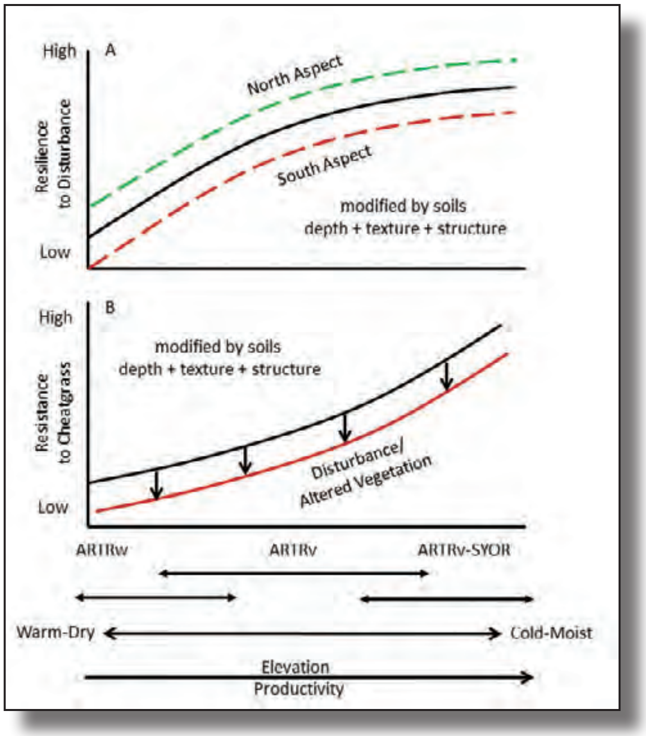

Figure 7. (**A)** Resilience to disturbance and (**B)** resistance to cheatgrass over a typical temperature/precipitation gradient in the cold desert. Dominant ecological sites occur along a continuum that includes Wyoming big sagebrush on warm and dry sites, to mountain big sagebrush on cool and moist sites, to mountain big sagebrush and root-sprouting shrubs on cold and moist sites. Resilience increases along the temperature/precipitation gradient and is influenced by site characteristics like aspect. Resistance also increases along the temperature/precipitation gradient and is affected by disturbances and management treatments that alter vegetation structure and composition and increase resource availability (modified from Chambers et al. 2014; Chambers et al. *in press*).

Smith and Nowak 1990). These relationships also are observed at local plant community scales where aspect, slope, and topographic position affect solar radiation, erosion processes, effective precipitation, soil development and vegetation composition and structure (Condon et al. 2011; Johnson and Miller 2006).

Resistance to invasive annual grasses depends on environmental factors and ecosystem attributes and is a function of (1) the invasive species' physiological and life history requirements for establishment, growth, and reproduction, and (2) interactions with the native perennial plant community including interspecific competition and response to herbivory and pathogens. In cold desert ecosystems, resistance is strongly influenced by soil temperature and moisture regimes (Chambers et al. 2007; Meyer et al. 2001). Germination, growth, and/or reproduction of cheatgrass is physiologically limited at low elevations by frequent, low precipitation years, constrained at high elevations by low soil temperatures, and optimal at mid elevations under relatively moderate temperature and water availability (fig. 7B; Meyer et al. 2001; Chambers et al. 2007). Slope, aspect, and soil characteristics modify soil temperature and moisture and influence resistance to cheatgrass at landscape to plant community scales (Chambers et al. 2007; Condon et al. 2011; Reisner et al. 2013). Genetic variation in cheatgrass results in phenotypic traits that increase survival and persistence in populations from a range of environments, and is likely contributing to the recent range expansion of this highly inbreeding species into marginal habitats (Ramakrishnan et al. 2006; Merrill et al. 2012).

The occurrence and persistence of invasive annual grasses in sagebrush habitats is strongly influenced by interactions with the native perennial plant community (fig. 7B). Cheatgrass, a facultative winter annual that can germinate from early fall through early spring, exhibits root elongation at low soil temperatures, and has higher nutrient uptake and growth rates than most native species (Mack and Pyke 1983; Arredondo et al. 1998; James et al. 2011). Seedlings of native, perennial plant species are generally poor competitors with cheatgrass, but adults of native, perennial grasses and forbs, especially those with similar growth forms and phenology, can be highly effective competitors with the invasive annual (Booth et al. 2003; Chambers et al. 2007; Blank and Morgan 2012).

Also, biological soil crusts, which are an important component of plant communities in warmer and drier sagebrush ecosystems, can reduce germination or establishment of cheatgrass (Eckert et al. 1986; Kaltenecker et al. 1999). Disturbances or management treatments that reduce abundance of native perennial plants and biological soil crusts and increase the distances between perennial plants often are associated with higher resource availability and increased competitive ability of cheatgrass (Chambers et al. 2007; Reisner et al. 2013; Roundy et al. *in press*).

The type, characteristics, and natural range of variability of stress and disturbance strongly influence both resilience and resistance (Jackson 2006). Disturbances like overgrazing of perennial plants by livestock, wild horses, and burros and more frequent or more severe fires are typically outside of the natural range of conditions and can reduce the resilience of sagebrush ecosystems. Reduced resilience is triggered by changes in environmental factors like temperature regimes, abiotic attributes like water and nutrient availability, and biotic attributes such as vegetation structure, composition, and productivity (Chambers et al. 2014) and cover of biological soil crusts (Reisner et al. 2013). Resistance to an invasive species can change when changes in abiotic and biotic attributes result in increased resource availability or altered habitat suitability that influences an invasive species' ability to establish and persist and/or compete with native species. Progressive losses of resilience and resistance can result in the crossing of abiotic and/or biotic thresholds and an inability of the system to recover to the reference state (Beisner et al. 2003; Seastedt et al. 2008).

Interactions among disturbances and stressors may have cumulative effects (Chambers et al. 2014). Climate change already may be shifting fire regimes outside of the natural range of occurrence (i.e., longer wildfire seasons with more frequent and longer duration wildfires) (Westerling et al. 2006). Sagebrush ecosystems generally have low productivity, and the largest number of acres burned often occurs a year or two after warm, wet conditions in winter and spring that result in higher fine fuel loads (Littell et al. 2009). Thus, annual grass fire cycles may be promoted by warm, wet winters and a subsequent increase in establishment and growth of invasive winter annuals. These cycles may be exacerbated by rising atmospheric CO_2 concentrations, N deposition, and increases in human activities that result in soil surface disturbance and invasion corridors (Chambers et al. 2014). Modern deviations from historic conditions will likely continue to alter disturbance regimes and sagebrush ecosystem response to disturbances; thus, management strategies that rely on returning to historical or "pre-settlement" conditions may be insufficient, or even misguided, given novel ecosystem dynamics (Davies et al. 2009).

Integrating Resilience and Resistance Concepts With Sage-Grouse Habitat Requirements to Manage Wildfire and Invasive Annual Grass Threats at Landscape Scales

The changes in sagebrush ecosystem dynamics due to invasive annual species and longer, hotter, and drier fire seasons due to a warming climate make it unlikely that these threats can be ameliorated completely (Abatzoglou and Kolden 2011; USFWS 2013). Consequently, a strategic approach is necessary to conserve sagebrush habitat and sage-grouse (Wisdom et al. 2005; Meinke et al. 2009; Wisdom and Chambers 2009; Pyke 2011). This strategic approach requires the ability to (1) identify those locations that provide current or potential habitat for sage-grouse and (2) prioritize management actions based on the capacity of the ecosystem to respond in the desired manner and to effectively allocate resources to achieve desired objectives. Current understanding of the relationship of landscape cover of sagebrush to sage-grouse habitat provides the capacity to identify those locations on the landscape that have a high probability of sage-grouse persistence (Aldridge et al. 2008; Wisdom et al. 2011; Knick et al. 2013). Similarly, knowledge of the relationships of environmental characteristics, specifically soil temperature and moisture regimes, to ecological types and their inherent resilience and resistance gives us the capacity to prioritize management actions based on probable effectiveness of those actions (Wisdom and Chambers 2009; Brooks and Chambers 2011; Miller et al. 2013; Chambers et al. 2014; Chambers et al. *in press*,).

In this section, we discuss the use of landscape cover of sagebrush as an indicator of sage-grouse habitat, and the use of soil temperature and moisture regimes as an indicator of resilience to disturbance, resistance to invasive annual grasses and, ultimately, the capacity to achieve desired objectives. We then show how these two concepts can be coupled in a sage-grouse habitat matrix and used to determine potential management strategies at the landscape scales on which sage-grouse depends.

Landscape Cover of Sagebrush as an Indicator of Sage-Grouse Habitat

Landscape cover of sagebrush is closely related to the probability of maintaining active sage-grouse leks, and is used as one of the primary indicators of sage-grouse habitat potential at landscape scales (Aldridge et al. 2008; Wisdom et al. 2011; Knick et al. 2013). Landscape cover of sagebrush less than about 25% has a low probability of sustaining active sage-grouse leks (Aldridge et al. 2008; Wisdom et al. 2011; Knick et al. 2013). Above 25% landscape cover of sagebrush, the probability of maintaining active sage-grouse leks increases with increasing sagebrush landscape cover. At landscape cover of sagebrush ranging from 50 to 85%, the probability of sustaining sage-grouse leks becomes relatively constant (Aldridge et al. 2008; Wisdom et al. 2011; Knick et al. 2013). For purposes of prioritizing landscapes for sage-grouse habitat management, we use 25% as the level below which there is a low probability of maintaining sage-grouse leks and 65% as the level above which there is little additional increase in the probability of sustaining active leks with further increases of landscape cover of sagebrush (fig. 8; Knick et al. 2013). Between about 25% and 65% landscape sagebrush cover, increases in landscape cover of sagebrush have a constant positive relationship with sage-grouse lek probability (fig. 8; Knick et al. 2013). Restoration and management activities that result in an increase in the amount of sagebrush dominated landscape within areas of pre-existing landscape cover between 25% and 65% likely will result in a higher probability of sage-grouse persistence, while declines in landscape cover of sagebrush likely will result in reductions in sage-grouse (Knick et al. 2013). It is important to note that

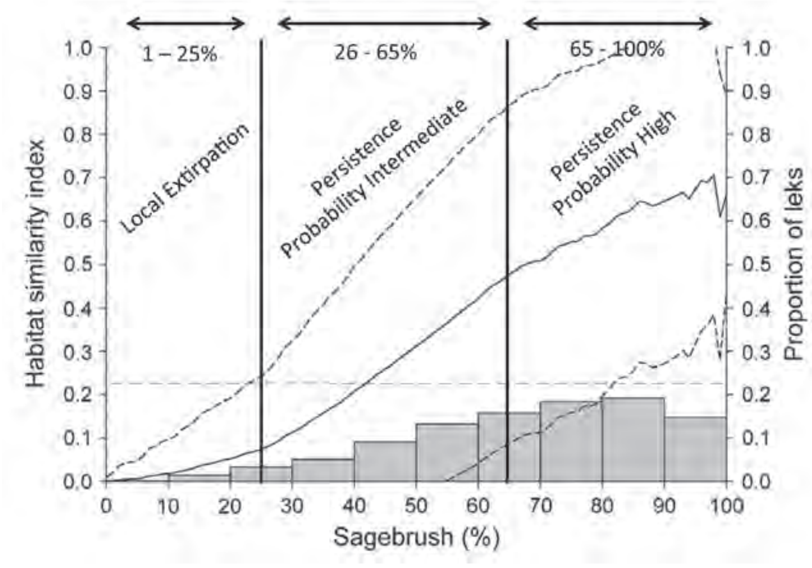

Figure 8. The proportion of sage-grouse leks and habitat similarity index (HSI) as related to the percent landscape cover of sagebrush. The HSI indicates the relationship of environmental variables at map locations across the western portion of the range to minimum requirements for sage-grouse defined by land cover, anthropogenic variables, soil, topography, and climate. HSI is the solid black line ± 1 SD (stippled lines). Proportion of leks are the grey bars. Dashed line indicates HSI values above which characterizes 90% of active leks (0.22). The categories at the top of the figure and the interpretation of lek persistence were added based on Aldridge et al. 2008; Wisdom et al. 2011; and Knick et al. 2013 (figure modified from Knick et al. 2013).

these data and interpretations relate only to persistence (i.e., whether or not a lek remains active) and it is likely that higher proportions of sagebrush cover or improved condition of sagebrush ecosystems may be required for population growth.

For the purposes of delineating sagebrush habitat relative to sage-grouse requirements for landscape cover of sagebrush, we calculated the percentage landscape sagebrush cover within each of the selected categories (1-25%, 26-65%, >65%) for the range of sage-grouse (fig. 9, 10). An explanation of how landscape cover of sagebrush is derived is in Appendix 2. Large areas of landscape sagebrush cover >65% are found primarily in Management Zones (MZ) II (Wyoming Basin), IV (Snake River Plains), and V (Northern Great Basin). In contrast, relatively small areas of landscape sagebrush cover >65% are located in MZ I (Great Plains), III (Southern Great Basin), VI (Columbia Basin), and VII (Colorado Plateau). Sagebrush is naturally less common in the Great Plains region compared to other parts of the range and previous work suggested that sage-grouse populations in MZ I may be more vulnerable to extirpation with further reductions in sagebrush cover (Wisdom et al. 2011). In the western portion of the range, where the threat of invasive annual grasses and wildfire is greatest, the area of sagebrush cover >65% differs among MZs. MZ III is a relatively arid and topographically diverse area in which the greatest extent of sagebrush cover >65% is in higher elevation, mountainous areas. MZs IV and V have relatively large extents of sagebrush cover >65% in relatively cooler and wetter areas, and MZs IV and VI have lower extents of sagebrush cover >65% in warmer and dryer areas and in areas with significant agricultural development. These differences in landscape cover of sagebrush indicate that different sets of management strategies may apply to the various MZs.

Soil Temperature and Moisture Regimes as Indicators of Ecosystem Resilience and Resistance

Potential resilience and resistance to invasive annual grasses reflect the biophysical conditions that an area is capable of supporting. In general, the highest potential resilience and resistance occur with ***cool*** to ***cold*** (frigid to cryic) soil temperature regimes and relatively ***moist*** (xeric to ustic) soil moisture regimes, while the lowest potential resilience and resistance occur with ***warm*** (mesic) soil temperatures and relatively ***dry*** (aridic) soil moisture regimes (Chambers et al. 2014, Chambers et al. *in press*). Definitions of soil temperature and moisture regimes are in Appendix 3. Productivity is elevated by high soil moisture and thus resilience is increased (Chambers et al. 2014); annual grass growth and reproduction is limited by cold soil temperatures and thus resistance is increased (Chambers et al. 2007). The timing of precipitation also is important because cheatgrass and many other invasive annual grasses are particularly well-adapted to Mediterranean type climates with cool and wet winters and warm and dry summers (Bradford and Lauenroth 2006; Bradley 2009). In contrast, areas that receive regular summer precipitation (ustic soil moisture regimes) often are dominated by warm and/or cool season grasses (Sala et al. 1997) that likely create a more competitive environment and result in greater resistance to annual grass invasion and spread (Bradford and Lauenroth 2006; Bradley 2009).

Much of the remaining sage-grouse habitat in MZs I (Great Plains), II (Wyoming Basin), VII (Colorado Plateau), and cool-to-cold or moist sites scattered across the range, are characterized by moderate to high resilience and resistance as indicated by soil temperature and moisture regimes (fig. 11). Sagebrush habitats across MZ I are unique from a range-wide perspective because soils are predominantly cool and ustic, or bordering on ustic as a result of summer precipitation; this soil moisture regime appears to result in higher resilience and resistance (Bradford and Lauenroth 2006).

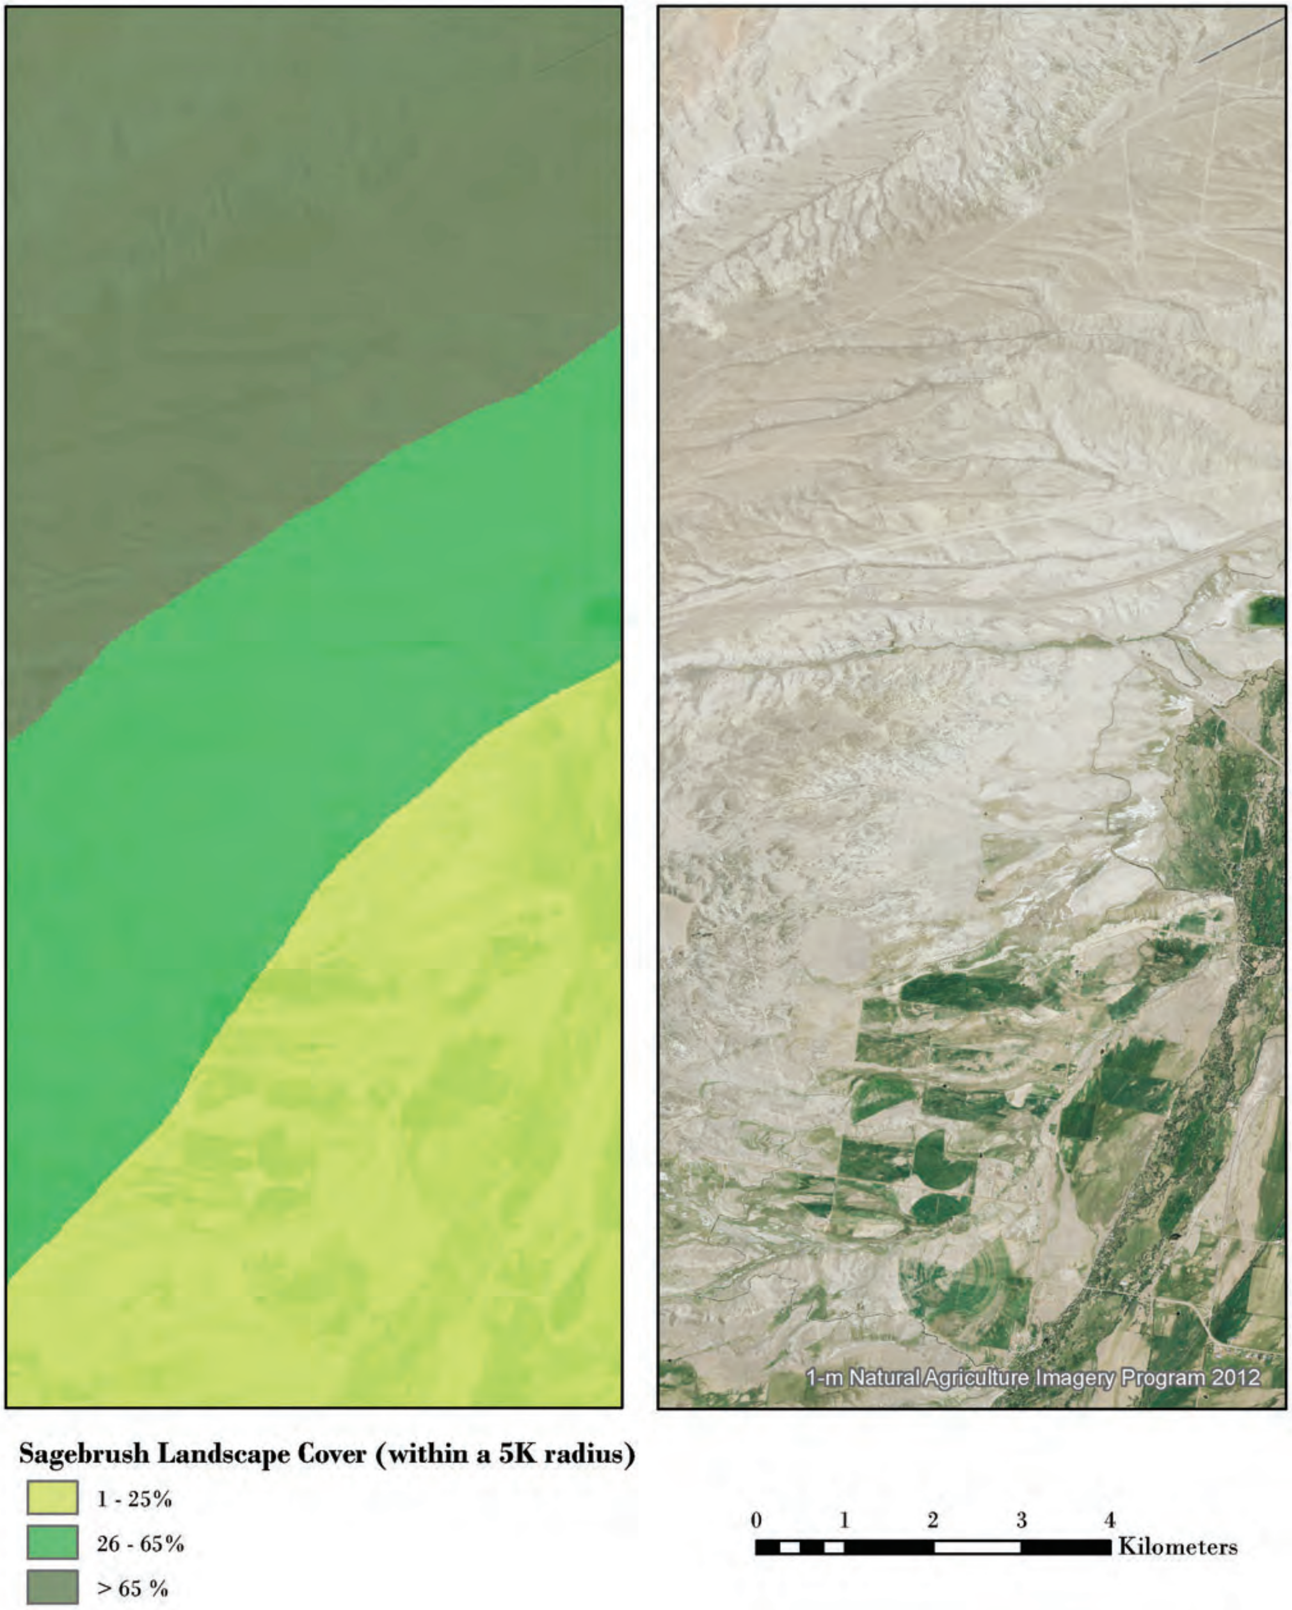

Figure 9. Landscape cover of sagebrush from 1-m National Agricultural Imagery (right) and the corresponding sagebrush landscape cover for the 1-25%, 26-65%, and >65% categories (left). See Appendix 2 for an explanation of how the categories are determined.

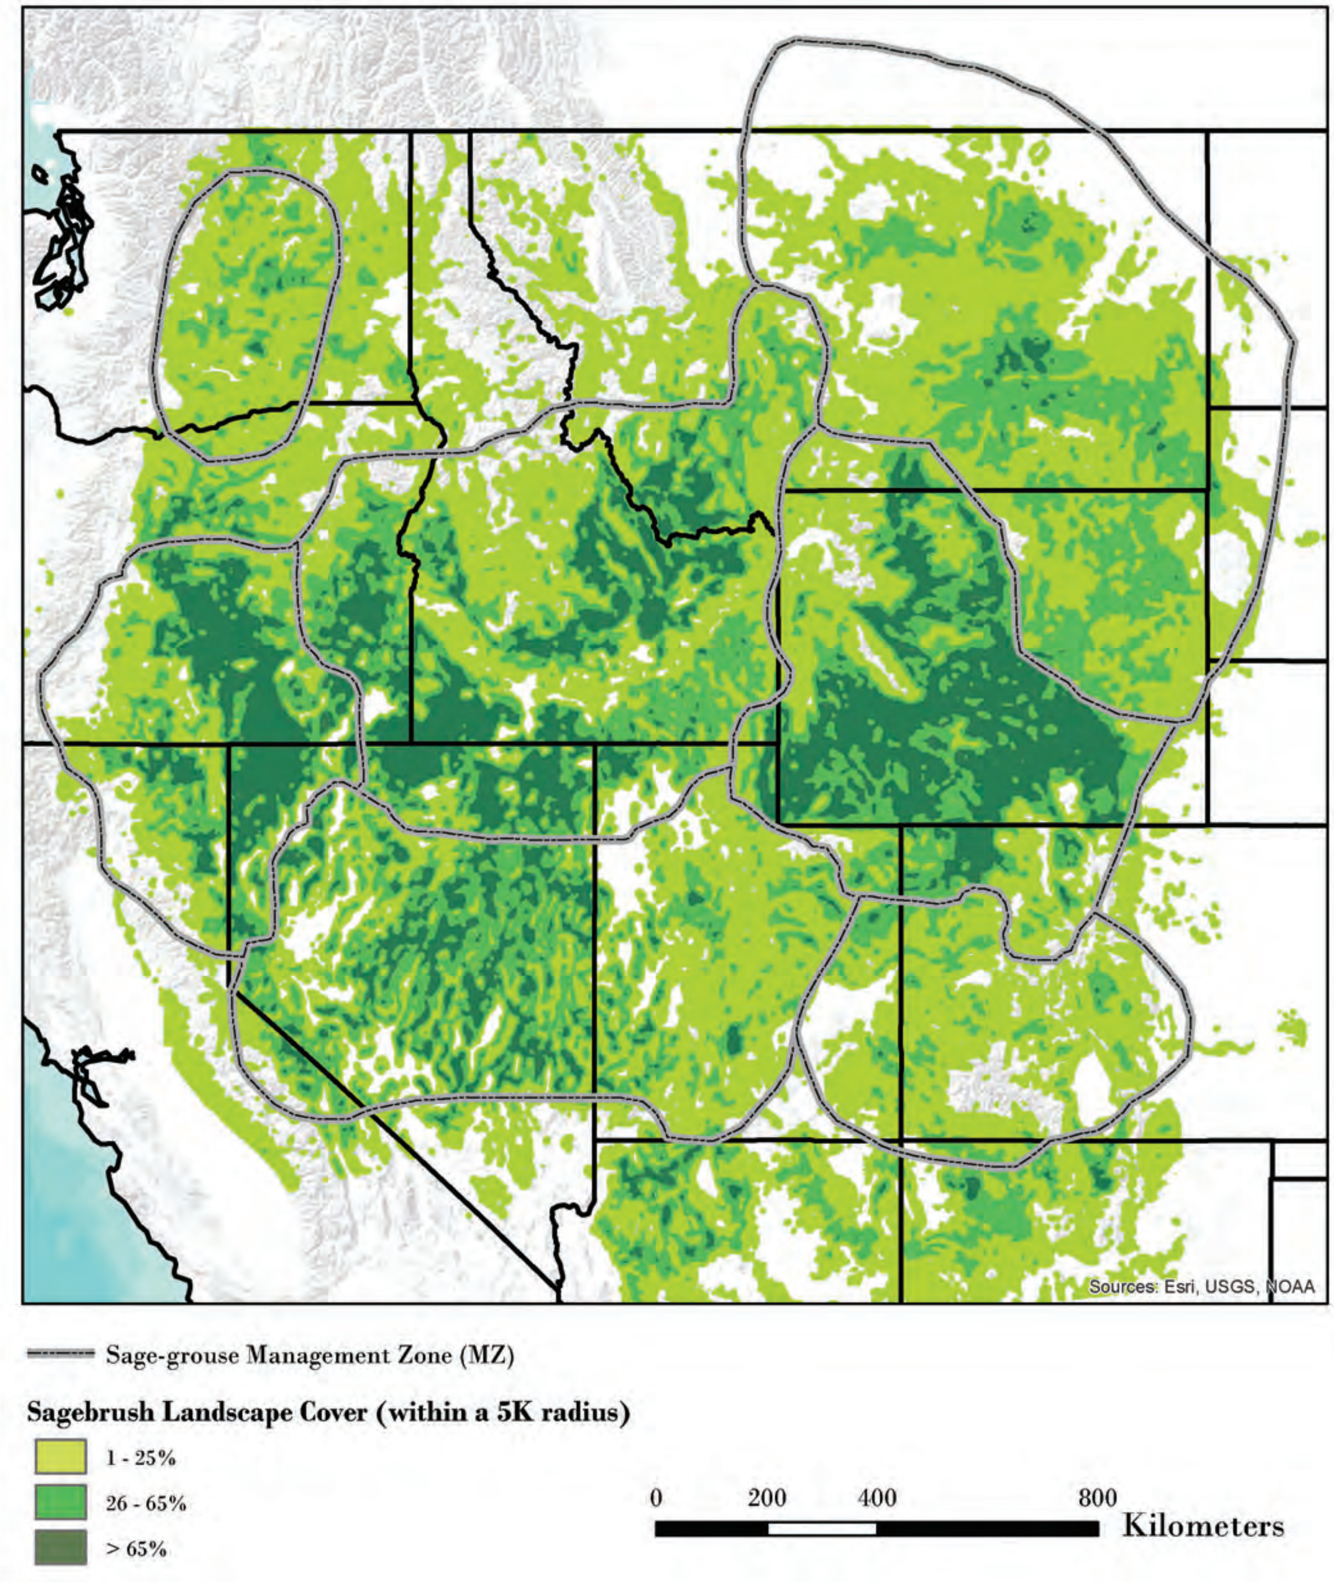

Figure 10. The landscape cover of sagebrush within each of three selected categories (1-25%, 26-65%, >65%) for the range of sage-grouse (Management Zones I – VII; Stiver et al. 2006). The proportion of sagebrush (USGS 2013) within each of the categories in a 5-km (3.1-mi) radius surrounding each pixel was calculated relative to other land cover types for locations with sagebrush cover.

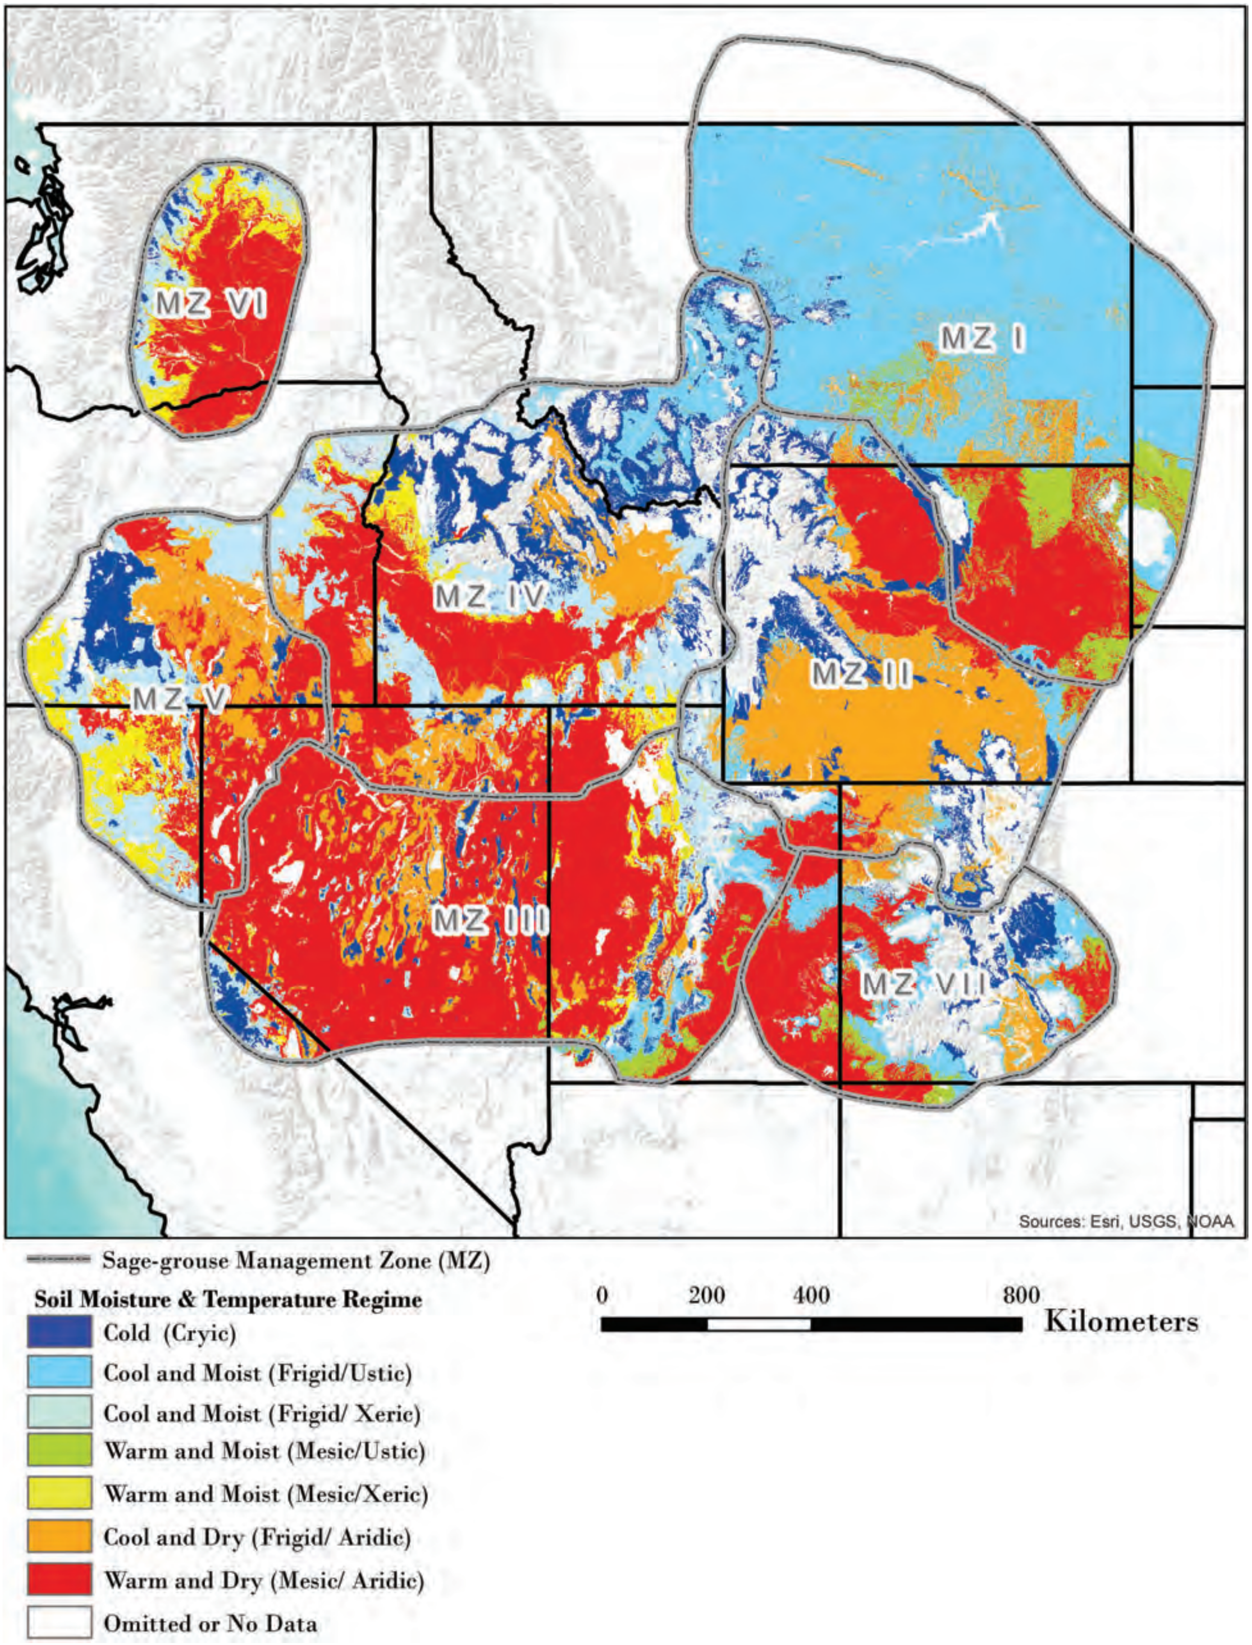

Figure 11. The soil temperature and moisture regimes for the range of sage-grouse (Management Zones I – VII; Stiver et al. 2006). Soil temperature and moisture classes were derived from the Natural Resources Conservation Service (NRCS) Soil Survey Geographic Database (SSURGO) (Soil Survey Staff 2014a). Gaps in that dataset were filled in with the NRCS State Soil Geographic Database (STATSGO) (Soil Survey Staff 2014b).

However, significant portions of MZs III (Southern Great Basin), much of IV (Snake River Plains), V (Northern Great Basin), and VI (Columbia Basin) are characterized largely by either warm and dry, or warm to cool and moist ecological types with moderate to low resilience and resistance (fig. 11; table 1). Areas within these MZs that have warm and dry soils are typically characterized by Wyoming big sagebrush ecosystems with low to moderately low resilience and resistance and are currently of greatest concern for sage-grouse conservation (fig. 12A). Areas with warm to cool soil temperature regimes and moist precipitation regimes are typically characterized by either Wyoming or mountain big sagebrush, have moderate to moderately low resilience and resistance,

Table 1. Predominant sagebrush ecological types in Sage-Grouse Management Zones III, IV, V, and VI based on soil temperature and soil moisture regimes, typical characteristics, and resilience to disturbance and resistance to invasive annual grasses (modified from Miller et al. 2014 a,b). Relative abundance of sagebrush species and composition of understory vegetation vary depending on Major Land Resource Area and ecological site type.

Ecological type	Characteristics	Resilience and resistance
Cold and Moist (Cryic/Xeric)	Ppt: 14 inches + Typical shrubs: *Mountain big sagebrush, snowfield sagebrush, snowberry, serviceberry, silver sagebrush, and/or low sagebrushes*	*Resilience* – **Moderately high**. Precipitation and productivity are generally high. Short growing seasons can decrease resilience on coldest sites. *Resistance*– **High**. Low climate suitability to invasive annual grasses
Cool and Moist (Frigid/Xeric)	Ppt: 12-22 inches Typical shrubs: *Mountain big sagebrush, antelope bitterbrush, snowberry, and/or low sagebrushes* Piñon pine and juniper potential in some areas	*Resilience* – **Moderately high**. Precipitation and productivity are generally high. Decreases in site productivity, herbaceous perennial species, and ecological conditions can decrease resilience. *Resistance* – **Moderate**. Climate suitability to invasive annual grasses is moderate, but increases as soil temperatures increase.
Warm and Moist (Mesic/Xeric)	Ppt: 12-16 inches Typical shrubs: *Wyoming big sagebrush, mountain big sagebrush, Bonneville big sagebrush, and/or low sagebrushes* Piñon pine and juniper potential in some areas	*Resilience* – **Moderate**. Precipitation and productivity are moderately high. Decreases in site productivity, herbaceous perennial species, and ecological conditions can decrease resilience. *Resistance* – **Moderately low**. Climate suitability to invasive annual grasses is moderately low, but increases as soil temperatures increase.
Cool and Dry (Frigid/Aridic)	Ppt: 6-12 inches Typical shrubs: *Wyoming big sagebrush, black sagebrush, and/or low sagebrushes*	*Resilience* – **Low**. Effective precipitation limits site productivity. Decreases in site productivity, herbaceous perennial species, and ecological conditions further decrease resilience. *Resistance* – **Moderate**. Climate suitability to invasive annual grasses is moderate, but increases as soil temperatures increase.
Warm and Dry (Mesic/Aridic, bordering on Xeric)	Ppt: 8-12 inches Typical shrubs: *Wyoming big sagebrush, black sagebrush and/or low sagebrushes*	*Resilience* – **Low.** Effective precipitation limits site productivity. Decreases in site productivity, herbaceous perennial species, and ecological conditions further decrease resilience. Cool season grasses susceptibility to grazing and fire, along with hot dry summer fire conditions, promote cheatgrass establishment and persistence. *Resistance* – **Low.** High climate suitability to cheatgrass and other invasive annual grasses. Resistance generally decreases as soil temperature increases, but establishment and growth are highly dependent on precipitation.

and have the potential for piñon and juniper expansion (Miller et al. 2014a; Chambers et al. *in press*). Many of these areas also are of conservation concern because piñon and juniper expansion and tree infilling can result in progressive loss of understory species and altered fire regimes (Miller et al. 2013). In contrast, areas with cool to cold soil temperature regimes and moist precipitation regimes have moderately high resilience and high resistance and are likely to recover in a reasonable amount of time following wildfires and other disturbances (Miller et al. 2013) (fig. 12B)

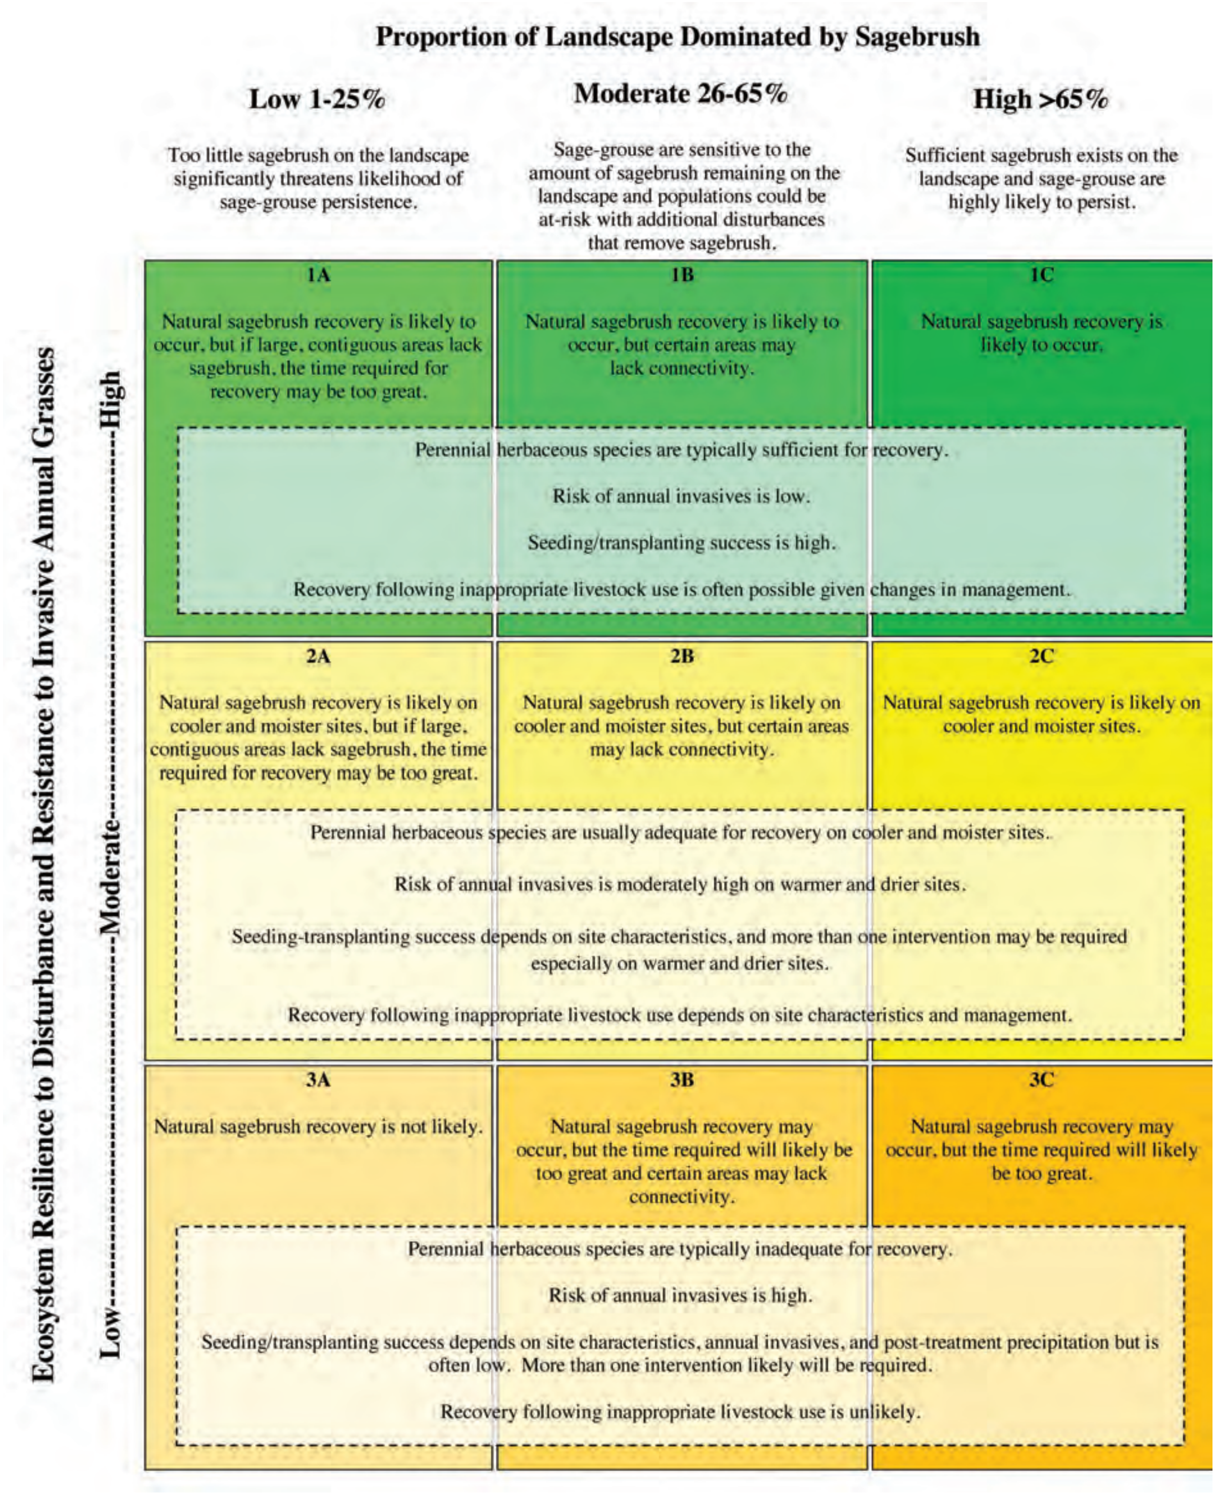
Figure 12. A Wyoming big sagebrush ecosystem with warm and dry soils in southeast Oregon (top) (photo by Richard F. Miller), compared to a mountain big sagebrush ecosystem with cool and moist soils in central Nevada (bottom) (photo by Jeanne C. Chambers).

Management Strategies Based on Landscape Cover of Sagebrush and Ecosystem Resilience and Resistance: The Sage-Grouse Habitat Matrix

Knowledge of the potential resilience and resistance of sagebrush ecosystems can be used in conjunction with sage-grouse habitat requirements to determine priority areas for management and identify effective management strategies at landscape scales (Wisdom and Chambers 2009). The sage-grouse habitat matrix (table 2) illustrates the relative resilience to disturbance and resistance to invasive annual grasses of sagebrush ecosystems in relation to the proportion of sagebrush cover on the landscape. As resilience and resistance go from high to low, as indicated by the rows in the matrix, decreases in sagebrush regeneration and abundance of perennial grasses and forbs progressively limit the capacity of a sagebrush ecosystem to recover after fire or other disturbances. The risk of annual invasives increases and the ability to successfully restore burned or otherwise disturbed areas decreases. As sagebrush cover goes from low to high within these same ecosystems, as indicated by the columns in the matrix, the capacity to provide adequate habitat cover for sage-grouse increases. Areas with less than 25% landscape cover of sagebrush are unlikely to provide adequate habitat for sage-grouse; areas with 26-65% landscape cover of sagebrush can provide habitat for sage-grouse but are at risk if sagebrush loss occurs without recovery; and areas with >65% landscape cover of sagebrush provide the necessary habitat conditions for sage-grouse to persist. Potential landscape scale management strategies can be determined by considering (1) resilience to disturbance, (2) resistance to invasive annuals, and (3) sage-grouse land cover requirements. Overarching management strategies to maintain or increase sage-grouse habitat at landscape scales based on these considerations are conservation, prevention, restoration, and monitoring and adaptive management (table 3; see Chambers et al. 2014). These strategies have been adapted for each of the primary agency programs including fire operations, fuels management, post-fire rehabilitation, and habitat restoration (table 4). Because sagebrush ecosystems occur over continuums of environmental conditions, such as soil temperature and moisture, and have differing land use histories and species composition, careful assessment of the area of concern always will be necessary to determine the relevance of a particular strategy (Pyke 2011; Chambers et al. 2014; Miller et al. 2014 a, b). The necessary information for conducting this type of assessment is found in the "Putting It All Together" section of this report.

Although the sage-grouse habitat matrix (table 2) can be viewed as partitioning land units into spatially discrete categories (i.e., landscapes or portions thereof can be categorized as belonging to one of nine categories), it is not meant to serve as a strict guide to spatial allocation of resources or to prescribe specific management strategies. Instead, the matrix should serve as a decision support tool for helping managers implement strategies that consider both the resilience and resistance of the landscape and landscape sagebrush cover requirements of sage-grouse. For example, low elevation Wyoming big sagebrush plant communities with relatively low resilience and resistance may provide important winter habitat resources for a given sage-grouse population. In a predominantly Wyoming big sagebrush area comprised of relatively low sagebrush landscape cover, a high level of management input may be needed to realize conservation benefits for sage-grouse. This doesn't mean that management activities should not be undertaken if critical or limiting sage-grouse habitat resources are present, but indicates that inputs will be intensive, potentially more expensive, and less likely to succeed relative to more resilient landscapes. It is up to the user of the matrix to determine how such tradeoffs influence management actions.

Table 2. Sage-grouse habitat matrix based on resilience and resistance concepts from Chambers et al. 2014, and sage-grouse habitat requirements from Aldridge et al. 2008, Wisdom et al. 2011, and Knick et al. 2013. Rows show the ecosystems relative resilience to disturbance and resistance to invasive annual grasses derived from the sagebrush ecological types in table 1 (1 = high resilience and resistance; 2 = moderate resilience and resistance; 3 = low resilience and resistance). Columns show the current proportion of the landscape (5-km rolling window) dominated by sagebrush (A = 1-25% land cover; B = 26-65% land cover; 3 = >65% land cover). Use of the matrix is explained in text. Overarching management strategies that consider resilience and resistance and landscape cover of sagebrush are in table 3. Potential management strategies specific to agency program areas, including fire operations, fuels management, post-fire rehabilitation, and habitat restoration are in table 4.



Proportion of Landscape Dominated by Sagebrush

Ecosystem Resilience and Resistance to Invasive Annual Grasses	Low 1-25%	Moderate 26-65%	High >65%
	Too little sagebrush on the landscape significantly threatens likelihood of sage-grouse persistence.	Sage-grouse are sensitive to the amount of sagebrush remaining on the landscape and populations could be at-risk with additional disturbances that remove sagebrush.	Sufficient sagebrush exists on the landscape and sage-grouse are highly likely to persist.
High	1A Natural sagebrush recovery is likely to occur, but if large, contiguous areas lack sagebrush, the time required for recovery may be too great.	1B Natural sagebrush recovery is likely to occur, but certain areas may lack connectivity.	1C Natural sagebrush recovery is likely to occur.
	Perennial herbaceous species are typically sufficient for recovery. Risk of annual invasives is low. Seeding/transplanting success is high. Recovery following inappropriate livestock use is often possible given changes in management.		
Moderate	2A Natural sagebrush recovery is likely on cooler and moister sites, but if large, contiguous areas lack sagebrush, the time required for recovery may be too great.	2B Natural sagebrush recovery is likely on cooler and moister sites, but certain areas may lack connectivity.	2C Natural sagebrush recovery is likely on cooler and moister sites.
	Perennial herbaceous species are usually adequate for recovery on cooler and moister sites. Risk of annual invasives is moderately high on warmer and drier sites. Seeding-transplanting success depends on site characteristics, and more than one intervention may be required especially on warmer and drier sites. Recovery following inappropriate livestock use depends on site characteristics and management.		
Low	3A Natural sagebrush recovery is not likely.	3B Natural sagebrush recovery may occur, but the time required will likely be too great and certain areas may lack connectivity.	3C Natural sagebrush recovery may occur, but the time required will likely be too great.
	Perennial herbaceous species are typically inadequate for recovery. Risk of annual invasives is high. Seeding/transplanting success depends on site characteristics, annual invasives, and post-treatment precipitation but is often low. More than one intervention likely will be required. Recovery following inappropriate livestock use is unlikely.		

Table 3. Potential management strategies based on resilience to disturbance, resistance to annual grass invasion, and sage-grouse habitat requirements based on Aldridge et al. 2008; Wisdom et al. 2011; and Knick et al. 2013 (adapted from Chambers et al. 2014).

Conserve – maintain or increase resilience to disturbance and resistance to invasive annuals in areas with high conservation value	
Priorities	• Ecosystems with low to moderate resilience to fire and resistance to invasive species that still have large patches of landscape sagebrush cover and adequate perennial grasses and forbs – *ecological types with warm and dry and cool and dry soil temperature/moisture regimes.* • Ecosystems with a high probability of providing habitat for sage-grouse, especially those with >65% landscape cover of sagebrush and adequate perennial herbaceous species – *all ecological types.*
Objective	• Minimize impacts of current and future human-caused disturbances and stressors.
Activities	• Immediately suppress fire in moderate to low resilience and resistance sagebrush and wooded shrublands to prevent an invasive annual grass-fire cycle. Large sagebrush patches are high priority for protection from wildfires. • Implement strategic fuel break networks to provide anchor points for suppression and reduce losses when wildfires escape initial attack. • Manage livestock grazing to prevent loss of perennial native grasses and forbs and biological soil crusts and allow natural regeneration. • Limit anthropogenic activities that cause surface disturbance, invasion, and fragmentation. (e.g., road and utility corridors, urban expansion, OHV use, and mineral/energy projects). • Detect and control new weed infestations.
Prevent – maintain or increase resilience and resistance of areas with declining ecological conditions that are at risk of conversion to a degraded, disturbed, or invaded state	
Priorities	• Ecosystems with moderate to high resilience and resistance – *ecological types with relatively cool and moist soil temperature and moisture regimes*. ○ Prioritize landscape patches that exhibit declining conditions due to annual grass invasion and/or tree expansion (e.g., at risk phase in State and Transition Models). • Ecosystems with a moderate to high probability of providing sage-grouse habitat, especially those with 26-65% landscape cover of sagebrush and adequate perennial native grasses and forbs – *all ecological types*.
Objectives	• Reduce fuel loads and decrease the risk of high intensity and high severity fire. • Increase abundance of perennial native grasses and forbs and of biological soil crusts where they naturally occur. • Decrease the longer-term risk of annual invasive grass dominance.
Activities	• Use mechanical treatments like cut and leave or mastication to remove trees, decrease woody fuels, and release native grasses and forbs in warm and moist big sagebrush ecosystems with relatively low resistance to annual invasive grasses that are in the early to mid-phase of piñon and/or juniper expansion. • Use prescribed fire or mechanical treatments to remove trees, decrease woody fuels, and release native grasses and forbs in cool and moist big sagebrush ecosystems with relatively high resistance to annual invasive grass that are in early to mid-phase of piñon and/or juniper expansion. • Actively manage post-treatment areas to increase perennial herbaceous species and minimize secondary weed invasion. • Consider the need for strategic fuel breaks to help constrain fire spread or otherwise augment suppression efforts.
Restore – increase resilience and resistance of disturbed, degraded, or invaded areas	

Priorities	• Areas burned by wildfire – *all ecological types*
	  ○ Prioritize areas with low to moderate resilience and resistance, and that have a reasonable expectation of recovery.
	  ○ Prioritize areas where perennial grasses and forbs have been depleted.
	  ○ Prioritize areas that experienced high severity fire.

(continued)

Table 3. (Continued).

	• Sage-grouse habitat – *all ecological types* ○ Prioritize areas where restoration of sagebrush and/or perennial grasses is needed to create large patches of landscape cover of sagebrush or connect existing patches of sagebrush habitat. ○ Prioritize areas with adequate landscape cover of sagebrush where restoration of perennial grasses and forbs is needed. • Areas affected by anthropogenic activities that cause surface disturbance, invasion, and fragmentation. (e.g., road and utility corridors, urban expansion, OHV use, and mineral/energy projects) – *all ecological types.*
Objectives	• Increase soil stability and curtail dust. • Control/suppress invasive annual grasses and other invasive plants. • Increase landscape cover of sagebrush. • Increase perennial grasses and forbs and biological soil crusts where they naturally occur. • Reduce the risk of large fires that burn sage-grouse habitat.
Activities	• Use integrated strategies to control/suppress annual invasive grass and other annual invaders. • Establish and maintain fuel breaks or greenstrips in areas dominated by invasive annual grasses that are adjacent to areas with >25% landscape sagebrush cover and adequate perennial native grasses and forbs. • Seed perennial grasses and forbs that are adapted to local conditions to increase cover of these species in areas where they are depleted. • Seed and/or transplant sagebrush to restore large patches of sagebrush cover and connect existing patches. • Repeat restoration treatments if they fail initially to ensure restoration success especially in warm and dry soil temperature moisture regimes where weather is often problematic for establishment. • Actively manage restored/rehabilitated areas to increase perennial herbaceous species and minimize secondary weed invasion.
Monitoring and Adaptive Management– implement comprehensive monitoring to track landscape change and management outcomes and provide the basis for adaptive management	
Priorities	• Regional environmental gradients to track changes in plant community and other ecosystem attributes and expansion or contraction of species ranges – *all ecological types.* • Assess treatment effectiveness – *all ecological types.*
Objectives	• Understand effects of wildfire, annual grass invasion, piñon and juniper expansion, climate change and other global stressors in sagebrush ecosystems • Increase understanding of the long- and short-term outcomes of management treatments.
Activities	• Establish a regional network of monitoring sites that includes major environmental gradients. • Collect pre- and post-treatment monitoring data for all major land treatments activities. • Collect data on ecosystem status and trends (for example, land cover type, ground cover, vegetation cover and height [native and invasive], phase of tree expansion, soil and site stability, oddities). • Use consistent methods to monitor indicators. • Use a cross-boundary approach that involves all major land owners. • Use a common data base for all monitoring results (e.g., Land Treatment Digital Library; http://greatbasin.wr.usgs.gov/ltdl/). • Develop monitoring products that track change and provide management implications and adaptations for future management. • Support and improve information sharing on treatment effectiveness and monitoring results across jurisdictional boundaries (e.g., Great Basin Fire Science Delivery Project; www.gbfiresci.org).

Table 4. Specific management strategies by agency program area for the cells within the sage-grouse habitat matrix (table 2). The rows indicate relative resilience and resistance (numbers) and the columns indicate landscape cover of sagebrush by category (letters). Resilience and resistance are based on soil temperature and moisture regimes (fig. 11) and their relationship to ecological types (table 1). Percentage of the landscape dominated by sagebrush is based on the capacity of large landscapes to support viable sage-grouse populations over the long term (fig. 8). Note that these guidelines are related to the sage-grouse habitat matrix, and do not preclude other factors from consideration when determining management priorities for program areas. The "Fire Operations" program area includes preparedness, prevention, and suppression activities.

High Resilience to Disturbance and Resistance to Invasive Annual Grasses (1A, 1B, 1C)

Natural sagebrush recovery is likely to occur. Perennial herbaceous species are sufficient for recovery. Risk of invasive annual grasses is typically low.

Fire Operations	• Fire suppression is typically third order priority, but varies with large fire risk and landscape condition (cells 1A, 1B, 1C). Scenarios requiring higher priority may include: ○ Areas of sagebrush that bridge large, contiguous expanses of sagebrush and that are important for providing connectivity for sage-grouse (cells 1B, 1C). ○ Areas where sagebrush communities have been successfully reestablished through seedings or other rehabilitation investments (cells 1A, 1B, 1C) ○ Areas with later phase (Phase III) post-settlement piñon and juniper that have high resistance to control, are subject to large and/or severe fires, and place adjacent sage-grouse habitat at risk (cells 1A, 1B). ○ All areas when critical burning environment conditions exist. These conditions may be identified by a number of products including, but not limited to: Predictive Services 7-Day Significant Fire Potential Forecasts; National Weather Service Fire Weather Watches and Red Flag Warnings; fire behavior forecasts or other local knowledge.
Fuels Management	• Fuels management to reduce large sagebrush stand losses is a second order priority, especially in cells 1B and 1C. Management activities include: ○ Strategic placement of fuel breaks to reduce loss of large sagebrush stands by wildfire. Examples include linear features or other strategically placed treatments that serve to constrain fire spread or otherwise augment suppression efforts. ○ Tree removal in early to mid-phase (Phases I, II), post-settlement piñon and juniper expansion areas to maintain shrub/herbaceous cover and reduce fuel loads. ○ Tree removal in later phase (Phase III), post-settlement piñon and juniper areas to reduce risks of large or high severity fires. Because these areas represent non-sage-grouse habitat, prescribed fire may be appropriate on cool and moist sites, but invasive plant control and restoration of sagebrush and perennial native grasses and forbs may be necessary.
Post-Fire Rehabilitation	• Post-fire rehabilitation is generally low priority (cells 1A, 1B, 1C). Areas of higher priority include: ○ Areas where perennial herbaceous cover, density, and species composition is inadequate for recovery. ○ Areas where seeding or transplanting sagebrush is needed to maintain habitat connectivity for sage-grouse. ○ Steep slopes and soils with erosion potential.
Habitat Restoration and Recovery	• Restoration is typically passive and designed to increase or maintain perennial herbaceous species, biological soil crusts and landscape cover of sagebrush (cells 1A, 1B, 1C). Areas to consider for active restoration include: ○ Areas where perennial herbaceous cover density, or composition is inadequate for recovery after surface disturbance. ○ Areas where seeding or transplanting sagebrush is needed to maintain habitat connectivity for sage-grouse.

Moderate Resilience to Disturbance and Resistance to Invasive Annuals (2A, 2B, 2C)

Natural sagebrush recovery is likely to occur on cooler and moister sites, but the time required may be too great if large, contiguous areas lack sagebrush. Perennial herbaceous species are usually adequate for recovery on cooler and moister sites. Risk of invasive annual grasses is moderately high on warmer and drier sites.

Fire Operations	• Fire suppression is typically second order priority (cells 2A, 2B, 2C). Scenarios requiring higher priority may include: ○ Areas of sagebrush that bridge large, contiguous expanses of sagebrush and that are important for providing connectivity for sage-grouse (cells 2B, 2C).

(continued)

Table 4. (Continued).

	○ Areas where sagebrush communities have been successfully reestablished through seedings or other rehabilitation investments (cells 2A, 2B, 2C) ○ Areas with later phase (Phase III), post-settlement piñon and juniper that have high resistance to control, are subject to large and/or severe fires, and place adjacent sage-grouse habitat at risk (cells 2A, 2B). ○ Areas where annual grasslands place adjacent sage-grouse habitat at risk (cell 2A). ○ All areas when critical burning environment conditions exist. These conditions may be identified by a number of products including, but not limited to: Predictive Services 7-Day Significant Fire Potential Forecasts; National Weather Service Fire Weather Watches and Red Flag Warnings; fire behavior forecasts or other local knowledge.
Fuels Management	• Fuels management to reduce large sagebrush stand losses is a first order priority, especially in cells 2B and 2C. Management activities include: ○ Strategic placement of fuel breaks to reduce loss of large sagebrush stands by wildfire. Examples include linear features or other strategically placed treatments that serve to constrain fire spread or otherwise augment suppression efforts. ○ Tree removal in early to mid-phase (Phase I, II), post-settlement piñon and juniper expansion areas to maintain shrub/herbaceous cover and reduce fuel loads. ○ Tree removal in later phase (Phase III), post-settlement piñon and juniper areas to reduce risks of large or high severity fires. Because these areas represent non-sage-grouse habitat, prescribed fire may be appropriate on cool and moist sites, but restoration of sagebrush and perennial native grasses and forbs may be necessary.
Post-Fire Rehabilitation	• Post-fire rehabilitation is generally low priority (cells 2A, 2B, 2C) in cooler and moister areas. Areas of higher priority include: ○ Areas where perennial herbaceous cover, density, and species composition is inadequate for recovery. ○ Areas where seeding or transplanting sagebrush is needed to maintain habitat connectivity for sage-grouse. ○ Relatively warm and dry areas where annual invasives are expanding. ○ Steep slopes with erosion potential.
Habitat Restoration and Recovery	• Restoration is typically passive on cooler and moister areas and is designed to increase or maintain perennial herbaceous species, biological soil crusts, and landscape cover of sagebrush (cells 2A, 2B, 2C). Areas to consider for active restoration include: ○ Areas where perennial herbaceous cover, density, and species composition is inadequate for recovery after surface disturbance. ○ Areas where seeding or transplanting sagebrush is needed to maintain habitat connectivity for sage-grouse. ○ Relatively warm and dry areas where annual invasives are expanding.

Low Resilience to Disturbance and Resistance to Invasive Annuals (3A, 3B, 3C)

Natural sagebrush recovery is not likely. Perennial herbaceous species are typically inadequate for recovery. Risk of invasive annual grasses is high.

Fire Operations	• Fire suppression priority depends on the landscape cover of sagebrush: ○ Areas with <25% landscape cover of sagebrush are typically third order priority (cell 3A). These areas may be a higher priority if they are adjacent to intact sage-grouse habitat or are essential for connectivity. ○ Areas with 26-65% landscape cover of sagebrush are typically second order priority (cell 3B). These areas are higher priority if they have intact understories and if they are adjacent to sage-grouse habitat. ○ Areas with >65% landscape cover of sagebrush are first order priority (cell 3C). ○ Areas where sagebrush communities have been successfully reestablished through seedings or other rehabilitation investments (cells 3A, 3B, 3C).

(continued)

Table 4. (Continued).

Fuels Management	• Fuels management priority and management activities depend on the landscape cover of sagebrush: ○ Areas with <25% landscape cover of sagebrush are typically third order priority (cell 3A). Strategic placement of fuel breaks may be needed to reduce loss of adjacent sage-grouse habitat by wildfire. Examples include linear features or other strategically placed treatments that serve to constrain fire spread or otherwise augment suppression efforts. ○ Areas with 26-65% landscape cover of sagebrush are typically second order priority (cell 3B). These areas are higher priority if they have intact understories and if they are adjacent to sage-grouse habitat. Strategic placement of fuel breaks may be needed to reduce loss of large sagebrush stands by wildfire. ○ Areas with >65% landscape cover of sagebrush are first order priority (cell 3C). Strategic placement of fuel breaks may be needed to reduce loss of large sagebrush stands by wildfire. ○ Areas where sagebrush communities have been successfully reestablished through seedings or other rehabilitation investments (cells 3A, 3B, 3C). Strategic placement of fuel breaks may be needed to protect investments from repeated loss to wildfire.
Post-Fire Rehabilitation	• Post-fire rehabilitation priority and management activities depend on the landscape cover of sagebrush: ○ Areas with <25% landscape cover of sagebrush are typically third order priority (cell 3A). Exceptions include (1) sites that are relatively cool and moist and (2) areas adjacent to sage-grouse habitat where seeding can be used to increase connectivity and prevent annual invasive spread. In highly invaded areas, integrated strategies that include seeding of perennial herbaceous species and seeding and/or transplanting sagebrush will be required. Success will likely require more than one intervention due to low and variable precipitation. ○ Areas with 26-65% landscape cover of sagebrush are typically second order priority (cell 3B). Exceptions include (1) sites that are relatively cool and moist or that are not highly invaded, and (2) areas adjacent to sage-grouse habitat where seeding can be used to increase connectivity and prevent annual invasive spread. Seeding of perennial herbaceous species will be required where cover, density and species composition of these species is inadequate for recovery. Seeding and/or transplanting sagebrush as soon as possible is necessary for rehabilitating sage-grouse habitat. Success will likely require more than one intervention due to low and variable precipitation. ○ Areas with >65% landscape cover of sagebrush are first order priority, especially if they are part of a larger, contiguous area of sagebrush (cell 3C). Seeding of perennial herbaceous species will be required where cover, density and species composition of these species is inadequate for recovery. Seeding and/or transplanting sagebrush as soon as possible is necessary for rehabilitating sage-grouse habitat. Success will likely require more than one intervention due to low and variable precipitation.
Habitat Restoration and Recovery	• Restoration priority and management activities depends on the landscape cover of sagebrush: ○ Areas with <25% landscape cover of sagebrush are typically third order priority. Exceptions include (1) surface disturbances and (2) areas adjacent to sage-grouse habitat where seeding can be used to prevent annual invasive spread (cell 3A). In highly invaded areas, integrated strategies that include seeding of perennial herbaceous species and seeding and/or transplanting sagebrush will be required. Success will likely require more than one intervention due to low and variable precipitation. ○ Areas with 26-65% landscape cover of sagebrush are typically second order priority (cell 3B). Exceptions include (1) surface disturbances, (2) sites that are relatively cool and moist or that are not highly invaded, and (3) areas adjacent to sage-grouse habitat where seeding can be used to increase connectivity and prevent annual invasive spread. Seeding of perennial herbaceous species may be required where cover, density and species composition of these species is inadequate. Seeding and/or transplanting sagebrush as soon as possible is necessary for restoring sage-grouse habitat. Success will likely require more than one intervention due to low and variable precipitation. ○ Areas with >65% landscape cover of sagebrush are first order priority, especially if they are part of a larger, contiguous area of sagebrush (cell 3C). Seeding of perennial herbaceous species may be required where cover, density, and species composition of these species is inadequate. Seeding and/or transplanting sagebrush as soon as possible is necessary for restoring sage-grouse habitat. Success will likely require more than one intervention due to low and variable precipitation.

Another important consideration is that ecological processes such as wildfire can occur either within or across categories in the sage-grouse habitat matrix and it is necessary to determine the appropriate spatial context when evaluating management opportunities based on resilience and resistance and sage-grouse habitat. For example, if critical sage-grouse habitat occurs in close proximity to landscapes comprised mainly of annual grass-dominated plant communities, then fire risk to adjacent sage-grouse habitat can increase dramatically (Balch et al. 2013). In this scenario, management actions could include reducing the influence of invasive annual grasses with a strategic fuel break on the perimeter of intact sagebrush. Thus, management actions may have value to sustaining existing sage-grouse habitat, even if these measures are applied in locations that are currently not habitat; the spatial relationships of sagebrush and invasive annual grasses should be considered when prioritizing management actions and associated conservation measures.

Informing Wildfire and Fuels Management Strategies to Conserve Sage-Grouse

Collectively, responses to wildfires and implementation of fuels management projects are important contributors to sage-grouse conservation. Resilience and resistance concepts provide a science-based background that can inform fire operations and fuels management strategies and allocation of scarce assets during periods of high fire activity. In fire operations, firefighter and public safety is the overriding objective in all decisions. In addition, land managers consider numerous other values at risk, including the Wildland-Urban Interface (WUI), habitats, and infrastructure when allocating assets and prioritizing efforts. Resilience and resistance concepts are especially relevant for evaluating tradeoffs related to current ecological conditions and rates of recovery and possible ecological consequences of different fire management activities. For example, prioritizing initial attack efforts based on ecological types and their resilience and resistance at fire locations is a possible future application of resilience and resistance concepts. Also, fire prevention efforts can be concentrated where human ignitions have commonly occurred near intact, high quality habitats that also have inherently low resilience and resistance.

Fuels management projects are often applied to (1) constrain or minimize fire spread; (2) alter species composition; (3) modify fire intensity, severity, or effects; or (4) create fuel breaks or anchor points that augment fire management efforts (fig. 13). These activities are selectively used based on the projected ecosystem response, anticipated fire patterns, and probability of success. For example, in areas that are difficult to restore due to low to moderate resilience, fuel treatments can be placed to minimize fire spread and conserve sagebrush habitat. In cooler and moister areas with moderate to high resilience and resistance, mechanical or prescribed fire treatments may be appropriate to prevent conifer expansion and dominance. Given projected climate change and longer fire seasons across the western United States, fuels management represents a proactive approach for modifying large fire trends. Fire operations and fuels management programs contribute to a strategic, landscape approach when coupled with data that illustrate the likelihood of fire occurrence, potential fire behavior, and risk assessments (Finney et al. 2010; Oregon Department of Forestry 2013). In tandem with resilience and resistance concepts, these data can further inform fire operations and fuels management decisions.

Figure 13. Fuel breaks may include roads, natural features, or other management imposed treatments intended to modify fire behavior or otherwise augment suppression efforts at the time of a fire. Such changes in fuel type and arrangement may improve suppression effectiveness by modifying flame length and fire intensity, and allow fire operations to be conducted more safely. The top photo shows a burnout operation along an existing road to remove available fuels ahead of an oncoming fire and constrain overall fire growth (photo by BLM Idaho Falls District). The bottom photo shows fuel breaks located along a road, which complimented fire control efforts when a fire intersected the fuel break and road from the right (photo by Ben Dyer, BLM).

Putting it all Together

Effective management and restoration of sage-grouse habitat will benefit from a collaborative approach that prioritizes the best management practices in the most appropriate places. This section describes an approach for assessing focal areas for sage-grouse habitat management based on widely available data, including (1) Priority Areas for Conservation (PACs), (2) breeding bird densities, (3) habitat suitability as indicated by the landscape cover of sagebrush, (4) resilience and resistance and dominant ecological types as indicated by soil temperature and moisture regimes, and (5) habitat threats as indicated by cover of cheatgrass, cover of piñon and juniper, and by fire history. Breeding bird density data are overlain with landscape cover of sagebrush and with resilience and resistance to spatially link sage-grouse populations with habitat conditions and risks. We illustrate the use of this step-down approach for evaluating focal areas for sage-grouse habitat management across the western portion of the range, and we provide a detailed example for a diverse area in the northeast corner of Nevada that is comprised largely of PACs with mixed land ownership. The sage-grouse habitat matrix (table 2) is used as a tool in the decision process, and guidelines are provided to assist in determining appropriate management strategies for the primary agency program areas (fire operations, fuels management, post-fire rehabilitation, habitat restoration) for each cell of the matrix.

We conclude with discussions of the tools available to aid in determining the suitability of an area for treatment and the most appropriate management treatments such as ecological site descriptions and state and transition models and of monitoring and adaptive management. Datasets used to compile the maps in the following sections are in Appendix 4.

Assessing Focal Areas for Sage-Grouse Habitat Management: Key Data Layers

Priority areas for conservation: The recent identification of sage-grouse strongholds, or Priority Areas for Conservation (PACs), greatly improves the ability to target management actions towards habitats expected to be critical for long-term viability of the species (fig. 14; USFWS 2013). Understanding and minimizing risks of large-scale loss of sagebrush and conversion to invasive annual grasses or piñon and juniper in and around PACs will be integral to maintaining sage-grouse distribution and stabilizing population trends. PACs were developed by individual states to identify those areas that are critical for ensuring adequate representation, redundance, and resilience to conserve sage-grouse populations. Methods differed among states; in general, PAC boundaries were identified based on (1) sage-grouse population data including breeding bird density, lek counts, telemetry, nesting areas, known distributions, and sightings/observations; and (2) habitat data including occupied habitat, suitable habitat, seasonal habitat, nesting and brood rearing areas, and connectivity areas or corridors. Sage-grouse habitats outside of PACs also are important in assessing focal areas for management where they provide connectivity between PACs (genetic and habitat linkages), seasonal habitats that may have been underestimated due to emphasis on lek sites to define priority areas, habitat restoration and population expansion opportunities, and flexibility for managing habitat changes that may result from climate change (USFWS 2013). If PAC boundaries are adjusted, they will need to be updated for future analyses.

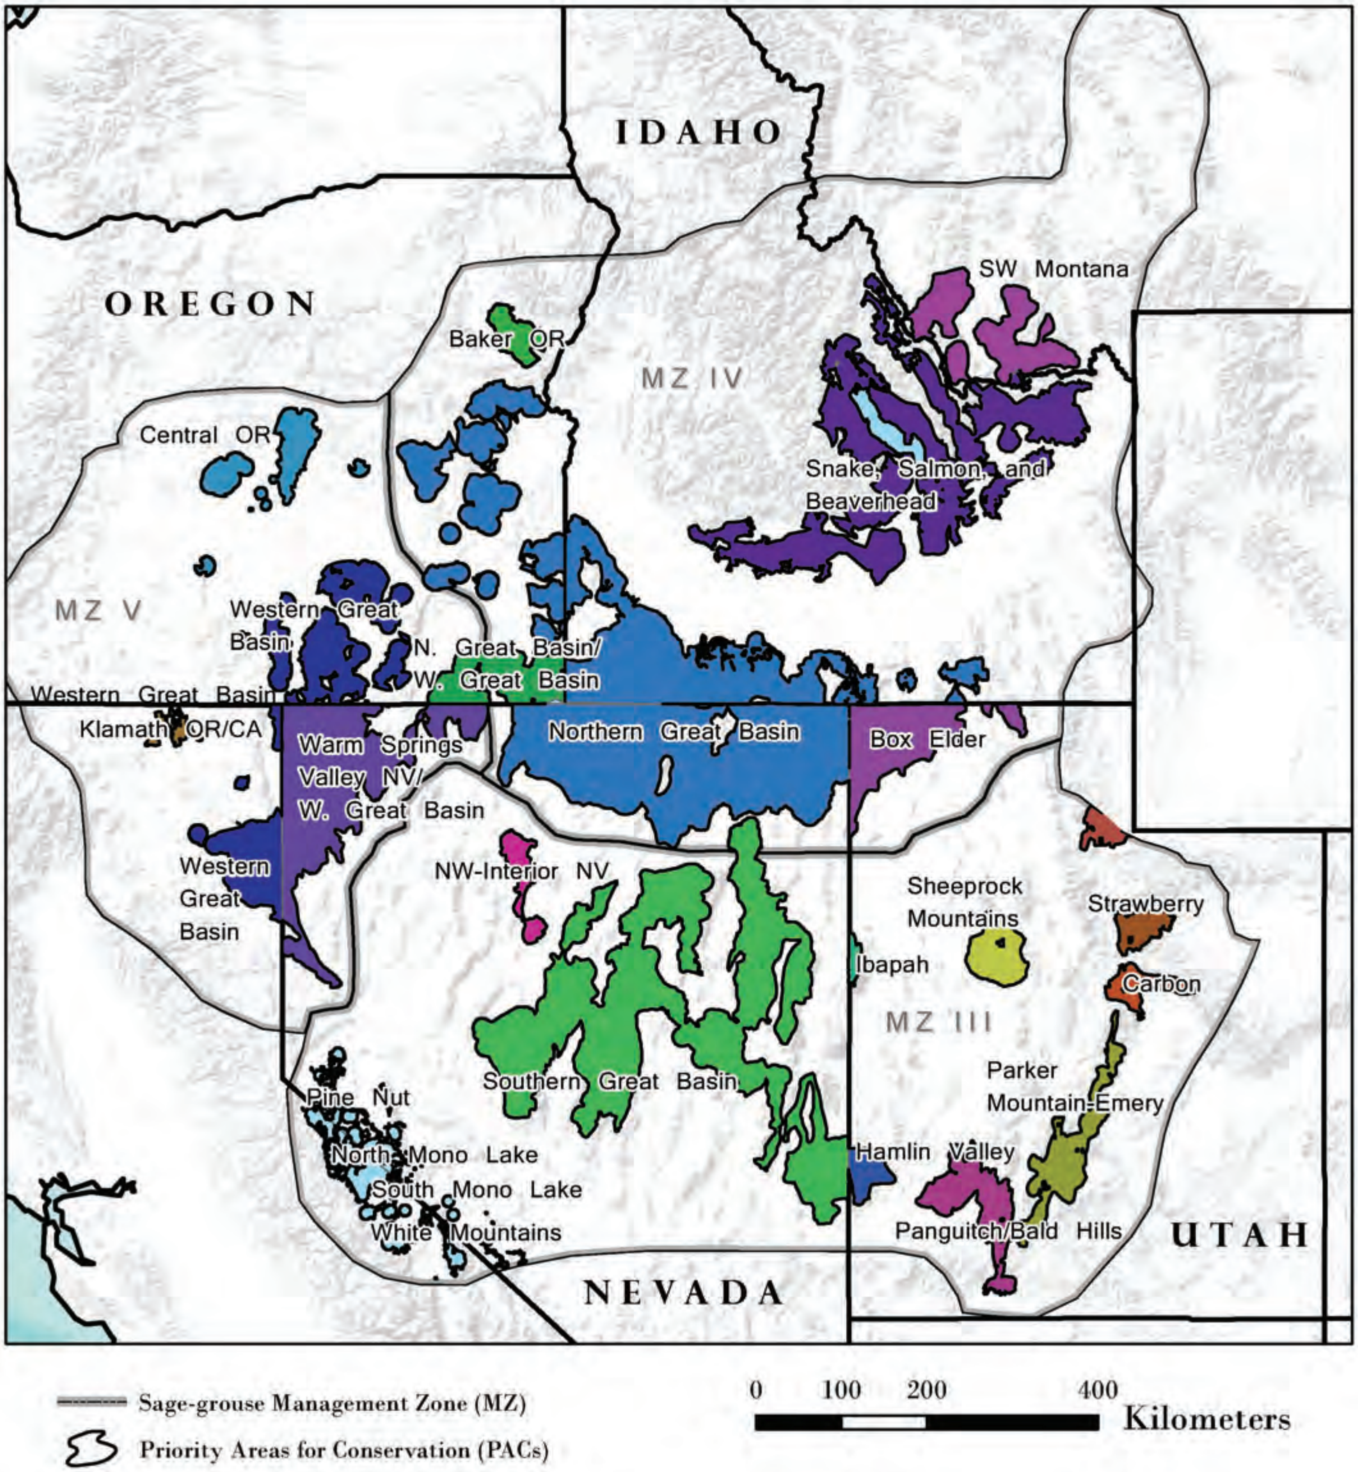


Figure 14. Priority Areas for Conservation (PACs) within the range of sage-grouse (USFWS 2013). Colored polygons within Management Zones delineate Priority Areas for Conservation (USFWS 2013).

Breeding bird density: Range-wide breeding bird density areas provide one of the few accessible data sets for further prioritizing actions within and adjacent to PACs to maintain species distribution and abundance. Doherty et al. (2010b) developed a useful framework for incorporating population data in their range-wide breeding bird density analysis, which used maximum counts of males on leks (n = 4,885) to delineate breeding bird density areas that contain 25, 50, 75, and 100% of the known breeding population (fig. 15). Leks were mapped according to these abundance values and buffered by a 6.4 to 8.5 km (4.0 to 5.3 mi) radius to delineate nesting areas. Findings showed that while sage-grouse occupy extremely large landscapes, their breeding distribution is highly aggregated in comparably smaller identifiable population centers; 25% of the known population occurs within 3.9% (2.9 million ha; 7.2 million ac) of the species range, and 75% of birds are within 27.0% of the species range (20.4 million ha; 50.4 million ac) (Doherty et al. 2010b). The Doherty et al. (2010b) analysis emphasized breeding habitats primarily because little broad scale data exist for summer and winter habitat use areas. Even though the current breeding bird density data provide the most comprehensive data available, they do not include all existing sage-grouse populations. Incorporating finer scale seasonal habitat use data at local levels where it is available will ensure management actions encompass all seasonal habitat requirements.

For this assessment, we chose to use State-level breeding bird density results from Doherty et al. (2010b) instead of range-wide model results to ensure that important breeding areas in MZs III, IV, and V were not underweighted due to relatively higher bird densities in the eastern portion of the range. It is important to note that breeding density areas were identified using best available information in 2009, so these range-wide data do not reflect the most current lek count information or changes in conditions since the original analysis. Also, breeding density areas should not be viewed as rigid boundaries but rather as the means to prioritize landscapes regionally where step-down assessments and actions may be implemented quickly to conserve the most birds.

Landscape cover of sagebrush: Landscape cover of sagebrush is one of the key determinants of sage-grouse population persistence and, in combination with an understanding of resilience to disturbance and resistance to invasive annuals, provides essential information both for determining priority areas for management and appropriate management actions (fig. 10; tables 2 and 3). Landscape cover of sagebrush is a measure of large, contiguous patches of sagebrush on the landscape and is calculated from remote sensing databases such as LANDFIRE (see Appendix 4). We used the three cover categories of sagebrush landscape cover discussed previously to predict the likelihood of sustaining sage-grouse populations (1-25%, 25-65%, >65%). The sagebrush landscape cover datasets were created using a moving window to summarize the proportion of area (5-km [3.1-mi] radius) dominated by sagebrush surrounding each 30-m pixel and then assigned those areas to the three categories (see Appendix 2). Because available sagebrush cover from sources such as LANDFIRE does not exclude recent fire perimeters, it was necessary to either include these in the analysis of landscape cover of sagebrush or display them separately. Although areas that have burned since 2000 likely do not currently provide desired sage-grouse habitat, areas with the potential to support sagebrush ecological types can provide conservation benefits in the overall planning effort especially within long-term conservation areas like PACs. The landscape cover of sagebrush and recent fire perimeters are illustrated for the western portion of the range (fig.16) and northeast Nevada (fig. 17).

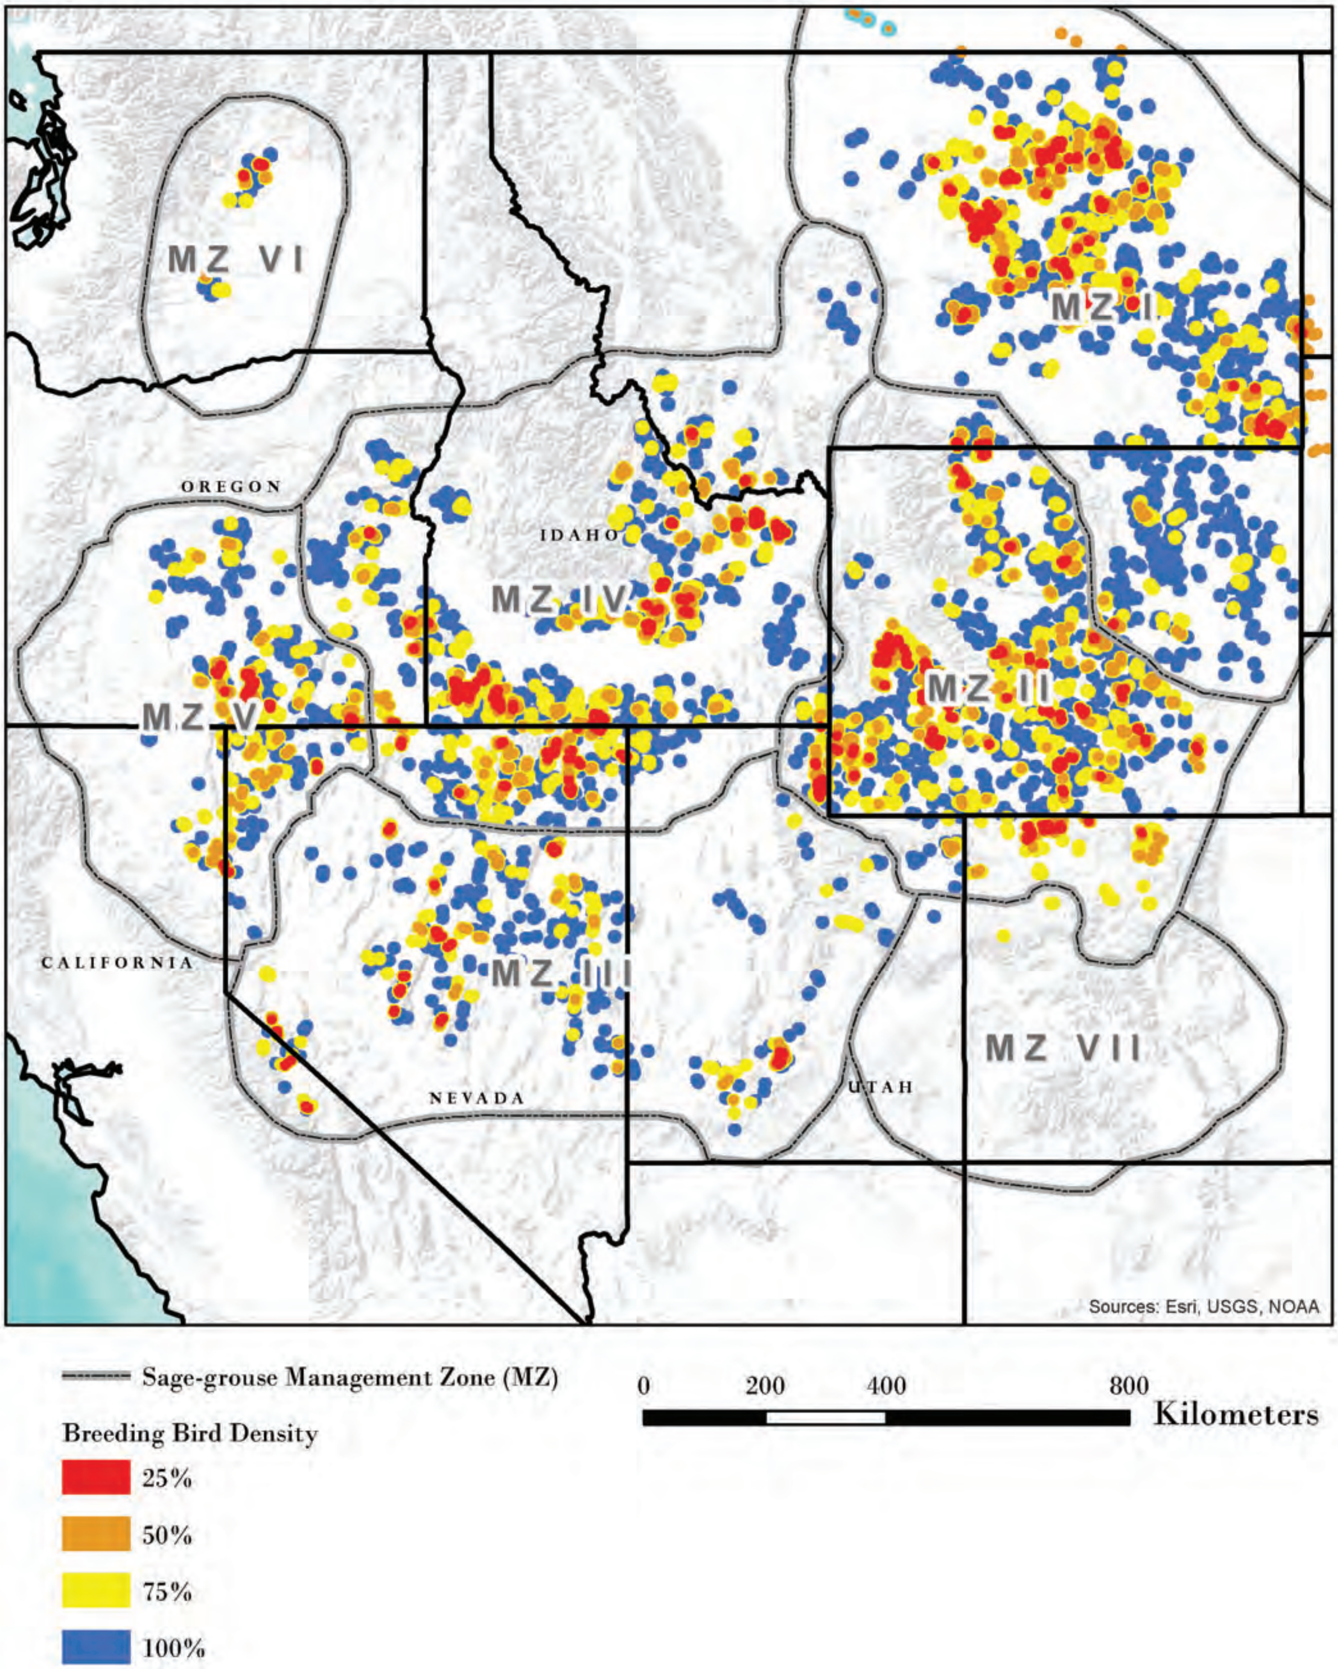

Figure 15. Range-wide sage-grouse breeding bird densities from Doherty et al. 2010. Points illustrate breeding bird density areas that contain 25, 50, 75, and 100% of the known breeding population and are based on maximum counts of males on leks (n = 4,885). Leks were mapped according to abundance values and buffered by 6.4 to 8.5 km (4.0 to 5.2 mi) to delineate nesting areas.

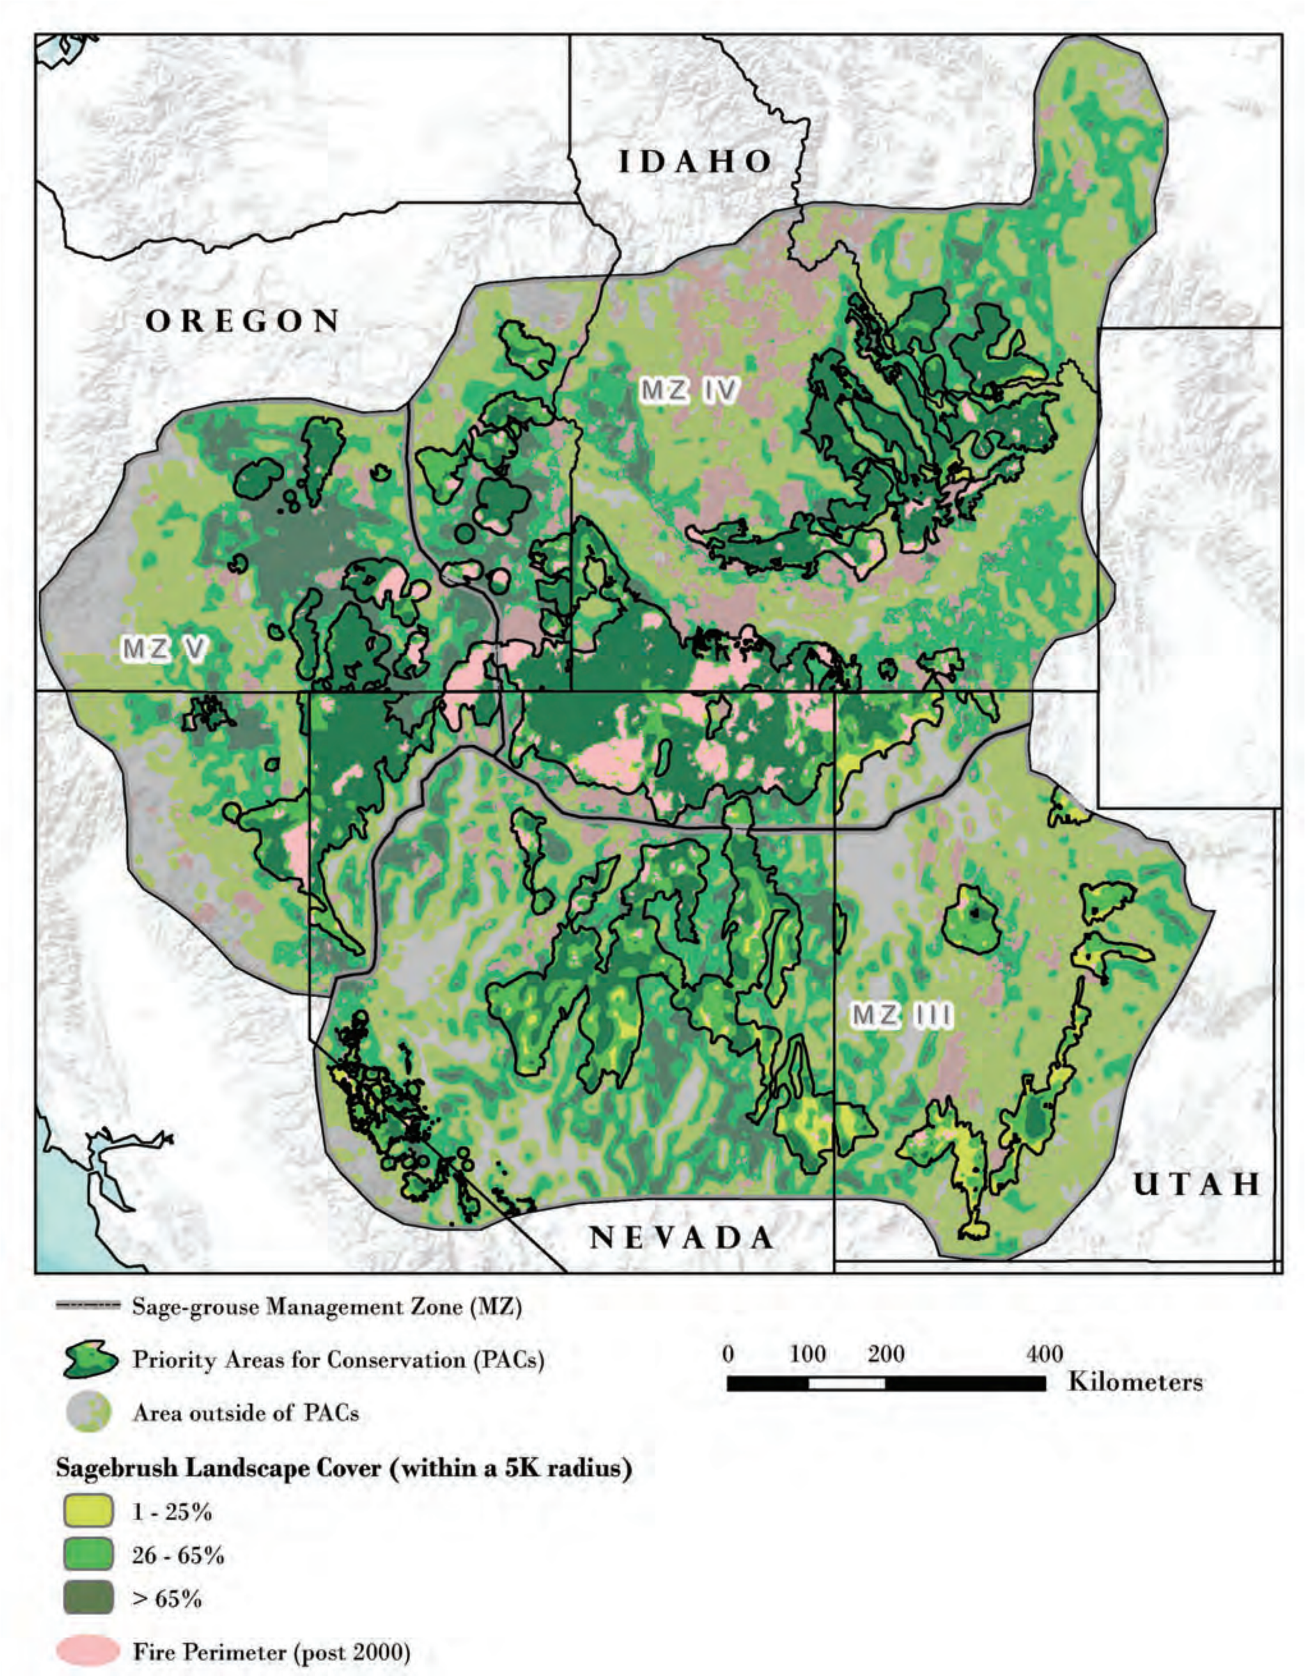

Figure 16. The landscape cover of sagebrush within each of three selected categories (1-25%, 26-65%, >65%) for Management Zones III, IV, and V (Stiver et al. 2006). The proportion of sagebrush (USGS 2013) within each of the categories in a 5-km (3.1-mi) radius surrounding each pixel was calculated relative to other land cover types for locations with sagebrush cover. Darker colored polygons within Management Zones delineate Priority Areas for Conservation (USFWS 2013).

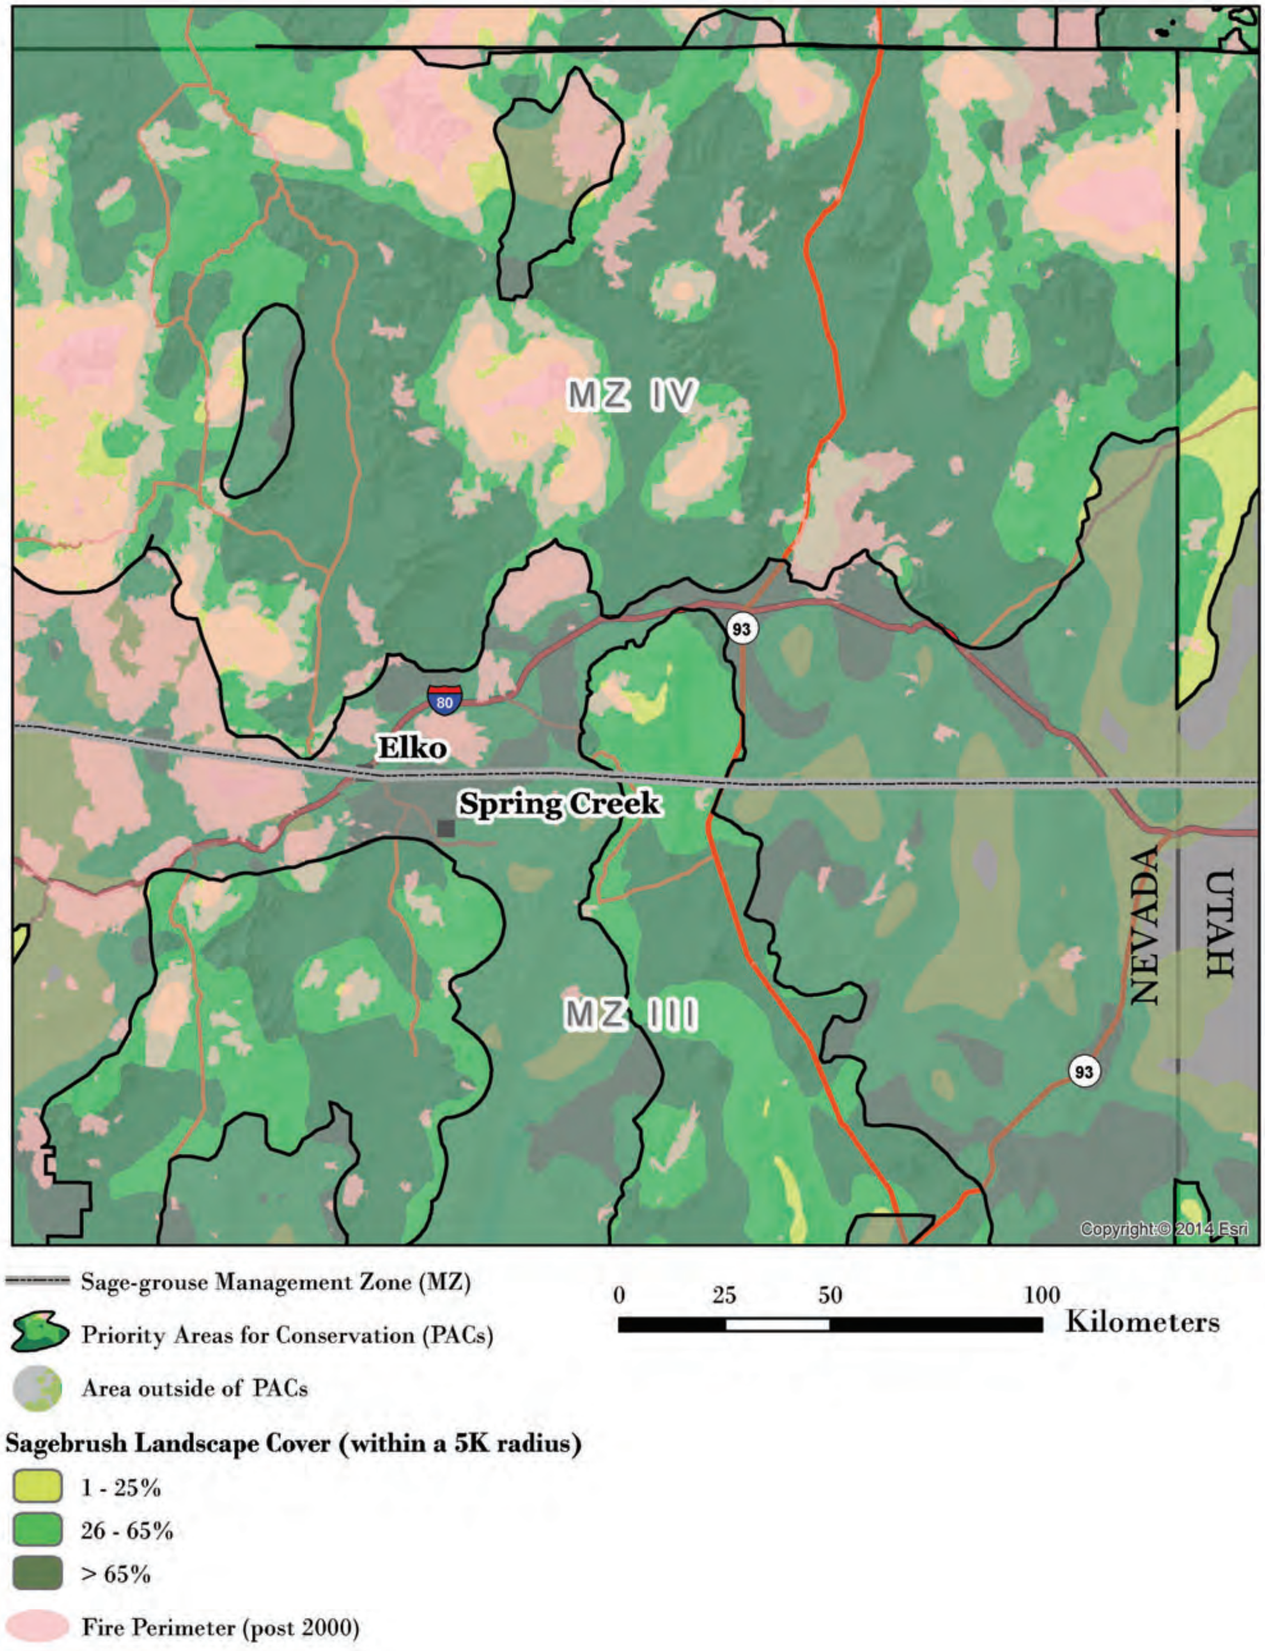

Figure 17. The landscape cover of sagebrush within each of the selected categories (1-25%, 26-65%, >65%) for the north-eastern portion of Nevada. The proportion of sagebrush (USGS 2013) within each of the categories in a 5-km (3.1-mi) radius surrounding each pixel was calculated relative to other land cover types for locations with sagebrush cover. Darker colored polygons delineate Priority Areas for Conservation (USFWS 2013).

Resilience to disturbance and resistance to annuals: Soil temperature and moisture regimes are a strong indicator of ecological types and of resilience to disturbance and resistance to invasive annual plants (fig. 11; table 1). Resilience and resistance predictions coupled with landscape cover of sagebrush can provide critical information for determining focal areas for targeted management actions (tables 2, 3, and 4). The available data for the soil temperature and moisture regimes were recently compiled to predict resilience and resistance (see Appendix 3). These data, displayed for the western portion of the range and northeast Nevada (figs. 18 and 19), illustrate the spatial variability within the focal areas. Soil temperature and moisture regimes are two of the primary determinants of ecological types and of more detailed ecological site descriptions, which are described in the section on "Determining the Most Appropriate Management Treatments at the Project Scale."

Habitat threats: Examining additional land cover data or models of invasive annual grasses and piñon and/or juniper, can provide insights into the current extent of threats in a planning area (e.g., Manier et al. 2013). In addition, evaluating data on fire occurrence and size can provide information on fire history and the rate and pattern of change within the planning area. Data layers for cheatgrass cover have been derived from Landsat imagery (Peterson 2006, 2007) and from model predictions based on species occurrence, climate variables, and anthropogenic disturbance (e.g., the Bureau of Land Management [BLM] Rapid Ecoregional Assessments [REAs]). The REAs contain a large amount of geospatial data that may be useful in providing landscape scale information on invasive species, disturbances, and vegetation types across most of the range of sage-grouse (http://www.blm.gov/wo/st/en/prog/more/Landscape_Approach/reas.html). Similarly, geospatial data for piñon and/or juniper have been developed for various States (e.g., Nevada and Oregon) and are becoming increasingly available rangewide. In addition, more refined data products are often available at local scales. Land managers can evaluate the available land cover datasets and select those land covers with the highest resolution and accuracy for the focal area. Land cover of cheatgrass and piñon and/or juniper and the fire history of the western portion of the range and northeast Nevada are in figures 20-25.

Assessing Focal Areas for Sage-Grouse Habitat Management: Integrating Data Layers

Combining resilience and resistance concepts with sage-grouse habitat and population data can help land managers further gauge relative risks across large landscapes and determine where to focus limited resources to conserve sage-grouse populations. Intersecting breeding bird density areas with soil temperature and moisture regimes provides a spatial tool to depict landscapes with high bird concentrations that may have a higher relative risk of being negatively affected by fire and annual grasses (figs. 26, 27). For prioritization purposes, areas supporting 75% of birds (6.4 to 8.5 km [4.0 to 5.2 mi] buffer around leks) can be categorized as high density while remaining breeding bird density areas (75-100% category; 8.5-km [5.2-mi] buffer around leks) can be categorized as low density. Similarly, warm and dry types can be categorized as having relatively low resilience to fire and resistance to invasive species and all other soil temperature and moisture regimes can be categorized as having relatively moderate to high resilience and resistance. Intersecting breeding bird density areas with landscape cover of sagebrush provides another spatial component revealing large and intact habitat blocks and areas in need of potential restoration to provide continued connectivity (fig. 28).

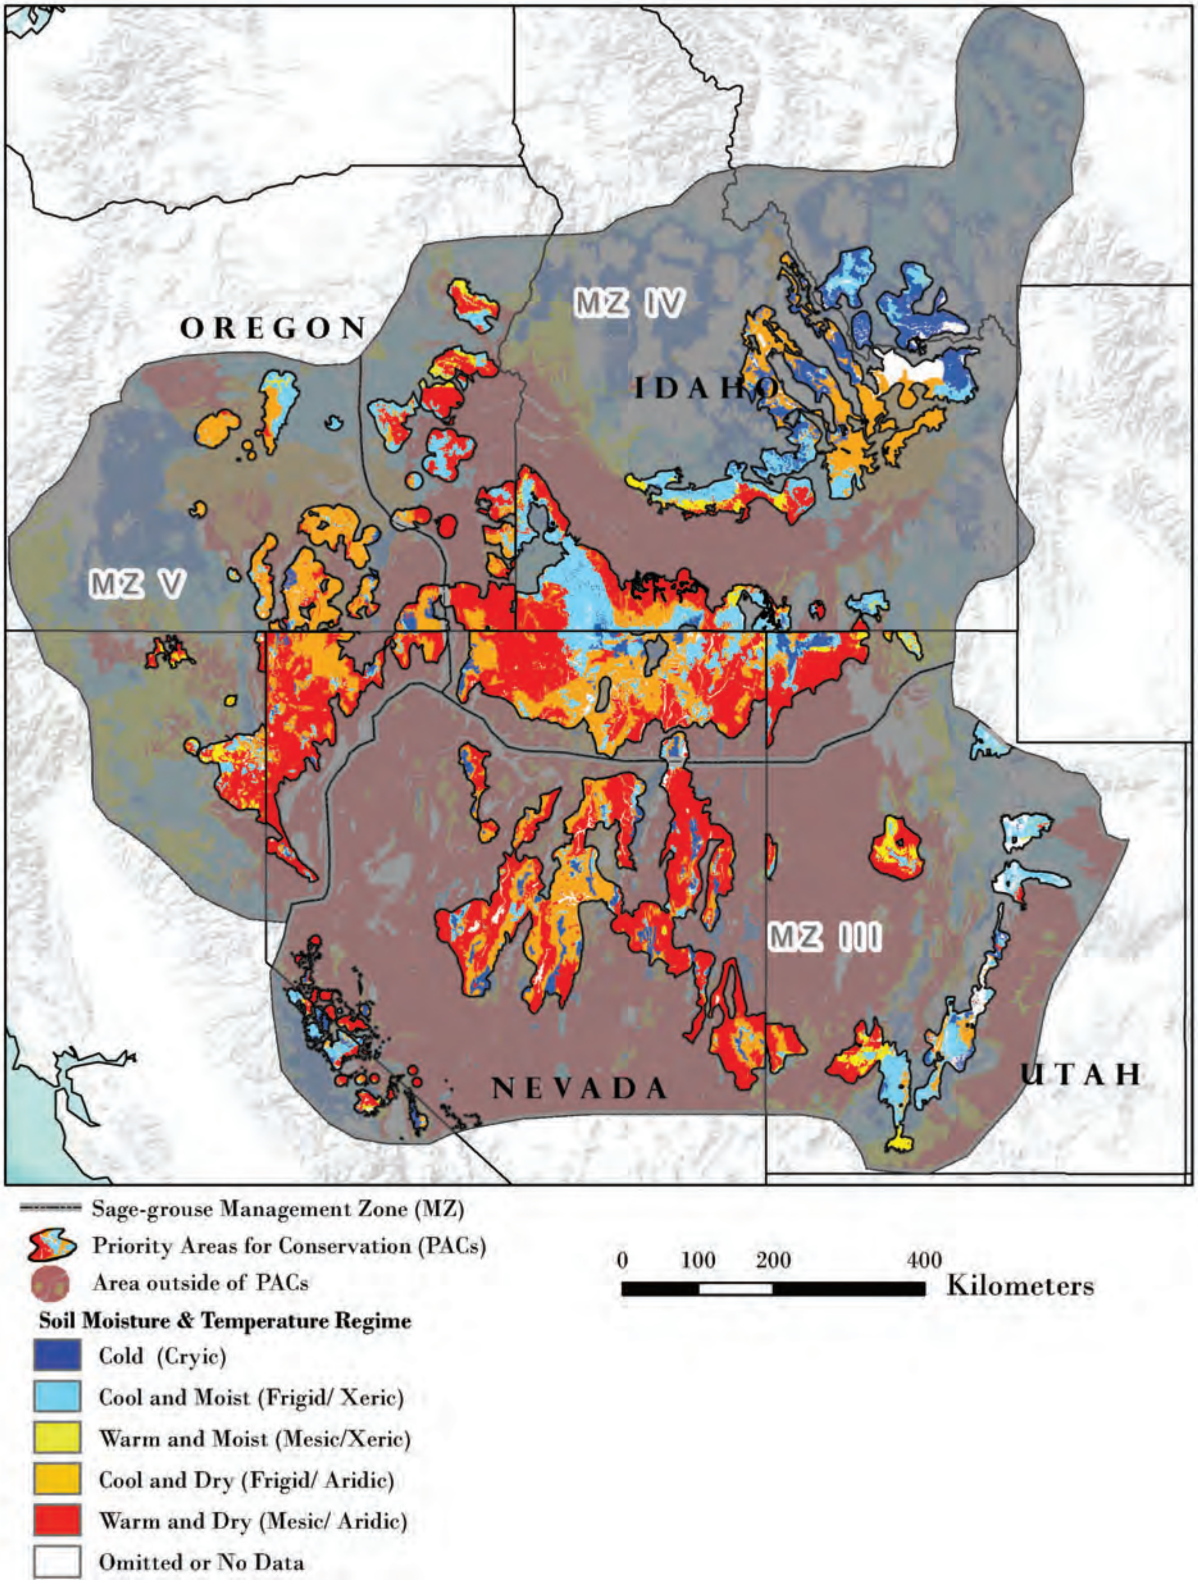

Figure 18. The soil temperature and moisture regimes within sage-grouse Management Zones III, IV, and V (Stiver et al. 2006). Soil temperature and moisture classes were derived from the Natural Resources Conservation Service (NRCS) Soil Survey Geographic Database (SSURGO) (Soil Survey Staff 2014a). Gaps in that dataset were filled in with the NRCS State Soil Geographic Database (STATSGO) (Soil Survey Staff 2014b). Darker colored polygons within Management Zones delineate Priority Areas for Conservation (USFWS 2013).

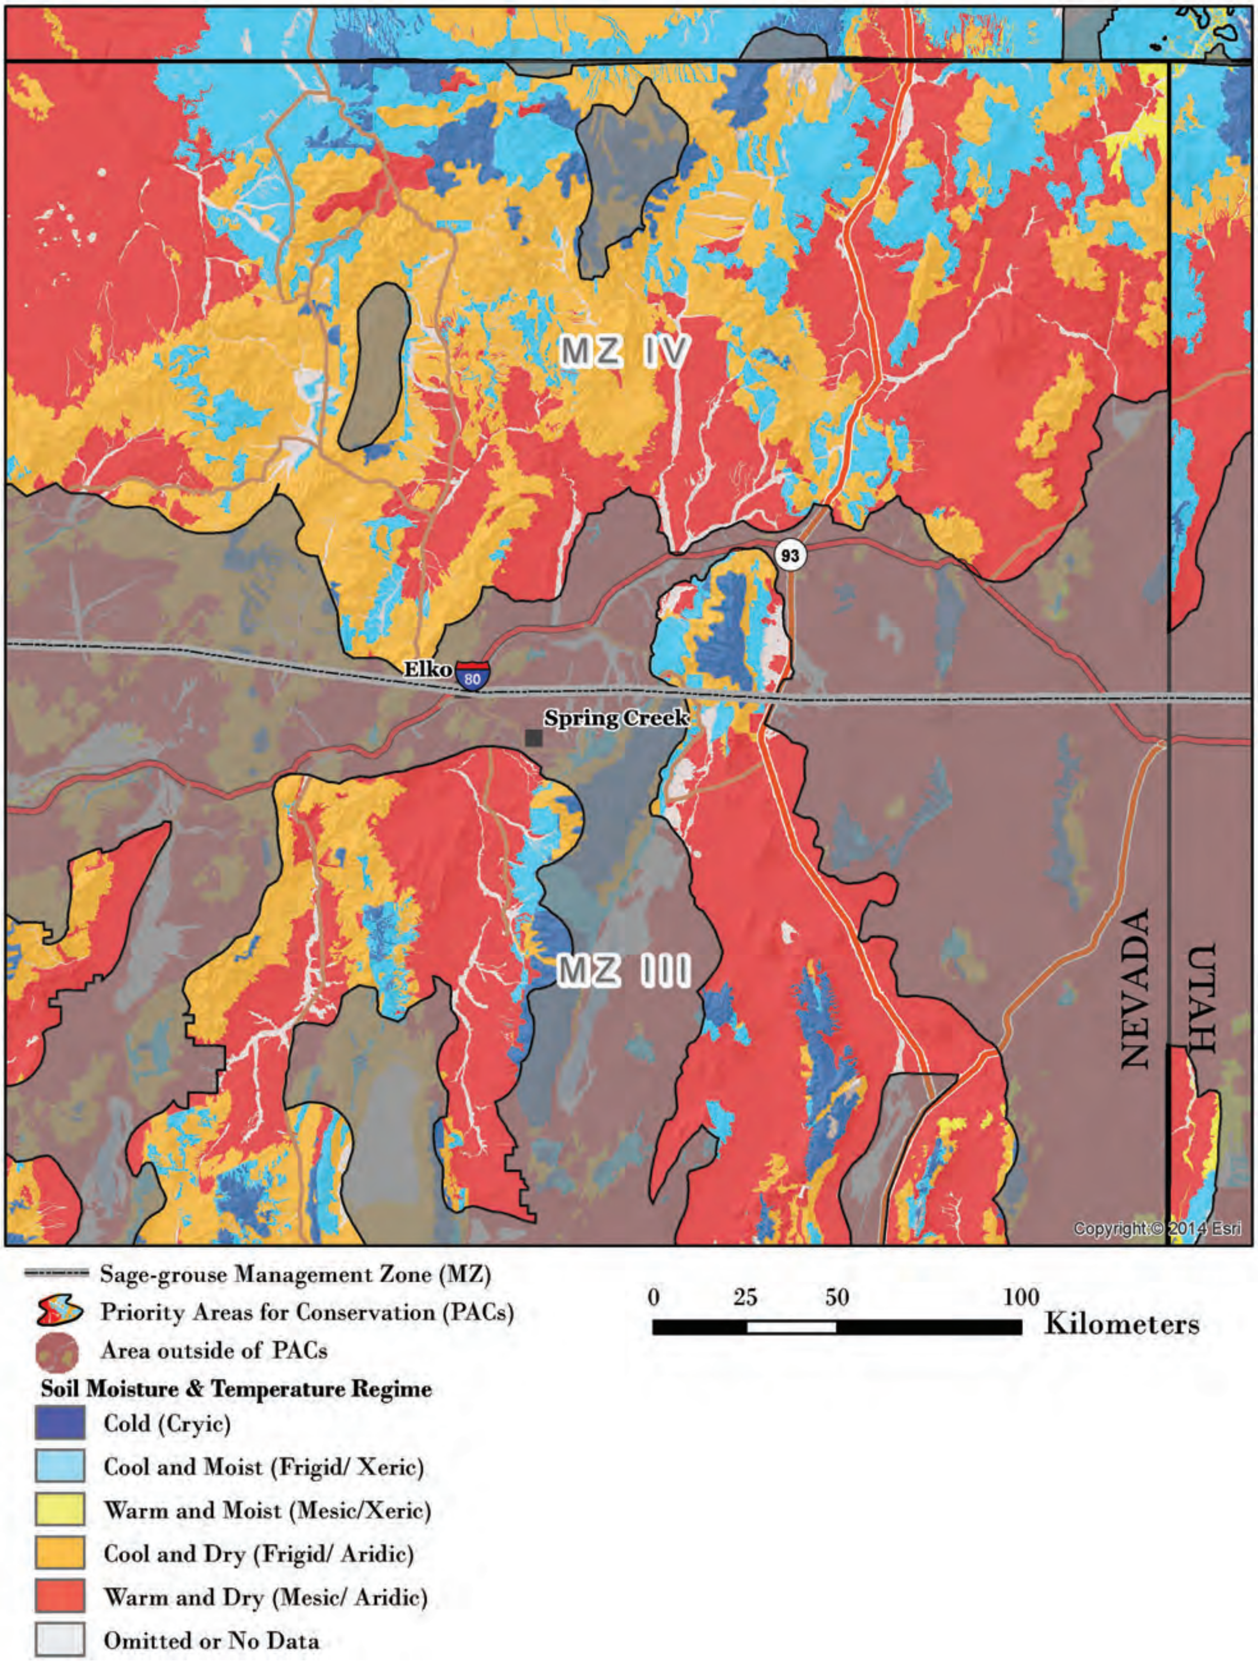

Figure 19. The soil temperature and moisture regimes for the northeast corner of Nevada. Soil temperature and moisture classes were derived from the Natural Resources Conservation Service (NRCS) Soil Survey Geographic Database (SSURGO) (Soil Survey Staff 2014a). Gaps in that dataset were filled in with the NRCS State Soil Geographic Database (STATSGO) (Soil Survey Staff 2014b). Darker colored polygons delineate Priority Areas for Conservation (USFWS 2013).

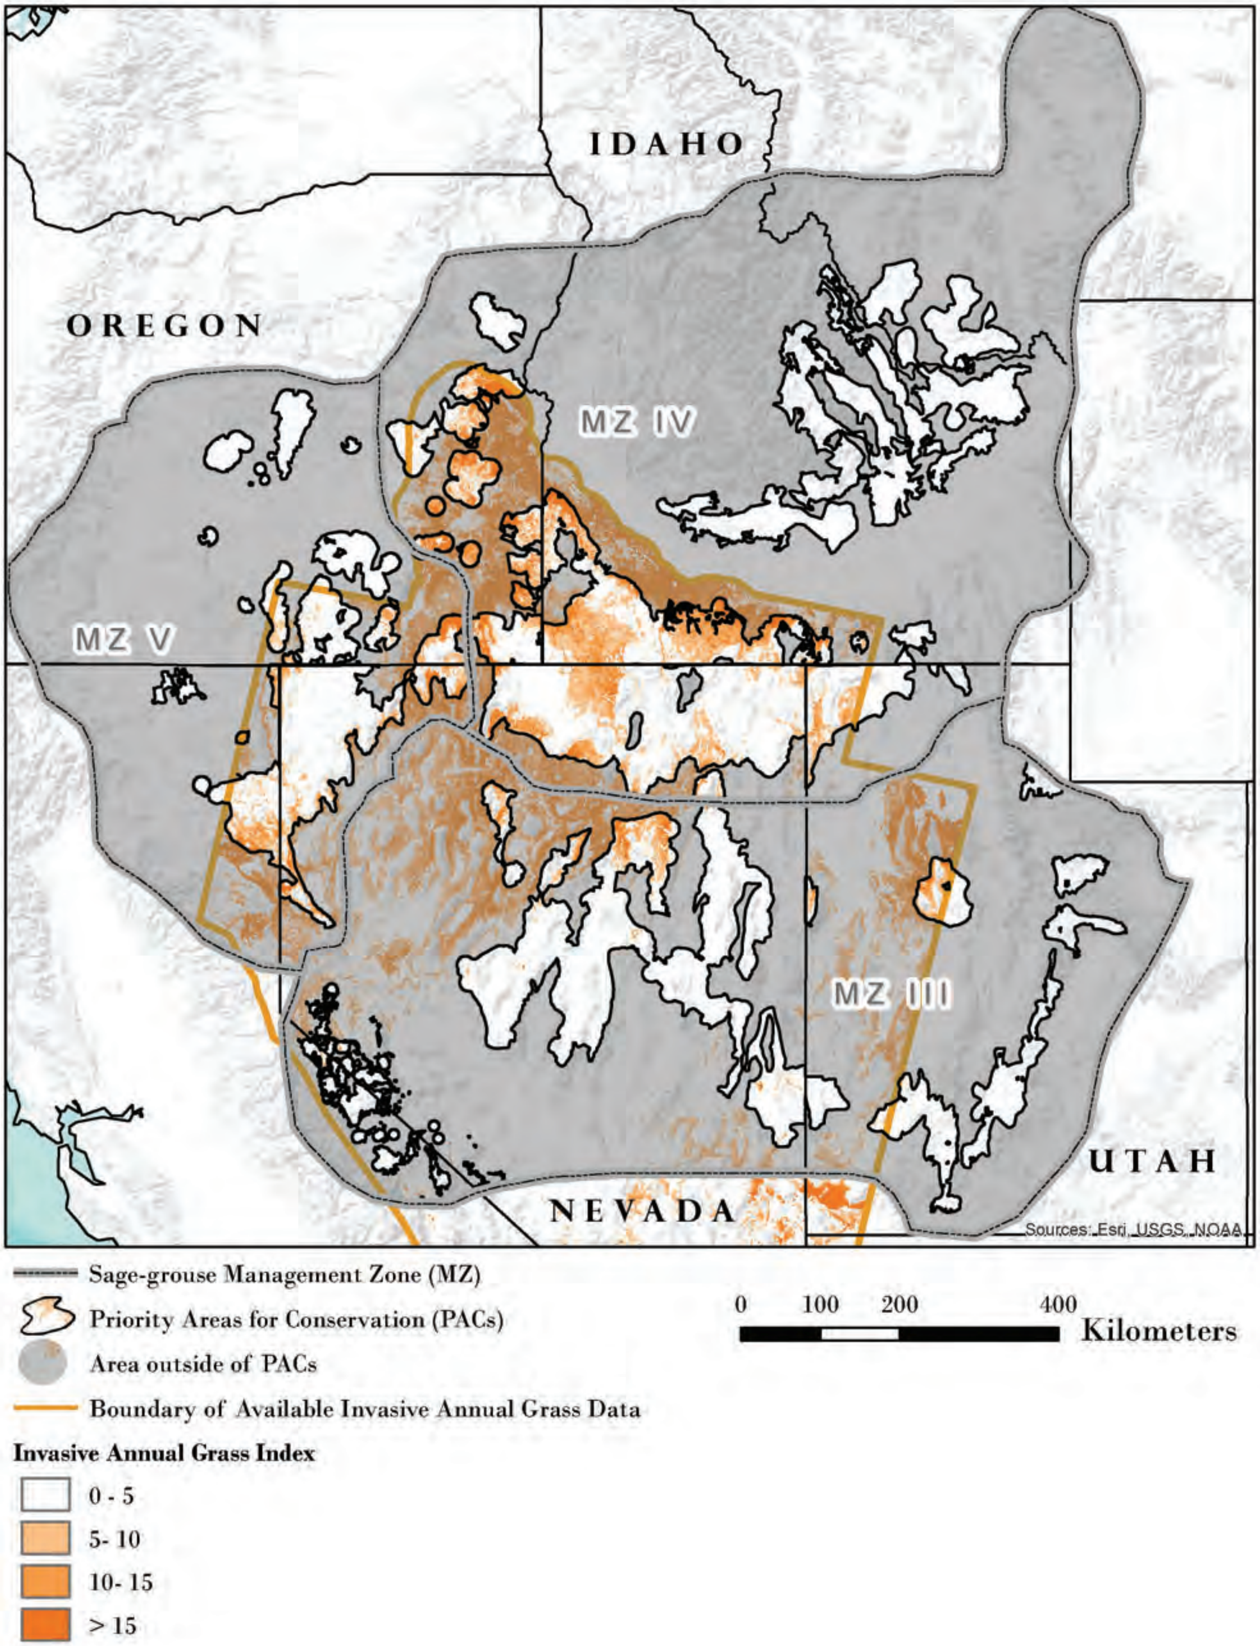

Figure 20. Invasive annual grass index for Nevada (Peterson 2006) and the Owhyee uplands (Peterson 2007) displayed for sage-grouse Management Zones III, IV, and V (Stiver et al. 2006). Lighter colored polygons within Management Zones delineate Priority Areas for Conservation (USFWS 2013).

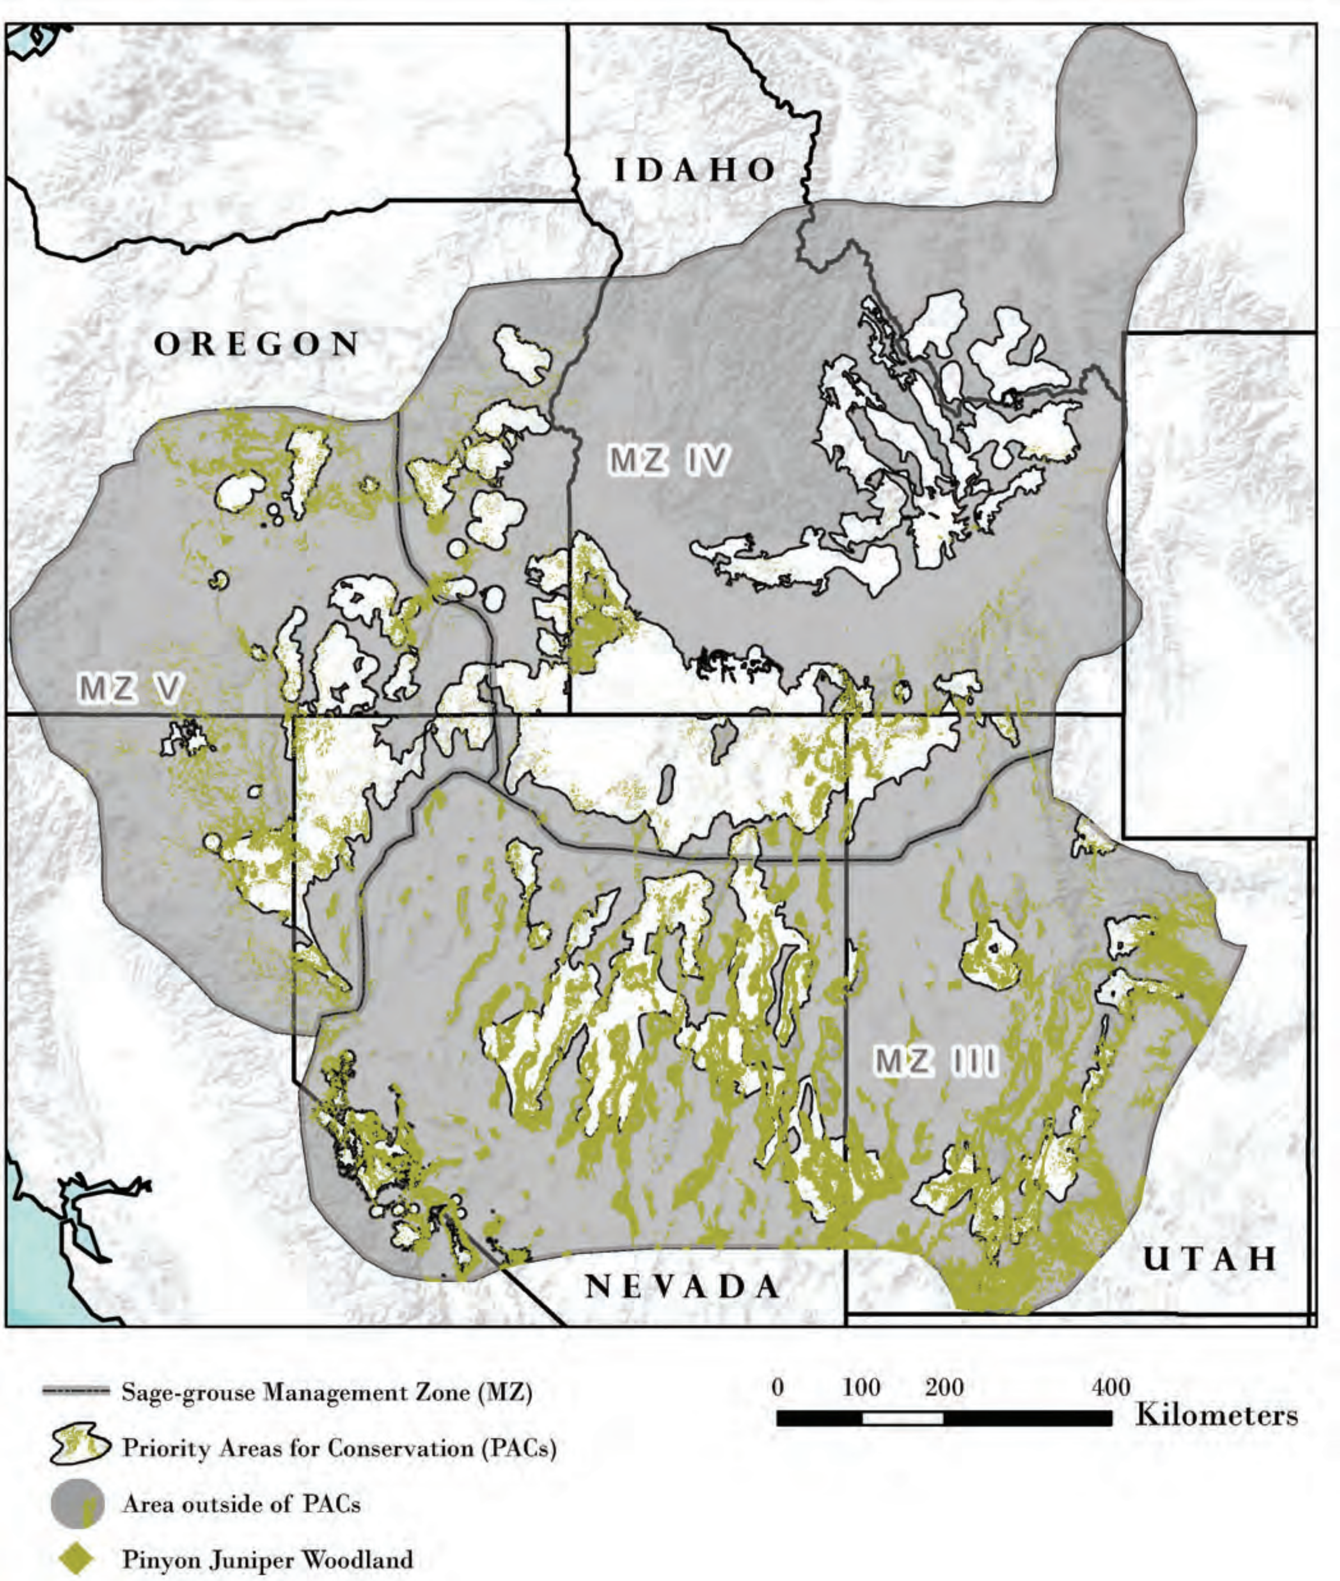

Figure 22. Piñon and/or juniper woodlands (USGS 2004; USGS 2013) within sage-grouse Management Zones III, IV, and V (Stiver et al. 2006). Lighter colored polygons within Management Zones delineate Priority Areas for Conservation (USFWS 2013).

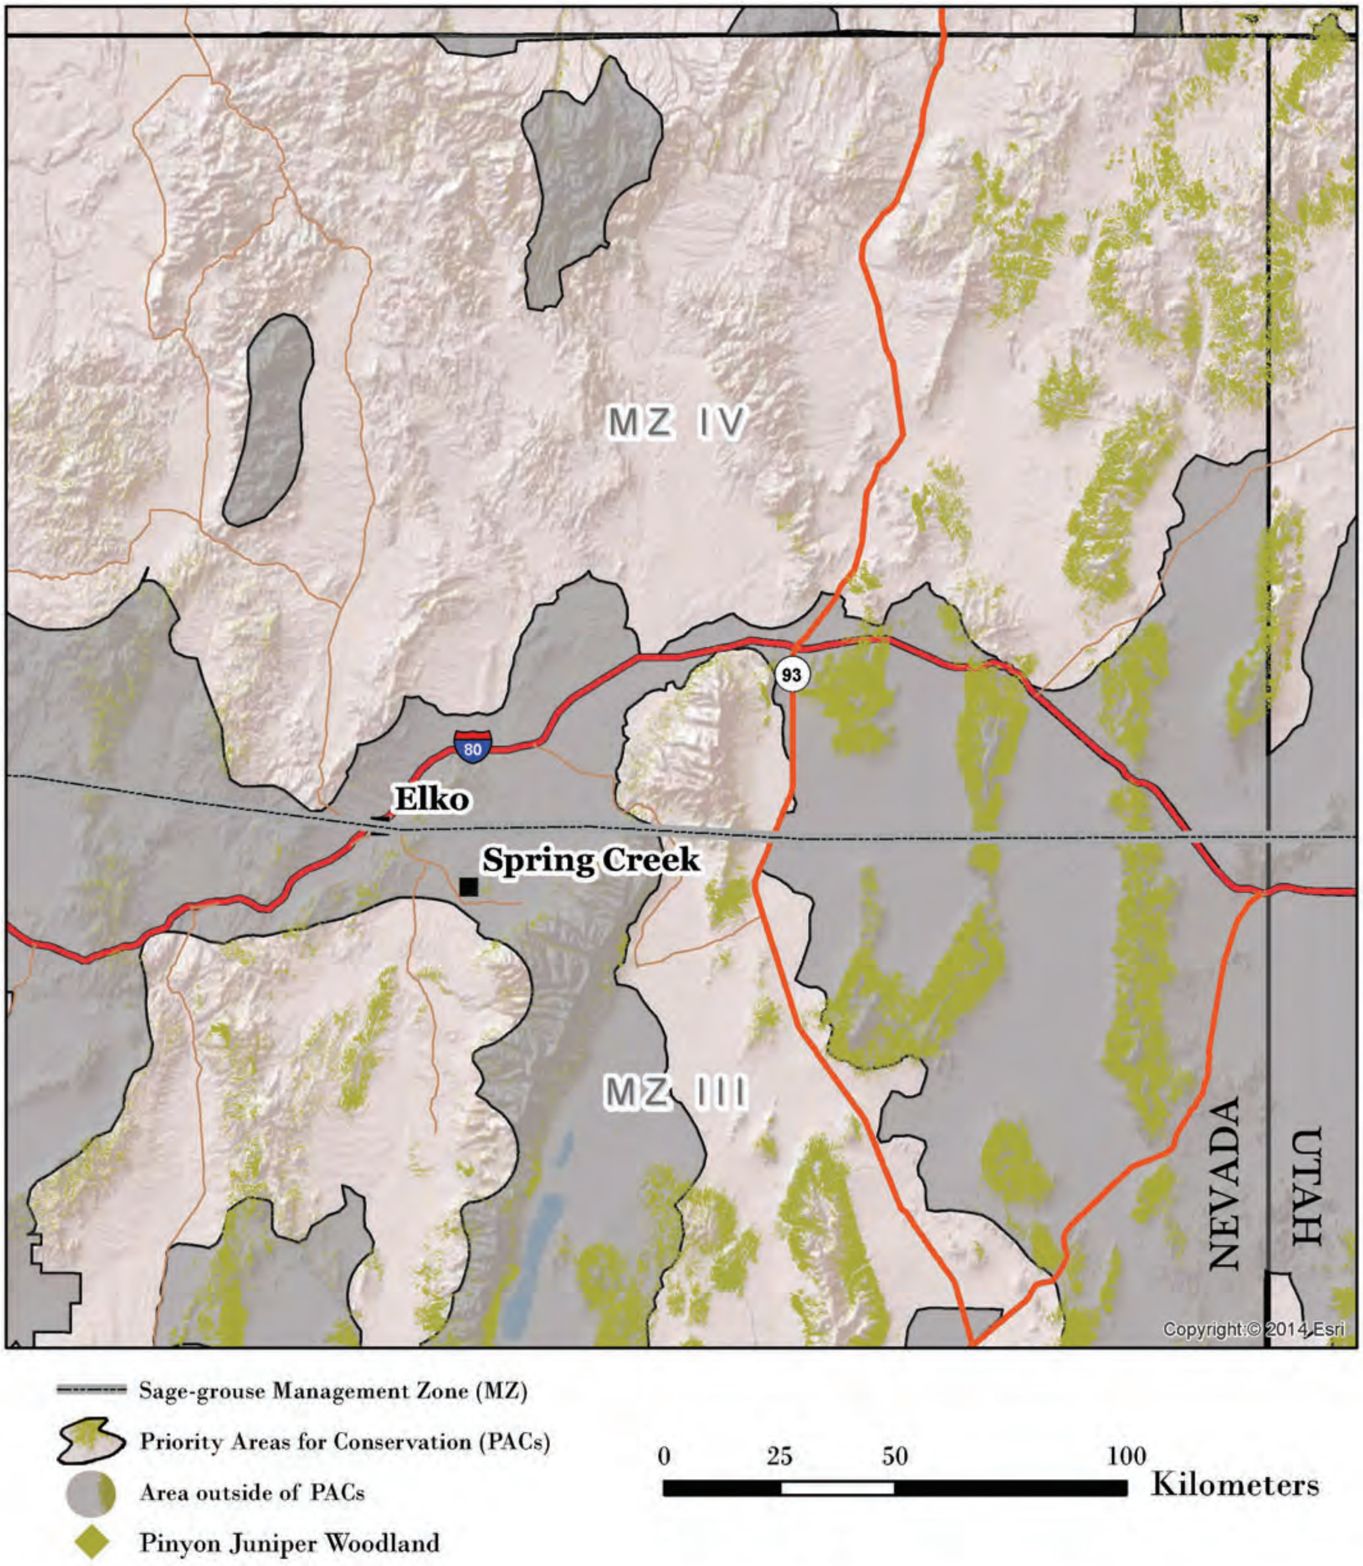

Figure 23. Piñon and/or juniper woodlands (USGS 2004; USGS 2013) within the northeast corner of Nevada. Lighter colored polygons delineate Priority Areas for Conservation (USFWS 2013).

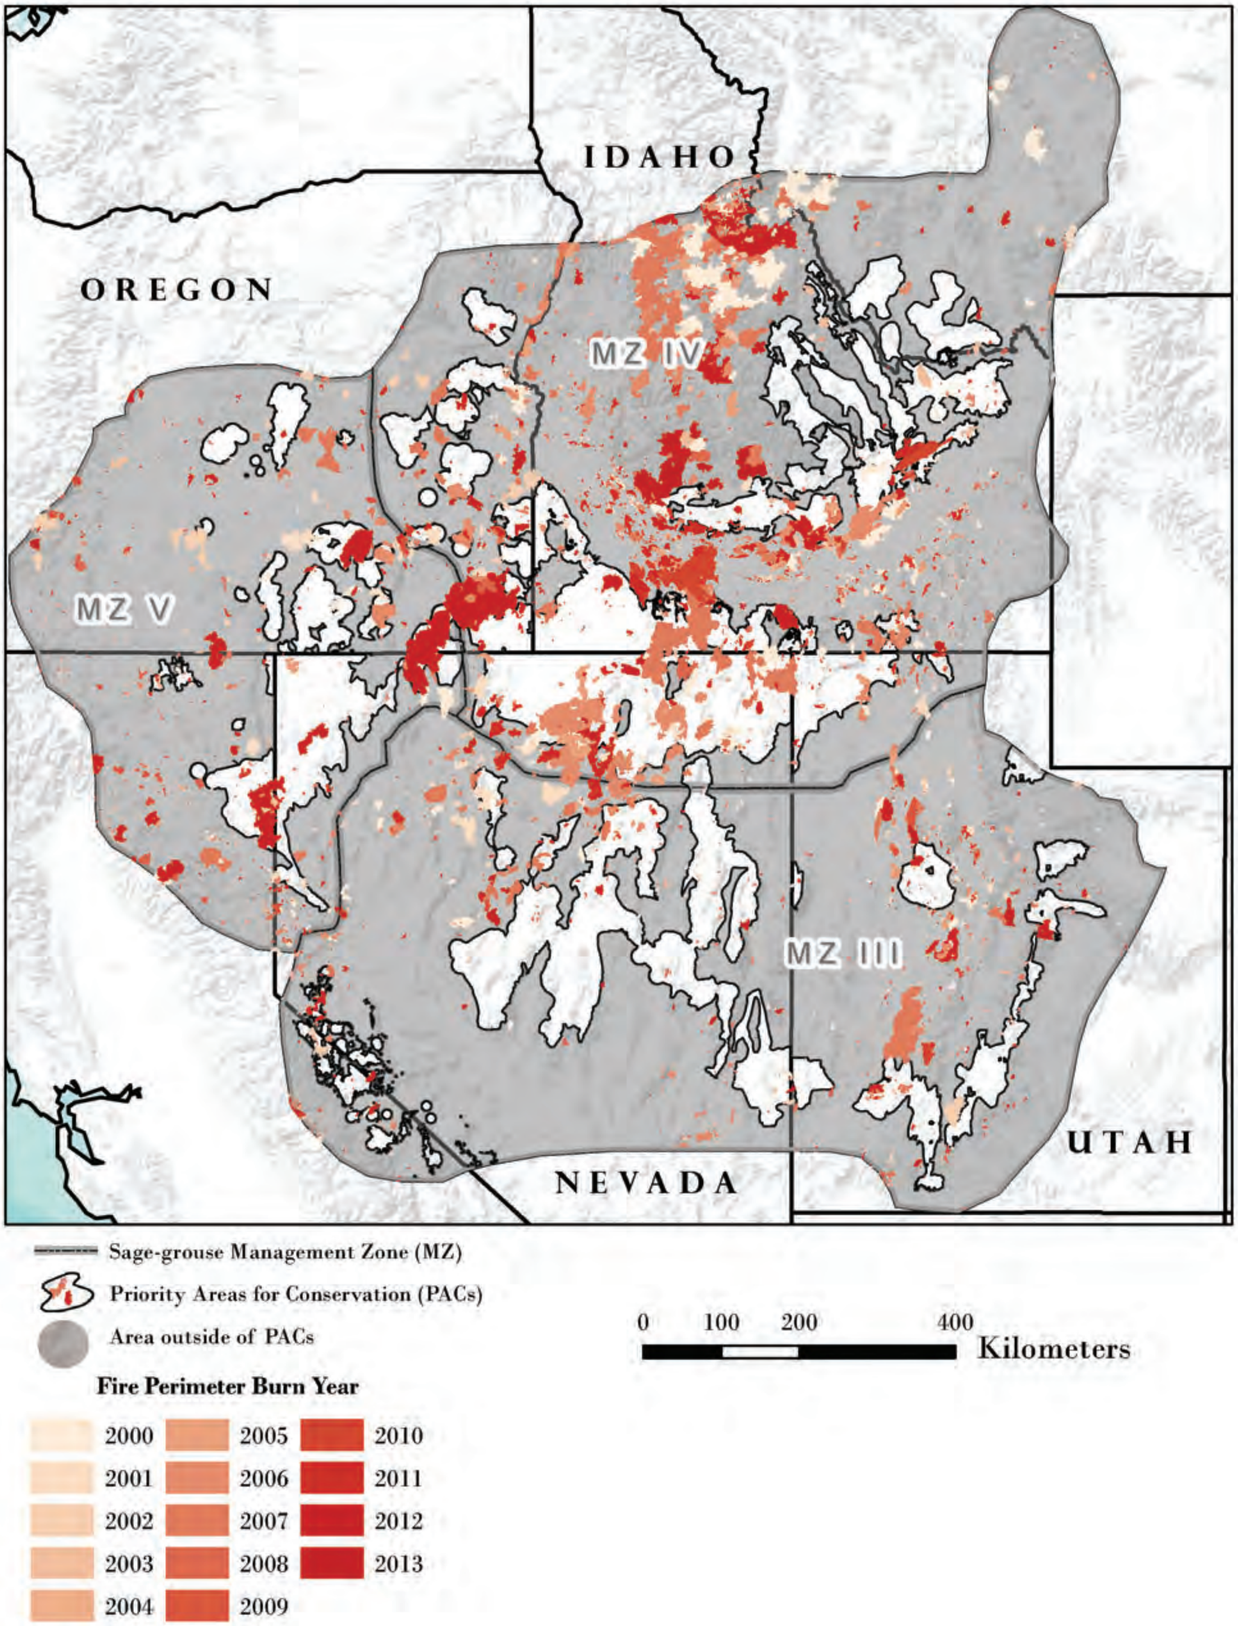

Figure 24. Fire perimeters (Walters et al. 2011; Butler and Bailey 2013) within sage-grouse Management Zones III, IV, and V (Stiver et al. 2006). Ligher colored polygons within Management Zones delineate Priority Areas for Conservation (USFWS 2013).

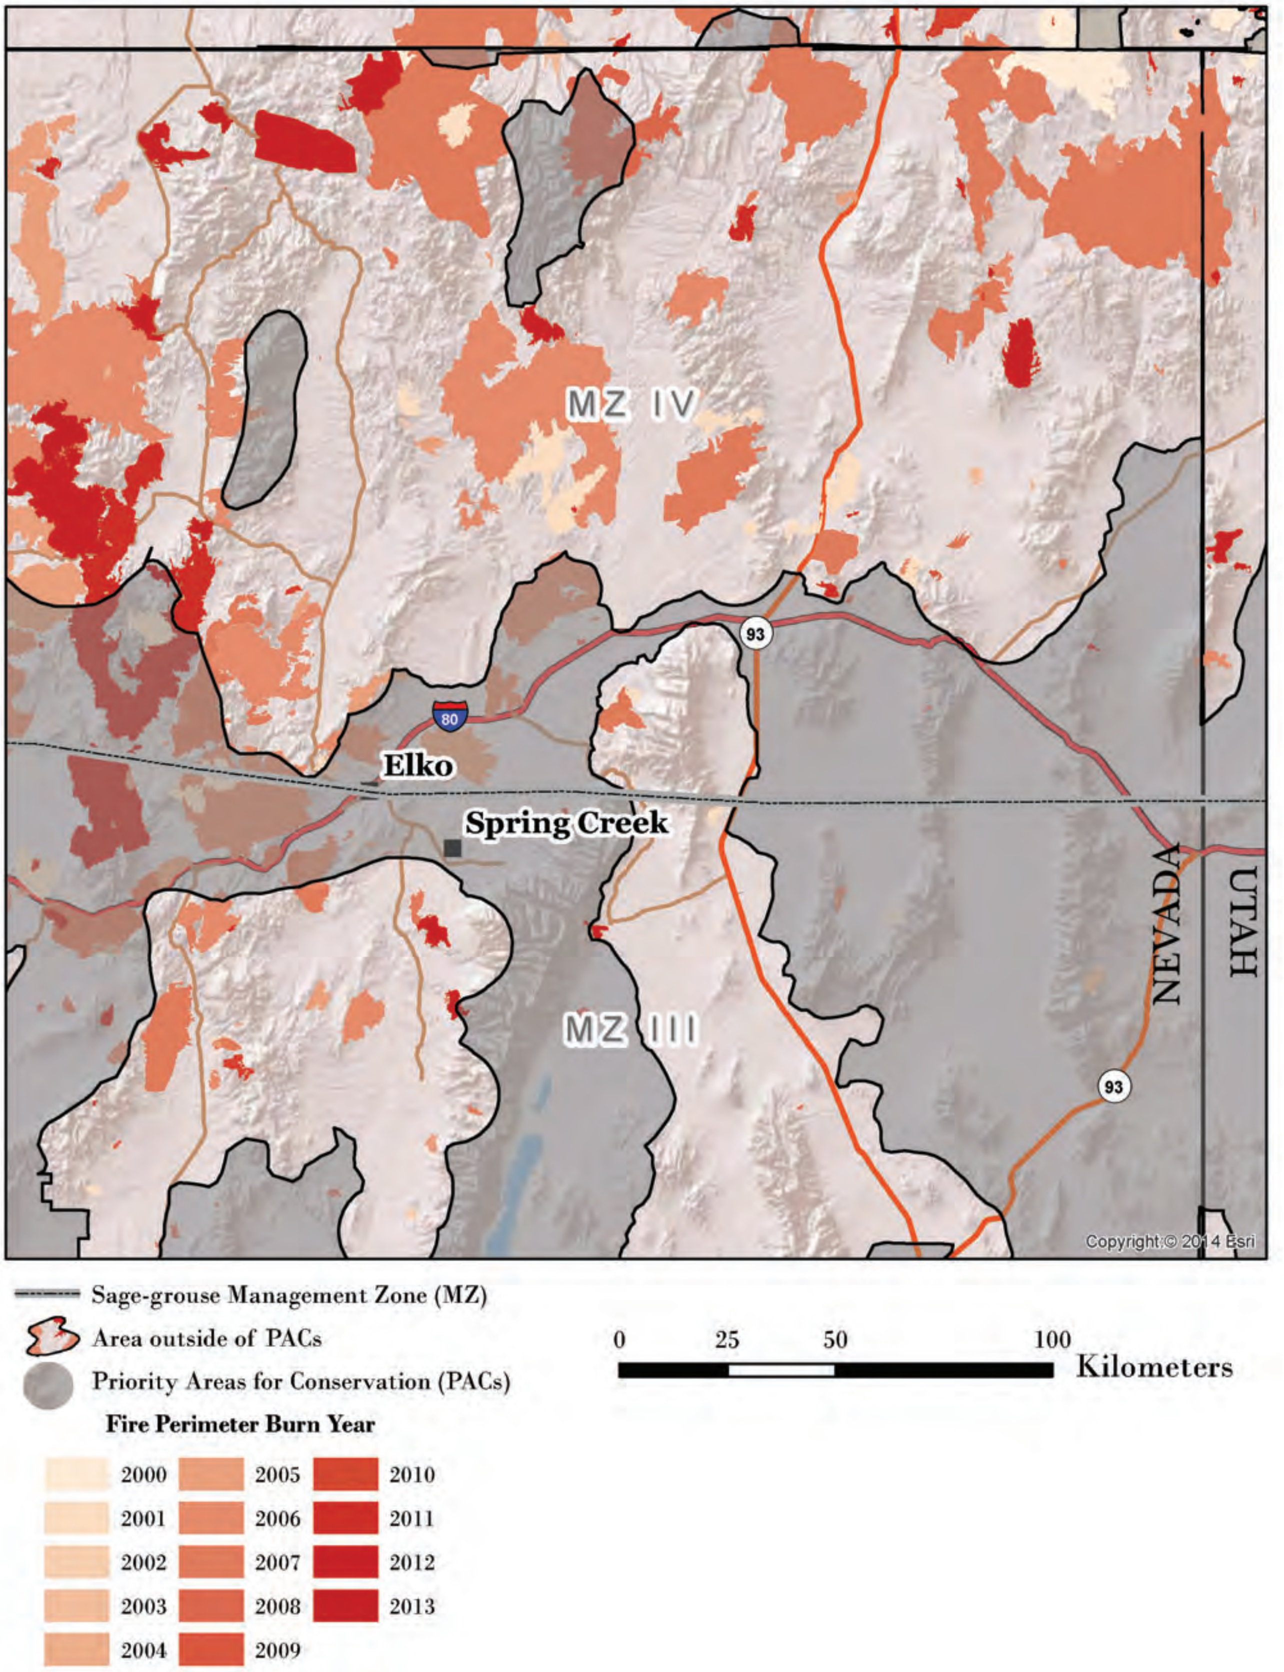

Figure 25. Fire perimeters (Walters et al. 2011; Butler and Bailey 2013) within the northeast corner of Nevada. Lighter colored polygons delineate Priority Areas for Conservation (USFWS 2013).

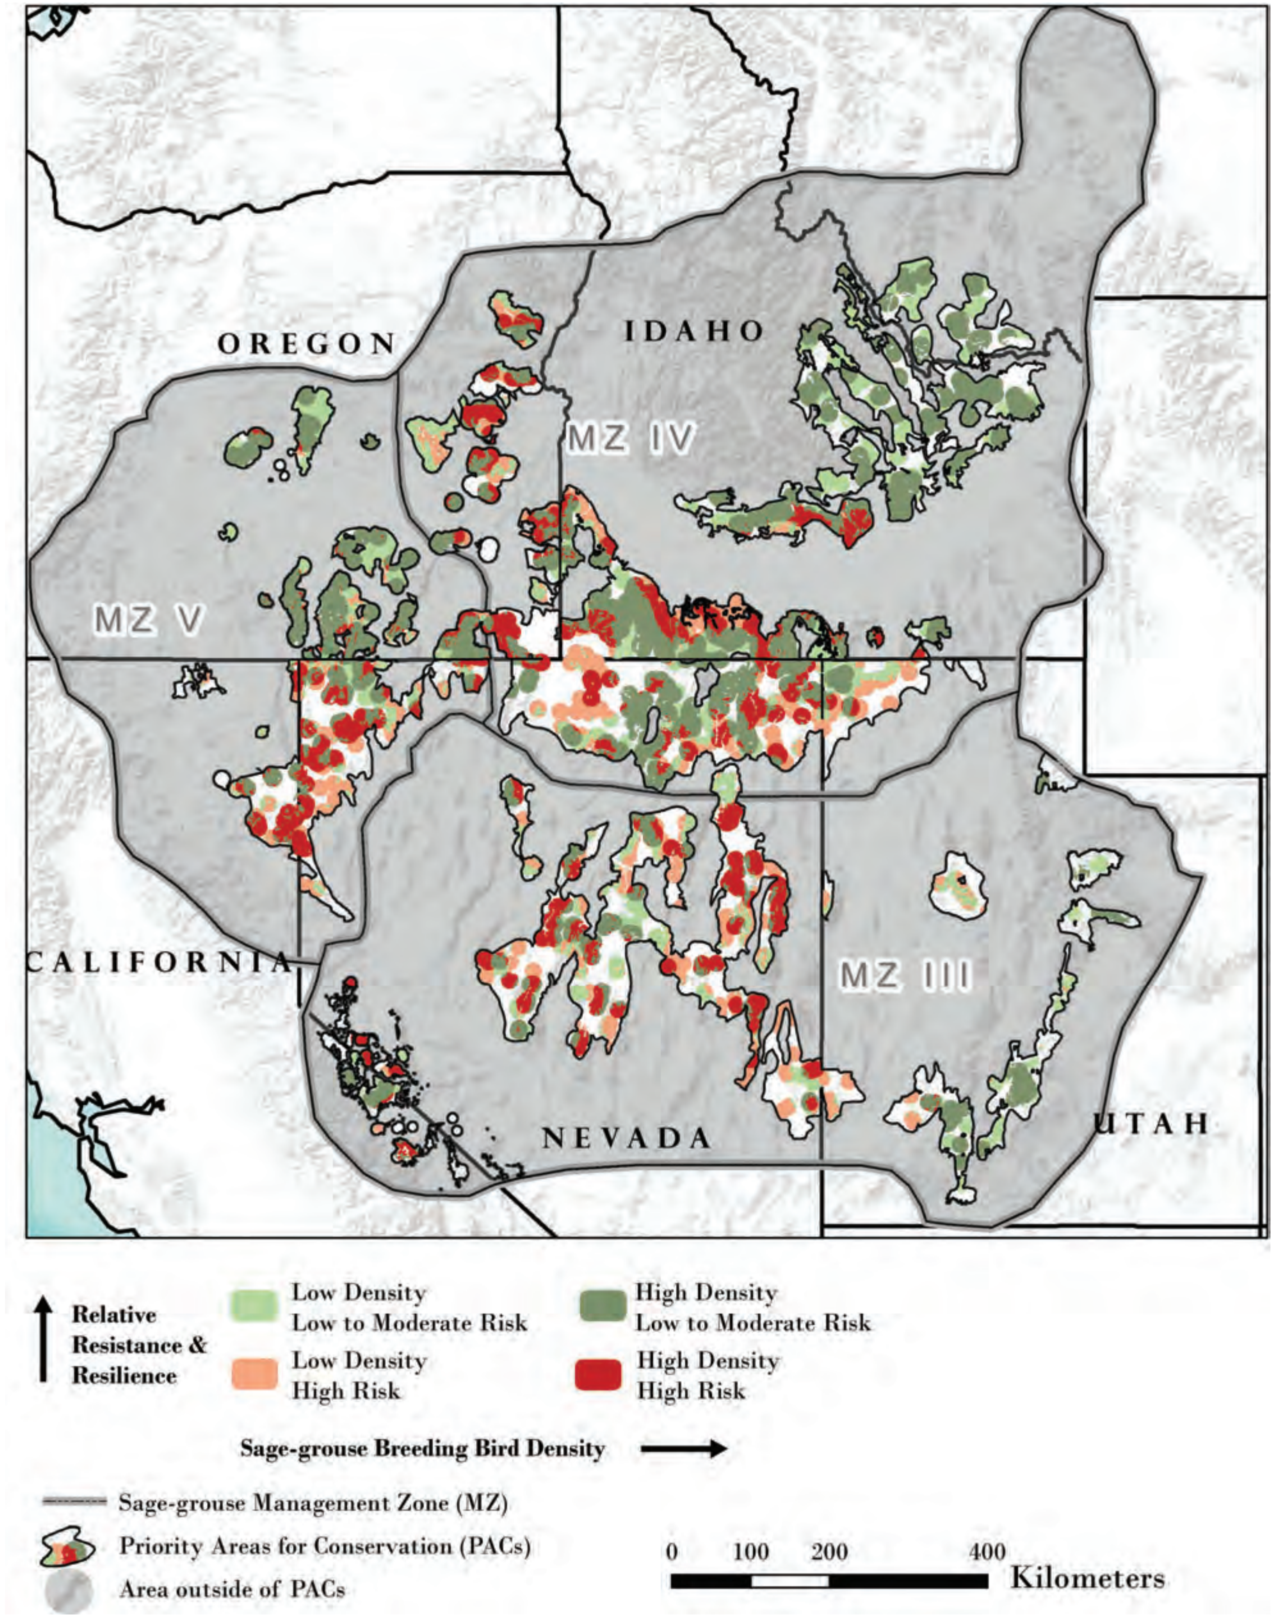

Figure 26. Sage-grouse breeding bird densities (Doherty et al. 2010) for high breeding bird densities (areas that contain 75% of known breeding bird populations) and low breeding bird densities (areas that contain all remaining breeding bird populations) relative to resilience and resistance within sage-grouse Management Zones III, IV, and V (Stiver et al. 2006). Relative resilience and resistance groups are derived from soil moisture and temperature classes (Soil Survey Staff 2014a, b) as described in text, and indicate risk of invasive annual grasses and wildfire. Lighter colored polygons within Management Zones delineate Priority Areas for Conservation (USFWS 2013).

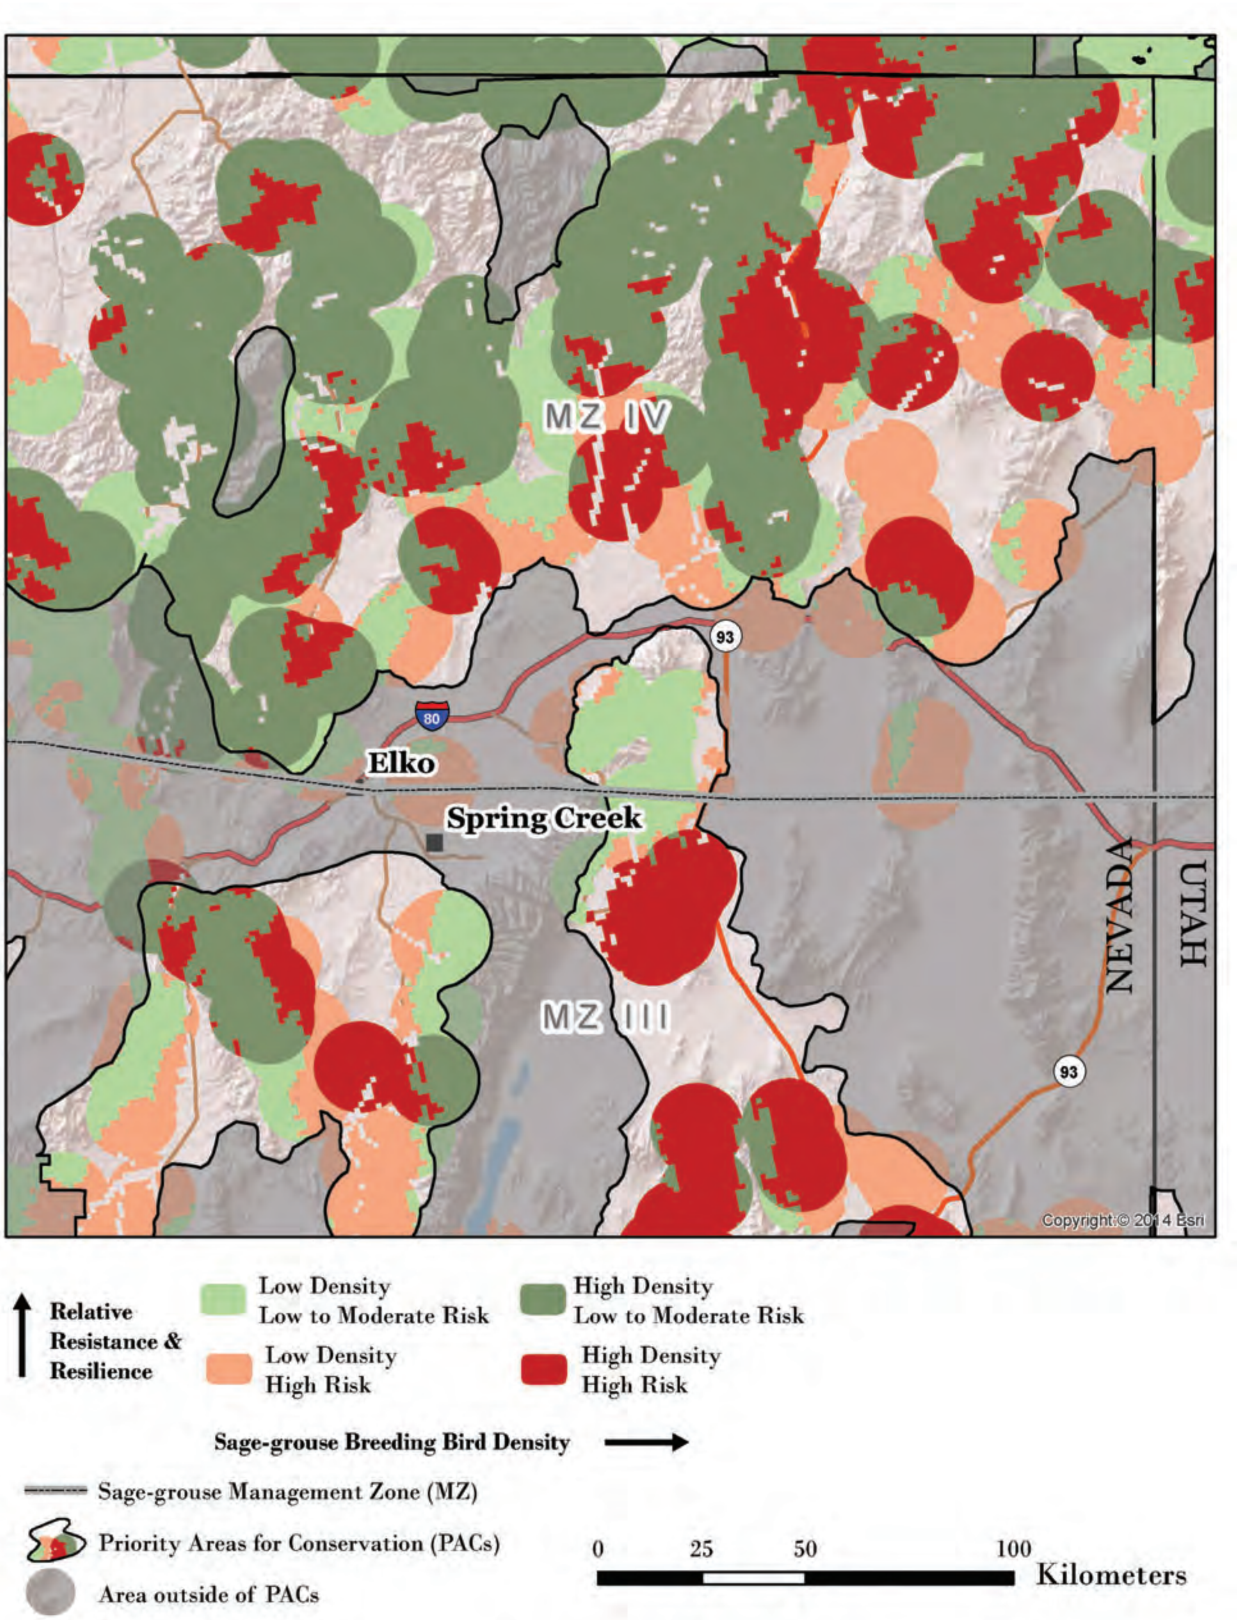

Figure 27. Sage-grouse breeding bird densities (Doherty et al. 2010) for high breeding bird densities (areas that contain 75% of known breeding bird populations) and low breeding bird densities (areas that contain all remaining breeding bird populations) relative to resilience and resistance in the northeast corner of Nevada. Relative resilience and resistance groups are derived from soil moisture and temperature classes (Soil Survey Staff 2014a, b) as described in text, and indicate risk of invasive annual grasses and wildfire. Lighter colored polygons within Management Zones delineate Priority Areas for Conservation (USFWS 2013).

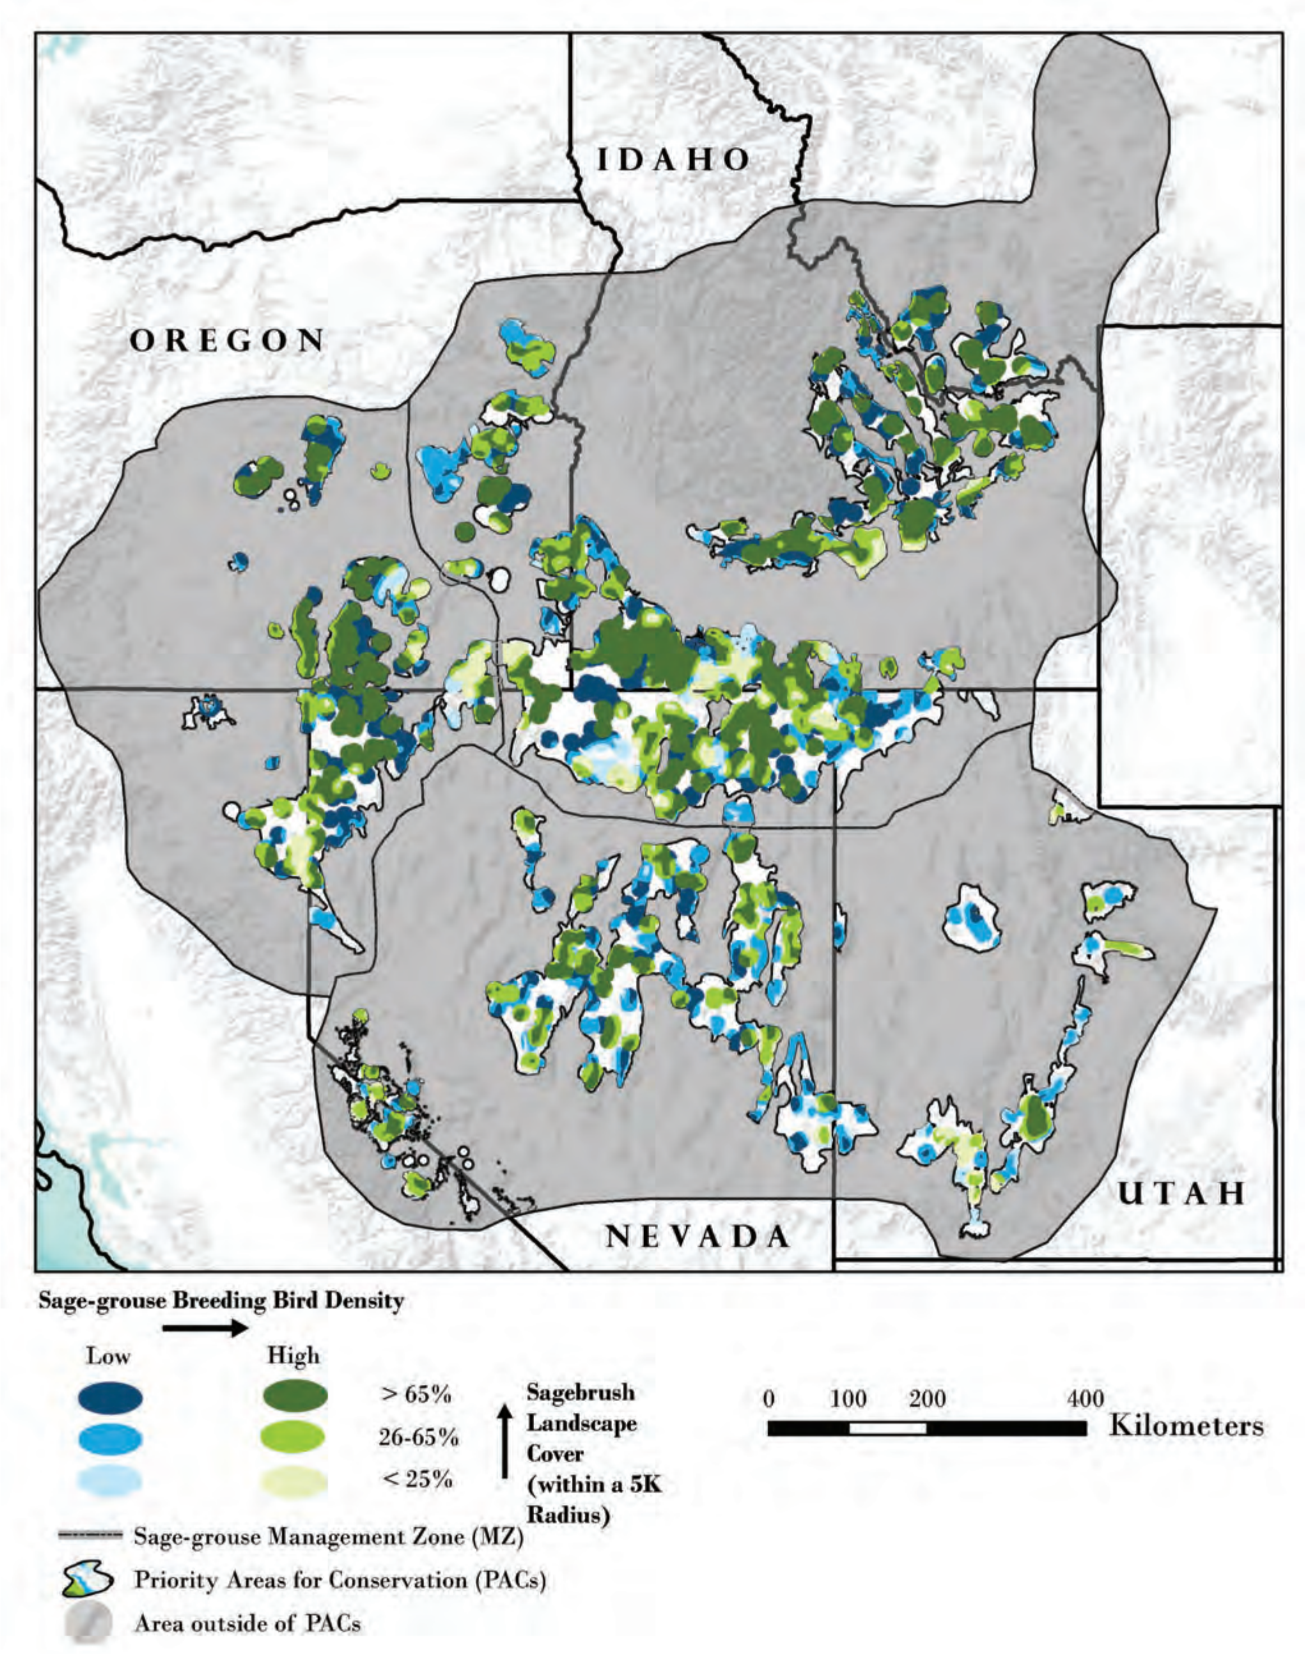

Figure 28. Sage-grouse breeding bird densities (Doherty et al. 2010) for high breeding bird densities (areas that contain 75% of known breeding bird populations) and low breeding bird densities (areas that contain all remaining breeding bird populations) relative to sagebrush cover. Lighter colored polygons within Management Zones delineate Priority Areas for Conservation (USFWS 2013).

Resilience and resistance and sagebrush cover combined with bird population density data provide land managers a way to evaluate trade-offs of particular management options at the landscape scale. For example, high density, low resilience and resistance landscapes with >65% sagebrush landscape cover may require immediate attention for conservation efforts because they currently support a high concentration of birds but have the lowest potential to recover to desired conditions post-fire and to resist invasive plants when disturbed. Similarly, high density but moderate-to-high resilience and resistance landscapes with 26-65% sagebrush cover may be priorities for preventative actions like conifer removal designed to increase the proportion of sagebrush cover and maintain ecosystem resilience and resistance. Mapping relative resilience and resistance and landscape cover of sagebrush for sage-grouse breeding areas should be viewed as a component of the assessment process that can help local managers allocate resources to accelerate planning and implementation.

Interpretations at the Management Zone (MZ) Scale: Western Portion of the Range

An examination of land cover and additional data layers for the western portion of the range reveals large differences among Management Zones (MZs) III, IV and V. MZs IV and V have larger areas with sagebrush cover >65% than MZ III (fig. 16). This may be partly explained by basin and range topography in MZ III, which is characterized by large differences in both environmental conditions and ecological types over relatively short distances. However, the cover of piñon and juniper in and adjacent to PACs in MZ III also is higher than in either MZ IV or V (fig. 22). The greater cover of piñon and juniper in MZ III appears to largely explain the smaller patches of sagebrush cover in the 26-65% and >65% categories.

Our capacity to quantify understory vegetation cover using remotely sensed data is currently limiting, but a visual examination of estimates for invasive annual grass (fig. 20; Peterson 2006, 2007) suggests a higher index (greater cover) in areas with relatively low resistance (warm soil temperatures) in all MZs (see fig. 18). This is consistent with current understanding of resistance to cheatgrass (Chambers et al. 2014; Chambers et al. *in press*). It is noteworthy that the invasive annual grass index is low for most of the central basin and range (central Nevada). Several factors may be contributing to the low index for this area including climate, the stage of piñon and juniper expansion and linked decrease in fire frequency, the relative lack of human development, and the relative lack of management treatments in recent decades (Wisdom et al. 2005; Miller et al. 2011). Not surprisingly, areas with a high annual grass index are outside or on the periphery of current PACs. However, it is likely that invasive annual grasses are present on many warmer sites and that they may increase following fire or other disturbances. In areas with low resistance to invasive annual grasses, they often exist in the understory of sagebrush ecosystems and are not detected by remote sensing platforms such as Landsat.

The number of hectares burned has been highest in MZ IV, adjacent areas in MZ V, and in areas with relatively low resilience and resistance in the northern portion of MZ III that have a high invasive annual grass index (figs. 18, 20, 24). A total of over 1.1 million hectares (2.7 million acres) burned in 2000 and 2006, while over 1.7 million hectares (4.2 million acres) burned in 2007 and 2012 and almost three quarters of these acres were in MZ IV (table 5). In some cases, these fires appear to be linked to the annual invasive grass index, but in others it clearly is not. At this point, there appears to be little relationship between cover of piñon and juniper and wildfire. Mega-fires comprised of hundreds of thousands of acres have burned in recent years, especially in MZ IV. These fires have occurred primarily in areas with low to moderate resilience and resistance and during periods with extreme burning conditions.

Table 5. The number of hectares (acres) burned in Management Zones III, IV, and V each year from 2000 to 2013.

Year	Management Zone III		Management Zone IV		Management Zone V		Total	
2000	155,159	(383,405)	868,118	(2,145,165)	88,871	(219,606)	1,112,148	(2,748,176)
2001	164,436	(406,330)	272,870	(674,276)	141,454	(349,541)	578,760	(1,430,147)
2002	85,969	(212,433)	100,308	(247,867)	113,555	(280,601)	299,833	(740,902)
2003	21,869	(54,038)	127,028	(313,892)	27,597	(68,192)	176,493	(436,123)
2004	20,477	(50,600)	11,344	(28,032)	13,037	(32,216)	44,858	(110,847)
2005	45,130	(111,520)	374,894	(926,382)	22,039	(54,458)	442,063	(1,092,360)
2006	198,762	(491,150)	860,368	(2,126,014)	117,452	(290,230)	1,176,582	(2,907,394)
2007	371,154	(917,140)	1,240,303	(3,064,853)	134,520	(332,406)	1,745,977	(4,314,399)
2008	14,015	(34,632)	109,151	(269,717)	43,949	(108,599)	167,115	(412,949)
2009	43,399	(107,242)	12,250	(30,271)	47,918	(118,408)	103,568	(255,921)
2010	31,597	(78,078)	280,662	(693,531)	21,940	(54,216)	334,200	(825,825)
2011	83,411	(206,114)	283,675	(700,977)	22,909	(56,608)	389,995	(963,699)
2012	203,680	(503,303)	946,514	(2,338,885)	574,308	(1,419,144)	1,724,501	(4,261,331)
2013	45,976	(113,610)	368,434	(910,419)	15,852	(39,170)	430,262	(1,063,199)
Total	1,485,034	(3,669,595)	5,855,920	(14,470,281)	1,385,400	(3,423,396)	8,726,354	(21,563,271)

Coupling breeding bird densities with landscape cover of sagebrush indicates that populations with low densities tend to occur in areas where sagebrush cover is in the 26-65% category, and few populations occur in areas with <25% sagebrush cover (fig. 27) (Knick et al. 2013). Combining the breeding bird densities with resilience and resistance indicates significant variability in risks among high density populations within PACs (fig. 26). A large proportion of remaining high density centers within PACs occurs on moderate-to-high resilience and resistance habitats, while low density/low resilience and resistance areas tend to occur along the periphery of PACs or are disproportionately located in MZ III and southern parts of MZ V.

Examination of other data layers suggests that different wildfire and invasive species threats exist across the western portion of the range, and that management should target the primary threats to sage-grouse habitat within focal areas. In MZs IV and V invasive annual grasses—especially on the periphery of the PACs—and wildfire are key threats. However, recent wildfires are not necessarily linked to invasive annual grasses. This suggests that management strategies for these MZs emphasize fire operations, fuels management focused on decreasing fire spread, and integrated strategies to control annual grasses and increase post-fire rehabilitation and restoration success. Differences in piñon and/or juniper landscape cover exist among MZs with 5,131,900 ha (12,681,202 ac) in MZ III, 528,377ha (1,305,649 ac) in MZ IV, and 558,880 ha (1,381,024 ac) in MZ V. Portions of MZs IV and V are still largely in early stages of juniper expansion indicating a need to address this threat before woodland succession progresses. Because of generally low resilience and resistance in MZ III, greater emphasis is needed on habitat conservation, specifically minimizing or eliminating stressors. Also, greater emphasis on reducing cover of piñon and juniper is needed to reduce woody fuels and increase sagebrush ecosystem resilience to fire by increasing the recovery potential of native understory species.

Interpretations at Regional and Local Land Management Scales: Northeast Nevada Example

The same land covers and data layers used to assess focal areas for sage-grouse habitat within MZs in the western portion of the species range can be used to evaluate focal areas for management in regional planning areas and land management planning units. The emphasis at the scale of the land planning area or management planning unit is on maintaining or increasing large contiguous areas of sagebrush habitat with covers in the 26-65% and especially >65% category. Resilience to disturbance and resistance to invasive annual grasses as indicated by soil temperature and moisture regimes is used to determine the most appropriate activities within the different cover categories. The sage-grouse habitat matrix in table 2 describes the capacity of areas with differing resilience and resistance to recover following disturbance and resist annual invasive grasses and provides the management implications for each of the different cover categories. Table 4 provides potential management strategies for the different sagebrush cover and resilience and resistance categories (cells) in the sage-grouse habitat matrix by agency program areas (fire operations, fuels management, post-fire rehabilitation, habitat restoration). Note that the guidelines in table 4 are related to the sage-grouse habitat matrix, and do not preclude other factors from consideration when determining management priorities for program areas.

Here, we provide an example of how to apply the concepts and tools discussed in this report by examining an important region identified in the MZ scale assessment. The northeastern corner of Nevada was selected to illustrate the diversity of sage-grouse habitat within planning areas and the need for proactive collaboration both within agencies and across jurisdictional boundaries in devising appropriate management strategies (figs. 17, 19, 21, 23, 25). This part of Nevada has large areas of invasive annual grasses and areas with piñon and juniper expansion, and it has experienced multiple large fires in the last decade. It includes a BLM Field Office, Forest Service (FS) land, State land, multiple private owners, and borders two States (fig. 29), which results in both complex ownership and natural complexity.

In the northeast corner of Nevada, an area 5,403,877 ha (13,353,271 ac) in size, numerous large fires have burned in and around PACs (fig. 25). Since 2000, a total of 1,144,317 ha (2,827,669 ac) have burned with the largest fires occurring in 2000, 2006, and 2007. This suggests that the primary management emphasis be on retaining existing areas of sagebrush in the 26-65% and especially >65% categories and promoting recovery of former sagebrush areas that have burned. Fire suppression in and around large, contiguous areas of sagebrush and also in and around successful habitat restoration or post-fire rehabilitation treatments is a first order priority. Fuels management also is a high priority and is focused on strategic placement of fuel breaks to reduce loss of large sagebrush stands by wildfire without jeopardizing existing habitat quality. Also, in the eastern portion of the area, piñon and juniper land cover comprises 471,645 ha (1,165,459 ac) (fig. 23). In this area, management priorities include (1) targeted tree removal in early to mid-phase (Phase I and II), post-settlement piñon and juniper expansion areas to maintain shrub/herbaceous cover and reduce fuel loads, and (2) targeted tree removal in later phase (Phase III) post-settlement piñon and juniper areas to reduce risk of high severity fire. In areas with moderate to high resilience and resistance, post-fire rehabilitation focuses on accelerating sagebrush establishment and recovery of perennial native herbaceous species. These areas often are capable of unassisted recovery and seeding is likely needed only in areas where perennial native herbaceous species have been depleted (Miller et al. 2013). Seeding introduced species can retard recovery of native perennial grasses and forbs that are important to sage-grouse and should be avoided in these areas (Knutson et al. 2014). Seeding or transplanting of sagebrush may be needed to accelerate establishment in focal areas.

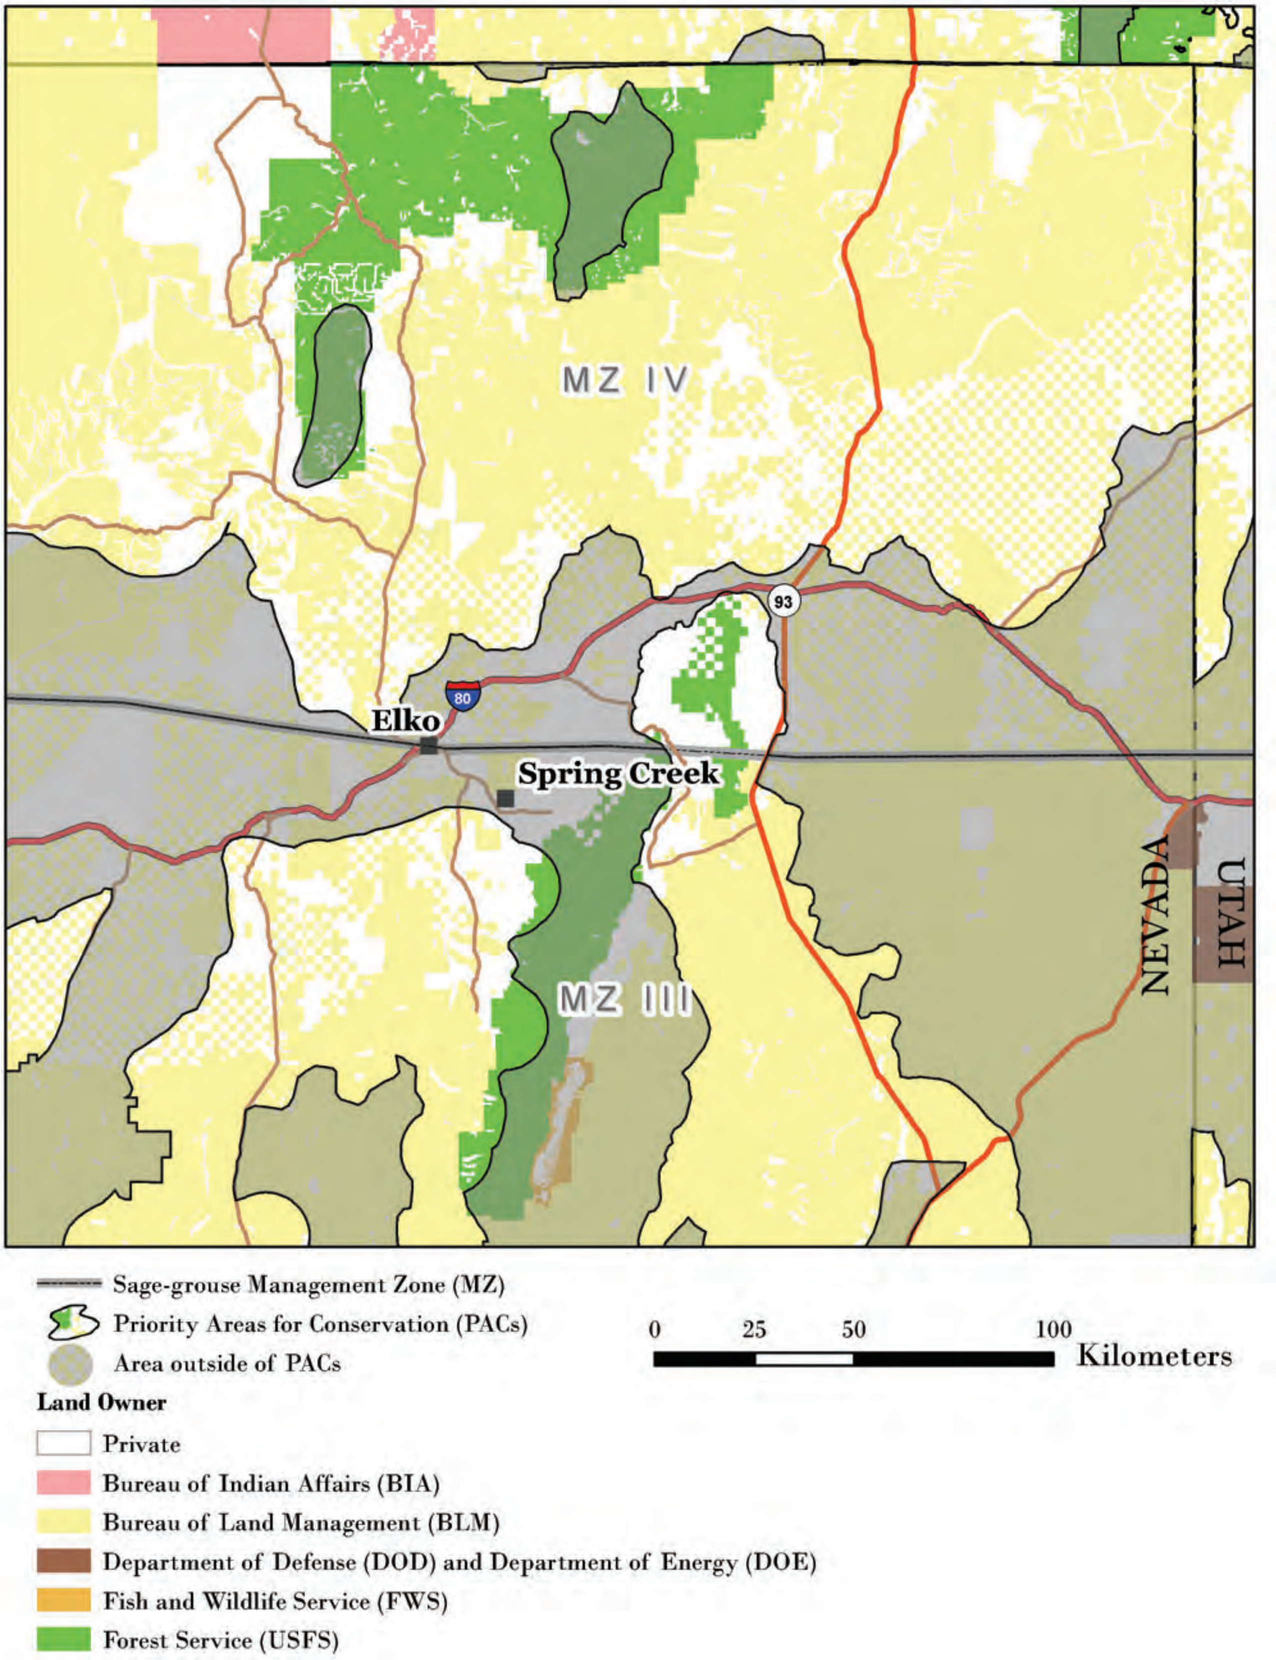

Figure 29. Land ownership for the northeast corner of Nevada. Lighter colored polygons delineate Priority Areas for Conservation (USFWS 2013).

In areas with lower resilience and resistance and high breeding bird densities, large, contiguous areas of sagebrush with intact understories are a high priority for conservation (figs. 17, 19, 27). In these areas, emphasis is on maintaining or increasing habitat conditions by minimizing stressors and disturbance. Post-fire rehabilitation and restoration activities focus on areas that increase connectivity among existing large areas of sagebrush. Because of low and variable precipitation, more than one intervention may be required to achieve restoration or rehabilitation goals. Appropriately managing livestock, wild horse and burro use (if applicable), and recreational use in focal areas is especially important to promote native perennial grass and forb growth and reproduction and to maintain or enhance resilience and resistance.

Determining the Most Appropriate Management Treatments at the Project Scale

Once focal areas and management priorities have been determined, potential treatment areas can be assessed to determine treatment feasibility and appropriate treatment methods. Different treatment options exist (figs. 30, 31) that differ in both suitability for a focal area and likely effectiveness. Field guides for sagebrush ecosystems and piñon and juniper expansion areas that incorporate resilience and resistance concepts are being developed to help guide managers through the process of determining both the suitability of an area for treatment and the most appropriate treatment. These guides are aligned with the different program areas and emphasize (1) fuel treatments (Miller et al. 2014a), (2) post-fire rehabilitation (Miller et al. 2014b), and (3) restoration (Pyke et al., in preparation). Additional information on implementing these types of management treatments is synthesized in Monsen et al. (2004) and Pyke (2011); additional information on treatment response is synthesized in Miller et al. (2013). In this section, we summarize the major steps in the process for determining the suitability of an area for treatment and the most appropriate treatment. We then provide an overview of two of the primary tools in the assessment process – ecological site descriptions (ESDs) and state and transition models (STMs). We conclude with a discussion of the importance of monitoring and adaptive management.

Steps in the process*:* Logical steps in the process of determining the suitability of an area for treatment and the most appropriate treatment(s) include (1) assessing the potential treatment area and identifying ecological sites, (2) determining the current successional state of the site, (3) selecting the appropriate action(s), and (4) monitoring and evaluation to determine post-treatment management. A general approach that uses questions to identify the information required in each step was developed (table 6). These questions can be modified to include the specific information needed for each program area and for treating different ecological sites. This format is used in the field guides described above.

Figure 30. Common vegetation treatments for sagebrush dominated ecosystems with relatively low resilience and resistance include seeding after wildfire in areas that lack sufficient native perennial grasses and forbs for recovery (top) (photo by Chad Boyd), and mowing sagebrush to reinvigorate native perennial grasses and forbs in the understory (bottom) (photo by Scott Schaff). Success of mowing treatments depends on having adequate perennial grasses and forbs on the site to resist invasive annual grasses and to promote recovery.

Figure 31. Vegetation treatments for sagebrush ecosystems exhibiting piñon and juniper expansion include cutting the trees with chainsaws and leaving them in place (top) (photo by Jeremy Roberts) and shredding them with a “bullhog” (middle) (photo by Bruce A. Roundy) on sites with relatively warm soils and moderately low resistance to cheatgrass. Prescribed fire (bottom) (photo by Jeanne C. Chambers) can be a viable treatment on sites with relatively cool and moist soils that have higher resilience to disturbance and resistance to invasive annual grasses. Treatment success depends on having adequate perennial grasses and forbs on the site to resist invasive annual grasses and promote recovery and will be highest on sites with relatively low densities of trees (Phase I to Phase II woodlands).

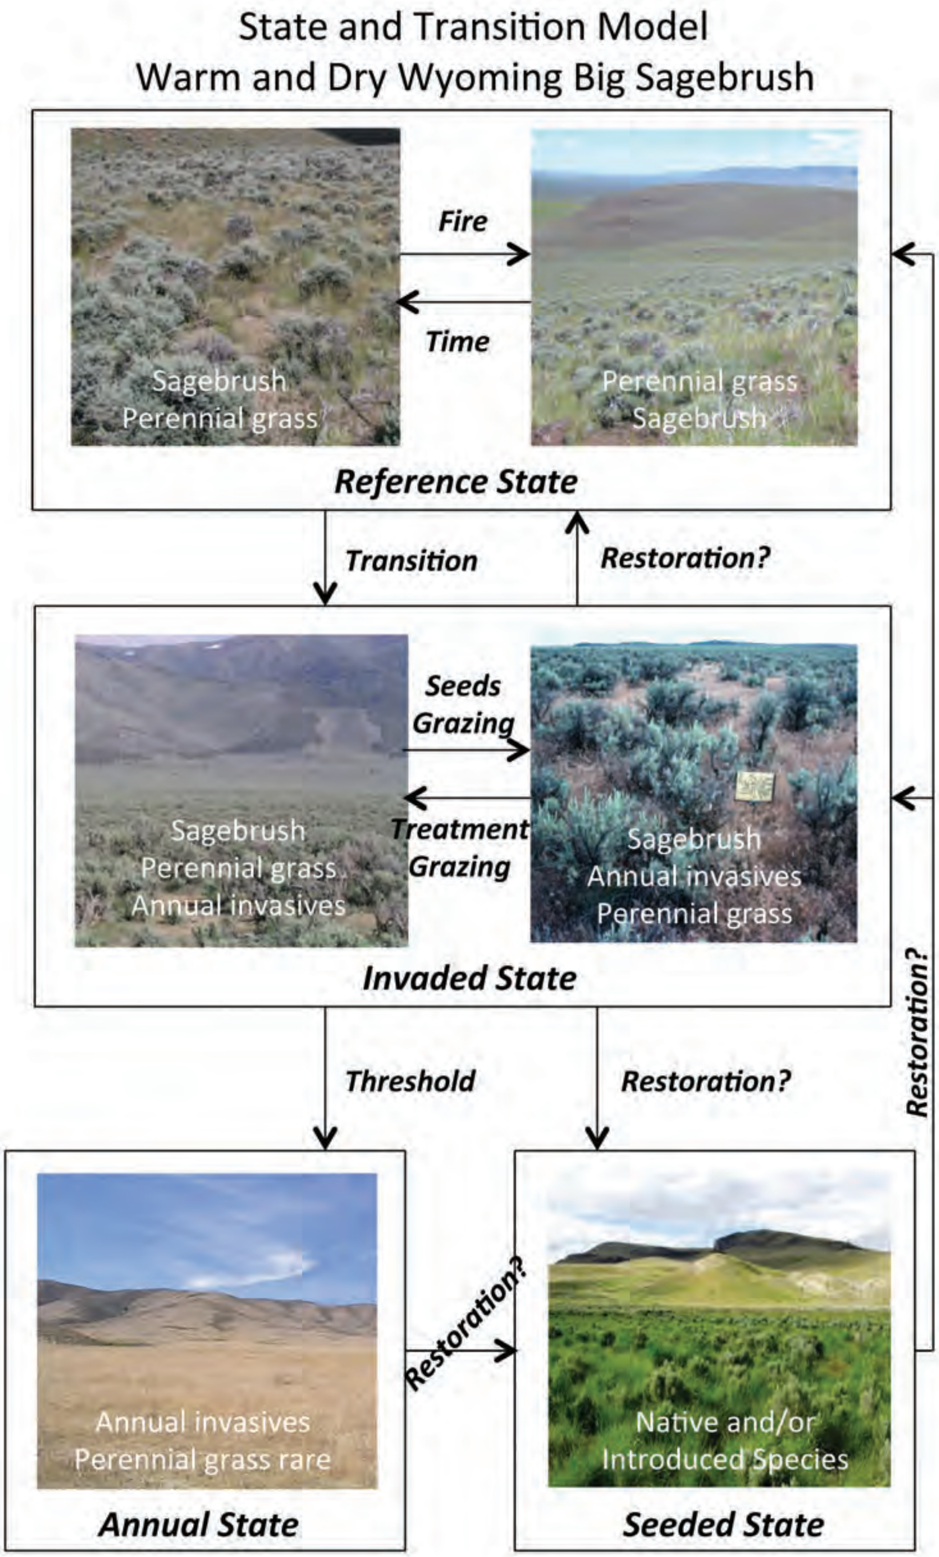
Table 6. General guidelines for conducting fuels management, fire rehabilitation, and restoration treatments (modified from Miller et al. 2007; Tausch et al. 2009; Pyke 2011; Chambers et al. 2013).

Steps in the process	Questions and considerations
I. Assess potential treatment area and identify ecological sites	1. Where are priority areas for fuels management, fire rehabilitation or restoration within the focal area? Consider sage-grouse habitat needs and resilience and resistance. 2. What are the topographic characteristics and soils of the area? Verify soils mapped to the location and determine soil temperature/moisture regimes. Collect information on soil texture, depth and basic chemistry for restoration projects. 3. How will topographic characteristics and soils affect vegetation recovery, plant establishment and erosion? Evaluate erosion risk based on topography and soil characteristics. 4. What are the potential native plant communities for the area? Match soil components to their correlated ESDs. This provides a list of potential species for the site(s).
II. Determine current state of the site	5. Is the area still within the reference state for the ecological site(s)?
III. Select appropriate action	6. How far do sites deviate from the reference state? How will treatment success be measured? 7. Do sufficient perennial shrubs and perennial grasses and forbs exist to facilitate recovery? 8. Are invasive species a minor component? 9. Do invasive species dominate the sites while native life forms are missing or severely under represented? If so, active restoration is required to restore habitat. 10. Are species from drier or warmer ecological sites present? Restoration with species from the drier or warmer sites should be considered. 11. Have soils or other aspects of the physical environment been altered? Sites may have crossed a threshold and represent a new ecological site type requiring new site-specific treatment/restoration approaches.
IV. Determine post-treatment management	12. How long should the sites be protected before land uses begin? In general, sites with lower resilience and resistance should be protected for longer periods. 13. How will monitoring be performed? Treatment effectiveness monitoring includes a complete set of measurements, analyses, and a report. 14. Are adjustments to the approach needed? Adaptive management is applied to future projects based on consistent findings from multiple locations.

Ecological site descriptions: ESDs and their associated STMs provide essential information for determining treatment feasibility and type of treatment. ESDs are part of a land classification system that describes the potential of a set of climate, topographic, and soil characteristics and natural disturbances to support a dynamic set of plant communities (Bestelmeyer et al. 2009; Stringham et al. 2003). NRCS soil survey data (http://soils.usda.gov/survey/), including soil temperature/moisture regimes and other soil characteristics, are integral to ESD development. ESDs have been developed by the NRCS and their partners to assist land management agencies and private land owners with making resource decisions, and are widely available for the Sage-grouse MZs except where soil surveys have not been completed (for a detailed description of ESDs and access to available ESDs see: http://www.nrcs.usda.gov/wps/portal/nrcs/main/national/technical/ecoscience/desc/). ESDs assist managers to step-down generalized vegetation dynamics, including the concepts of resilience and resistance, to local scales. For example, variability in soil characteristics and the local environment (e.g., average annual precipitation as indicated by soil moisture regime) can strongly influence both plant community resilience to fire as well as the resistance of a plant community to invasive annual grasses after fire (table 1). Within a particular ESD, there is a similar level of resilience to disturbance and resistance to invasive annuals and this information can be used to determine the most appropriate management actions.

State and transition models: STMs are a central component of ecological site descriptions that are widely used by managers to illustrate changes in plant communities and associated soil properties, causes of change, and effects of management interventions (Stringham et al. 2003; Briske et al. 2005; USDA NRCS 2007) including in sagebrush ecosystems (Forbis et al. 2006; Barbour et al. 2007; Boyd and Svejcar 2009; Holmes and Miller 2010; Chambers et al. *in press*). These models use ***state*** (a relatively stable set of plant communities that are resilient to disturbance) and ***transition*** (the drivers of change among alternative states) to describe the range in composition and function of plant communities within ESDs (Stringham and others 2003; see Appendix 1 for definitions). The reference state is based on the natural range of conditions associated with natural disturbance regimes and often includes several plant communities (***phases***) that differ in dominant plant species relative to type and time since disturbance (Caudle et al. 2013). Alternative states describe new sets of communities that result from factors such as inappropriate livestock use, invasion by annual grasses, or changes in fire regimes. Changes or transitions among states often are characterized by ***thresholds*** that may persist over time without active intervention, potentially causing irreversible changes in community composition, structure, and function. ***Restoration pathways*** are used to identify the environmental conditions and management actions required for return to a previous state. Detailed STMs that follow current interagency guidelines (Caudle et al. 2013), are aligned with the ecological types (table 1), and are generally applicable to MZs III (Southern Great Basin), IV (Snake River Plains), V (Northern Great Basin), and VI (Columbia Basin) are provided in Appendix 5.

A generalized STM to illustrate the use of STMs is shown in figure 32 for the warm and dry Wyoming big sagebrush ecological type. This ecological type occurs at relatively low elevations in the western part of the range and has low to moderate resilience to disturbance and management treatments and low resistance to invasion (table 1). This type is abundant in the western portion of the range, but as the STM suggests, it is highly susceptible to conversion to invasive annual grass and repeated fire and is difficult to restore. Intact sagebrush areas remaining in the reference state within this ecological type are a high priority for conservation. Invaded states or locations with intact sagebrush that lack adequate native perennial understory are a high priority for restoration where they bridge large, contiguous areas of sagebrush. However, practical methods to accomplish this are largely experimental and/or costly and further development, including adaptive science and management, is needed.



Reference State - There is a continuum from shrub to grass dominance depending on time since fire and other factors like climate, insects, and pathogens.

Invaded State - An invasive seed source and/or improper grazing result in a transition to an invaded state. Perennial grass decreases and invasive grasses increase with improper grazing or stressors resulting in an at-risk phase. Management treatments and proper grazing are unlikely to result in return to the reference on all but cool and moist sites.

Annual State - Fire or other disturbances that remove sagebrush result in crossing a threshold to an annual state. Perennial grass is rare and recovery potential is low. Repeated fire causes further degradation.

Seeded State - Seeding following fire and/or invasive species control results in a seeded state. Sagebrush may establish on cooler and moister sites. Success and return to the reference state are related to site conditions, seeding mix, and post-treatment weather, and livestock use.

Figure 32. A state and transition model that illustrates vegetation dynamics and restoration pathways for the warm and dry, Wyoming big sagebrush ecological type. This ecological type occurs at relatively low elevations in the western part of the range and has low to moderate resilience to disturbance and management treatments and low resistance to invasion.

Monitoring and adaptive management: Monitoring programs designed to track ecosystem changes in response to both stressors and management actions can be used to increase understanding of ecosystem resilience and resistance, realign management approaches and treatments, and implement adaptive management (Reever-Morghan et al. 2006; Herrick et al. 2012). Information is increasing on likely changes in sagebrush ecosystems with additional stress and climate warming, but a large degree of uncertainty still exits. Currently, the NRCS National Resource Inventory is being used on private lands and is being implemented on public lands managed by BLM to monitor trends in vegetation attributes and land health at the landscape scale under the AIM (Assessment Inventory and Monitoring) strategy. Strategic placement of monitoring sites and repeated measurements of ecosystem status and trends (e.g., land cover type, ground cover, vegetation cover and height of native and invasive species, phase of tree expansion, soil and site stability, oddities) can be used to decrease uncertainty and increase effectiveness of management decisions. Ideally, monitoring sites span environmental/productivity gradients and sagebrush ecological types that characterize sage-grouse habitat. Of particular importance are (1) ecotones between ecological types where changes in response to climate are expected to be largest (Loehle 2000; Stohlgren et al. 2000), (2) ecological types with climatic conditions and soils that are exhibiting invasion and repeated fires, and (3) ecological types with climatic conditions and soils that are exhibiting tree expansion and increased fire risk. Monitoring the response of sagebrush ecosystems to management treatments, including both pre- and post-treatment data, is a first order priority because it provides information on treatment effectiveness that can be used to adjust methodologies.

Monitoring activities are most beneficial when consistent approaches are used among and within agencies to collect, analyze, and report monitoring data. Currently, effectiveness monitoring databases that are used by multiple agencies do not exist. However, several databases have been developed for tracking fire-related and invasive-species management activities. The National Fire Plan Operations and Reporting System (NFPORS) is an interdepartmental and interagency database that accounts for hazardous fuel reduction, burned area rehabilitation and community assistance activities. To our knowledge, NFPORS is not capable of storing and retrieving the type of effectiveness monitoring information that is needed for adaptive management. The FEAT FIREMON Integrated (FFI; https://www.frames.gov/partner-sites/ffi/ffi-home/) is a monitoring software tool designed to assist managers with collection, storage and analysis of ecological information. It was constructed through a complementary integration of the Fire Ecology Assessment Tool (FEAT) and FIREMON. This tool allows the user to select among multiple techniques for effectiveness monitoring. If effectiveness monitoring techniques were agreed on by the agencies, FFI does provide databases with standard structures that could be used in inter-agency effectiveness monitoring. Also, the National Invasive Species Information Management System (NISIMS) is designed to reduce redundant data entry regarding invasive species inventory, management and effectiveness monitoring with the goal of providing information that can be used to determine effective treatments for invasive species. However, NISIMS is currently available only within the BLM.

Common databases can be used by agency partners to record and share monitoring data. The Land Treatment Digital Library (LTDL [USGS 2010]) provides a method of archiving and collecting common information for land treatments and might be used as a framework for data storage and retrieval. Provided databases are relational (maintain a common field for connecting them), creating single corporate databases is not necessary. However, barriers that hinder database access within and among agencies and governmental departments may need to be lowered while still maintaining adequate data security. The LTDL has demonstrated how this can work by accessing a variety of databases to populate useful information relating to land treatments.

For effectiveness of treatments to be easily useable for adaptive management, the agencies involved will need to agree on monitoring methods and a common data storage and retrieval system. Once data can be retrieved, similar treatment projects can be evaluated to determine how well they achieve objectives for sage-grouse habitat, such as the criteria outlined in documents like the Habitat Assessment Framework (Stiver et al. 2006). Results of monitoring activities on treatment effectiveness are most useful when shared across jurisdictional boundaries, and several mechanisms are currently in place to improve information sharing (e.g., the Great Basin Fire Science Delivery Project; www.gbfiresci.org).

Appendix 1. Definitions of Terms Used in This Document

At-Risk Community Phase — A community phase that can be designated within the reference state and also in alternative states. This community phase is the most vulnerable to transition to an alternative state (Caudle et al. 2013).

Community Phase — A unique assemblage of plants and associated soil properties that can occur within a state (Caudle et al. 2013).

Ecological Site (ES) — An Ecological Site (ES) is a conceptual division of the landscape that is defined as a distinctive kind of land based on recurring soil, landform, geological, and climate characteristics that differs from other kinds of land in its ability to produce distinctive kinds and amounts of vegetation and in its ability to respond similarly to management actions and natural disturbances (Caudle et al. 2013).

Ecological Site Descriptions (ESD) — The documentation of the characteristics of an ecological site. The documentation includes the data used to define the distinctive properties and characteristics of the ecological site; the biotic and abiotic characteristics that differentiate the site (i.e., climate, topography, soil characteristics, plant communities); and the ecological dynamics of the site that describes how changes in disturbance processes and management can affect the site. An ESD also provides interpretations about the land uses and ecosystem services that a particular ecological site can support and management alternatives for achieving land management (Caudle et al. 2013).

Ecological Type — A category of land with a distinctive (i.e., mappable) combination of landscape elements. The elements making up an ecological type are climate, geology, geomorphology, soils, and potential natural vegetation. Ecological types differ from each other in their ability to produce vegetation and respond to management and natural disturbances (Caudle et al. 2013).

Historical Range of Variability — Range of variability in disturbances, stressors, and ecosystem attributes that allows for maintenance of ecosystem resilience and resistance and that can be used to provide management targets (modified from Jackson 2006).

Resilience — Ability of a species and/or its habitat to recover from stresses and disturbances. Resilient ecosystems regain their fundamental structure, processes, and functioning when altered by stresses like increased CO_2 , nitrogen deposition, and drought and to disturbances like land development and fire (Allen et al. 2005; Holling 1973).

Resistance — Capacity of an ecosystem to retain its fundamental structure, processes and functioning (or remain largely unchanged) despite stresses, disturbances, or invasive species (Folke et al. 2004).

Resistance to Invasion — Abiotic and biotic attributes and ecological processes of an ecosystem that limit the population growth of an invading species (D'Antonio and Thomsen 2004).

Restoration Pathways — Restoration pathways describe the environmental conditions and practices that are required for a state to recover that has undergone a transition (Caudle et al. 2013).

State — A state is a suite of community phases and their inherent soil properties that interact with the abiotic and biotic environment to produce persistent functional and structural attributes associated with a characteristic range of variability (adapted from Briske et al. 2008).

State-and-Transition Model — A method to organize and communicate complex information about the relationships between vegetation, soil, animals, hydrology, disturbances (fire, lack of fire, grazing and browsing, drought, unusually wet periods, insects and disease), and management actions on an ecological site (Caudle et al. 2013).

Thresholds — Conditions sufficient to modify ecosystem structure and function beyond the limits of ecological resilience, resulting in the formation of alternative states (Briske et al. 2008).

Transition — Transitions describe the biotic or abiotic variables or events, acting independently or in combination, that contributes directly to loss of state resilience and result in shifts between states. Transitions are often triggered by disturbances, including natural events (climatic events or fire) and/or management actions (grazing, burning, fire suppression). They can occur quickly as in the case of catastrophic events like fire or flood, or over a long period of time as in the case of a gradual shift in climate patterns or repeated stresses like frequent fires (Caudle et al. 2013).

Appendix 2. An Explanation of the Use of Landscape Measures to Describe Sagebrush Habitat

Understanding landscape concepts of plant cover relative to typical management unit concepts of plant cover is important for prioritizing lands for management of sage-grouse. Ground cover measurements of sagebrush made at a management unit (for example, line-intercept measurements) should not be confused for landscape cover and may not relate well to landscape cover since the areas of examination differ vastly (square meters for management units and square kilometers for landscapes).

A landscape is defined rather arbitrarily as a large area in total spatial extent, somewhere in size between sites (acres or square miles) and regions (100,000s of square miles). The basic unit of a landscape is a patch, which is defined as a bounded area characterized by a similar set of conditions. A habitat patch, for example, may be the polygonal area on a map representing a single land cover type. Landscapes are composed of a mosaic of patches. The arrangement of these patches (the landscape configuration or pattern) has a large influence on the way a landscape functions and for landscape species, such as sage-grouse, sagebrush habitat patches are extremely important for predicting if this bird will be present within the area (Connelly et al. 2011).

Remotely sensed data of land cover is typically used to represent landscapes. These data may combine several sources of data and may include ancillary data, such as elevation, to improve the interpretation of data. These data are organized into pixels that contain a size or grain of land area. For example, LandSat Thematic Mapper spectral data used in determining vegetation cover generally have pixels that represent ground areas of 900 m^2 (30- x 30-m). Each pixel's spectral signature can be interpreted to determine what type of vegetation dominates that pixel. Groups of adjacent pixels with the same dominant vegetation are clustered together into polygons that form patches.

Landscape cover of sagebrush is determined initially by using this vegetation cover map, but a 'rolling window' of a predetermined size (e.g., 5 km^2 or 5,556 pixels that are 30- by 30-m in size) is moved across the region one pixel at a time. The central pixel of the 'window' is reassigned a value for the proportion of pixels where sagebrush is the dominant vegetation. The process is repeated until pixels within the region are completely reassigned to represent the landscape cover of sagebrush within for the region drawn from a 5 km^2 window.

Appendix 3. An Explanation of Soil Temperature and Moisture Regimes Used to Describe Sagebrush Ecosystems

Soil climate regimes (temperature and moisture) are used in Soil Taxonomy to classify soils; they are important to consider in land management decisions, in part, because of the significant influence on the amounts and kinds of vegetation that soils support. Soil temperature and moisture regimes are assigned to soil map unit components as part of the National Cooperative Soil Survey program. Soil survey spatial and tabular data for the Sage-grouse Management Zones (Stiver et al. 2006) were obtained for each State within the zones at the Geospatial Data Gateway (http://datagateway.nrcs.usda.gov/). Gridded Soil Survey Geographic (gSSURGO) file geodatabases were used to display a 10-meter raster dataset. Multiple soil components made up a soil map unit, and soil moisture and temperature regimes were linked to individual soil map components. Soil components with the same soil moisture and temperature class regime were aggregated, and the dominant soil moisture and temperature regime within each soil map unit was used to characterize the temperature and moisture regime. Only temperature and moisture regimes applicable to sagebrush ecosystems were displayed.

Abbreviated definitions of each soil temperature and moisture regime class are listed below. Complete descriptions can be found in *Keys to Soil Taxonsomy, 11th edition*, available at ftp://ftp-fc.sc.egov.usda.gov/NSSC/Soil_Taxonomy/keys/2010_Keys_to_Soil_Taxonomy.pdf.

Soil temperature regimes	
Cryic (Cold)	Soils that have a mean annual soil temperature of <8 °C, and do not have permafrost, at a depth of 50 cm below the surface or at a restrictive feature, whichever is shallower.
Frigid (Cool)	Soils that have a mean annual soil temperature of <8 °C and the difference between mean summer and mean winter soil temperatures is >6 °C at a depth of 50 cm below the surface or at a restrictive feature, whichever is shallower.
Mesic (Warm)	Soils that have a mean annual soil temperature of 8-15 °C and the difference between mean summer and mean winter soil temperatures is >6 °C at a depth of 50 cm below the surface or at a restrictive feature, whichever is shallower.
Soil moisture regimes	
Ustic (summer precipitation)	Generally there is some plant-available moisture during the growing season, although significant periods of drought may occur. Summer precipitation allows presence of warm season plant species.
Xeric (Moist; generally mapped at >12 inches mean annual precipitation)	Characteristic of arid regions. The soil is dry for at least half the growing season and moist for less than 90 consecutive days.
Aridic (Dry; generally mapped at <12 inches mean annual precipitation)	Characteristic of arid regions. The soil is dry for at least half the growing season and moist for less than 90 consecutive days.

Note: Soil moisture regimes are further divided into moisture subclasses, which are often used to indicate soils that are transitional to another moisture regime. For example, a soil with an Aridic moisture regime and a Xeric moisture subclass may be described as "Aridic bordering on Xeric." Understanding these gradients becomes increasingly important when making interpretations and decisions at the site scale where aspect, slope, and soils affect the actual moisture regime on that site. More information on taxonomic moisture subclasses is available at http://www.nrcs.usda.gov/wps/portal/nrcs/detail/soils/ref/?cid=nrcs142p2_053576.

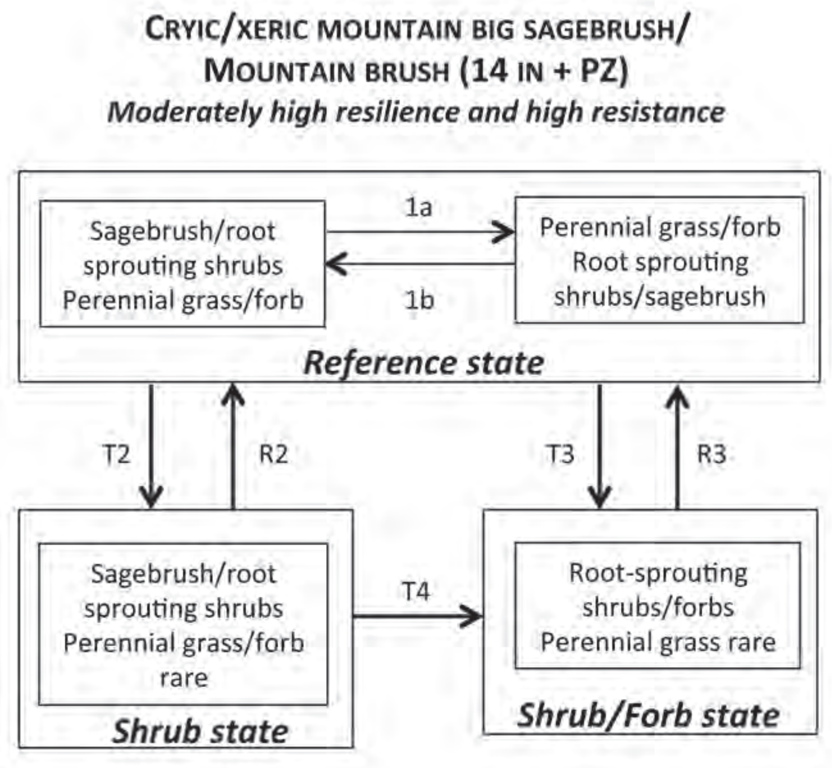
Appendix 5. State-and-transition models (STMs) for five generalized ecological types for big sagebrush (from Chambers et al. *in press*; Miller et al. 2014 a, b)

These STMs represent groupings of ecological sites that are characterized by Wyoming or mountain big sagebrush, span a range of soil moisture/temperature regimes (warm/dry to cold/moist), and characterize a large portion of Management Zones III (Southern Great Basin), IV (Snake River Plains), V (Northern Great Basin), and VI (Columbia Basin). Large boxes illustrate states that are comprised of community phases (smaller boxes). Transitions among states are shown with arrows starting with T; restoration pathways are shown with arrows starting with R. The "at risk" community phase is most vulnerable to transition to an alternative state. Precipitation Zone is designated as PZ.



(1a) Perennial grass/forb increases due to disturbances that decrease sagebrush like wildfire, insects, disease, and pathogens.

(1b) Sagebrush and other shrubs increase with time.

(T2) Improper grazing triggers a shrub dominated state.

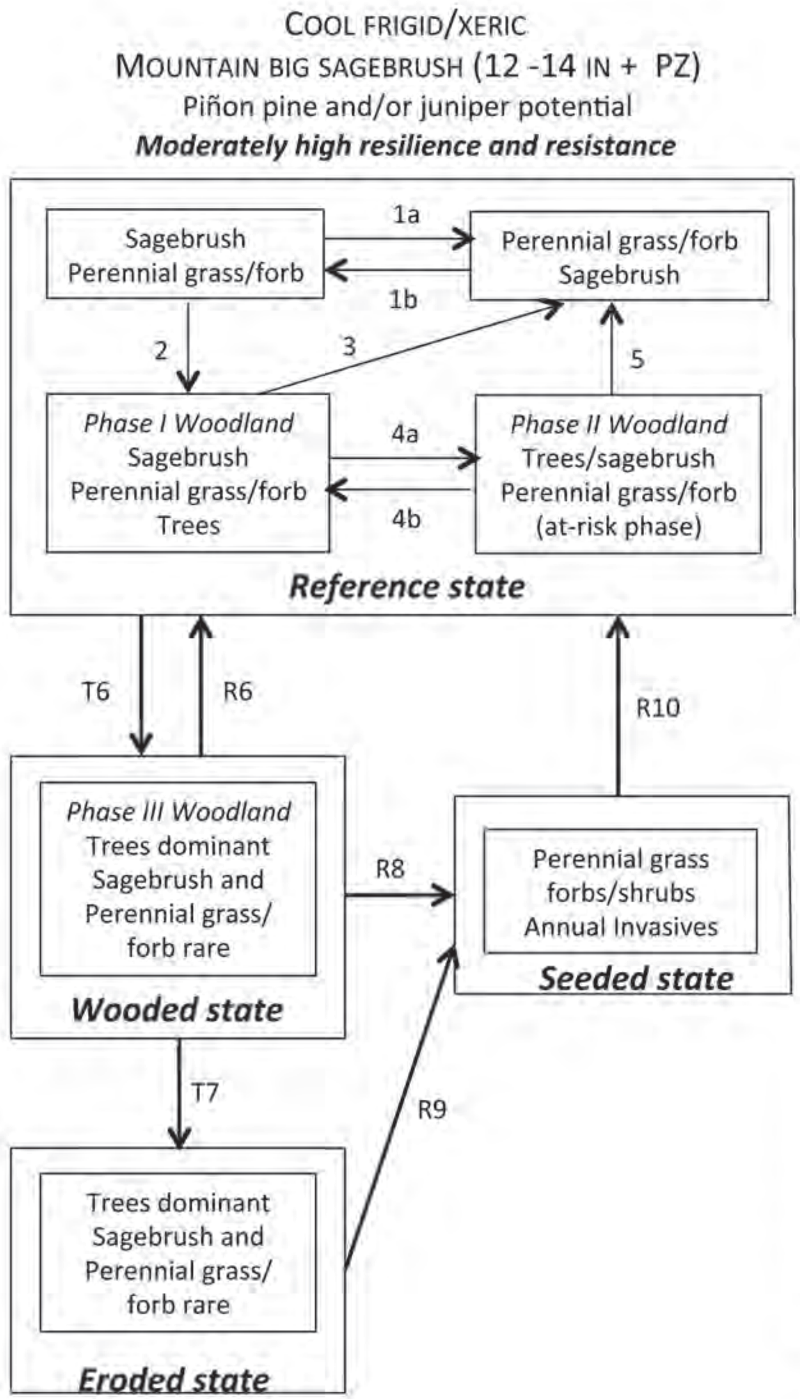
(R2) Proper grazing results in a return to the reference state.

(T3 and T4) Fire or other disturbances that remove sagebrush result in dominance by root-sprouting shrubs and an increase in native forbs like lupines.

(R3) Proper grazing and time result in return to the reference state.

Note: Resilience is lower on cold cryic sites due to short growing seasons.

Figure A.5A. STM for a cryic/xeric mountain big sagebrush/mountain brush ecological type characterized by moderately high resilience and high resistance.



(1a) Disturbances such as wildfire, insects, disease, and pathogens result in less sagebrush and more perennial grass/forb.

(1b) Sagebrush increases with time .

(2) Time combined with seed sources for piñon and/or juniper trigger a Phase I Woodland.

(3 and 5) Fire and or fire surrogates (herbicides and/or mechanical treatments) that remove trees may restore perennial grass/forb and sagebrush dominance.

(4a) Increasing tree abundance results in a Phase II woodland with depleted perennial grass/forb and shrubs and an at-risk phase.

(4b) Fire surrogates (herbicides and/or mechanical treatments) that remove trees may restore perennial grass/forb and sagebrush dominance.

(T6) Infilling of trees and/or improper grazing can result in a biotic threshold crossing to a wooded state with increased risk of high severity crown fires .

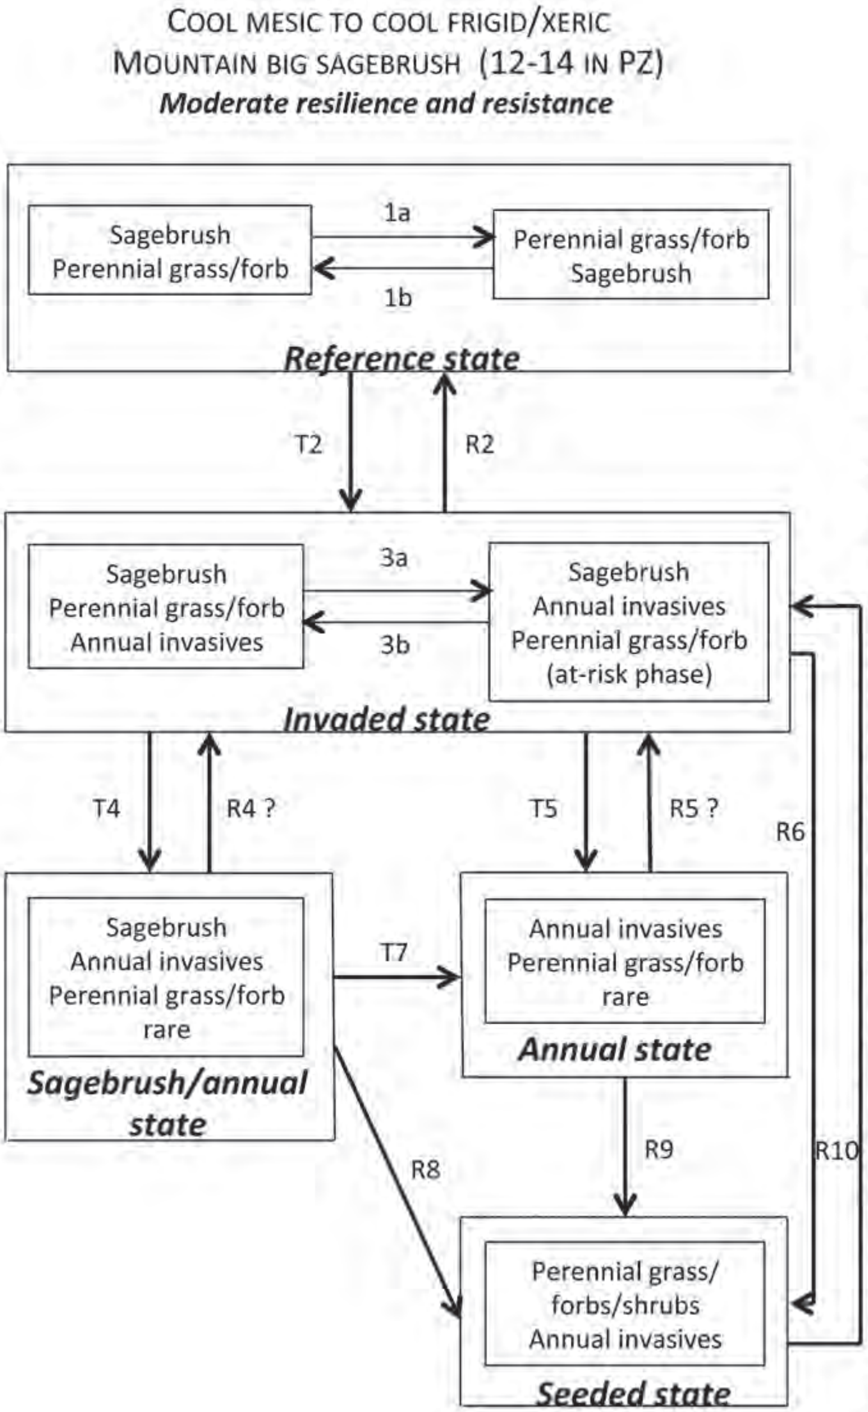
(R6) Fire, herbicides and/or mechanical treatments that remove trees may restore perennial grass/forb and sagebrush dominance.

(T7) An irreversible abiotic threshold crossing to an eroded state can occur depending on soils, slope, and understory species.

(R8 and R9) Seeding after fire may be required on sites with depleted perennial grass/forb, but seeding with aggressive introduced species can decrease native perennial grass/forb. Annual invasives are typically rare. Seeded eroded states may have lower productivity.

(R10) Depending on seed mix and grazing, return to the reference state may be possible if an irreversible threshold has not been crossed.

Figure A.5B. STM for a cool frigid/xeric mountain big sagebrush ecological type that has piñon pine and/or juniper potential and is characterized by moderately high resilience and resistance.



(1a) Perennial grass/forb increases due to disturbances that decrease sagebrush like wildfire, insects, disease, and pathogens.

(1b) Sagebrush increases with time .

(T2) An invasive seed source and/or improper grazing trigger an invaded state.

(R2) Proper grazing, fire, herbicides, and/or mechanical treatments may restore perennial grass/forb and sagebrush dominance with few invasives.

(3a) Perennial grass/forb decreases and sagebrush and invasives increase with improper grazing by livestock resulting in an at-risk phase. Decreases in sagebrush due to insects, disease or pathogens can further increase invasives.

(3b) Proper grazing, herbicides, or mechanical treatments that reduce sagebrush may increase perennial grass/forb and decrease invasives.

(T4) Improper grazing results in a sagebrush/annual state.

(R4) Proper grazing may facilitate return to the invaded state on cooler/wetter sites if sufficient grass/forb remains .

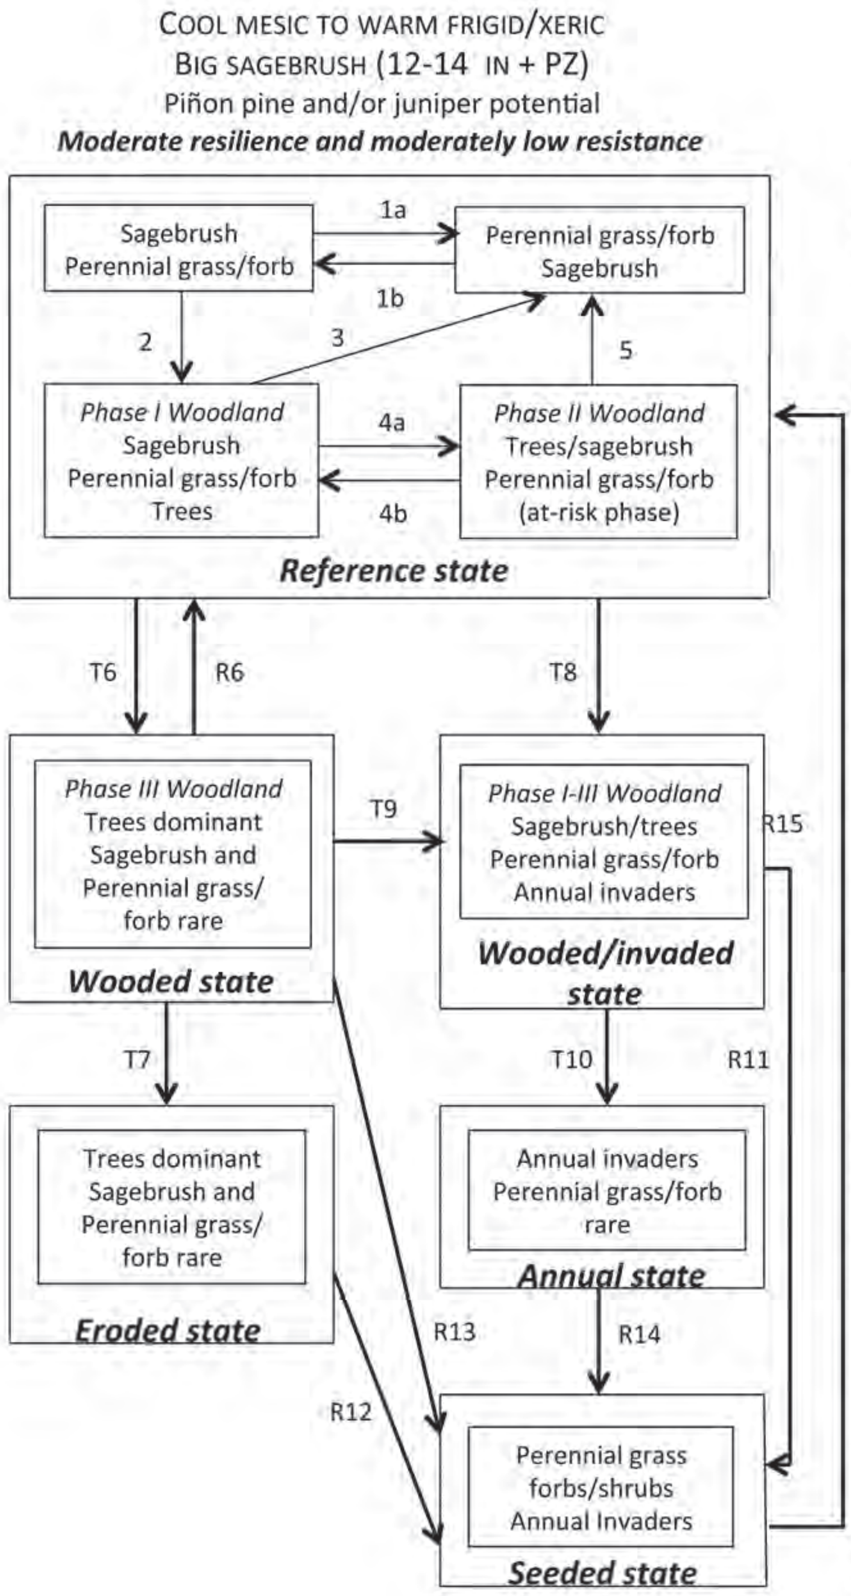
(T5 and T7) Fire or other disturbances that remove sagebrush result in an annual state. Perennial grass/forb are rare and recovery potential is reduced. Repeated fire can result in a biotic threshold crossing to annual dominance on warmer/drier sites, and root-sprouting shrubs may increase.

(R5) Cooler and wetter sites may return to the invaded or reference state with lack of fire, proper grazing, and favorable weather.

(R6, R8 and R9) Seeding following fire and/or invasive species control results in a seeded state. Sagebrush may recolonize depending on patch size, but annual invaders are still present.

(R10) Cooler and wetter sites may return to the invaded or possibly reference state depending on seeding mix, grazing and weather.

Figure A.5C. STM for a cool mesic to cool frigid/xeric mountain big sagebrush ecological type that is characterized by moderate resilience and resistance.



(1a) Disturbances such as wildfire, insects, disease, and pathogens result in less sagebrush and more perennial grass/forb.

(1b) Sagebrush increases with time .

(2) Time combined with seed sources for piñon and/or juniper trigger a Phase I Woodland.

(3 and 5) Fire and or fire surrogates (herbicides and/or mechanical treatments) that remove trees may restore perennial grass/forb and sagebrush dominance on cooler/wetter sites. On warmer/drier sites with low perennial grass/forb abundance resistance to invasion is moderately low.

(4a) Increasing tree abundance results in a Phase II woodland with depleted perennial grass/forb and shrubs and an at-risk phase.

(4b) Fire surrogates (herbicides and/or mechanical treatments) that remove trees may restore sagebrush and perennial grass/forb dominance .

(T6) Infilling of trees and improper grazing can result in a biotic threshold crossing to a wooded state with increased risk of high severity crown fires.

(R6) Fire, herbicides and/or mechanical treatments that remove trees may restore perennial grass/forb and sagebrush dominance on cooler/wetter sites.

(T7) An irreversible abiotic threshold crossing to an eroded state can occur depending on soils, slope, and understory species.

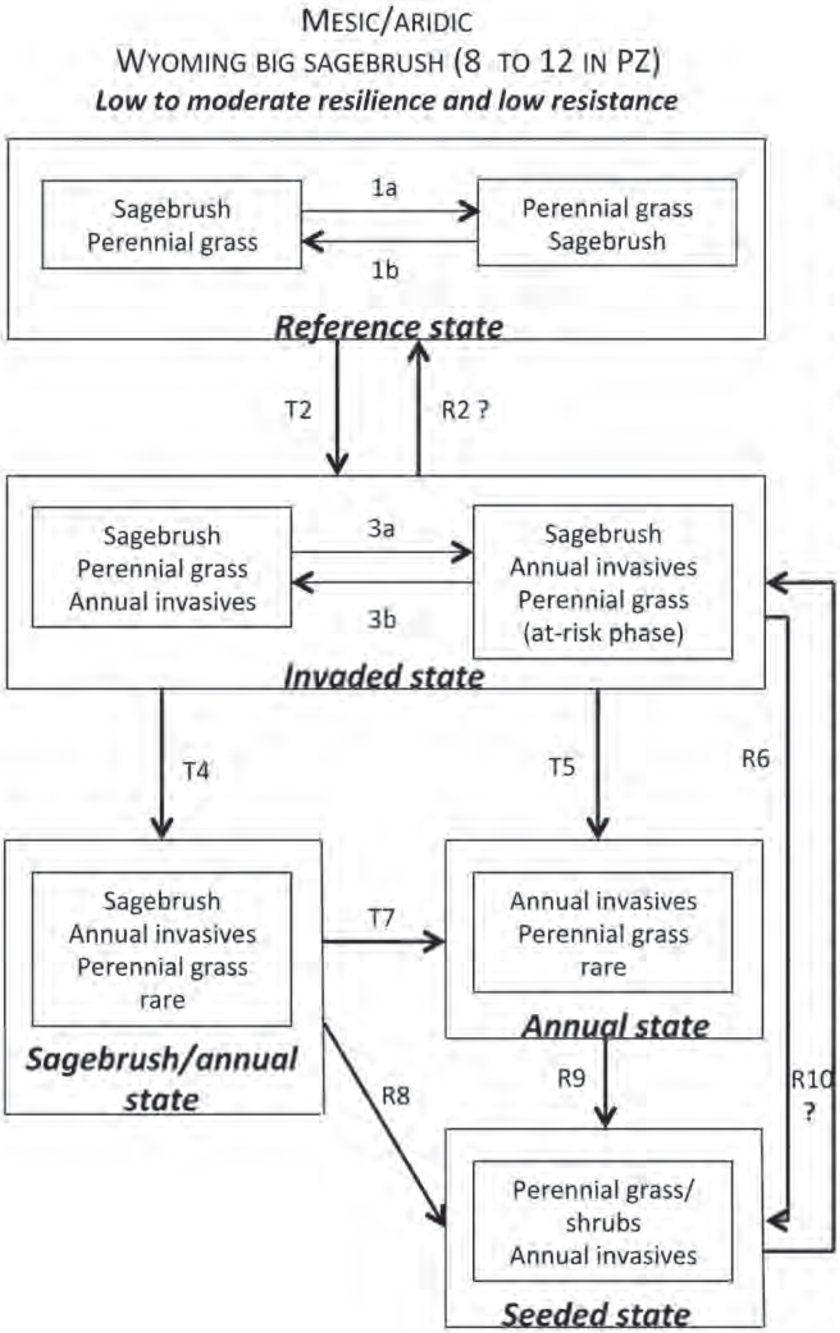
(T8 and T9) An invasive seed source and/or improper grazing can trigger a wooded/invaded state.

(T10) Fire or other disturbances that remove trees and sagebrush can result in a biotic threshold crossing to annual dominance on warmer/drier sites with low resilience.

(R11, R12, R13, and R14) Seeding after fire and/or invasive species control increases perennial grass/forb. Sagebrush may recolonize depending on seed sources, but annual invaders are still present. Seeded eroded states may have lower productivity.

(R15) Depending on seed mix , grazing, and level of erosion, return to the reference state may occur on cooler and wetter sites if an irreversible threshold has not been crossed.

Figure A.5D. STM for a cool mesic to warm frigid/xeric mountain big sagebrush ecological type type that has piñon pine and/or juniper potential and is characterized by moderate resilience and moderately low resistance.



(1a) Perennial grass increases due to disturbances that decrease sagebrush like wildfire, insects, disease, and pathogens.

(1b) Sagebrush increases with time .

(T2) An invasive seed source and/or improper grazing trigger an invaded state.

(R2) Proper grazing, fire, herbicides and/or mechanical treatments are unlikely to result in return to the reference state on all but the coolest and wettest sites.

(3a) Perennial grass decreases and both sagebrush and invasives increase with improper grazing resulting in an at-risk phase. Decreases in sagebrush due to insects, disease or pathogens can further increase invasives.

(3b) Proper grazing and herbicides or mechanical treatments that reduce sagebrush may restore perennial grass and decrease invaders on wetter sites (10-12"). Outcomes are less certain on drier sites (8-10") and/or low abundance of perennial grass.

(T4) Improper grazing triggers a largely irreversible threshold to a sagebrush/annual state.

(T 5 and T7) Fire or other disturbances that remove sagebrush result in an annual state. Perennial grass is rare and recovery potential is low due to low precipitation, mesic soil temperatures, and competition from annual invasives. Repeated fire can cause further degradation.

(R6, R8 and R9) Seeding following fire and/or invasive species control results in a seeded state. Sagebrush may recolonize depending on patch size, but annual invasives are still present.

(R10) Seeding effectiveness and return to the invaded state are related to site conditions, seeding mix, and post-treatment weather.

Figure A.5E. STM for a mesic/aridic Wyoming big sagebrush ecological type with low to moderate resilience and low resistance.

Top 5 Gap Strategy 04.10.2014 Draft.docx
33K

The Honorable Brian Sandoval
Governor of Nevada
Carson City, Nevada 89701

Dear Governor Sandoval:

Thank you for your commitment to working with us to reduce the risks to the Greater Sage-grouse. Our collaborative efforts to protect and conserve habitat in areas where fire damage and invasive weeds are the greatest threat to the bird will be the key to the determination of whether or not the species gets listed.

One way to reduce fire damage is to increase our firefighting capability. As we have discussed on several occasions, we stand ready to assist you with training and the integration of Rangeland Fire Protection Associations (RFPAs) in to our fire suppression operations. Through our federal, state, local, and tribal partnerships, we are over 95 percent effective at stopping fires at less than 1,000 acres. ~~Our damage~~ Damage from wildfire comes from the less than five percent of fires that escape initial attack. In many cases, local first responders, RFPAs and Volunteer Fire Departments (VFDs) are first on the fire scene. I share the opinion of most of the Western Governors, that a citizen based response in the form of RFPAs and VFDs needs to be supported and strengthened where they exist and encouraged and developed where they do not.

~~Our damage comes from the less than five percent of fires that escape initial attack.~~ Science and history demonstrate that increasing suppression capacity alone will not significantly increase initial attack success. Various partners in the west use proactive fuels treatment measures such as mowing and green-stripping on existing roads and other disturbed areas to break up continuous fuel beds to improve firefighting effectiveness. There are challenges to this approach such as managing invasive plants and potential habitat fragmentation, but we are confident that if we and our partners do more of this work we can reduce the fire damage to property and resources.

We are committed to work with your office and Western Governors Association (WGA) to address these challenges. These suggestions are our initial thoughts and I am sure you may have many other ideas on ways we can collaboratively address this problem. We welcome your comments and suggestions on these ideas. Please let me know if you wish to discuss this in more detail. For specific information and coordination, please contact Joe Freeland at (202) 208-4147 or email at jfreeland@blm.gov

The BLM Response to the Western Association of Fish and Wildlife Agencies (WAFWA) Wildfire and Invasive Species Gap Analysis for the Great Basin.

April 10, 2012

1. **"Need for a long term pre and post fire fuels, stabilization, and restoration funding initiative."**
    - Sixty percent of the Healthy Lands and Fuels funds are allocated annually to benefit sage grouse through restoration activities.
    - Development of Healthy Lands Focus Areas positions BLM to strategically use regional mitigation funds and the potential new fire/resource program, Resilient Landscapes referenced in the FY15 President's Budget.
    - Will establish Healthy Lands and Fuels funding priorities for FY2016 – 2020 that address the threat of fire, invasive species and other landscape resilence priorities.
        - Identify national priorities with a geographical funding focus - Reduce random acts of restoration

    Needs:

    - Support current efforts to restructure the Suppression account and eliminate the need to "borrow" from existing accounts.
    - Modify business practices to support multi-year, all-lands projects and to simplify alignment of federal agency conservation programs with partner programs.
    - An annual funding increase ($30-50 million) to "fill the gap" of unfilled requests from the field.

2. **"Lack of comprehensive range-wide maps of vegetation types, ecological conditions, and soil surveys."**
    - Developing Ecological Site Descriptions (ESD) with NRCS and working to complete soil surveys to assist in vegetative and habitat potential mapping.
        - Outcomes: Landscape condition assessment (June 2014) and an occupied Greater Sage-grouse condition report (2015).
    - Pilot projects to accelerate the development and update of soil surveys and ESD by utilizing the key indicator information.
    - Incorporating the WAFWA resistance and resilience matrix into our plans to develop a strategic approach in addressing the treat of wildfire/invasive species.

    Needs:

    - Additional funds ($6 million) needed to satisfy the monitoring commitments in the proposed Greater Sage-grouse plans and plan amendments.

3. **"Need for improved seeding methods, seed mixes, and equipment used for post fire rehabilitation or habitat restoration."**
    - Host the "Seed Conference" in the summer of 2014 to increase strategic interagency cooperation and coordination of resources and science.
    - Using proven plan material (native and non-native) that is competitive, fire resistant, and effective in combating erosion and invasive plant establishment.
    - Seed Warehouse System updated to acquire the best seed, for the best value, maintained at state-of-the-art storage facilities.

    Needs:

    - Prioritize a research agenda with USGS and others that address plant establishment methods and techniques at both the individual plan and landscape scale levels.
    - Annual program increase ($20 million) to complete the work associated with a surge of native plant materials development and plant conservation for the Great Basin.

4. **There is a need for increased "rancher, private land owner, and agency (local, state and federal) fire management coordination. Similarly coordination between public land managers and private land owners such as Cooperative Weed Management Areas needs to be accelerated and funded throughout the range of the species.**
    - Approximately 20 Rangeland Fire Protection Associations (RFPA's) and over 200 Rural Volunteer Fire Departments (VFD's) in the Great Basin states that contribute to initial attack effectiveness in sage grouse habitat.
    - Providing training, funding, and coordination support to rural volunteer fire efforts in partnership with state agencies.
    - Encouraging, supporting, and integrating RFRP and VFD into all fire suppression activities.
    - Examine provisions within the 2014 Farm Bill that could be used to benefit sage grouse habitat and increase alignment of conservation efforts across state, federal and private lands.

    Needs:

    - Additional funds ($1-3 million) to support coordination with the DOI and Western Governors to develop a support structure for RFPA's and VFD's within the Great Basin.

5. **There is a "lack of necessary information, policy, and administrative support to adequately manage livestock grazing".**
    - Prioritizing use supervision and effectiveness monitoring of grazing activities to ensure compliance with permit conditions and health standards in Priority Habitat.
    - Prioritizing land health evaluations and permit renewals in sage grouse areas to determine if changes in livestock management are necessary in Priority Habitat.
    - Coordinating with permittees and others to implement changes in livestock grazing management including habitat treatments and structural improvements.
    - Coordinating with USGS to determine existing gaps in research to quantify, prioritize our immediate and future research needs (1 – 5 years).

    Needs:

    - Prioritize livestock grazing authorizations by implementing BLM policies as they relate to setting work priorities (Monitoring, Land Health Evaluations).
    - Long-term funding (minimum 5 years) of $15 million annually to increase permit renewals.
    - Legislation and rulemaking to streamline permit renewal processing.

Preface

This study was conducted to provide timely scientific information regarding the effects of wildfire on greater sage-grouse (*Centrocercus urophasianus*) demography within the Great Basin over the last 30 years. Findings are provided to fill a prominent information gap in the threat assessment for greater sage-grouse populations as part of the listing decision process by the U.S. Fish and Wildlife Service under the Endangered Species Act of 1973. The primary purpose of the current report is to present a Bayesian approach to estimate the effects of wildfire on greater sage-grouse population rate of change while accounting for influential interactions with climatic conditions (that is, precipitation). We also used the derived parameters (medians from posterior probability distributions) of those relationships to estimate population size in 2044 relative to measured abundance in 2013–2014. The findings of this report were based on multiple long-term datasets, including 30 years (1984 to 2013) of wildfire history, and spatially explicit data of climatic conditions, soil moisture and temperature, and lek (breeding grounds) counts that were restricted to the 30-year analysis period. A complementary report using a wildfire dataset that spans the geographic range of greater sage-grouse was concurrently published with this report. The concurrent study focused on recent spatiotemporal patterns of fire regime characteristics during the same 30-year time period with implications for conservation and management of the greater sage-grouse (Brooks and others, 2015).

Acknowledgments

We greatly appreciate the cooperation of all State fish and wildlife agencies in the Great Basin who graciously provided lek count data under the auspices of the Western Association of Fish and Wildlife Agencies (WAFWA). These agencies included Idaho Department of Fish and Game, Nevada Department of Wildlife, Oregon Department of Fish and Wildlife, California Department of Fish and Wildlife, and Utah Division of Wildlife Resources. We extend particular gratitude to T. Remington (WAFWA), who compiled and diligently executed quality assurance and quality control for all lek data across agencies. We thank the WAFWA Wildfire and Invasives Work Group, specifically K. Mayer, J. Chambers, D. Pyke, D. Havlina, S. Espinosa, L. Niell, J. Maestas, T. Koch, and T. Hopkins for helpful suggestions on improving this presentation and analysis. We also are grateful to S. Campbell (NRCS) for providing soil moisture and temperature data. Reviews of previous manuscript drafts by B. Fedy (University of Waterloo), J. Dinkins (University of Wyoming), J. Yee (U.S. Geological Survey), and D. Delehanty were particularly helpful. B. Halstead and J. Yee (U.S. Geological Survey) provided expert statistical advice, and downscaled PRISM precipitation data were graciously provided by P. Flint and L. Flint (U.S. Geological Survey). Expert GIS analyses, data management, and problem solving were provided by T. Kroeger and K. Mauch (U.S. Geological Survey).

Long-Term Effects of Wildfire on Greater Sage-Grouse—Integrating Population and Ecosystem Concepts for Management in the Great Basin

By Peter S. Coates[1], Mark A. Ricca[1], Brian G. Prochazka[1], Kevin E. Doherty[2], Mathew L. Brooks[1], and Michael L. Casazza[1]

Abstract

Greater sage-grouse (*Centrocercus urophasianus*; hereinafter, sage-grouse) are a sagebrush obligate species that has declined concomitantly with the loss and fragmentation of sagebrush ecosystems across most of its geographical range. The species currently is listed as a candidate for federal protection under the Endangered Species Act (ESA). Increasing wildfire frequency and changing climate frequently are identified as two environmental drivers that contribute to the decline of sage-grouse populations, yet few studies have rigorously quantified their effects on sage-grouse populations across broad spatial scales and long time periods. To help inform a threat assessment within the Great Basin for listing sage-grouse in 2015 under the ESA, we conducted an extensive analysis of wildfire and climatic effects on sage-grouse population growth derived from 30 years of lek-count data collected across the hydrographic Great Basin of Western North America. Annual (1984–2013) patterns of wildfire were derived from an extensive dataset of remotely sensed 30-meter imagery and precipitation derived from locally downscaled spatially explicit data. In the sagebrush ecosystem, underlying soil conditions also contribute strongly to variation in resilience to disturbance and resistance to plant community changes (R&R). Thus, we developed predictions from models of post-wildfire recovery and chronic effects of wildfire based on three spatially explicit R&R classes derived from soil moisture and temperature regimes. We found evidence of an interaction between the effects of wildfire (chronically affected burned area within 5 kilometers of a lek) and climatic conditions (spring through fall precipitation) after accounting for a consistent density-dependent effect. Specifically, burned areas near leks nullifies population growth that normally follows years with relatively high precipitation. In models, this effect results in long-term population declines for sage-grouse despite cyclic periods of high precipitation. Based on 30-year projections of burn and recovery rates, our population model predicted steady and substantial long-term declines in population size across the Great Basin. Further, example management scenarios that may help offset adverse wildfire effects are provided by models of varying levels of fire suppression and post-wildfire restoration that focus on areas especially important to sage-grouse populations. These models illustrate how sage-grouse population persistence likely will be compromised as sagebrush ecosystems and sage-grouse habitat are degraded by wildfire, especially in a warmer and drier climate, and by invasion of annual grasses that can increase wildfire frequency and size in the Great Basin.

[2] U.S. Fish and Wildlife.

Introduction

Contemporary theoretical and applied ecology has focused increasingly on understanding the processes and management of alternative ecosystem states, whereby recognizing that disturbances can profoundly alter underlying processes that shape ecosystems and reorganizes community composition and species abundance (Scheffer and others, 2001; Beisner and others, 2003). Importantly, variation in disturbance intensity and effects on underlying processes can either allow an ecosystem to recover and ultimately retain its pre-disturbance state (that is, 'helpful resilience'), or drive it to a persistent alternative state with new functional processes once a disturbance threshold has been surpassed (that is, 'unhelpful resilience') (Standish and others, 2014). In the latter case, hysteresis can become operative if recovery is decoupled from pathways that maintained the pre-disturbance state (Suding and others, 2004). Moreover, lack of resistance to invading species can result in altered species composition following disturbance events, which can result in a positive feedback that drives an ecosystem further away from its original state (Suding and others, 2004). These state-changing mechanisms ultimately may yield an ecosystem that has no historical analog (Seastedt and others, 2008; Hobbs and others, 2009). Accordingly, emphasis recently has been placed on managing ecosystems for resilience to disturbance and resistance to invasive species (R&R). In this case, factors that may change ecosystem processes and disturbance thresholds are identified so that resources for restoration can be allocated most effectively and with a higher probability of success (Seastedt and others, 2008; Chambers and others, 2014a; Standish and others, 2014). Equally important is identifying how populations of constituent species inhabiting these ecosystems respond to disturbance and subsequent ecosystem transitions along ecologically meaningful time-frames (Agrawal and others, 2007). It follows that managing for R&R can be improved by integrating concepts from ecosystem and population ecology.

Habitat degradation within the Great Basin ecoregion of the Intermountain West of North America is a contemporary example of how disturbance is driving rapid changes in ecosystem structure and function across enormous spatial scales. The hydrographic Great Basin comprises more than 72.7 million ha across five States. The vastness of the affected area results in strong ecological and socio-political ramifications. Wildfire has been identified as a primary disturbance leading to shifts in ecosystem state and concomitant declines in sagebrush-steppe obligate species in the Great Basin (Brooks and Pyke, 2001; Connelly and others, 2011; Miller and others, 2011; Chambers and others, 2014b). Nearly all species of sagebrush (*Artemisia* spp.) in the Great Basin are killed by wildfire and do not re-sprout (Schlaepfer and others, 2014). At the landscape level, wildfire frequency and magnitude have increased significantly subsequent to invasion of annual grasses, particularly cheatgrass (*Bromus tectorum*) and medusahead-rye (*Taeniatherum canput-medusae*) following disturbance in the Great Basin. Annual grass invasion acts as a positive feedback for spreading wildfire to adjacent stands of intact sagebrush (that would otherwise be less likely to burn) and subsequent re-burning over shorter return intervals (for example, D'Antonio and Vitousek, 1992*;* Brooks and others, 2004; Chambers and others, 2007; Balch and others, 2013; Baruch-Mordo and others, 2013; Chambers and others, 2014a). Depending on local soil temperature and moisture regimes influencing variation in R&R (Chambers and others, 2014a, 2014b; Brooks and others, in press), the end result can be an ecosystem with novel, albeit deleterious and hysteretic, properties (for example, altered water and nutrient cycling, diminished wildlife and livestock value, and higher susceptibility to disturbance effects) (Miller and others, 2011).

From a population ecology perspective, greater sage-grouse (*Centrocercus urophasianus*, hereinafter referred to as "sage-grouse") are an umbrella or indicator species for the ecological health and integrity of sagebrush ecosystems at large spatial scales (Rowland and others, 2006; Knick and Connelly, 2011). Sage-grouse populations have declined concomitantly with the loss and degradation of sagebrush ecosystems and sage-grouse now occupy approximately one-half of their former range

(Schroeder and others, 2004; Knick and Connelly, 2011). Following an initial ruling of warranted but precluded (U.S. Fish and Wildlife Service, 2010), sage-grouse are now classified as warranted for listing under the Endangered Species Act (ESA) with a final determination scheduled for September 2015. Increased recognition of risks posed by interactions between wildfire, drought, and invasive annual grasses to the ecological and socio-economic integrity of sagebrush ecosystems and threats to the persistence of sage-grouse populations led to the recent issuance of Secretarial Order 3336, which aims to improve strategies for fire suppression and post-wildfire restoration across the Great Basin (U.S Department of the Interior, 2015).

Critical to these efforts is a sound understanding of how sage-grouse populations respond demographically to variation in the frequency and extent of wildfire, post-wildfire recovery times related to R&R, and interactions with climate and resource availability across large spatial scales. Most studies of sage-grouse–wildfire relations have been site-specific and focused either on effects of prescribed fire on sage-grouse population growth (Connelly and others, 2000a), movements and habitat associations (Fischer and others, 1996, 1997; Nelle and others, 2000; Rhodes and others, 2010), shorter-term (<10 year) effects of wildfire and climate on population growth (Blomberg and others, 2012) and habitat suitability (Davis and Crawford, 2014), or relied primarily on simulations (Pedersen and others, 2003). No analyses to date have linked multi-decadal patterns of wildfire across the Great Basin with concomitant data on sage-grouse population dynamics and climate. Such an analysis is important because it would provide a means for identifying mechanisms driving prevailing trends in sage-grouse population size and predict long-term population change while reducing the chance of mistaken inference arising from examining short-term data only. For example, given sage-grouse population cycles over time, examining short-term data alone may reveal transient spikes that run counter to actual long-term trajectories. Long-term evaluation may identify populations that are most at risk from wildfire or changing climate and lead to more effective targeting of management resources for conservation of sagebrush and sage-grouse populations.

Species using central-placed breeding strategies, such as lek breeding sage-grouse, are well-suited to spatially explicit and large-scale analyses of the effects of environmental and demographic stochasticity on population growth rate. One hypothesis of lek evolution posits that leks are located in nesting habitat where males are most likely to encounter females for breeding opportunities (Gibson and Langen, 1996), and several studies support this mechanism for sage-grouse (Schroeder and White, 1993; Gibson, 1996; Holloran and Anderson, 2005; Doherty and others, 2010, 2011; Coates and others, 2013). Hence, measurements of the extent and persistence of wildfire along with the timing and amount of precipitation within biologically relevant distances to leks should be good predictors of sage-grouse population growth rates determined from lek counts across the Great Basin. The prior absence of such an analysis across broad temporal and spatial scales in the Great Basin in large part is due to the difficulty in gathering lek count data, which normally is collected on a state-by-state basis, and forming spatially explicit wildfire and climate data from records within State and Federal databases. Now, these data have been compiled by the Western Association of Fish and Wildlife Agencies, Monitoring Trends in Burn Severity (Eidenshink and others, 2007), and PRISM Climate Group (Daly and others, 2008). In addition, spatially explicit data describing landscape-level variation in R&R based on measurable environmental gradients of elevation, aspect, and precipitation that influence soil temperature and moisture regimes in the Great Basin have been developed recently (Campbell, 2014; Chambers and others, 2014b). Hence, sage-grouse population trends can be linked directly to probabilities of ecosystem state transition and variation in post-wildfire recovery times derived from wildfire-related disturbance activity and underlying R&R, while simultaneously accounting for other sources of environmental (for example, precipitation) (Blomberg and others, 2012) and demographic (for example, density dependence) (Garton and others, 2011, 2015) stochasticity that can be similarly strong determinants of sage-grouse population growth patterns.

The objectives of the report were 3-fold:

1. Model sage-grouse population growth as a function of wildfire, precipitation, and density-dependence over a 30-year period (1985–2013) at leks with different underlying R&R properties across the Great Basin. Our modeling approach identifies influential environmental drivers that are thought to explain variation in population growth rates through time, rather than modeling growth rate explicitly as a function of time. Thus, factors that are thought to be responsible for the cyclic patterns (Fedy and Aldridge, 2011) of sage-grouse population growth were modeled explicitly.
2. Predict future (for example, next 30 years) patterns of sage-grouse population rate of change based on R&R-specific projections of cumulative burned area within close (that is, 5 km) proximity of breeding leks across the Great Basin while accounting for variation in precipitation and density-dependence effects.
3. Evaluate projected patterns of sage-grouse population decline across multiple example management scenarios that target varying levels of reduction of wildfire in areas with the greatest sage-grouse habitat quality and breeding densities.

Description of Study Area

Our study encompassed nearly 650,000 km^2 within the hydrographic boundary of the Great Basin. It comprises parts of five States (Nevada [43 percent], Utah [17 percent], Idaho [16 percent], Oregon [14 percent], and California [10 percent]) and four Sage-Grouse Management Zones (MZ III - Southern Great Basin [47 percent], MZ IV - Snake River Plain [33 percent], MZ V - Northern Great Basin [19 percent], and MZ II - Wyoming Basins [1 percent]) (fig. 1). Across the Great Basin, elevation ranges from 400 to 3,000 m within a mosaic of mountain ranges and lowland basins (Miller and others, 2013). Most precipitation falls in winter, and ranges annually from 150 to 300 mm in southern regions and at low elevations, and 300–400 mm in more northern regions and at mid-to-high elevations. Plant communities assemble along elevation and precipitation gradients, ranging from salt-desert shrublands in dry-lowland basins to Wyoming big sagebrush (*Artemisia tridentate wyomingensis*) associations in semi-arid regions to mountain big sagebrush (*Artemisia tridentata vaseyana*), mixed montane shrubland, pinyon pine (*Pinus* spp.) and juniper (*Juniperus* spp.) woodland, and coniferous forest associations in wetter and higher elevation regions.

The sampling area (grain) of our study specifically focused on areas within 5 km of sage-grouse leks, areas which primarily are comprised of sagebrush communities. These sagebrush communities occur on 63 percent of landscapes within the western range of sage-grouse populations (Brooks and others, 2015) and encompass over 80 percent of areas within 5 km of leks. Sagebrush communities can be partitioned into sagebrush steppe occupying more northern areas lying within high precipitation zones where sagebrush and perennial grasses co-dominate, and Great Basin sagebrush occupying drier and warmer southern areas where perennial grasses are less common (Küchler, 1970; Miller and others, 2011) with relatively low rates of annual net primary production (Noy-Meir, 1973). The timing and length of the wildfire season within the geographical range of sage-grouse in the Great Basin can vary widely among years, but generally begins in June and ends in September (Brooks and others, 2015). The amount of fire area, fire recurrence, and fire rotation also can vary widely among sage-grouse management zones and vegetation types in the Great Basin.

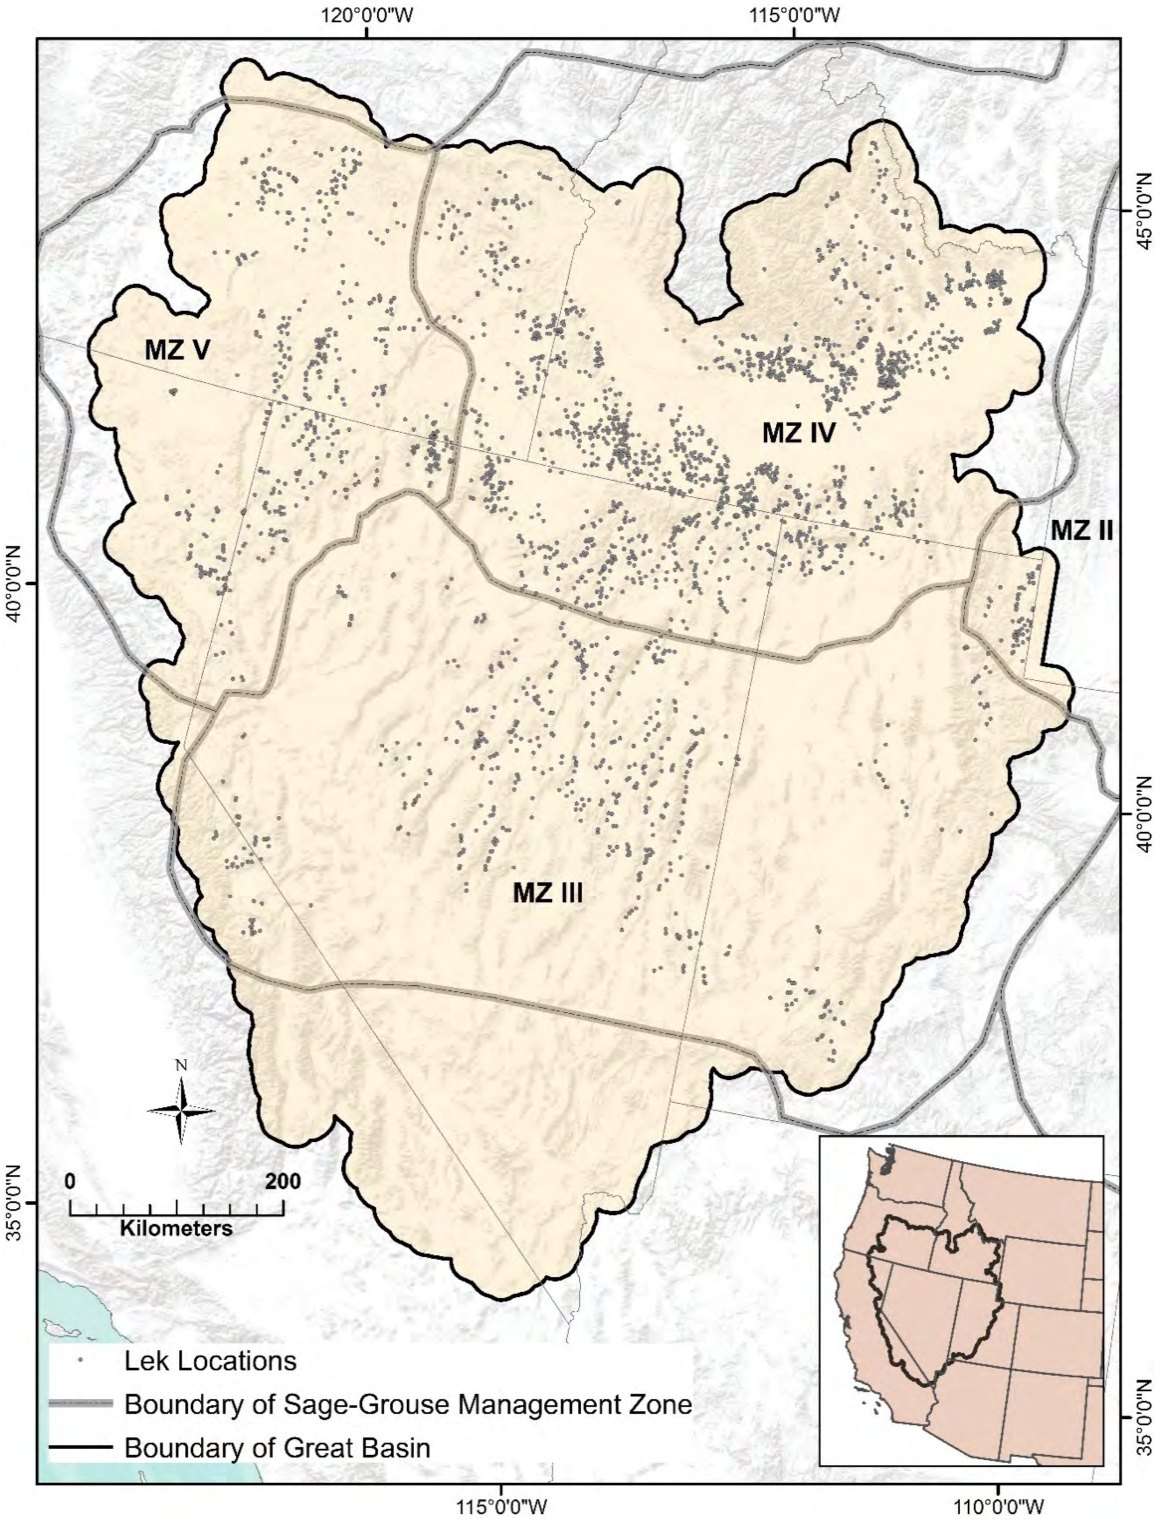

Figure 1. Map of the hydrographic Great Basin, sage-grouse management zones, and locations of sage-grouse leks.

Methods

Data Sources

Lek Counts

Counts of male sage-grouse attending breeding leks provide reliable and widely used spatially explicit data for analyses of population trends (Fedy and Aldridge, 2011). State fish and wildlife agencies use established protocols for defining leks, counting male sage-grouse at leks, and systematically searching for new leks. Counts of males at leks are typically conducted 3–4 times per season and the maximum count is recorded (Connelly and others, 2003). We used data from annual lek counts collected by all agencies within the Great Basin from 1985 to 2014. This time frame was selected to coincide with the range of available wildfire and climate data (see sections, “Annual Wildfire” and “Precipitation”). Because protocols and data treatments can vary slightly among agencies, data were compiled and subjected to further quality control and assurances (QA/QC) by the Western Association of Fish and Wildlife Agencies (2015). These QA/QC included: (1) removing counts obtained by aerial survey owing to lower probabilities of detection associated with this method; (2) removing counts obtained outside conventional calendar (March 15–May 15) periods and early morning hours (earlier than 0.5 hours before sunrise or later 1.5 hours after sunrise); (3) removing counts comprised entirely of birds of unknown gender; (4) combining leks within 1.2 km of each other in order to pool likely satellite leks into a single lek cluster; and (5) assuming that a recorded count of zero equaled no males were observed and a blank value indicated the lek was not counted or not available (NA); and (6) removing consecutive zero counts bracketed by non-zero–zero and zero–non-zero counts (see section, “Population Rate of Change”). For example, the sequence of counts {50, 0, 0, 0, 100} would become {50, 0, NA, 0, 100}; another sequence {50, 0, 0, 100} would stay {50, 0, 0, 100}; and {50, 0, 0, 0} would become {50, 0, NA, NA}.

Annual Wildfire

Spatially explicit data on wildfire extent and severity in the Great Basin extent from 1984 to 2013 were downloaded from the Monitoring Trends in Burn Severity (MTBS) database (http://mtbs.gov/index.html) (Eidenshink and others, 2007). Only burned surface areas greater than 405 ha as a result of wildfires were included in the Western United States portion of the MTBS database, yet these wildfires account for more than 95 percent of burned surface-area in the Western United States (Eidenshink and others, 2007) and 96 percent are within the range of the sage-grouse (Brooks and others, 2015). These data are generated by MTBS using several steps. Scenes are first identified using digitized fire histories from agency databases, other fire records, and peak photosynthetic activity estimates from Advanced Very High Resolution Radiometer (AVHRR) satellite data. Normalized burn ratio (NBR) indices are then calculated using thermal mapping (TM) bands from corresponding 30-m^2 Landsat pre- and post-fire imagery, where

$$\mathrm{NBR} = \frac{\mathrm{TM4}-\mathrm{TM7}}{\mathrm{TM4}+\mathrm{TM7}} \tag{1}$$

Bands of red light are measured with TM4 and longer short-wave infrared bands are measured with TM7. Values for differenced normalized burn ratios (dNBR) are then calculated by subtracting post- from pre-fire NBR values. Values for dNBR are then binned into five ecologically relevant fire severity classes: (0) increased greenness; (1) unburned to low, (2) low; (3) moderate; and (4) high. Fire perimeters are digitized around fire-severity classes 1 through 4, which indicate some minimum level of fire-associated changes in vegetation. Because we were most concerned with quantifying effects of wildfire stemming from fire-driven changes in vegetation (and not overestimating effects of wildfire on sage-grouse population growth), we excluded fire-severity class 1 values that likely result in minimal vegetation change, and reclassified fire-severity classes 2, 3, and 4 values into a single binary raster using Spatial Analyst in ArcGIS^{TM} 10.1. Hence, we erred on the side of reducing commission error rather than omission error (that is, we excluded those low-severity areas that may have actually burned rather than including low-severity areas that did not burn), and revised fire perimeters were redrawn around pixels representing likely vegetation change as a result of wildfire.

Precipitation

Spatially explicit data for local measurements of precipitation at a spatial resolution of 4 km from 1985 to 2013 were obtained from the PRISM Climate Group (http://www.prism.oregonstate.edu/), and then downscaled to 800 m (P. Flint and L. Flint, U.S. Geological Survey, unpub. data, 2014). We chose to index climatic effects on sage-grouse population rate of change according to variation in annual and seasonal precipitation (see section, “Model Covariates,” for rationale). We restricted our analyses to include variables related to precipitation to limit the number of covariates in our climatic model set, and because effects due to precipitation are more readily explained from a perspective of sage-grouse life-history (for example, relations between rainfall, primary productivity, and available resources for grouse) than from extremes in temperature, particularly for a cold-adapted gallinaceous species.

Resilience and Resistance

Extensive research effort in recent years has been devoted to determining how sagebrush ecosystem structure and function influences resilience to disturbance and resistance to annual grass invasion. In general, R&R increases along a gradient based on elevation and aspect that correlates with variation in soil moisture and temperature, where corresponding habitats with underlying cold or cool and moist soils have higher R&R than habitats with underlying warm and dry soils (Chambers and others, 2014a, 2014b). To create a landscape level surface depicting broad patterns in underlying R&R processes, three broad classes that index resilience to wildfire-related disturbance and resistance to annual grass invasion (that is, high, moderate, and low; table 1, fig. 2) were created by the Fire and Invasive Assessment Team (FIAT) from finer scale soil temperature and moisture subclass data extracted from maps developed by Campbell (2014). Although data were unavailable to classify some areas in the southern portion of the Great Basin, the R&R classification encompassed all sage-grouse leks and areas surrounding leks that were relevant to this analysis. We then used R&R index classes to calculate different recovery times in calculations of cumulative burned area and chronic wildfire effects (as described in section, “Wildfire”).

Table 1. Simplified index for overall resilience to disturbance and resistance to cheatgrass invasion (R&R) predicted by soil temperature/moisture regimes underlying sagebrush habitats in the Great Basin.

[Derived by the Fire and Invasive Assessment Team based on Chambers and others (2014b) and Campbell (2014). Sagebrush habitats excludes aquic or oxyaquic soils, which generally are too moist to support sagebrush species, as well as ustic (summer moist) moisture regimes (for example, wetlands, lakes)]

Soil temperature/moisture regime - moisture subclass	Common name	R&R index
Cryic/Xeric-Typic	Cold/moist	High
Cryic/Aridic bordering on Xeric	Cold/dry bordering on moist	High
Frigid/Xeric-Typic	Cool/moist	High
Cryic/Aridic-Typic	Cold/dry	Moderate
Cryic/Xeric bordering on Aridic	Cold/moist bordering on dry	Moderate
Frigid/Xeric bordering on Aridic	Cool/moist bordering on dry	Moderate
Frigid/Aridic-Typic	Cool/dry	Moderate
Frigid/Aridic bordering on Xeric	Cool/dry bordering on moist	Moderate
Mesic/Xeric-Typic	Warm/moist	Moderate
Mesic/Aridic bordering on Xeric	Warm/dry bordering on moist	Low
Mesic/Aridic-Typic	Warm/dry	Low
Mesic/Xeric bordering on Aridic	Warm/moist bordering on dry	Low

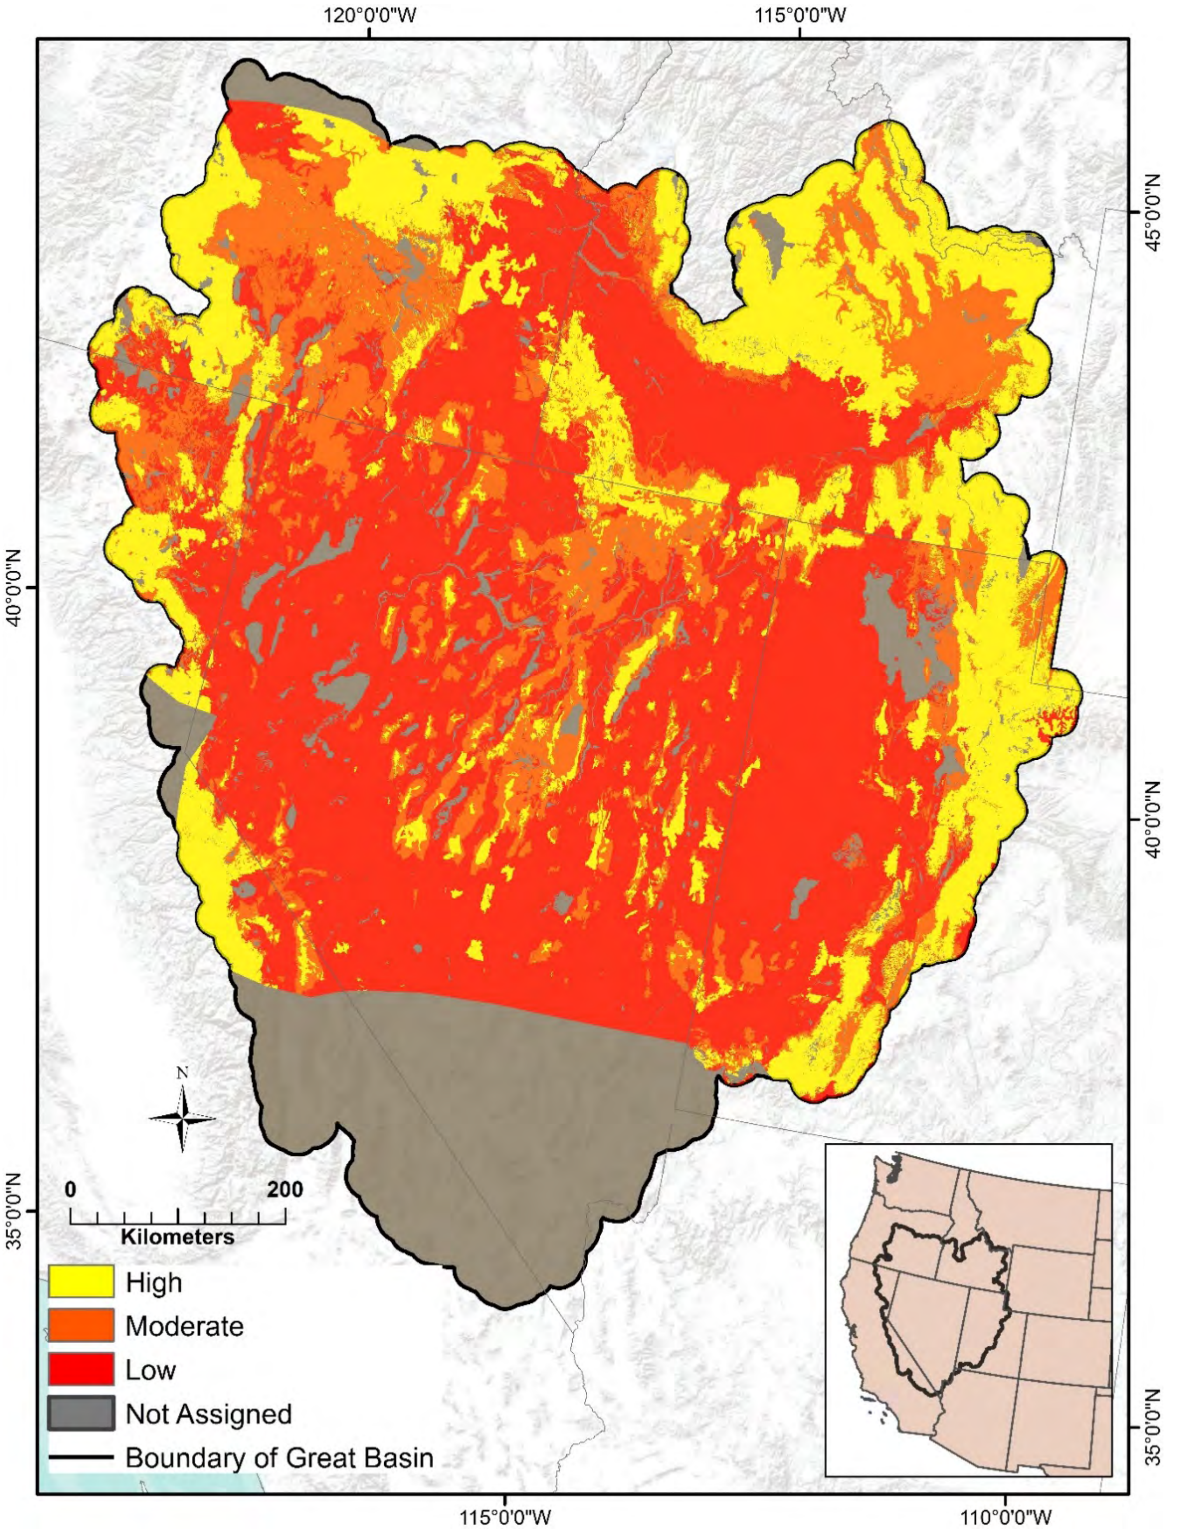

Figure 2. Map of Resilience and Resistance (R&R) index classes in the Great Basin. Classification of R&R were derived from soil moisture and temperature subclasses from Campbell (2014).

Model Response and Covariate

Population Rate of Change

We calculated the instantaneous (or intrinsic) annual per-capita rate of change (*r*; Gotelli and Ellison, 2004) for sage-grouse populations, which took the form:

$$r_{ij} = ln \frac{\mathrm{N}_{ij}}{\mathrm{N}_{ij-1}} \tag{2}$$

where N represents maximum male lek count, *i* represents lek, *j* represents year, and *j*-1 represents a previous year. We used *r* as the response variable in all predictive models for population growth (see section, “Modeling Wildfire and Climate Effects on Population Growth”). We added a constant of 0.1 to all counts to avoid division by zero when no birds were detected at N_{ij}. Where applicable for illustration and interpretation purposes, we convert to finite rates of change (λ; Caswell, 2001; Gotelli and Ellison, 2004), and expressed as:

$$\lambda = e^r \tag{3}$$

Density-Dependence

We formulated models to test and account for density-dependent reductions in population growth observed within some sage-grouse populations (Garton and others, 2011, 2015). Density-dependence from time-series data are typically evaluated using Ricker (Dennis and Taper, 1994) and Gompertz (Dennis and others, 2006) methods that estimate population rate of change as a function of raw and logarithmic abundance, respectively. Furthermore, time lags can be incorporated to model delayed density-dependent feedbacks that can yield cyclic patterns of population growth often displayed by sage-grouse in Wyoming (Fedy and Aldridge, 2011; Fedy and Doherty, 2011). Recent analyses of stochastic population growth from 1965 to 2013 found consistent support for Gompertz-type density-dependence lagged one-year log[N_{j-2}]); hereinafter, ‘lag-Gompertz’) across all sage-grouse management zones encompassed by our study area (Garton and others, 2015). To allow interpretation across studies, we *a priori* selected lag-Gompertz to be tested against the null model without predictors, and, if supported by the data, then carried this effect forward for inclusion in all predictive models.

Wildfire

Wildfire effects on sage-grouse population growth were indexed with three spatially explicit covariates derived from the MTBS data for each year: (1) distance to burned perimeter; (2) burned area; and (3) wildfire perimeter-to-area (PA) ratio (an index for amount burned to unburned edge). Distance to burned perimeter measured the Euclidean distance between lek centers and nearest burned edge (zero distance if lek was inside the fire area), and allowed for estimation of ‘burn over’ effects (for example, wildfires that completely burned over lek centers). Burned area and PA ratio within circular buffers of 5 km (78.5 km^2) and 10 km (314 km^2) from lek centers were extracted from raster layers created from corresponding moving windows of 5,160 and 10,560 m, respectively. These distances bracketed the range of values proposed for limiting surface-disturbance near leks (Coates and others, 2013; Manier and others, 2014) and encompassed most nesting habitat as described previously. Burned area represented the amount of fire-severity class 2 through 4 within a wildfire perimeter, and PA ratio represented the amount of total burned edge relative to its total area.

Burned area and PA ratio also were calculated with two methods. Annual time series analyses typically measure fire dynamics as a spatially static and ephemeral covariate, whereby landscapes burn at particular extents (area) and configurations (PA ratio) in a given year, but burns do not compound across years (that is, annual estimates of burn reset to zero at the conclusion of the fire year) (for example, Baker, 2006; Miller and others, 2011). We term this an 'acute' effect, whereby wildfire influences on population rate of change were modeled as a discrete process confined to a single year (for example, immediate effects of wildfire) (table 2). In contrast, wildfires can have long-lasting effects based on longer term reduction of resources necessary to sage-grouse (for example, loss of sagebrush cover and annual grass invasion), and the recovery time of these resources were then modeled as a function of underlying soil moisture and temperature processes influencing R&R. We term this a 'chronic' effect, whereby persistence of wildfire scars and associated effects on sage-grouse varied across years according to the predominant underlying R&R index class within 5 km of leks (for example, longer term effects of wildfire) (table 2). Evaluating both acute and chronic effects allowed for an investigation of immediate impacts (that is, temporary displacement of sage-grouse) versus those that are long-lasting and likely associated with changes in land cover (that is, reduced local persistence). Recovery times for chronically affected areas (hereinafter, chronic areas) were based on a published meta-analysis of post-wildfire recovery in mountain big sagebrush communities that ranged from 1.28 percent of pre-fire sagebrush per year ("slow-track") to 2.28 percent ("fast-track") per year (Baker, 2011). Mountain big sagebrush communities are among the most resilient of all big sagebrush types, and by assuming their fast-track and slow-track recovery rates for our high and moderate R&R index classes, respectively, we modeled a "best case scenario" of sagebrush recovery that likely underestimates the length of time to recovery for other sagebrush types (for example, Wyoming big sagebrush).

Table 2. Summary of fire recovery models used to evaluate how sage-grouse population growth rates were best explained by variation in post-recovery times relative to R&R index class.

[Years to recovery for high and moderate R&R classes were calculated as 20 percent divided *p*, where *p* is the fast-track (2.28 percent per year) or slow-track rate (1.28 percent per year) of recovery, respectively]

Fire effect	Recovery scenario	R&R index class	Years to recovery
Acute	NA	NA	1
Chronic	Normal	High	9
		Moderate	16
		Low	NA
	Accelerated	High	5
		Moderate	8
		Low	NA
	Decelerated	High	18
		Moderate	30
		Low	NA

By conservatively defining recovery as a minimum threshold of 20 percent pre-fire sagebrush cover within 5 km of leks necessary to fulfill important sage-grouse life history requirements (for example, brood-rearing and wintering) (Connelly and others, 2000b), we constructed three scenarios of 'normal', 'accelerated', and 'decelerated' recovery times for high and moderate R&R pixels. These scenarios represent variation in recovery times across a broader range of sagebrush ecosystems (Baker, 2006, 2011; Nelson and others, 2014). Under the 'normal' scenario, we calculated recovery time of high R&R pixels to 20 percent of pre-fire sagebrush using the fast-track rate (2.28 percent) as 9 years, (that is, 20 divided by 2.28, rounded to the nearest whole number) while recovery of moderate R&R pixels to 20 percent sagebrush using the slow-track rate (1.28 percent) occurred after 16 years (that is, 20 divided by 1.28, rounded to the nearest whole number). We cut normal recovery times approximately in one-half for the 'accelerated' scenario (5 and 8 years for high and moderate R&R pixels, respectively). We doubled recovery times under the 'decelerated' scenario but these were not allowed to exceed the 30-year span of the data (18 and 30 years for high and moderate R&R pixels, respectively). In all scenarios, the 'recovery clock' reset to zero if a new wildfire burned over a previously burned pixel with high or moderate R&R before recovery occurred. In contrast, we did not allow for any recovery in low R&R pixels, and assumed permanent conversion to annual grass following fire. This assumption was based on: (1) slow recovery following fire in Wyoming big sagebrush communities that often comprise low R&R habitat (for example, < 5 percent of pre-fire sagebrush cover typically returns after 25 years) (Miller and others, 2011); and (2) the high likelihood of state-transition without extensive management intervention (Chambers and others, 2014a, 2014b). Hence, burned low R&R pixels represented a permanent wildfire-scar and loss of resources available to sage-grouse.

We recognize that full recovery within 5 km of leks can take much longer than our three R&R-based recovery scenarios suggest. However, modeling full recovery in more resilient mountain big sagebrush and perennial grass communities or less resilient and low-elevation Wyoming big sagebrush communities was untenable because the 30 years of available MTBS data fell short of including the full range of years required for full recovery in both communities (ca. 25–120 years) (Baker, 2006, 2011). Hence, these assumptions allowed for relatively quick return of some recovery-based benefits to sage-grouse (based on an estimated post-fire 20 percent return of sagebrush) that ameliorated the chronic wildfire effect for leks dominated by high and moderate R&R, and no recovery in low R&R represented by cheatgrass invasion.

Precipitation

Similar to the wildfire covariates, we extracted mean precipitation data within 5- and 10-km radius buffers from lek centers using raster layers created from moving windows of 5,160 and 10,560 m, respectively. We aggregated precipitation into seasonal (spring, summer, fall, and winter) and annual intervals based on *a priori* hypotheses that synchronized with the timing of sage-grouse life stages. For example, spring spanned March to May and indexed resources available during the sage-grouse nesting period (for example, forb growth), whereas summer spanned June to August and indexed resources available during the brood-rearing period (for example, wet meadow productivity, delay of plant senescence). We classified fall as September through November to represent spurts of new growth during extended brood-rearing that could increase survival of juveniles entering winter. Winter spanned December to February, and indexed precipitation (primarily as snow) that contributed to increased runoff that was thought to drive more productive and possibly longer growing seasons. We also formed four multi-season groups by combining: (1) spring and summer (nesting + brood rearing); (2) spring, summer, and fall (nesting + brood rearing + extended brood rearing/juvenile); (3) winter, spring, and summer (snowpack runoff + nesting + brood rearing); and (4) annual (total across all seasons). Heavy snowfall during winter also can influence overwinter mortality and thus subsequent numbers of birds that survive to the following years' lek count (Anthony and Willis, 2009). However, other studies indicate relatively high over winter survival (Blomberg and others, 2013), so we aligned winter at the beginning rather than the end of the precipitation year to allow for carry-over effects of winter precipitation (for example, snowpack melt) on plant growth and phenology in the subsequent spring that should affect successful reproduction and increase the potential number of recruits in the next year.

Modeling Wildfire and Climatic Effects on Population Growth

A two-step Bayesian mixed-effects model framework was used to investigate density-dependence, precipitation, and wildfire as linear predictors for annual population growth rates from 1985 to 2013. Our mixed effects model equation is structured as

$$\log(\lambda) = \beta_0 + \sum_i \beta_i X_i + \zeta_{\text{Lek}} + \zeta_{\text{Year}} \tag{4}$$

where X_i represent model covariates to describe density-dependence, climate, and/or wildfire (absent in the null model), the β terms represent model coefficient parameters, and the ζ terms represent random effects variation among leks and years. Bayesian modeling is well suited for generating projections of growth rates and are readily derived from posterior distributions of parameter estimates (Halstead and others, 2011). Thus, we chose to use derived distributions for effects of wildfire (estimated while accounting for variation in precipitation and sage-grouse density) to forecast how future changes in cumulative burned area might influence population trajectories of Great Basin sage-grouse over the next 30 years. Posterior distributions were derived using Program JAGS within the rjags package (Plummer and others, 2015) in R version 3.1.1 (R-Core-Team, 2014). Specifically, posterior distributions of parameter estimates were generated from three chains of 10,000 iterations each, after a burn-in of 10,000 (step 1) to 20,000 (step 2) iterations using Markov-chain Monte Carlo (MCMC) methods. Convergence of MCMC output was assessed visually with history plots and the R-*hat* statistic, where values $\leq$ 1.1 indicated convergence (Gelman and others, 2014).

Posterior distributions of estimated covariate effects were derived from distributions of uninformative prior probabilities (table 3) during both steps, and all models were fitted with the random-effects structure to account for intraclass correlations associated with leks and years. Step 1 was designed to select and carry-forward the covariates with the most support from groups of variables representing: (1) density-dependence; (2) wildfire; and (3) precipitation. Input data were aligned so that wildfire and precipitation covariates at year *j* influenced numbers of grouse counted at leks in year *j*+1. Within groups, fitted models representing singular-additive effects were compared against each other, a null model (that is, random effects only), and a density-dependence only model (that is, lag-Gompertz with random effects; when applicable) using deviance information criterion (DIC, lower is better), a goodness-of-fit statistic calculated for every model. Although use of DIC for model selection has limitations (Hooten and Hobbs, 2014), this criteria is commonly used to rank competing Bayesian models because of its computational ease and similarity to maximum-likelihood based Akaike Information Criterion (AIC). Furthermore, we calculated DIC because this criteria is reliable when used with models with similar attributes to those in this study (for example, linear and independent data, large sample size, low number of parameters). We defined three different ΔDIC values to facilitate comparisons among models: $\Delta\text{DIC}_{\text{Group}}$ as DIC minus the minimum DIC value within the same group or subgroup, to compare models within each group or subgroup; $\Delta\mathrm{DIC}_{\mathrm{DD}}$ as DIC minus the DIC of the density-dependent-only model, to compare each model to the Gompertz (1-year lag) density-dependent model; and $\Delta\mathrm{DIC}_{\mathrm{null}}$ as DIC minus the DIC of the null model to compare each model to the random intercept-only model. For each subgroup, single covariate effects were carried forward if they met three criteria: (1) consisted of lowest DIC within the subgroup (that is, $\Delta\mathrm{DIC}_{\mathrm{group}}$ equaled zero); (2) DIC was at least two units less than DIC for the null model (that is, $\Delta\mathrm{DIC}_{\mathrm{null}}$ was less than or equal to negative two); and (3) DIC was at least two units less than DIC for the lag-Gompertz model (that is, $\Delta\mathrm{DIC}_{\mathrm{DD}}$ was less than or equal to negative two). Covariates from the models that met these DIC criteria for each group or subgroup were carried forward to step 2.

Table 3. Description of parameters in the mixed effects model for sage-grouse annual population rate of change (λ) in the Great Basin from 1985 to 2013, based on density, wildfire, climate, and interaction effects, and random effects among lek sites and years.

[All parameters are estimated using Bayesian techniques assuming minimal prior information, using Uniform (U) or Normal (N) prior distributions, and include baseline (β_0), coefficients of effects (β_i), random effects (ζ), and their standard deviations (σ). All effects relate to population λ according to the equation $\log(\lambda) = \beta_0 + \sum_i \beta_i X_i + \zeta_{\mathrm{Lek}} + \zeta_{\mathrm{Year}}$, where X_i represent model covariates and the summation includes zero (null model), one (lagged-Gompertz only model), or multiple effects]

Symbol	Description	Prior distribution
σ_{r}	Standard deviation for annual per capita instantaneous rate of increase (model error)	$\mathrm{U}(0,50)$
β_0	Baseline annual per capita instantaneous rate of increase	$\mathrm{U}(-20,20)$
β_{DD}	Coefficient of lagged Gompertz density-dependence effect	$\mathrm{N}(0,\sigma_{\mathrm{DD}})$
σ_{DD}	Prior standard deviation β_{DD}	$\mathrm{U}(0,50)$
β_{FDist}	Coefficient of fire effect (Distance subgroup)	$\mathrm{N}(0,\sigma_{\mathrm{FDist}})$
σ_{FDist}	Prior standard deviation for β_{FDist}	$\mathrm{U}(0,50)$
β_{FArea}	Coefficient of fire effect (Area subgroup)	$\mathrm{N}(0,\sigma_{\mathrm{FArea}})$
σ_{FArea}	Prior standard deviation for β_{FArea}	$\mathrm{U}(0,50)$
β_{Edge}	Coefficient of fire effect (Edge subgroup)	$\mathrm{N}(0,\sigma_{\mathrm{Edge}})$
σ_{Edge}	Prior standard deviation for β_{FEdge}	$\mathrm{U}(0,50)$
β_{Precip}	Coefficient of precipitation effect	$\mathrm{N}(0,\sigma_{\mathrm{Precip}})$
σ_{Precip}	Prior standard deviation of β_{Precip}	$\mathrm{U}(0,50)$
$\beta_{\mathrm{Interaction}}$	Coefficient of interaction effect between fire and precipitation	$\mathrm{N}(0,\sigma_{\mathrm{Interaction}})$
$\sigma_{\mathrm{Interaction}}$	Prior standard deviation for $\beta_{\mathrm{Interaction}}$	$\mathrm{U}(0,50)$
$\zeta_{\mathrm{Lek\ s}}$	Random lek effect, for lek s, where s = 1,…,1770	$\mathrm{N}(0,\sigma_{\mathrm{Lek}})$
σ_{Lek}	Prior standard deviation for $\zeta_{\mathrm{Lek\ s}}$	$\mathrm{U}(0,50)$
$\zeta_{\mathrm{Year\ s}}$	Random year effect, for year t, where t = 1985 – 2013.	$\mathrm{N}(0,\sigma_{\mathrm{Year}})$
σ_{Year}	Year standard deviation of $\zeta_{\mathrm{Year\ t}}$	$\mathrm{U}(0,50)$

During step 1, within the density-dependence group, we evaluated a lag-Gompertz model against the null model. The DIC was less than that of the null model, so we carried it forward for inclusion in all models within the wildfire and precipitation groups to consistently account for density-dependence. Within the wildfire group, we created three subgroups of covariates to singularly evaluate the effects of: (1) distance to burned perimeter; (2) burned area; and (3) burned edge. Distance to burned perimeter only included distance to acutely affected burned areas (hereinafter, acute distance). Burned area and PA ratio were based on acutely and chronically affected areas at the 5- and 10-km scale. Chronically affected burn and edge (hereinafter, chronic area and chronic edge) included measurements of cumulative area calculated using the different R&R-based recovery rates (that is, normal, accelerated, decelerated). Within the precipitation group, we used the same criteria to carry-forward the single-best model of seasonal or annual precipitation at the 5- or 10-km scale. Precipitation did not include any subgroups. All wildfire and precipitation covariates were centered and standardized using Z-scores (Zar, 1996) to allow for consistent scales of measurement and improve model convergence. Density-dependence variable represented by lag-Gompertz conversion was already log-transformed.

In step 2, we fit two additive models that combined lag-Gompertz with wildfire and precipitation covariates carried forward from step 1. We also fit a model that included an interaction between the effects of precipitation and wildfire to test if wildfire effects on population rate of change varied by precipitation. The model with the lowest DIC was chosen for predictive modeling. Multicollinearity among covariates ($r > |0.65|$) was not detected among any step 2 models. We followed the suggestions of Kéry (2010) to assess model fit by constructing plots of residuals against predicted values, developing posterior predictive distributions, and calculating Bayesian *p*-values, whereby $p \sim 0.5$ indicates good fit. We reduced the number of posterior iterations to 1,000 owing to the large number of parameters required for calculating residual plots, and increased the burn-in to 20,000 iterations to facilitate better convergence for more complex models. To interpret covariate effects, we report the median parameter estimates of the posterior distribution and 95 percent credible intervals (CI; that is, 2.5 and 97.5 percentiles of the posterior distribution that represent the lower and upper bounds, respectively, of the CI).

Modeling Cumulative Burned Area in Relation to Leks

A Bayesian linear model was used to describe increases in cumulative burned area through time from 1984 to 2014, and resulting posterior distributions were then used to forecast future changes in cumulative burned area out to 30 years. We selected the burned area covariate from a subgroup of models formed to test different combinations of spatial scale (that is, 5 and 10 km from lek) and acute and chronic R&R-based recovery times (that is, accelerated, normal, decelerated) that best described variation in annual population change (described in step 1 above), and regressed it against year as a continuous fixed effect. Separate models were run for each R&R index class to evaluate changes in burned area near leks over time relative to spatially explicit predictions of R&R, and then each model was compared to a null (intercept only) model using DIC. Parameter estimates were derived from distributions of uninformative prior probabilities (table 4).

Table 4. Description of parameters in the model for estimating change in cumulative fire area within 5-km of leks in the Great Basin from 1984 to 2013.

[All parameters are estimated using Bayesian techniques assuming minimal prior information, using Uniform (U) or Normal (N) prior distributions, and include coefficients of trend (β_{Year}), and standard deviations (σ). Cumulative fire area is modeled as $\beta_{\mathrm{Year}}\,Year$]

Symbol	Description	Prior distribution
σ_{r}	Standard deviation for annual rate of recovery	$\mathrm{U}(0{,}1.5e7)$
β_{Year}	Mean effect for year	$\mathrm{N}(0, \sigma_{\mathrm{Year}})$
σ_{Year}	Standard deviation for year effect	$\mathrm{U}(0{,}1.5e7)$

Management Scenarios

Indices of habitat suitability and animal abundance provide useful proxy-based measures for use in adaptive management (Coates and others, 2014; Stephens and others, 2015). Doherty and others (U.S. Fish and Wildlife Service, written commun., 2015) derived a range-wide population index model for sage-grouse using such indices that incorporated sage-grouse habitat suitability generated from Random Forest models (Evans and others, 2011), and spatially explicit abundance measures based on fixed kernel density functions on lek locations. The kernels were generated using two bandwidth distances representing the majority of breeding habitat in relation to leks (6.4 km) and seasonal movements (18.0 km). We evaluated relationships between abundance indices and the overall population index model to demarcate areas that are the most meaningful to sage-grouse populations. Specifically, we clipped the range-wide continuous population index layer to the Great Basin study extent (buffered by 10 km), and extracted isopleths for the percentage of cumulative volume under the layer at 5 percent increments starting at 65 percent. Following Doherty and others (2015), we overlaid locations of active leks (that is, greater than two males observed in greater than two of the previous 5 years) and pending leks (that is, greater than two males observed only once over the previous 5 years) on the clipped layer and extracted the maximum lek count from 2009 to 2014 as an index of population size within each isopleth class. Active and pending leks (*n* = 1,896) had at least one count greater than two males during the time interval. For each successive isopleth class, we calculated the ratio of the cumulative increase in population size to cumulative area added to the population index model, and rescaled the ratio between zero and 100. To determine a cut-point for the population index model that represented where sage-grouse density was most concentrated, we fit an exponential regression between population index model isopleth values and the cumulative ratio of increasing population size to area added, and determined where the slope of the line equaled 1.0 (Vander Wal and Rodgers, 2012). The slope equaled 1.0 at the 76.4 percent isopleth, which when rounded to 75 percent was used to demarcate example ‘core areas’ (fig. 3). To inform decisions of conservation actions by State and Federal agencies, we ran simulations to examine how targeted 25, 75, and 99 percent reductions in the rate (trend) of annual cumulative burned area in these core areas might alter sage-grouse population trajectories over the next 30 years. Posterior distributions are reported.

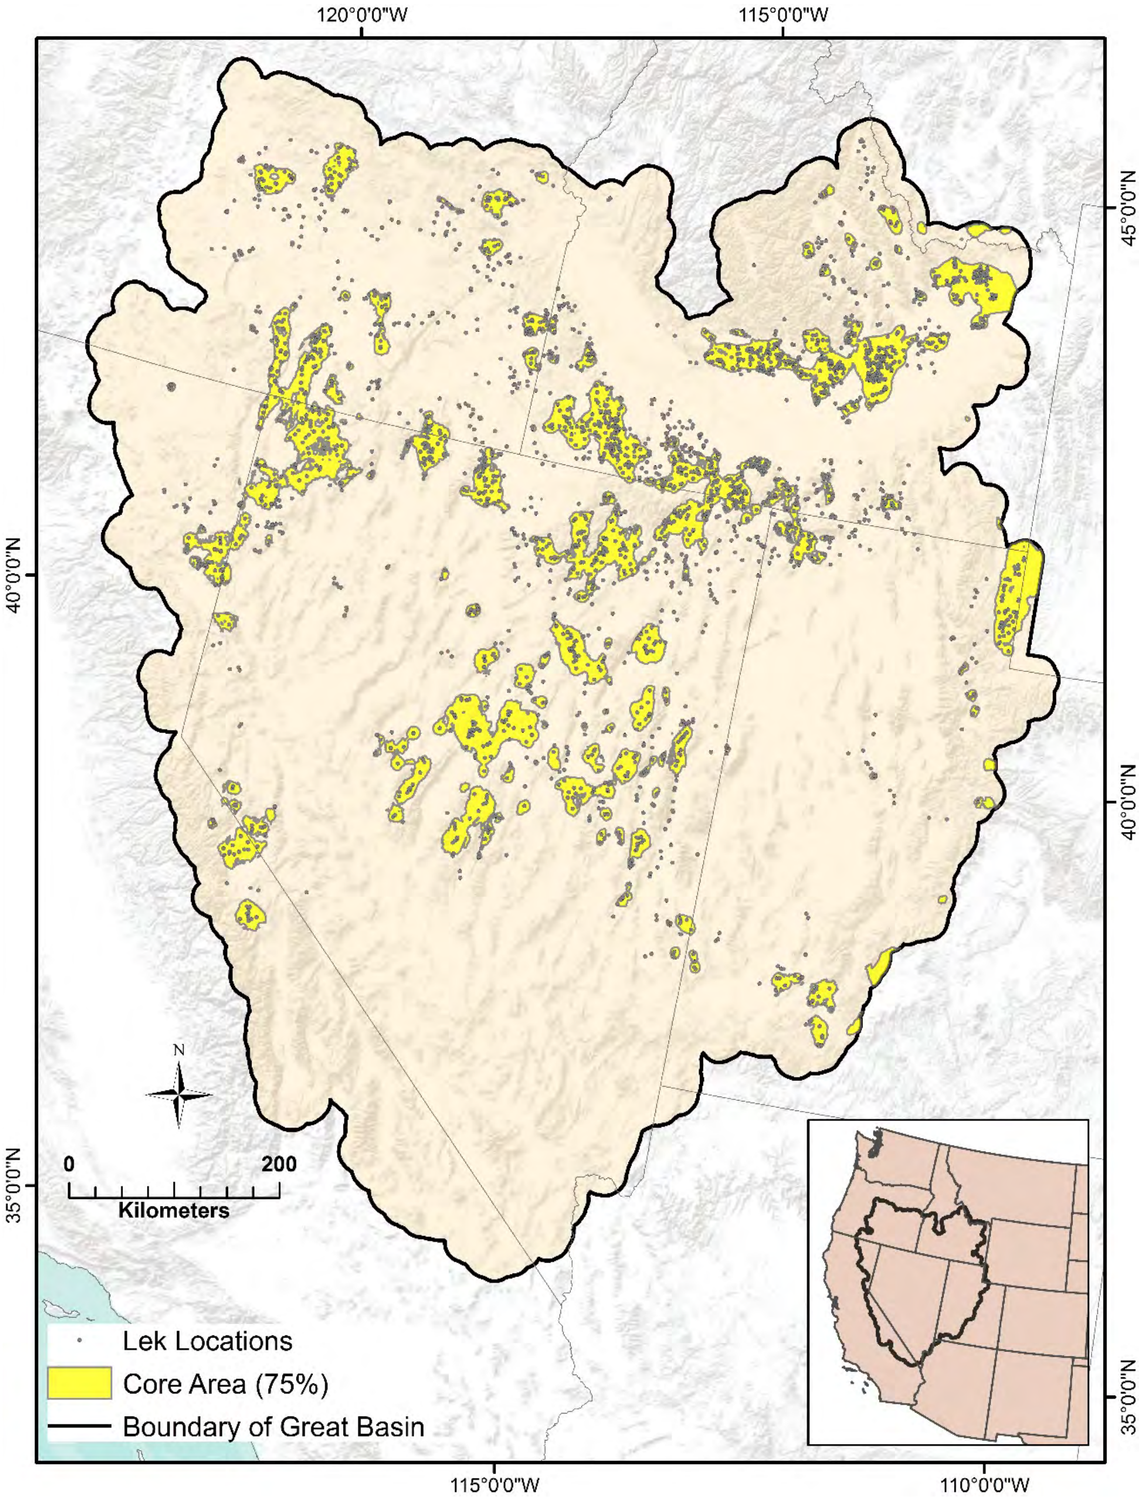

Figure 3. Map of estimated sage-grouse core areas and associated distribution of breeding leks in the Great Basin.

Results of Wildfire Effects on Sage-Grouse

General 30-Year Wildfire Patterns across the Great Basin

The MTBS-based dataset used for wildfire modeling comprised a pool of 3,102 fire perimeters in the Great Basin from 1984 to 2013. Although substantial variation existed among years, total burned area increased by an average of 153 km^2/yr. Some variation could be explained by annual precipitation relative to the 30-year average of precipitation (32.3 cm), where total burned area was greater, on average, during years of below-average precipitation (524,134 ha burned per year) compared to those years of above average precipitation (239,873 ha burned per year) (fig. 4). Additional variation could be explained by R&R index class burned, whereby total burned area tended to be higher for wildfires burning over land cover with low underlying R&R compared to those with moderate and high underlying R&R (fig. 5). When evaluated on a cumulative basis that allowed for normal recovery (based on results below) a total of 13,173 km^2 of land cover with low underlying R&R burned from 1984 to 2013 compared to 6,390 km^2 of moderate and 4,349 km^2 of high underlying R&R during the same period (fig. 6). We assumed all land cover types within these generalized R&R classes recovered at the same R&R-specific rates as sagebrush for illustrative purposes, and because this calculation is across the Great Basin and our analysis is in relation to 5 km of leks, this trend was not used for model projections.

Wildfire and Precipitation Effects on Annual Population Rate of Change

After subjecting all lek count data to QA/QC screening, the final dataset used to model wildfire and precipitation effects on annual population rate of change comprised of 1,770 leks across the Great Basin (table 5). Idaho and Nevada had the most leks (69.8 percent of total) and California had the least (4.6 percent of total). Average number of males per lek was less than 30. Posterior distributions of parameters were then generated from 14,834 estimates of instantaneous population rate of change (r) derived from consecutive pairs of lek counts.

For step 1, Gompertz type density-dependence with a 1-year lag (lag-Gompertz) explained more variance in annual population growth than the null (random effects only), and was thus carried forward to all models with wildfire and precipitation covariates (table 6). Within the wildfire covariate group, the model with distance to burned perimeter had a lower DIC compared to the random intercept model ($\Delta DIC_{null} < -72.0$) and the lag-Gompertz only model ($\Delta DIC_{DD} < -8.0$), so this covariate was carried forward to step 2. Within the burned area subgroup, chronic area with normal recovery rate within 5 km of a lek had the lowest DIC compared to the random intercept model, and was 6.8 ΔDIC_{DD} units better than the lag-Gompertz only model, so this covariate was carried forward to step 2.

Competing evidence ($\Delta\text{DIC}_{\text{group}} < 2.0$) existed for chronic area with normal and accelerated recovery rate within 10 and 5 km of a lek, respectively, but we only carried forward the single best model to limit complexity of step 2. Notably, all models of acute burned area had a poorer DIC than the lag-Gompertz only model ($\Delta\text{DIC}_{\text{DD}} > 0.0$). Within the burned edge subgroup, no models were supported by the data better than the lag-Gompertz only model. Hence, no PA ratio covariates were carried forward to step 2. Finally, within the precipitation group, the model with precipitation within 10 km of a lek during spring, summer, and fall had the lowest DIC, and improved significantly on the lag-Gompertz only model ($\Delta\text{DIC}_{\text{DD}} < -2$), and this covariate was carried forward to step 2. No other precipitation group models satisfied the rule of $\Delta\text{DIC}_{\text{DD}} < -2.0$, so no other precipitation covariates were carried forward. Convergence criteria was met for all models (R-*hat* < 1.1).

For step 2, main effects models containing additive effects of density-dependence, wildfire, and precipitation explained less variation in λ compared to the model containing interaction effects between wildfire and precipitation (table 6). The equation for the final model including all carried-forward variables took the form:

$$\log(\lambda_t) = \beta_0 + \beta_{\text{DD}} \log(N_{t-1}) + \beta_{\text{FDist}} X_{\text{FDist}} + \beta_{\text{FArea}} X_{\text{FArea}} + \beta_{\text{Precip}} X_{\text{Precip}} + \beta_{\text{Interaction}} X_{\text{FArea}} X_{\text{Precip}} + \zeta_{\text{Lek}} + \zeta_{\text{Year}} \qquad (4)$$

where βs represent coefficients for intercept (0), lag-Gompertz density-dependence (DD), distance to perimeter burned (FDist), cumulative burned area (FArea), and seasonal precipitation (Precip; spring through fall), ζs represent random effects for lek and year. Descriptions are provided in table 3. Fit of the final model was excellent (Bayesian $P = 0.496$), and indicated that effects of wildfire varied inconsistently across the range of precipitation while accounting for density-dependence. Posterior probability distributions of the parameters for wildfire effects indicated that variation in population rate of change was positively related to distance away from the burned perimeter and negatively related to cumulative burned area with normal recovery rate within 5 km of a lek. On average, rate of change increased by approximately 1.1 percent (posterior median = 0.011, 95-percent CI = 0.007–0.015) with every 10 km increase in distance to burned perimeter (fig. 7), and decreased by 2.1 percent (0.021, 95-percent CI = 0.012–0.031) with every 10 km^2 increase in cumulative burned area (fig. 8). Interactive effects between cumulative wildfire and total precipitation during spring, summer, and fall indicated intriguing and complex patterns (fig. 9). Increasing precipitation correlated with increasing population size, whereby λ was predicted to exceed 1.0 during years of above-average precipitation if cumulative burned area was not too large. However, the positive effect of precipitation on population growth decreased as cumulative burned area increased, whereby λ was predicted to be below 1.0 during years with high precipitation at leks associated with relatively large amounts of cumulative burned area.

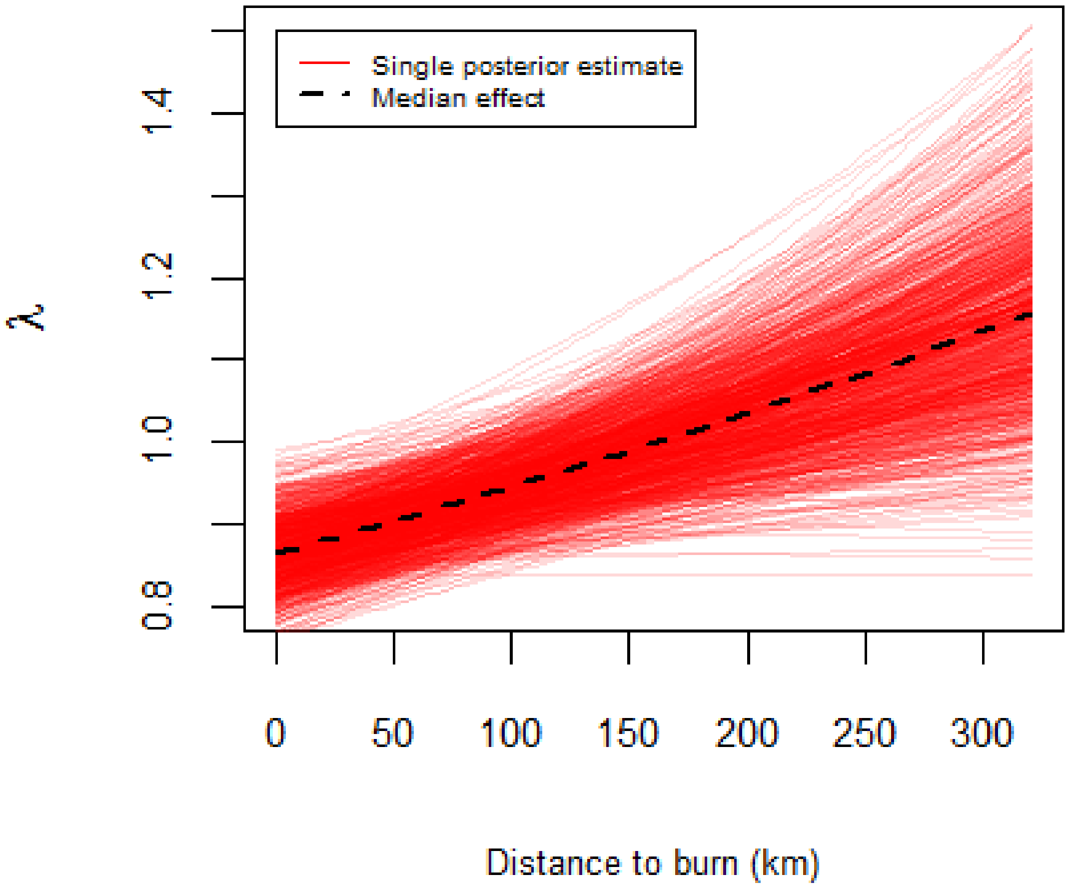

Figure 7. Effect of distance to burn perimeter on the annual population rate of change (λ) of sage-grouse across the Great Basin from 1985 to 2014. Ten thousand samples from the posterior distributions of model parameters were used to represent the range of uncertainty in this relationship.

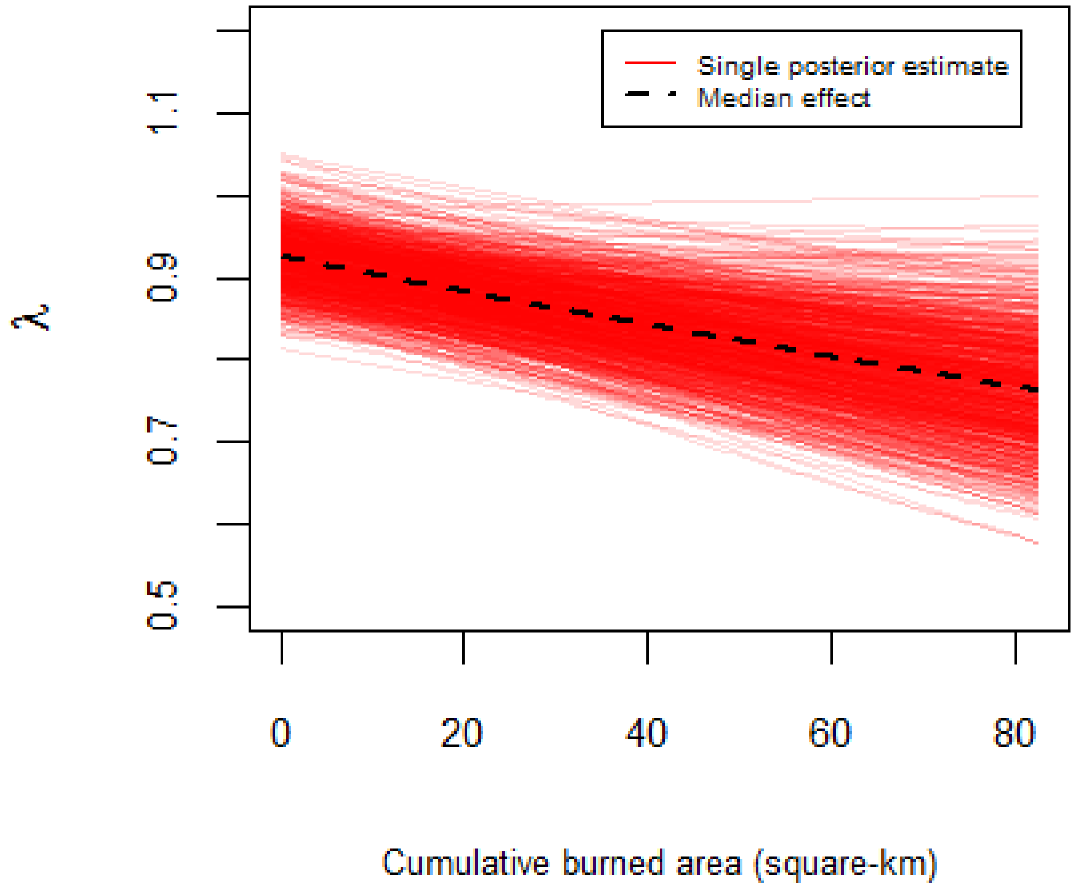

Figure 8. Effect of cumulative burned area (square-km) on the annual population rate of change (λ) of sage-grouse across the Great Basin from 1985 to 2014. Ten thousand samples from the posterior distributions of model parameters were used to represent the range of uncertainty in this relationship.

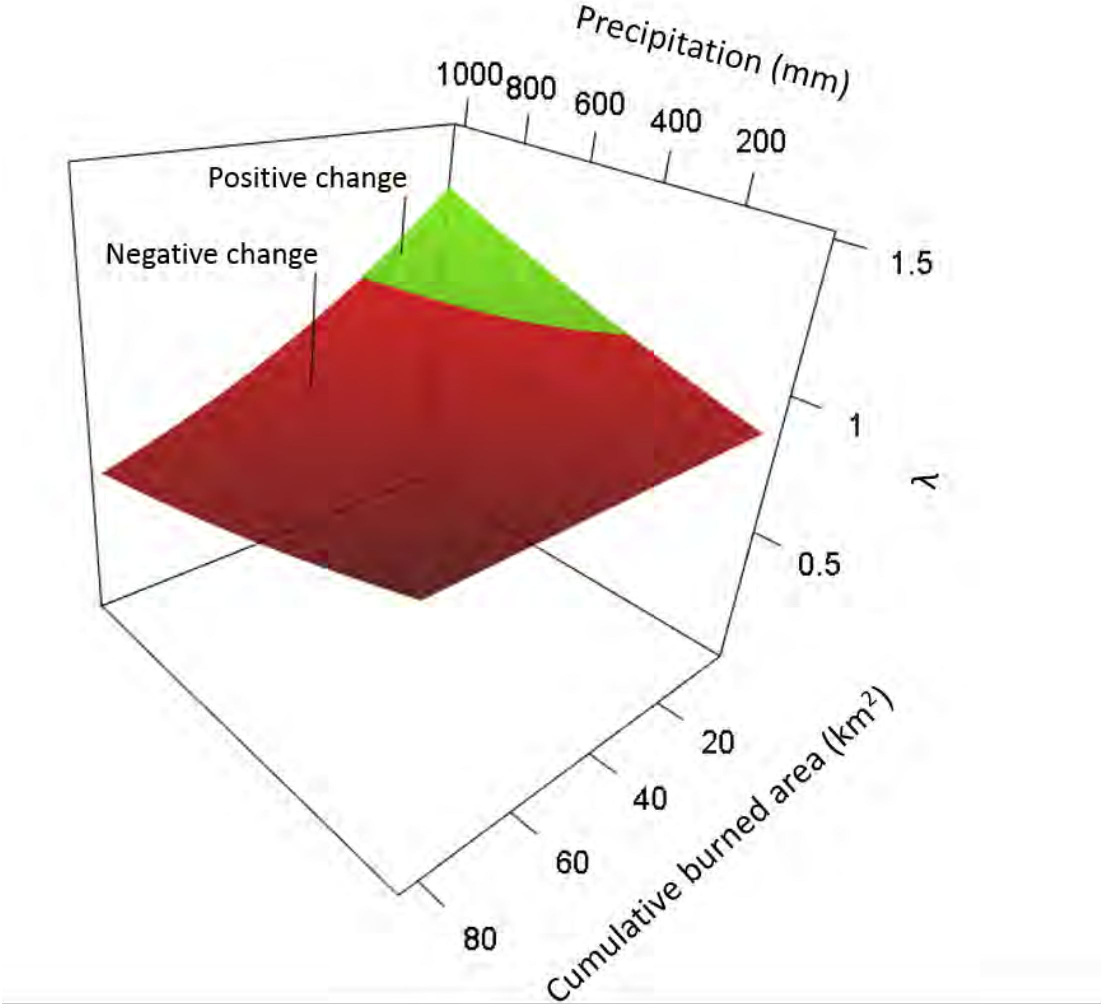

Figure 9. Three-dimensional display of the interaction effects between precipitation (spring through fall) and cumulative burned area on population rate of change (λ) of sage-grouse in the Great Basin from 1985 to 2014.

Patterns of Cumulative Burned Area and Recovery Near Leks

Based on results from the burned area subgroup test in step 1 above, we modeled cumulative burned area per year within 5 km of leks using the normal burn recovery rate to describe past and predict future changes in the amount of burned areas, which explained more variation than the null model (ΔDIC = 6.85) and adequately converged (R-*hat* $\leq$ 1.1). The inter-annual trend estimate (median value of posterior probability distribution) indicated that 3.4 km^2 (0.4 percent) per lek burned annually when averaged across all three R&R classes (fig. 10). When expressed as cumulative averages for the burned proportional area within 5 km of a lek for each resilience and resistance index classes: high R&R burned at 0.36 percent per year (95-percent CI = 0.0034–0.0039), moderate R&R burned at 0.34 percent per year (95-percent CI = 0.0031–0.0037 percent), and low R&R burned at 0.53 percent (95-percent CI = 0.0050–0.0056; fig. 10). By 2013, an average of 89.1, 89.7, and 84.2 percent of unburned area with high, moderate, and low R&R, respectively, remained within 5 km of a lek.

30-Year Predictions of Cumulative Burned Area and Sage-Grouse Population Persistence

We estimated future cumulative burned area based on normal recovery rate for each R&R class by extracting 30,000 samples from the posterior probability distribution for area burn rate and extrapolating future cumulative burned area over 30 more years. By 2044, an average of 77.8, 79.1, and 67.8 percent of unburned area with high, moderate, and low R&R, respectively, was projected to remain within 5 km of a lek (fig. 10). We then took each sample of the posterior probability distribution for the projected cumulative burned area for each year, and multiplied it by the effect of cumulative burned area on annual population λ (derived from step 2) to project proportional changes in population size separately by R&R index class over the next 30 years. Because the effect of cumulative burned area was confounded by the interaction with precipitation, we generated projections under normal (50th percentile), below-average (25th percentile), and above-average (75th percentile) levels of precipitation from spring through fall. We assumed a stable population ($\lambda = 1.0$) at the start of projections in order to better mimic environmental conditions facing sage-grouse in the absence of wildfire. Starting population size for projections was based on the mean of the 2014 lek counts within each R&R class, and subsequent annual changes in population size were expressed as a proportion of the population in 2014.

Sage-grouse populations under normal precipitation conditions declined steadily, resulting in 48, 52, and 30 percent of grouse in high, moderate, and low R&R leks, respectively, projected to remain by 2044 according to the 50th percentile parameter (median) of the posterior probability distribution (fig. 11A). Sage-grouse populations declined more sharply under below-average precipitation conditions, for which 36, 38, and 22 percent of grouse in high, moderate, and low R&R leks, respectively, were projected to remain by 2044 on a median basis (fig. 11B). In contrast, sage-grouse populations in high and moderate R&R leks remained stable under above-average precipitation conditions through approximately 2025 on a median basis, and some upper percentile distributions showed some population growth. However, high and moderate R&R leks began to decline after 2025, and only 67 and 71 percent, respectively, remained by 2044. Population decline was invariant to higher precipitation for low R&R leks, and only 40 percent remained by 2044 (fig. 11C).

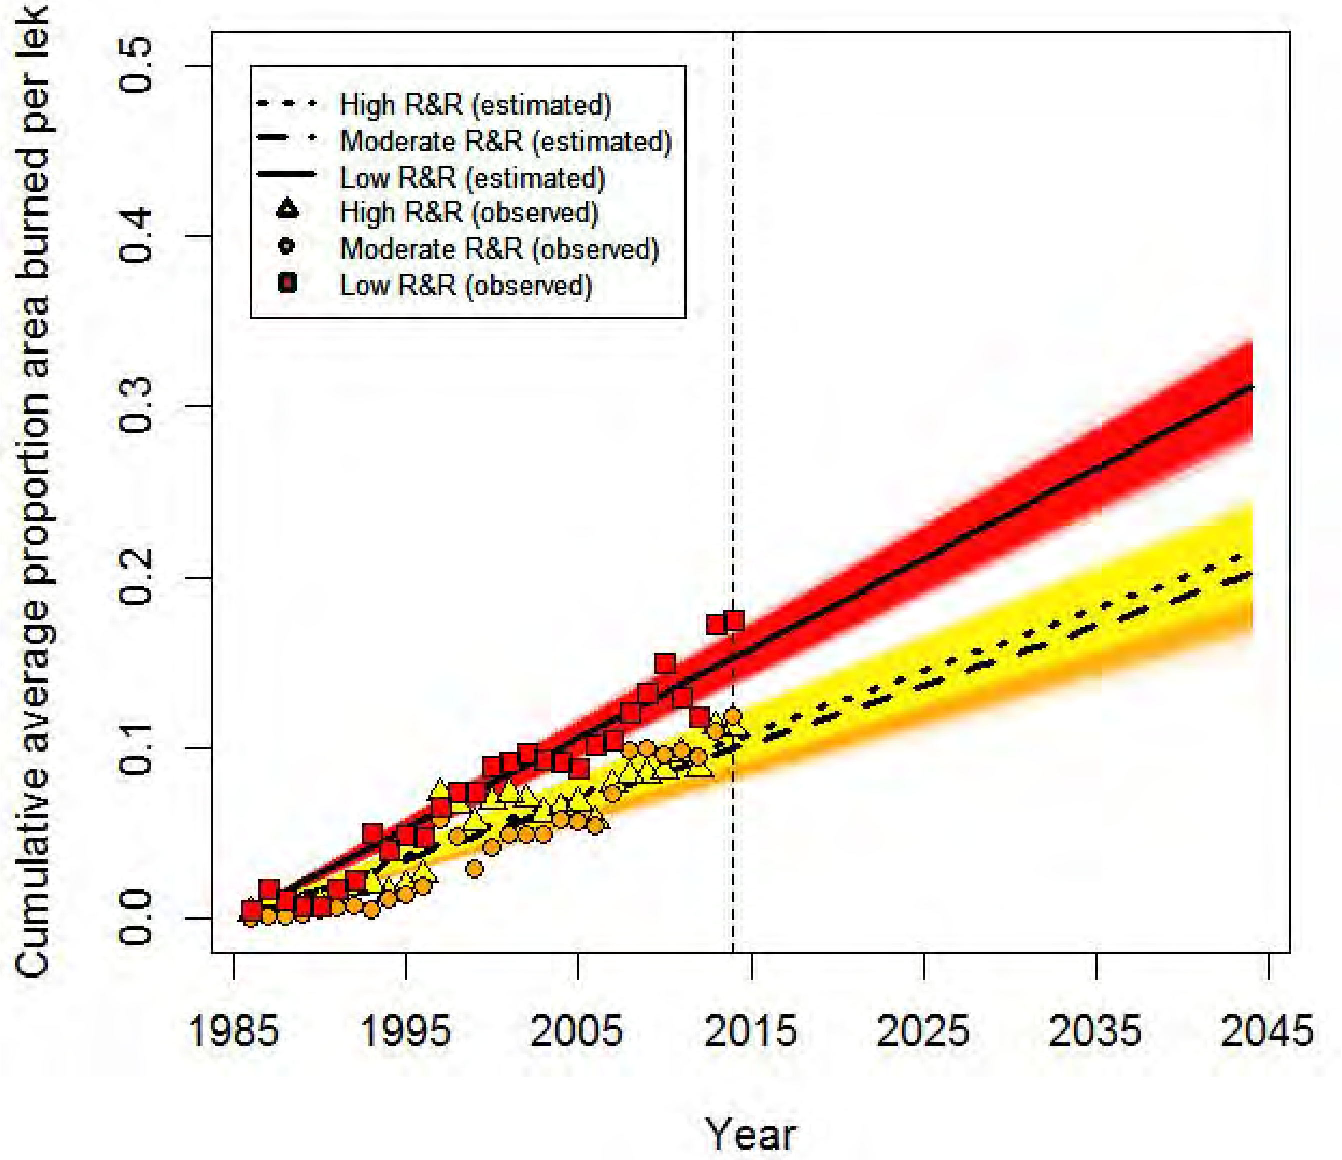

Figure 10. Observed and predicted changes in cumulative burned area over time by R&R class. Y-axis values represent the average proportion of a 5 km circular lek buffer.

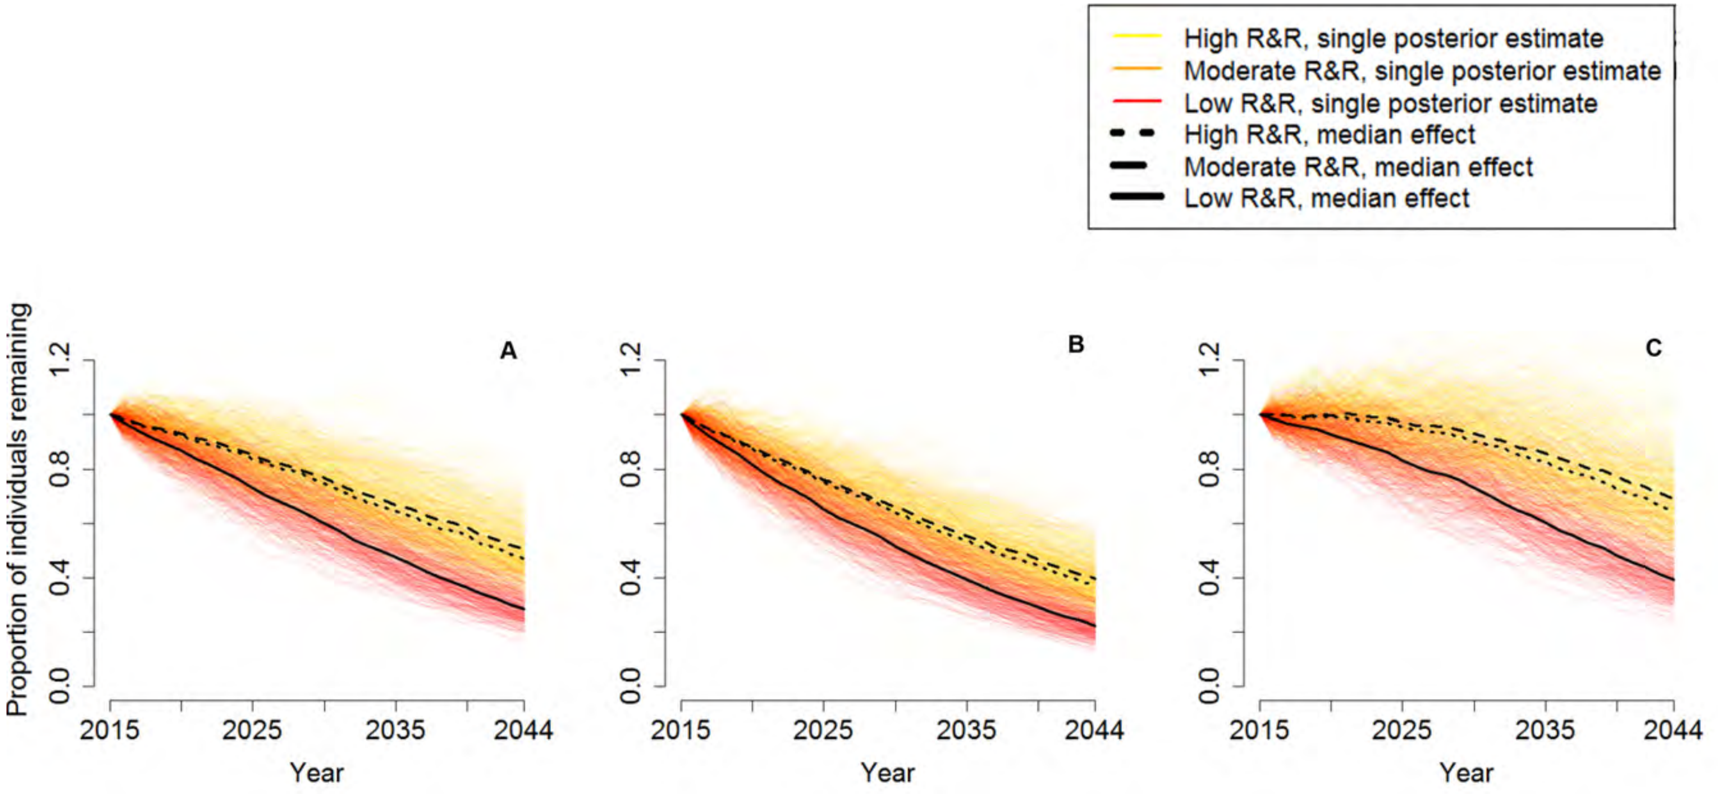

Figure 11. Thirty year predictions for proportion of sage-grouse populations remaining in the Great Basin given modeled effects of cumulative fire on rates of change under projected median (50th percentile; A), low (25th percentile; B), and high (75th percentile; C) amounts of precipitation during spring, summer, and fall.

Management Scenarios

Slowing forecasted population declines of Great Basin sage-grouse over the next 30 years may depend on intensity of fire suppression efforts in population ‘core areas’ and long-term patterns of precipitation (fig. 12). On a median basis, based on our simulations, reducing the rate of annual cumulative burned area by 25 percent in defined ‘core areas’ under all three modeled precipitation conditions did little to prevent population declines, and trajectories tracked those outside core areas where models allowed wildfires to continue to burn at the original modeled rate. However, reducing the cumulative burned area by 75 percent substantially slowed the rate of population decline under below-average precipitation conditions, stabilized population growth under normal precipitation conditions, and resulted in population growth under above-average precipitation conditions. Near complete fire suppression (99 percent) in core areas resulted in slightly increased population growth under all precipitation conditions on a median basis, especially for normal and above-average precipitation.

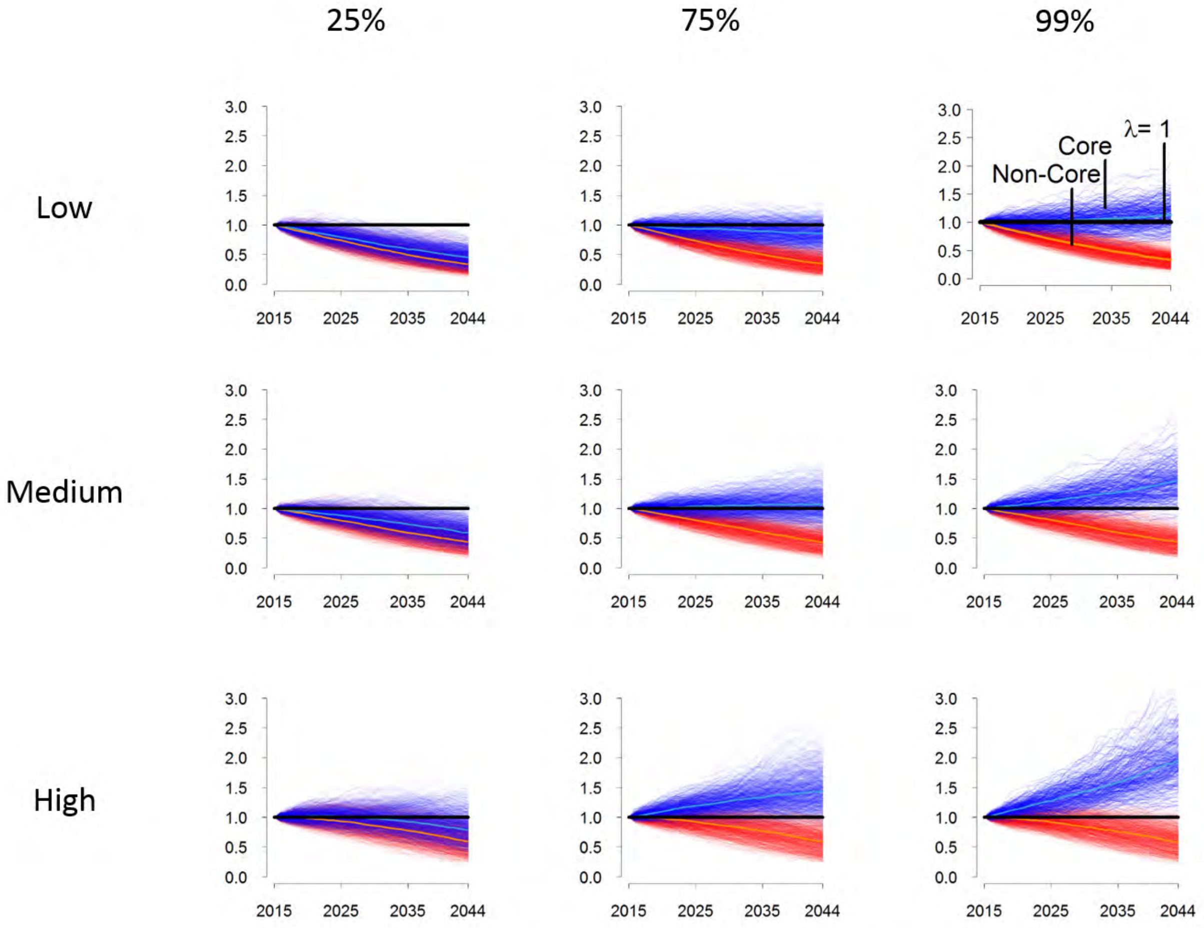

Figure 12. Examples illustrating projected sage-grouse population rate of change (λ) over the next 30 years under example management scenarios of 25, 75, and 99 percent reductions in annual average cumulative burned area within 5 km of lek sites under low, median, and high amounts of precipitation. Solid black line indicates stable population growth (λ = 1.0).

Interpretation and Conclusions

We quantified relatively long-term effects of wildfire and precipitation on sage-grouse population growth across the Great Basin, a significant proportion of the species range. Our results indicate that wildfire has persistently and negatively impacted sage-grouse population growth over the past three decades. Although wildfire is a natural process in sagebrush ecosystems, burn frequency and size of wildfires within the boundaries of the hydrographic Great Basin have increased artificially over the past few decades in response to the range expansion of invasive annual grasses (that is, primarily cheatgrass native to Eurasia) and changes in land-management practices (Baker, 2006, 2011; Brooks and others, 2015; Ielmini and others, 2015). However, trends in burn frequency, wildfire size, and other attributes have been shown to vary substantially across the range of sage-grouse (Brooks and others, 2015). Within the Great Basin, wildfire is highly probable when cover of annual grass increases to values greater than 45 percent (Link and others, 2006; cited by Miller and others, 2011), and a large majority of sagebrush ecosystems within the Great Basin are at high risk of wildfire if cheatgrass expansion continues at its unfettered pace (Suring and others, 2005; cited by Miller and others, 2011). Importantly, evidence of the chronic effect suggests that the adverse impacts associated with wildfire on sage-grouse populations are primarily driven by replacement of sagebrush following fire to invasive grasses. These findings indicate that model-predicted increases in cumulative burned area (that is, wildfire-scars) over the next 30 years will have significant negative impacts on sage-grouse habitat and long-term sage-grouse population trajectory.

Given current rates of cumulative burned area within 5 km of leks, model-based projections indicate continued declines for sage-grouse in the Great Basin over the next three decades under most scenarios. Across all R&R classes within the Great Basin, we projected a median of 44 percent (95-percent confidence limit; 22 to 69 percent) of current sage-grouse population numbers will remain by the mid-2040s. Our projections are similar to those of another recent study conducted across the four sage-grouse management zones within the Great Basin, which projected a 50-percent reduction (range 32−60 percent) in carrying capacity (a surrogate for population size) by 2043 (Garton and others, 2015). These consensus findings were reached despite distinctly different methodologies between these studies. For example, our study employed Bayesian inferences derived from individual lek complexes modeled with density-dependence, wildfire, and precipitation covariates while implementing random effects to account for random variation among site and year. Because these environmental conditions (that is, wildfire and precipitation) often change over time and can demonstrate cyclical patterns (Fedy and Doherty, 2011), our modeling approach allowed for temporal variation in rate of change as a function of short-term changes in those environmental factors over the past 30 years. In other words, our population rate of change was not constrained to fit a linear time trend. However, our 30-year projections were based on predicted average annual changes in cumulative burned area over time (that is, linear change) under different precipitation scenarios. In contrast, Garton and others (2015) applied maximum likelihood estimates derived from larger regional clusters of leks modeled with density-dependence and temporal (that is, year) effects, instead of environmental covariates. Year effects also can serve as a proxy for environmental conditions that change over time. Thus, similar projections among studies, coupled with exceptional fit of our model, indicate that wildfire and precipitation patterns explain temporal patterns in sage-grouse population size in the Great Basin. Although estimation of growth rate is sensitive to variation in absolute population size relative to carrying capacity and cyclic dynamics (May, 1974), similar conclusions reached by both studies indicate that estimated effects are not spurious artifacts of a specific modeling technique.

Sage-grouse in the Great Basin essentially inhabit a cold desert where ecosystem productivity is tied strongly to water availability (Noy-Meir, 1973). It follows that periods of above-average precipitation result in food and cover resources that boost survival of young sage-grouse and contribute to population recruitment (Blomberg and others, 2012; Guttery and others, 2013). Precipitation supports moisture recharge of upland mesic sites where forbs and invertebrates become abundant as food for young grouse (Casazza and others, 2011). Thus, precipitation may provide a population-level buffer against subsequent periods of drought, where prolonged drought is likely to have deleterious impacts on population persistence, independent of wildfire. In our study, sage-grouse population growth responded positively to increases in total precipitation during spring, summer, and fall months, supporting grouse reproduction. However, this positive effect was counteracted as cumulative burned area in relation to leks increased across the Great Basin, and was nullified where burned areas were the largest. Blomberg and others (2012) found a similar pattern at a local study site located within central Nevada. Hence, wildfire acts to negate the positive effects of cyclically favorable weather on sage-grouse population growth and appears to do so across multiple spatial scales.

Our modeling approach has two informative and novel aspects. The first of which is our spatially explicit incorporation of different recovery times for sagebrush with range-wide concepts of resilience and resistance that are currently a cornerstone of sagebrush ecosystem management. Habitat in the low R&R comprises approximately 40 percent of all habitat with mapped R&R values in the Great Basin, and an ecosystem that is highly susceptible to cheatgrass invasion following disturbance. Accordingly, current R&R-based management strategies call for protecting intact low R&R habitat "of high conservation value" from wildfire, and enhancing R&R in moderate and high R&R habitats in the early stages of cheatgrass invasion where restoration success is high because, in part, of increasing cover of perennial grasses and forbs and reducing large-woody fuel loads such as encroaching pinyon-juniper (Chambers and others, 2014a, 2014b). Our model-simulated conversion of burned habitat with low R&R to a permanent burn-scar integrates the rather high likelihood of a hysteretic transition to a cheatgrass-invaded state without intensive (and sometimes ineffective) management intervention. It follows that wildfire had the most substantial impact on sage-grouse inhabiting these habitats where projected population declines were greatest.

However, these R&R based projections also predicted 30-year declines for sage-grouse inhabiting moderate and high R&R habitats. Although moderate and high R&R habitats may recover relatively quickly in ecological time and restoration of sagebrush ecosystems are thought to have a high likelihood of success (Chambers and others, 2014a, 2014b), our findings suggest that wildfires within these habitats still can be harmful to sage-grouse survival and recruitment, especially if wildfires increase in size and frequency. Hence, relatively fast ecosystem recovery times in moderate and high R&R habitats under the current burn trends in the Great Basin may be asynchronous with sage-grouse demographic response to post-wildfire recovery of sagebrush. Management of wildfire in sagebrush from a perspective of plant-soil dynamics and disturbance regimes can benefit from a greater understanding of sage-grouse demographic responses to wildfire provided by our modeling.

The second informative and novel aspect of our approach stems from our example management scenarios, which simulated focused reductions in cumulative burned area near leks within sage-grouse 'core areas' across the Great Basin. These areas are most meaningful to sage-grouse based on response indices of habitat suitability and abundance (Doherty and others, 2015). For example, high resolution maps depicting habitat suitability for sage-grouse have been developed recently in Nevada and northeast California (Coates and others, 2014). Core areas calculated in this Nevada and California region overlap with approximately 20 percent of overall sage-grouse habitat (48 percent of high quality) but encompass about 90 percent of the males counted. It follows that targeted fire suppression in these core areas could help conserve large blocks of the ‘best’ areas for sage-grouse in the Great Basin. A straightforward calculation between males counted per hectare within core versus non-core areas, revealed an approximate 32.8-fold increase (3,180 percent increase) in ‘return’ by focusing on core opposed to non-core areas, and a 4-fold increase (298 percent increase) in return compared to random area of sage-grouse. In our example scenarios, reducing cumulative burned area per year by 25 percent in core areas under current regimes of median precipitation slows, but does not halt, projected rates of overall sage-grouse decline based on the 50th percentile of the posterior distributions of model derived parameters. However, reducing this area by 75 percent in core area under the current median or below average precipitation regimes may result in locally stable sage-grouse populations.

Importantly, our analysis incorporated recovery times as a function of their corresponding R&R index values. Thus, reduction in cumulative burned area can be achieved through management actions aimed at fire suppression as well as those that accelerate sagebrush recovery. We recognize that federal wildfire managers have reported that 97 percent of fires burned less than 1,000 acres of area, which may have been the result of initial attack fire suppression activities, and less than 1 percent were greater than 10,000 acres (Havlina and others, 2015). Although additional modeling would help us achieve reliable estimates of suppression rates and, perhaps, understand relationships between fire suppression rates versus burned areas in the Great Basin, increased suppression could lead to a significant reduction in cumulative burned area if potentially large wildfires (that is, mega-wildfires) are suppressed before they grow to unmanageable sizes. Importantly, approximately 32 percent of the estimated sage-grouse population within core areas (based on the maximum of lek counts between 2009 and 2014) is comprised primarily of low R&R habitat within 5 km of leks. Because these sites are highly susceptible to invasive grass following wildfire and, thus, permanent loss of sagebrush, management actions focused on suppression and protection should be most effective. However, it follows that core area leks surrounded by moderate or high R&R may benefit from recovery actions, as well as suppression. This is important because sage-grouse core areas comprised 35 and 39 percent of high and moderate R&R classes, respectively. It is also important to recognize that the predicted ‘success’ of reducing cumulative burned area varies with amounts of precipitation. Although climate models predict future increases in winter precipitation in latitudes above 40°, the Great Basin as a whole is predicted to receive lower precipitation in upcoming years (Intergovernmental Panel on Climate Change, 2014; Schlaepfer and others, 2014). Thus, predicted outcomes of increasing sage-grouse populations with reductions of cumulative wildfire in core areas under high precipitation conditions will likely be most effective in northern areas where R&R is relatively high and conditions generally are colder and wetter. However, reductions may be less effective in more southern areas of the Great Basin if climate model predictions hold.

Several caveats need to be considered when interpreting or implementing our results. First, recovery times specific to R&R classes did not take implemented restoration efforts into account (for example, Emergency Stabilization and Rehabilitation; Pilliod and Welty, 2013). However, restoration success is highly variable (Arkle and others, 2014), and often dependent on local conditions (for example, wet sites with established perennial grasses) or intensity of restoration (for example, drill seeding) (Knutson and others, 2014). Thus, modeling restoration efficacy and success was beyond the scope of our Great Basin-wide analysis of wildfire effects on sage-grouse, but may contribute to additional variation in sage-grouse demographic response to wildfire. Similarly, post-wildfire recovery times for sagebrush can vary widely along elevation and precipitation gradients across the species’ range. For example, Baker (2011) estimated that post-fire recovery times in mountain big sagebrush communities can take either fast (25–35 years) or slow (75–100 years) tracks for recovery. In contrast, recovery in arid Wyoming big sagebrush communities can be more prolonged (for example, 50–120 years, Baker, 2006). The temporal duration of our time series (that is, 30 years) precluded testing of different recovery times to complete pre-wildfire conditions, so we focused on recovery times for minimal resources necessary (that is, 20 percent sagebrush return) to meet some sage-grouse life history requirements based on published estimates. Notably, our slower 'decelerated' recovery model showed less support from the data than the 'normal' recovery model. Collection of field-data to quantify a chronological sequence of wildfire-related vegetation change or recovery among R&R index classes could prove beneficial to these and other analyses, and is currently underway.

The second caveat is that our analysis did not parse the effects of prescribed fire versus wildfire, or potential beneficial effects of fire in sagebrush ecosystems. As stated previously in this report, most studies of fire effects on sage-grouse and their habitat have focused on prescribed fire. Connelly and others (2000a) described a significant decline in lek attendance following a prescribed fire that removed nearly 60 percent of existing sagebrush, while other studies have reported prescribed fire-related reductions in forage availability and quality (Nelle and others, 2000; Rhodes and others, 2010). However, low intensity prescribed fire followed by higher-than-normal annual precipitation has been associated with increased flowering and extended phenology of several forb taxa selected by sage-grouse and their chicks (Wrobleski and Kauffman, 2003). In addition, approximately 66 percent of sage-grouse leks tend to occur in sagebrush habitats with low to moderate R&R that are being subjected to larger and more persistent wildfire scars according to our models. Yet, this pattern may not pertain to montane habitats at high elevation that our model did not specifically measure (Brooks and others, 2015), as well as other areas outside the Great Basin but within the range of sage-grouse with a preponderance of high R&R habitats (for example, sage-grouse management zones I and II). Historical wildfire may have been beneficial in these wet and productive montane habitats where resilience is intrinsically high (Brooks and others, 2015). Suppression of wildfire at higher elevations also may have the unintended consequence of facilitating encroachment of pinyon-juniper woodlands across the Intermountain West (Miller and Rose, 1999; Miller and others, 2013), which decreases resilience to wildfire (Chambers and others, 2014a) and substantially reduces sage-grouse habitat suitability (Casazza and others, 2011; Baruch-Mordo and others, 2013).

Finally, several aspects of our empirical modeling and future projections incorporated 'best case' assumptions that require additional discussion of caveats. First, our 30-year projections began with stable populations ($\lambda = 1.0$) without explicit incorporation of modeled density-dependent or climatic parameter estimates. Rather, and for the sake of focusing on the primary question of interest (that is, fire), we drew from posterior distributions of parameter estimates for the effect of burned area that accounted for variation in density and precipitation. Second, we modeled and projected increases in cumulative burned area as a linear function with time (year). Notably, empirical data points for burned area near the end of the time-series fell outside the upper tail of the 95-percent prediction interval (fig. 10), which appears to take an exponential form. We chose to conservatively model a linear relationship owing to uncertainty in future rates of fire suppression and restoration efficacy.

A third point that likely led to more optimistic predictions was our estimation of post-fire recovery rates for R&R index classes based on meta-analyses for mountain and Wyoming big sagebrush communities, where we assumed mountain big sagebrush comprised high and moderate R&R, and Wyoming big sagebrush comprised low R&R. Recovery for leks classified as high and moderate R&R could be biased high if they also comprised some proportion of Wyoming big sagebrush. Moreover, our 'recovered' criteria of 20 percent return of pre-fire sagebrush cover only meets partial life history requirements, and may be too low to maintain adequate sage-grouse survival or recruitment. High sagebrush cover is not always associated with winter and brood rearing habitat, but large expanses of intact sagebrush often associates with high nesting success, and tall sagebrush is critical for providing forage in deep snow conditions (Connelly and others, 2000b; P. Coates and M. Casazza, U.S. Geological Survey, unpub. data, 2008).

We additionally defined burned area based on MTBS severity classes most indicative of vegetation change resulting from fire (that is, severity class ≥ 2), yet MTBS severity classes are prone to errors of omission and commission. A recent analysis of MTBS fires within big sagebrush, black and low sagebrush, and grassland vegetation types across the range of the sage-grouse indicated that 70 percent of fires were classified using "initial assessment" imagery from the same growing season as the fire (typically a few months later) and the other 30 percent used "extended assessment" imagery from the first growing season after the fire (Brooks and others, 2015). In areas where the latter imagery is used, vegetation recovery prior to the imagery acquisition in the following growing season can result in lower dNBR values than if initial assessment imagery were used. Among all the 30-m MTBS pixels within the fires evaluated in Brooks and others (2015), initial assessment fires contained 13 percent fire-severity class 1 pixels, whereas extended assessment fires contained 35 percent fire-severity class 1 pixels. We do not know the specific proportions of initial versus extended assessment fires, and thus a potential underestimation of fire area is possible using the fires in this current study. However, by focusing on MTBS fires (that is, greater than 405 ha), we likely omitted approximately 5 percent of the total fire area that would have otherwise been represented by smaller fires (Eidenshink and others, 2007; Brooks and others, 2015). Thus, the absolute fire area values reported in the current study should be considered conservative underestimates. Departure from these 'best case' aforementioned assumptions or realization of caveats would likely lead to more rapid projected population declines and accentuated negative effects on sage-grouse.

Using large-scale datasets and well-founded R&R concepts, our study identifies clear and predictable patterns of major sagebrush habitat loss associated with cumulative wildfire effects. R&R concepts, which has often resulted in major losses of sagebrush habitat. Importantly, even under 'best case' assumptions, we demonstrate that adverse impacts associated with accelerating positive feedbacks between wildfire and invasive annual grass on sage-grouse populations are non-trivial in the Great Basin and, under some conditions, wildfire can nullify positive effects on sage-grouse that are normally associated with increased precipitation. Balancing management resources between post-wildfire restoration actions versus those of fire suppression is a challenging task facing land and wildlife agencies. Dependent on sagebrush ecosystem concepts and population responses of sage-grouse, our work provides an initial modeling framework and decision support tool to help land and wildlife managers sustain sage-grouse populations within the Great Basin.

AN INTEGRATED RANGELAND FIRE MANAGEMENT STRATEGY

Final Report to the Secretary of the Interior

May 2015

This Page is Intentionally Blank

March 3, 1849

THE DEPUTY SECRETARY OF THE INTERIOR
WASHINGTON

MAY 19 2015

Memorandum

To: Secretary

From: Deputy Secretary

Subject: SO 3336 – The Final Report: *An Integrated Rangeland Fire Management Strategy*

Secretary Order 3336, *Rangeland Fire Prevention, Management and Restoration* (Order), established a Rangeland Fire Task Force (Task Force) with the charge to present a final report no later than May 1, 2015. As Chair of the Task Force, I am pleased to present for your review our report, entitled, "*SO 3336 - The Final Report: An Integrated Rangeland Fire Management Strategy.*"

The Strategy outlines activities for implementation prior to both the 2015 and 2016 Western fire seasons. It also outlines longer-term actions to implement the policy and strategy set forth in the Order, including the continued implementation of approved actions associated with the Strategy.

On behalf of the Task Force, I recommend you accept and approve these actions and direct the entities identified as the Responsible Parties for each action proceed with implementation.

Concur:

Sally Jewell
Sally Jewell

MAY 19 2015
Date

This Page is Intentionally Blank

Dear Reader,

A draft version of this report entitled, Draft Report, *A Set of Longer-Term Actions and Activities*, was available for public comment on April 2, 2015. As part of the outreach in developing this Strategy, the Department of the Interior held government-to-government tribal consultations and additional outreach to other stakeholders and partners. The actions identified in the Final Report, *An Integrated Rangeland Fire Management Strategy,* incorporates comments received from a wide range of stakeholders and partners and from the tribal consultation meetings. In an effort to enhance the coordination between related activities, reduce overlap, and efficiently utilize federal and other resources, some of the proposed actions in the April 2, 2015 Draft Report were consolidated, moved, or otherwise revised. As a result, the actions identified in the Final Report may differ from those identified in the April 2, 2015 Draft Report.

Sincerely,

The Rangeland Fire Task Force

FUNDAMENTAL PRINCIPLES

Promote "All Hands, All Lands" Management

Employ a Risk-Based Approach

Improve Application of Science and Technology

Monitor and Adapt for Success

An Integrated Rangeland Fire Management Strategy (the Strategy) is intended to improve the efficiency and efficacy of actions to address rangeland fire, to better prevent and suppress rangeland fire, and improve efforts to restore fire-impacted landscapes. These activities involve targeted investments to enhance efforts to manage rangeland fire in specific portions of the Great Basin region, consistent with efforts of tribal, state, and other lands, and in keeping with the trust responsibilities to Indian tribes and other statutory obligations.

Essential to the success of the Strategy is improving efforts to work on a landscape-level and better employing science and technology to target areas of high priority for preventing, suppressing, and restoring fire-impacted landscapes using a risk-based approach. Through application of "All Hands, All Lands" management, increased collaboration among Federal, state, tribal, and local officials, natural resource managers, and the fire community can improve the efficiency and effectiveness of the overall rangeland fire management effort. A commitment to monitoring changes in resource conditions to evaluate the effectiveness of different management strategies will improve learning and, through adaptive management, increase the success of the Strategy.

Better managing rangeland vegetation and reversing the spread of invasive, non-native grasses, such as cheatgrass, is critical to breaking the invasive species-fire cycle that has contributed to the increased frequency and intensity of rangeland fires. By planning projects at a landscape scale to reduce and control invasive species and rapidly restore lands impacted by fire to native vegetation, progress in protecting and restoring the iconic sagebrush-steppe ecosystem for the benefit of all can be achieved.

Introduction

The Department of the Interior (DOI) manages millions acres of public land across the United States. These lands – and the many resources and services they provide – are for the benefit of current and future generations. The protection and recovery of imperiled species of plants and animals and the ecosystems upon which they depend is one of DOI's management objectives across these lands.

In the Great Basin region – including portions of the states of Oregon, Idaho, Utah, Nevada, and California – a significant portion of the landscape administered by the Bureau of Land Management (BLM) is comprised of the sagebrush-steppe ecosystem. This ecosystem is one of the most imperiled in the United States.[1] The accelerated invasion of non-native annual grasses—in particular cheatgrass and medusahead rye—and the spread of pinyon-juniper into the sagebrush-steppe ecosystem, coupled with the effects of intensified drought and climate change, are creating conditions that are leading to larger, more intense rangeland fires across the Great Basin.

Cheatgrass (*Bromus tectorum*) is of particular concern. It is one of the most aggressive, non-native species that thrives in areas disturbed by wildfire and other land-use activities, and can dominate large areas across the landscape. The plant dries early in the summer and remains highly flammable throughout the fire season creating dangerous conditions on the ground. When fire strikes, firefighter safety is the paramount concern because escape routes and safety zones are difficult to establish due to rangeland fire's rapid spread. With high temperatures, low relative humidity, and strong winds, rangeland fires can spread quickly and produce flame lengths that often prevent direct attack. A wind-driven rangeland fire in cheatgrass can easily burn thousands of acres in an hour, destroying homes, livelihoods, and habitat along the way. If left unchecked, cheatgrass often invades sagebrush habitat after rangeland fires, creating conditions for more frequent, intense fires in the future. For these reasons, the "fire-and-cheatgrass cycle" is a particularly difficult challenge for land managers.

Figure 1. Fire-Cheatgrass-Cycle

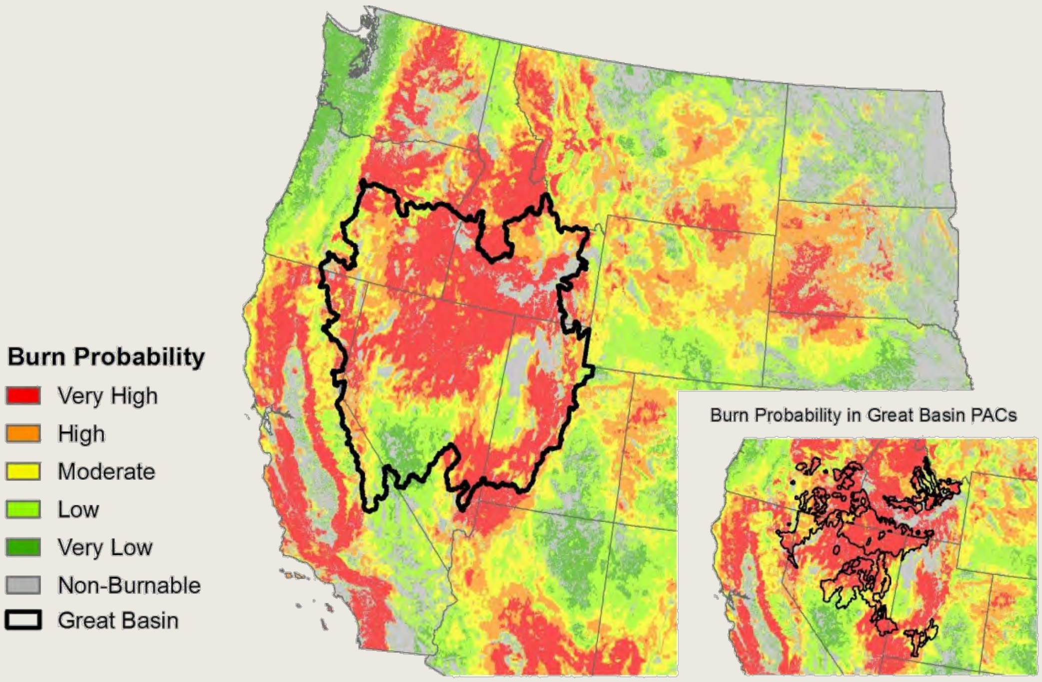
The increasing frequency and intensity of rangeland fires and conversion of sagebrush-steppe ecosystems to invasive annual grasses poses a major threat to ranchers, local communities, and others who live and work on the iconic sagebrush-steppe landscape and depend on these lands and resources to sustain their livelihoods and quality of life. This unique American landscape supports energy development, ranching, and outdoor recreation such as hunting, hiking, and camping. According to BLM, over 1,000 communities are near sage-grouse habitat, and many of the Nation's treasured cultural and archaeological sites dot the sagebrush-steppe landscape.

More intense rangeland fires also pose an increased threat to the more than 350 species of birds, plants, and animals, including the greater sage-grouse that rely on this critically important ecosystem.

In 2010, the U.S. Fish and Wildlife Service (FWS) identified the invasion of non-native annual grasses and the loss of habitat, from the increased frequency and intensity of wildfire in the Great Basin, as the primary threat to the greater sage-grouse in that portion of its remaining range. The threat is particularly great in places identified as primary areas of conservation (PACs) where greater sage-grouse experts have indicated that protecting existing habitat is critical to the birds' continued viability[2]. The FWS is currently considering whether the species warrants protection under the Endangered Species Act.

Figure 2. Extent of the fire probability in Great Basin sagebrush-steppe habitat (most current information as of May 2015)



---

[2] U.S. Fish and Wildlife Service. 2013. Greater Sage-grouse (*Centrocercus urophasianus*) Conservation Objectives: Final report. US Fish and Wildlife Service, Denver, Colorado, February 2013.

Nationally, annual average acres burned by wildfire rose from 2.9 million acres per year in the 1980s to 3.3 million in the 1990s, and then jumped to an average of 6.6 million acres burned per year from 2000 through 2009. Since the 1960's when accurate recordkeeping began, 8 of the 10 worst fire seasons, for national acres burned, have occurred since 2000. This trend is particularly problematic for the sagebrush-steppe ecosystem, where the pace of fire dwarfs the rate of recovery. During just 3 fire seasons from 2012 to 2014, nationally nearly 17 million acres burned, of which nearly 3.8 million were greater sage-grouse habitat in the western states.

The increased frequency and impact of rangeland fires necessitates an enhanced approach to address rangeland fire in the Great Basin and other sagebrush-steppe areas. The DOI, U.S. Department of Agriculture (USDA), tribes, other Federal, state, and local agencies, private industry, and various non-governmental organizations (NGOs) are working to meet the challenge to address rangeland fire more effectively. In particular, they are working together to better prevent fires, improve efforts to suppress fires when they occur, and to increase the effectiveness of efforts to restore landscapes impacted by fire. Reducing the frequency and intensity of rangeland fires is essential to protect the safety of communities in the sagebrush-steppe landscape and the livelihoods of their residents. In addition, a more effective strategy for addressing the threat of rangeland fire is critical to reducing the risk it poses to the continued viability of the greater sage-grouse, an important component of the overall strategy to conserve the species across its range.

Departmental Response

> ***Protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, priority greater sage-grouse habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department.***

Recognizing the conditions on the land and the need to protect and conserve the sagebrush-steppe ecosystem and greater sage-grouse habitat, DOI convened *The Next Steppe: Sage-Grouse and Rangeland Fire in the Great Basin* Conference (*Next Steppe* Conference)[3] in November 2014. The *Next Steppe* Conference brought together leading scientists and researchers in restoration, fire, and invasive species ecology, and wildland fire management, key policymakers, land managers, natural resource managers, fire managers and firefighters, tribal, and community leaders, and other stakeholders to discuss how to address the escalating threat of rangeland fire. The *Next Steppe* Conference provided important information on the means to improve rangeland fire prevention, suppression, and the restoration of fire-impacted landscapes, and provided an additional and important source of knowledge, information, and expertise. The *Next Steppe* Conference was an opportunity to build upon the experiences and successes of addressing rangeland fire prevention, suppression, and restoration efforts to date, including the *National Cohesive Wildland Fire Management Strategy* (Cohesive Strategy) to inform an improved effort to reduce the threat of rangeland fire in the future.

Following the *Next Steppe* Conference, on January 5, 2015, DOI Secretary Jewell signed *Secretarial Order 3336 - Rangeland Fire Prevention, Management, and Restoration* (the Order). The Order emphasizes that rangeland fire management is a *critical priority* for "protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, greater sage-grouse habitat, while maintaining safe and efficient operations." The Order also emphasizes that the "allocation of fire resources and assets before, during, and after wildland fire incidents will reflect this priority." The Order directed the creation of a Rangeland Fire Task Force to deliver a science-based comprehensive strategy to reduce the threat of large-scale rangeland fire to greater sage-grouse habitat and the sagebrush-steppe ecosystem, and set forth guiding principles and overarching expectations in Sections 5 and 6 of the Order, respectively. Elements of the Strategy include effective rangeland management, fire prevention, fire suppression, and restoration at a landscape-scale.

The Order directed the Task Force to develop and deliver an Implementation Plan, Initial Report, and Final Report to the Secretary. The *Implementation Plan*, completed and issued on February 1, 2015, outlined the work plan for implementing the Order. The Initial Report, *S.O. 3336 – The Initial Report: A Strategic Plan for Addressing Rangeland Fire Prevention, Management, and Restoration in 2015*, delivered to the Secretary on March 1, 2015, identified specific actions for

---

[3] For more information on the Next Steppe Conference please go to: http//www.nifc.gov/fireandsagegrouse/

DOI, and its partners, to undertake prior to the onset of the 2015 Western fire season to improve the efficiency and effectiveness of rangeland fire management efforts (see Appendix B).

Building on the Initial Report, this Final Report, *An Integrated Rangeland Fire Management Strategy* outlines an approach for improving the efficiency and efficacy of actions to better prevent and suppress rangeland fire and to improve efforts to restore fire-impacted landscapes both including and beyond 2015 (see Appendix B). These activities involve targeted investments to enhance efforts to manage rangeland fire in specific portions of the Great Basin region, based on relative resilience and resistance to fire, consistent with efforts on tribal, state, and other lands, and in keeping with the trust responsibilities to Indian tribes and various statutory obligations. The actions in this Final Report primarily focus on the needs of the Great Basin, but the strategies developed (or lessons learned) will be applied range-wide where there is benefit to sagebrush-steppe habitat and greater sage-grouse.

The DOI held a listening session and two government-to-government tribal consultations and considered feedback from tribal leaders in developing the actions and activities included in the Strategy. In addition, DOI hosted two conference call sessions to answer questions on development of the Strategy and invited partners, stakeholders, and the public to submit formal public comment on the draft reports. Tribes, states, and partner agencies provided input to the task groups responsible for drafting the actions incorporated into the Strategy. Federal partner agencies include the USDA's Forest Service (USFS) and Natural Resources Conservation Service (NRCS), and the Department of Homeland Security's (DHS) U.S. Fire Administration (USFA).

Continued active engagement, involvement and input from states, tribes, stakeholders and other partners is critical as we move forward. The goals for engagement related to this Order are to (1) explain the Order, its genesis, and its implementation; (2) continue state, tribal and stakeholder involvement in implementing the Order; and (3) gather and consider state, tribal and stakeholder input during implementation into the future. Implementation of the Strategy will take place in continued consultation with tribes and cooperation and coordination with other Federal, state, local, private partners, and NGOs.

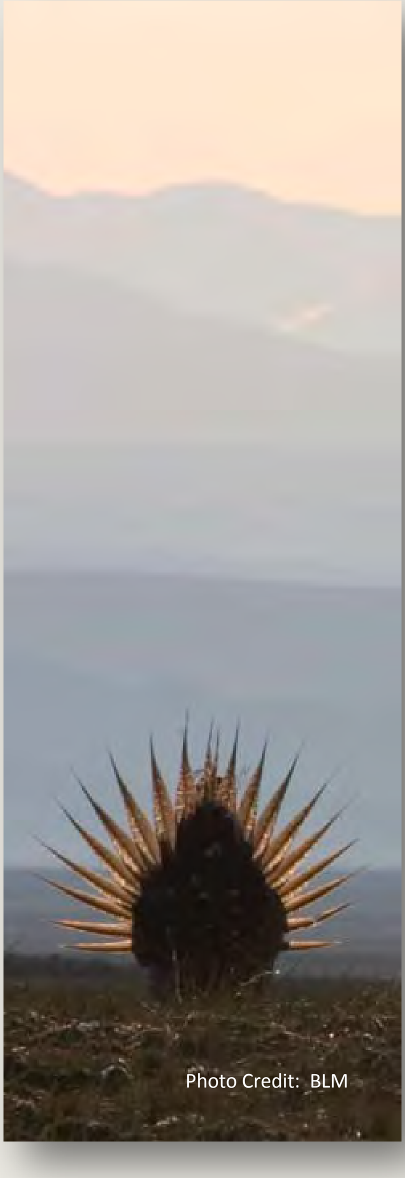

Photo Credit: BLM

The Strategy

The Strategy addresses all aspects of rangeland fire management, including improved fire prevention, enhanced fire suppression, and an increased emphasis on successful rangeland restoration. Key to the development and implementation of this Strategy are certain principles that are applicable to all aspects of rangeland fire and invasive plant species management; and, if properly applied, can significantly improve rangeland fire management and restoration efforts for sustainable sagebrush-steppe ecosystems.

Principles for Success

Work on a Landscape Scale

Photo Credit: NRCS

Protecting, conserving, and restoring healthy sagebrush-steppe ecosystems is a landscape-scale issue and requires a landscape-scale approach. A landscape-scale approach to management is one that emphasizes sustainability of entire ecosystems, integrates stakeholder collaboration, and addresses the present and possible future conditions of lands across ownerships. Since the sagebrush-steppe ecosystem crosses 11 western states and 2 Canadian Provinces, and has species such as the greater sage-grouse that range across this expansive area, it is important to conduct science and make management decisions at a larger scale. Use of this strategic, rather than opportunistic, approach will focus management actions that will result in more effective, cumulative efforts to maintain, restore, and sustain this important ecosystem.

The DOI agencies and their partners understand that short-term, isolated treatments alone do not result in long-term recovery or sustainability of a large landscape. Vegetation inventories, treatments, and preventative measures to reduce the risk of rangeland fire such as the appropriate use of herbicides, biological controls, biocides; prescribed fire, greenstripping, and fuel breaks; and the prioritization of efforts to restore fire-impacted landscapes, must be planned and conducted on a landscape-scale, across jurisdictional boundaries in collaboration with tribes, states and key stakeholders for lasting effectiveness. Thinking and planning holistically, and applying actions that take into consideration the needs of an entire ecosystem will result in a healthy sagebrush-steppe landscape that can support sustainable populations of greater sage-grouse.

Planning at a landscape-level can reduce the time and expense associated with developing management actions at multiple individual sites. Working at a landscape level can also facilitate and expedite National Environmental Policy Act (NEPA) analysis, permitting expeditious completion of individual projects that are associated with a larger landscape management plan by tiering to landscape-level environmental analysis. Time is of the essence in re-vegetating fire-scarred lands. For this reason, more efficient, timely, and strategic planning for restoration projects can reduce costs and expedite implementation of appropriate management measures to restore healthy landscapes.

Promote "All Hands, All Lands" Management

Just as wildfires know no boundaries, planning, projects, and collaborative work to address them must, with mutual agreement, cross ownership lines and jurisdictional boundaries to be effective. Embracing an "All-Hands, All-Lands" management approach and building on the goals of the Cohesive Strategy are essential to this concept. Further expansion of collaboration with other Federal, state, and local agencies, tribal governments, private industry, and NGOs to work smarter, leverage resources, and enhance effectiveness is vital to reducing the habitat lost improving the health of the sagebrush-steppe ecosystem and achieving social, economic, and ecological goals. Including tribes and state agencies in the identification of fuels (vegetation) management priorities and in aligning resources to leverage assets for fuels treatment can help further reduce fire risk.

Photo Credit: NRCS

An important "advance" in this regard is to bring together resource managers, biologists, and other scientists, and fire program leaders at all levels to identify ways in which they can help each other understand how to manage landscapes to reduce fuels and fire risk and improve restoration success of lands impacted by fire. For example, because reducing fuels – particularly the rapid spread of invasive species such as cheatgrass – is a critical part of the strategy for reducing future rangeland fires and protecting important habitat, it is important that vegetation management and habitat restoration (not simply building firebreaks or applying prescribed fire) be an integral part of the solution.

Addressing improper grazing practices, where they occur, can reduce the likelihood of non-native annual grass invasion. However, grazing can also be a tool which, when properly used, can help manage fuels at critical times. Technical support and incentives for livestock producers to work with Federal and state partners to implement targeted fuel treatments would capitalize on their knowledge and could align essential resources. Similarly, technical assistance and incentives for livestock producers and grazing permittees accelerate and increase the success of efforts to restore fire-impacted lands to native grasses, forbs, and sagebrush and help prevent cheatgrass and other non-native invasive species from becoming established.

Partnerships make it easier to work across agency and other jurisdictional boundaries, not just to expand treatments, but also to leverage funding, experience, capability, and knowledge about best management practices. Partnerships must go beyond improvements in collaboration among Federal land and resource management agencies and must be inclusive. Collaborative efforts should include groups with an interest and expertise in rangeland fire prevention, suppression, and restoration. At a minimum, the following groups will be invited to collaborate: the Western Governors' Association; the Western Association of Fish and Wildlife Agencies; Great Basin Landscape Conservation Cooperative; Intermountain West Joint Venture; Great Basin Fire Science Exchange; state wildland fire, wildlife, and agricultural agencies; Indian tribes, including incorporation of traditional ecological knowledge; scientists and researchers; local/rural fire departments and Rangeland Fire Protection Associations (RFPAs); weed collaboratives; native seed production organizations; soil and water conservation districts; NGOs, and the conservation community.

Employ a Risk-Based Approach

Management resources are limited; some lands will recover naturally, but many require active restoration. Not every acre can be effectively treated to prevent rangeland fires, nor can every acre impacted by fire be restored. Setting priorities for prevention, suppression, and restoration is essential to increase the efficiency of operations and the efficacy of treatments.

For this reason, the Strategy relies, in part, on the Fire and Invasive Assessment Tool (FIAT)[4] to assess the major threats to the sagebrush-steppe in order to conserve the greater sage-grouse and its habitat. "Resilience" and "resistance" to rangeland fire is the basis of FIAT. In simple terms, "resilience" is the ability of an area to recover from a disturbance, such as wildfire or drought. "Resistance" is the ability of an area of land to remain largely unchanged in the face of stress, disturbance, or invasive species. A resilient, resistant landscape will have integrity and be less susceptible to conversion to invasive annual grasses and landscape-scale, high-intensity fires and their effects.

---

[4] The purpose of the FIAT is to identify priority habitat areas and management strategies to reduce the threats to greater sage-grouse resulting from impacts of invasive annual grasses, wildfires, and conifer expansion. The FIAT is a process that uses the best available information from many disciplines including ecology, biology, soils, fire science as part of a strategic framework. The cornerstone of the FIAT protocol is recent scientific research on resistance and resilience of Great Basin ecosystems (Chambers, et al., 2014). The final FIAT process report was completed in June 2014 by the Fire and Invasive Assessment Team.

Applying these key concepts to vegetation management will contribute to sage-grouse habitat conservation and restoration and will support fire operations by helping to limit the size and dangers associated with fast-moving fires.

The BLM and partners, designated specialists, and land managers completed a landscape assessment process using the FIAT (see Appendix C). The teams' efforts culminated in five detailed assessments focused on how BLM and its partners can work together to protect the greater sage-grouse, and in turn, improve the health of the sagebrush-steppe ecosystem. The FIAT is not a one-time assessment, rather developed to incorporate new data and complete a reassessment as needed to inform management actions. The use of risk-based, landscape-scale tools, such as the FIAT, will help prioritize treatment areas to reduce fire risk as well as set priorities to strategically-guide the allocation and pre-positioning of resources for fire suppression and better align funding sources for post-fire restoration efforts.

Improve the Application of Science and Technology

Resistance/Resilience

The Difference

In simple terms, "resilience" is the ability of an area to recover from a disturbance, such as wildfire or drought. "Resistance" is the ability of an area of land to deflect the same kind of disturbances.

Inherent in the Strategy is recognition that a strong science foundation is fundamental to successful rangeland fire prevention, suppression, and restoration. As demonstrated by the development and application of the FIAT to guide future sagebrush-steppe and greater sage-grouse conservation efforts, improved coordination of science and research and field experimentation, testing and application of the products of this work is essential.

This includes continual improvement in integrating natural resource and fire management objectives in order to coordinate efforts toward achieving common overall goals and objectives, and more effectively using science to help identify, conserve, and create resilient and resistant landscapes for the long term. Innovative practices, supported by emerging science, need to move forward, be tested, and rapidly deployed where safe and effective to do so.

In addition, better use of technology to communicate key information quickly and simply to resource managers and wildland firefighting personnel, such as the location of previously identified resistant and resilient landscapes and high priority habitats, can improve the efficacy of firefighting and restoration efforts. Fire crews at the *Next Steppe Conference* spoke of the value of having maps of these areas readily available to them in the field as they make critical decisions regarding firefighting strategy. Existing technology, with geospatial capability such as tablets and smart phones, if made available to resource managers, incident commanders, and fire management officers, could speed the translation of science into management actions quickly and effectively at low cost.

Monitor and Adapt for Success

Photo Credit: SGI

SUCCESS MEANS

- Reducing acres of sagebrush lost to fire
- Reducing acres of sagebrush lost to invasive species
- Increasing acres of healthy sagebrush habitat to benefit human and natural communities

Established monitoring and metrics to evaluate the effectiveness of management actions must occur to determine the success of fire prevention, suppression, and restoration actions. Developing a monitoring and evaluation framework with protocols, standards, and capacity will provide compatible indicators, methods, and sample designs and ensure consistent data and data management, resulting in readily accessible and comparable data. Lessons learned from evaluations can be shared and inform changes to, (1) correct for ineffective management prescriptions, (2) respond to changes in resource conditions, (3) guide new science and research needs, and (4) address changes in management policy and direction. Monitoring and evaluation is an essential part of adaptive management and depends upon timely information, analysis, and learning.

Strategic application of new management techniques, improved use of risk analysis to set management priorities, and the translation of science and research findings into tools for easy use on the ground to prioritize prevention, suppression, and restoration efforts can help improve the efficacy and efficiency of rangeland fire management. However, we cannot be certain that we are achieving desired outcomes without careful monitoring and evaluation of our management efforts. This is an essential part of learning and central to the application of the adaptive management approach we will apply to better manage the sagebrush-steppe ecosystem and conserve the greater sage-grouse.

The key principles, (1) work on a landscape-scale, (2) promote “All Hands, All Lands” management, (3) employ a risk-based approach, (4) improve the application of science and technology, and (5) monitor and adapt for success**,** are fundamental to our ability to successfully implement the Strategy.

Success is effectively reducing the sagebrush-steppe acres lost to fire and invasive species in a safe and efficient manner, while increasing the sagebrush-steppe acres restored to a healthy condition. If successful, we can increase the habitat restored to a healthy condition for the greater sage-grouse and other sagebrush-steppe dependent species and assure that all communities associated with the sagebrush-steppe ecosystem realize the benefits.

Fire Prevention, Suppression, and Restoration

Improve Fire Prevention: Manage Vegetation to Reduce Fire Risk

Photo Credit: BLM

Invasive annual grasses, primarily cheatgrass, dominate about 25 million acres of the Great Basin. Cheatgrass contributes to the size and frequency of fires and directly threatens the habitat of the greater sage-grouse and other sagebrush-steppe dependent wildlife. Vegetation management at this scale is complex and requires aggressive and targeted application of both proven techniques and the rapid investigation and implementation of new practices to control cheatgrass and mitigate habitat impacts from unwanted rangeland fire. Land managers need tools to reduce cheatgrass while simultaneously restoring resilient sagebrush-steppe ecosystems that can withstand fire and resist re-invasion of cheatgrass or other invasive species. This work necessitates increased coordination and efficient use of NEPA procedures, partnerships, and funding, to increase capacity to treat more acres effectively. The goal is to protect, conserve, and restore greater sage-grouse habitat at a faster rate than it is lost to invasive species and rangeland fire. Effective strategies developed for early detection and rapid response (EDRR) and implemented in collaboration with a wide range of stakeholders, can help check the rapid expansion of invasive non-native species. Monitoring for success will continue to highlight what technique work most effectively and cost efficiently.

The expansion of native pinyon and juniper into sage-grouse habitat can also degrade the sagebrush-steppe ecosystem. Altered fire regimes allow pinyon and juniper to expand into long-established sagebrush-steppe ecosystems, where they out-compete native grass and understory vegetation and convert these areas to woodlands.

Vegetation treatments to reduce pinyon and juniper must consider the cultural importance of native vegetation to tribes, along with the need to restore sagebrush-steppe habitat. Generally, the treatments aim to remove younger trees that are expanding into sagebrush-steppe vegetation communities, while maintaining historic woodlands. Improved communication and partnership with tribes on management strategies to conserve traditional uses and recognize cultural values is essential to finding an appropriate balance to this issue.

Target Suppression: Protect Remaining Priority Habitat

Wildland fire managers already coordinate closely and leverage resources to apply a risk-based, integrated, collaborative fire response across jurisdictional boundaries. The Strategy will enhance efforts to identify important sagebrush-steppe habitat and inform fire response in these areas. Effective integrated response begins before the fire season starts, is communicated from leadership to the field, and is included in dispatch plans to ensure that the priority sagebrush-steppe habitat is recognized as a critical fire management priority when rangeland fires occur.

Improve Preparedness

Photo Credit: BLM

Where priority greater sage-grouse habitat exists, pre-positioning of firefighting assets to improve preparedness and suppression capability in the initial stages of a wildfire increases the chances of keeping fires small and limits loss of greater sage-grouse habitat. Pre-positioning firefighting assets from other parts of the country (as they are available) will bolster Great Basin rangeland firefighting resources during critical times of the year. For example, in the Southeast, Southwest, and Alaska geographic areas, when fire season is winding down, the Great Basin is historically experiencing increased wildfire activity. Movement of agency rangeland firefighting assets from those areas to priority locations improves initial attack capability. In addition, established “draw-down levels” in the Great Basin will reduce the risk of a shortage of firefighting assets in greater sage-grouse habitat.

Increase Natural Resource and Fire Management Collaboration

Natural resource advisors and fire managers, at all levels, must coordinate and work collaboratively to identify priority habitats before and throughout the wildfire season to improve fire response and protection of priority sage-grouse habitat. The DOI is taking additional steps to help firefighters know where important greater sage-grouse habitat is located. Continuing in the 2015 fire season, when rangeland fires affect priority greater sage-grouse habitat, particularly in the FIAT identified areas, managers will dispatch resource advisors and provide maps depicting highest priority locations of greater sage-grouse habitat to crews working in key areas.

Enhance the Use of Veterans and Other Trained Resources

Employment of veterans is one of the highest priorities of DOI, and, in particular, for BLM. Active recruitment of returning veterans to the civilian workforce supplements and augments the existing veterans in the Federal wildland firefighting ranks, and increases the number of qualified firefighters available to respond. Increasing the training, coordination, and technical assistance for local/rural fire departments and RFPAs is essential to provide local protection and offers another way of extending suppression assets and ensuring that we have as many trained "boots on the ground" for initial attack as possible. Immediate response and successful initial attack are keys to keeping rangeland fires small, reducing risk to firefighters, and limiting the potential loss of important habitat. Proper training is a critical component to ensure firefighter safety and DOI will continue to invest in training and equipping local volunteers, RFPAs, and veterans' crews to add to the overall suppression capability.

Improve Restoration Success

One of the primary challenges to restoring the health of the sagebrush-steppe ecosystem is achieving effective long-term restoration and post-fire recovery. Arid sagebrush-steppe rangelands face many environmental and site condition stresses exacerbated by drought, climate change, and spread of invasive plants, leading to more frequent and catastrophic fires. While restoration can be successful at the small scale, a landscape level effort and adequate long-term funding is required to achieve effective and sustainable restoration of the sagebrush-steppe. As with vegetation management, to maximize success, restoration approached on a landscape scale in partnership with cooperators, is vital. This includes identification and efficient use of NEPA procedures and other environmental compliance processes, strong monitoring programs, metrics for success, incorporating science, and adaptive management. Landowners and land managers across the Great Basin are addressing challenges on a number of fronts with the intent of enhancing, promoting, and succeeding in rehabilitating and restoring the health of the sagebrush-steppe landscape and greater sage-grouse habitat, in particular.

Photo Credit: Conservation Media

Link Short and Long-term Restoration Efforts

One key element of this effort is to use a risk-based approach in setting priorities for and implementing rangeland restoration strategies. When needed in the short-term, the Emergency

Stabilization (ES) and Burned Area Rehabilitation (BAR) programs provide funding to establish vegetation quickly on areas impacted by fire in order to reduce the potential of further resource damage. Currently, other agency land and resource management programs provide the funding, as available, for long-term restoration and recovery. Establishment of vegetation on these landscapes is essential for reducing habitat loss and conversion to cheatgrass and other invasive species.

Consistent with the policy articulated in the Order, the ES and BAR programs are undergoing an update to include restoration of rangelands, linking ES and BAR investments with overall restoration and recovery activities. Agency land and resource management programs that provide funding for long-term restoration and recovery must link to the ES and BAR programs to ensure that funding is adequate to address both short-term revegetation needs and the long-term goal of successful restoration of fire-impacted landscapes. Added flexibility in the use of short-term funds and a clear commitment to ensure that funding for long-term restoration is made available are essential if fire-impacted lands are to be restored to native vegetation in a timely manner.

Expand Use of Native Seeds and Seedlings

Native plant communities, especially those containing perennial native grasses and forbs essential to ecosystem integrity and diversity, provide ecosystem services that sustain wildlife, such as greater sage-grouse and native pollinators. Perennial grasses are the best competitors with invasive annual grasses and promote resilience. A reliable supply of genetically appropriate and locally adapted seed, as well as seeding technology and equipment, is needed for effective restoration of the sagebrush-steppe ecosystem. Through the Plant Conservation Alliance, more than 300 non-federal and 12 Federal agencies are currently working collaboratively to develop the *National Seed Strategy*[5]. When complete, the *National Seed Strategy* will guide the development, availability, and use of seed needed for timely and effective restoration. Maintaining an effective and efficient supply of seeds, seedlings, and other plant materials, with emphasis on enhancing the production and use of native seeds and seedlings, is at the core of a successful, landscape-scale post-fire restoration effort.

While the use of genetically-appropriate plant materials is strongly encouraged, the Strategy does not preclude the use of non-native plant materials in instances where and when they are appropriate. It is important to note that the Strategy recognizes that land managers in some agencies may plant non-native species to achieve site stabilization, wildfire breaks, or invasive plant control, but that the use of non-natives should be limited to transitional, non-invasive species, replaced by natives in subsequent ecological restoration or during natural successional processes.

---

[5] The National Seed Strategy will include objectives and actions to meet four main goals: (1) Identify seed needs and ensure the reliable availability of genetically appropriate seed reserves; (2) Identify research needs and conduct research to provide genetically appropriate seed reserves and to improve technology for seed production and ecological restoration; (3) Develop tools that enable managers to make timely, informed seeding decisions for ecological restoration; and (4) Develop strategies for internal and external communication.

Establish a Coordinated Science Action Plan

In the past two years, Federal and state agencies have made considerable strides in identifying and prioritizing science needs for suppressing unwanted rangeland fire, controlling invasive plants, and restoring sagebrush-steppe. Examples include the USGS *Greater Sage-Grouse National Research Strategy*, WAFWA report, *Wildfire and Invasive Species in the West: Challenges that Hinder Current and Future Management and Protection of the Sagebrush-steppe Ecosystem—A Gap Report,* and USFS's draft *Sage-Grouse Conservation Science Strategy*. A review of these and other reports, and a multi-agency analysis of the gaps in our understanding of invasive species, wildland fire impacts, and management techniques will determine the highest priority science and research needs related to sagebrush-steppe ecosystems. This analysis will guide new actions aimed at filling the greatest knowledge gaps, define implementation needs, and direct science information delivery to practitioners on the ground. One excellent demonstration of the benefit of the application of research and science to management, in the context of our efforts to conserve the greater sage-grouse, has been the success of the NRCS Sage-Grouse Initiative (SGI). Land managers, landowners, and other stakeholders rely on scientific information to improve their ability to reduce the threat of fires and restore rangeland habitats. Considerable research is underway to address rangeland health, habitat, and fire effects. Successful application of that science in the field is crucial to enhance and improve success across the landscape in fuels management, rehabilitation, and restoration efforts.

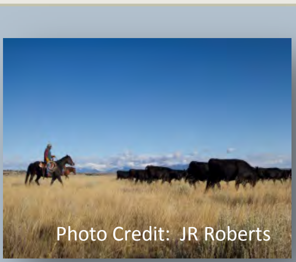

Photo Credit: JR Roberts

NRCS SAGE-GROUSE INITATIVE

One excellent demonstration of the benefit of the application of research and science to management in the context of our efforts to conserve the greater sage-grouse has been the success of the NRCS Sage-Grouse Initiative.

Long-term success of rangeland fire management efforts relies largely on creating and restoring landscapes that are resistant to invasive species and resilient to disturbance. Recent and emerging science is linking the resistance and resilience of sagebrush-steppe ecosystems to restoration and conservation strategies. Future research on new management options will enhance success while diminishing the costs of rangeland fire prevention, suppression, and restoration efforts.

Fast-paced research on restoring sagebrush-steppe habitat and controlling invasive plants is looking at what works, and what does not. For example, research regarding effective biocide controls of cheatgrass and studies on successfully establishing sagebrush-steppe are vital in addressing non-native invasive species control and successfully restoring or rehabilitating rangelands for the landowners and wildlife species that depend on them. Improving access to

Photo Credit: Conservation Media

applicable scientific information will facilitate and enhance efforts to protect, conserve, and restore important habitats and overall rangeland health. Creating a system that delivers the most current scientific information, interprets its use for management, provides a feedback loop to identify new research needs based on field results, and provides tools and services needed by managers will improve understanding and use of science. Mechanisms to accelerate registration and labelling of new, environmentally safe, and effective control agents would also help stem the conversion of native grasslands to cheatgrass and other invasive species and accelerate restoration of the health of sagebrush-steppe landscapes.

We can strengthen our efforts by linking existing Great Basin research and information groups, such as the Great Basin Research and Management Partnership, the Great Basin Landscape Conservation Cooperative, the Great Basin Fire Science Exchange, the Great Basin Native Plant Project, and the Sagebrush-Steppe Evaluation Project as well as universities and land grant colleges involved in similar research. Additionally, by increasing dissemination, interpretation, and application of new fire science and research through an improved system for science delivery, we will enhance use of science in day-to-day management decisions.

A science action plan aimed at expanding collaboration between science and management communities to discover, synthesize, interpret, and deliver new information to resource managers will improve the effectiveness of fire prevention, suppression, and restoration efforts.

Improve Management Efficiency and Effectiveness

Photo Credit: JR Roberts, Conservation Media

The successful implementation of the Strategy will require measures to improve management actions across agencies, jurisdictions, and programs. It will challenge resource managers, scientists and researchers, fire managers, and policy makers at the Federal, state, tribal, and local levels in government and among various private interests and stakeholders to collaborate, coordinate, and innovate in new ways.

Implementation, Coordination, and Accountability

Successful implementation of the Strategy and supporting actions requires a clear and sustained commitment to interdisciplinary and interagency collaboration, in all aspects of rangeland fire management – from prevention to suppression and restoration. Given that responsibility and authority for various aspects of fire management are shared among bureaus and agencies, organizations, and programs in the DOI, other Federal departments, tribes, and at regional, state, and local levels, a commitment to collaboration is essential.

Developing a dedicated, interagency, interdisciplinary executive team to lead the implementation and oversight of this Strategy, with adequate staff-level support, is an important first step. The benefit of this approach is that it could help breakdown the "silos" that traditionally inhibit the kind of partnership, innovation, and collaboration envisioned in the further development and implementation of this Strategy.

Geospatial Management Strategies

Identification of geospatially-explicit management strategies to limit the likelihood of habitat loss due to fire and targeted management strategies to improve resilience will further efforts to conserve important greater sage-grouse habitats. Geospatial tools and enhanced data sharing can provide a common framework, data, and terminology to support the implementation of the Strategy by helping to provide a common set of metrics to monitor resource conditions and the effectiveness of management actions consistent with an adaptive management paradigm.

Environmental Review and Compliance

Successful implementation of greater sage-grouse conservation at the landscape-scale requires timely and efficient environmental compliance procedures. Soon, land use and resource management plans will be amended with supporting environmental reviews to reflect the goals of protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, greater sage-grouse habitat. Programmatic and other streamlined environmental reviews to support vegetation management, restoration investments, and other activities can achieve additional efficiencies. By planning at a landscape-scale, environmental review and compliance can be more efficient and less costly and time consuming.

Resources and Funding

Photo Credit: BLM

At present, resources (e.g., staffing and expertise) are shared between multiple agencies and organizations, including, but not limited, to DOI, USFS, and NRCS, and various state and local agencies. To fully implement the Strategy and supporting activities, will require a commitment of funding over multiple years, and coordination among the agencies and organizations involved in the Strategy, with an integrated approach to budget development and implementation. A multi-year, integrated funding plan will help identify requirements, priorities, sources, and opportunities for shared and leveraged funding across agencies and disciplines.

The current approach to budgeting for wildland firefighting and restoration stymies efforts to implement a more efficient and effective strategy for the prevention and restoration work envisioned by this Strategy.

The President’s fiscal year 2016 budget request renews the call for a new funding framework for wildfire suppression, similar to how the costs for other natural disasters are met. The initiative proposes base level funding of 70 percent of the 10-year average for suppression costs within the discretionary budget with the remaining identified suppression funding need provided through a budget cap adjustment. One percent of the most severe fires comprise 30 percent of the costs. This is a commonsense proposal, with bipartisan Congressional support, that helps ensure DOI and USDA do not take funding from other important program budgets, such as fire prevention, in order to fight the Nation’s most catastrophic fires. Providing stability to the fire budget through the budget cap adjustment will enhance the long-term implementation of actions identified in this Strategy that would help to reduce the risk and harm of rangeland fires, as well as the associated costs.

Summary

The DOI, along with our partners, is prepared to respond to rangeland fire on important landscapes and to implement best-management practices to improve fire management and restoration efforts. While the strategy illustrates DOI's commitment to improving our efforts to protect and conserve important rangeland and sagebrush-steppe ecosystems and habitat, DOI remains firmly committed to the safety of firefighters and the public. Safety is and will remain the number one fire management priority.

The DOI is committed to implementing the vision articulated in the Order to improve measures for the effective and efficient implementation of a landscape-scale, science-based, collaborative strategy that addresses the critical priority of rangeland fire in the West and reduces the risk it presents to the people, communities, and resource and cultural values of the region. This effort will depend on a coordinated and collaborative approach involving Federal departments and agencies, the states, tribes, local governments, research institutions and universities, and the many stakeholders with a stake in the health of the sagebrush-steppe ecosystem, the greater sage-grouse, and the hundreds of other species associated with this unique and iconic American landscape.

This Page is Intentionally Blank

Appendix A - A Set of Longer-Term Actions and Activities[6]

Cross-Cutting Action Items

Issue Description/Overview

These actions cut across multiple topical areas and support the overall implementation of the Strategy.

Action Item #1

Develop interagency capability and functionality to provide ongoing coordination, oversight, and accountability to ensure timely and appropriate implementation of the Strategy and supporting action items. Dedicated interagency executive and staff-level direction, coordination, and oversight will enhance integration and commitment to long-term, multi-year restoration investments by providing continuity over time as well as providing accountability for completion of the action items.

Responsibility:

Leads: Rangeland Fire Task Force

Target to Complete: Third Quarter 2015 and ongoing

Action Item #2

Develop and share a geospatial tool that highlights areas of concern and priority habitats in the Great Basin, including within priority greater sage-grouse habitat, particularly in areas identified using the FIAT. This tool will provide a common framework and common terminology to support the implementation of the Order.

Responsibility:

Co-Leads: USGS Associate Director for Core Science Systems

Support: BLM Assistant Director for Fire and Aviation, BLM Assistant Director for Renewable Resources and Planning, and DOI Geospatial Information Officer

Target to Complete: Third Quarter 2016

Action Item #3

Establish an interagency framework with protocols, standards, and capacity to conduct long and short-term monitoring at all appropriate scales, of the sagebrush-steppe ecosystem condition and the effectiveness of fire prevention, fire suppression, and habitat restoration. Use adaptive management to respond to changing conditions, guide new science, and adjust management practices and policy. The approach will focus on evaluating the effectiveness of

---

[6] Quarters are defined as calendar year (e.g., first quarter ends March 31; second quarter ends June 30; third quarter ends September 30, and fourth quarter ends December 31 each year).

management actions, including fuels treatments, invasive species control, and restoration efforts, and the effects of these actions on habitat condition and trends. Resultant data and information informs resource management, at multiple scales, and supports the process of adaptive management.

Responsibility:

Co-Leads: USGS Associate Director for Ecosystems for development of monitoring framework; BLM Assistant Director for Renewable Resources and Planning for field implementation of monitoring

Support: USFS and other appropriate Federal and state agencies and tribes

Target to Complete: Fourth Quarter 2016

Action Item #4

Develop and implement efficient and appropriate National Environmental Policy Act (NEPA) and other environmental compliance processes. Develop approaches within existing law to implement NEPA, Endangered Species Act (ESA) and National Historic Preservation Act (NHPA) compliance effectively, to shorten planning times for conducting analysis of projects at a landscape and site-specific scale, and lengthen usability times of environmental documents by incorporating adaptive management alternative analyses. Initiate and complete programmatic NEPA, ESA, and NHPA processes in the FIAT assessment areas for landscape-level fuels treatments and restoration.

Responsibility:

Co-Leads: Assistant Secretary – Policy, Management and Budget, Assistant Secretary – Land and Minerals Management

Support: BLM, FWS, BIA, NPS, and other supporting agencies

Target to Complete: Third Quarter 2015 to develop process, including schedule for implementation

Action Item #5

Develop multi-year resource and action plan to implement the Strategy and supporting actions and develop tools to facilitate integrated budget development and track implementation. A multi-year, integrated resource and action plan would identify requirements, priorities, sources, and opportunities for shared and leveraged funding across agencies and disciplines.

Responsibility:

Lead: Assistant Secretary – Policy, Management and Budget

Support: DOI Assistant Secretaries and Bureau Directors, coordinated with USDA

Target to Complete: Ongoing

Action Item #6

Enhance Funding Leverage and Collaboration with Partners. Leverage and expand current collaborative landscape efforts that integrate partnership interactions among Federal, tribal, state, and local governments, and private and NGO collaborators, including to identify (and make known) available Federal funding tools for work within and outside of Federal agencies to implement fuels treatments and restoration across jurisdictions on Federal, tribal, state, and private lands. Programs include but are not limited to: Stewardship Contracting, Wyden Amendment (Public Law 109-54, Section 434), Sikes Act (16 USC 670a-670o, 74 Stat. 1052), Service First (Public Law 106-291), Interagency Agreements, Good Neighbor Authority (16 U.S. Code § 2113a), DOI-Resilient Landscapes (RL) BLM's Healthy Lands program, USDA-Joint Chiefs' Initiative, USFS-Collaborative Forests Landscape Restoration Program and NRCS Sage-Grouse Initiative and other programs. In addition, as appropriated funds allow, the Department can use the following statutes to leverage improvement when working with tribes: The National Indian Forest Resources Management Act of 1990; 25 USC Chapter 33: the Indian Self-Determination and Education Assistance Act of 1975, as amended; 25 USC § 450 et seq.; and the Tribal Self-Governance Act of 1994, as amended, 25 USC §§ 458aa – 458hh.

Responsibility:

Lead: Assistant Secretary – Policy, Management, and Budget

Support: DOI Assistant Secretaries and Bureau Directors, coordinated with USDA

Target to Complete: Ongoing

Section 7(b) i. – Integrated Response Plans

Issue Description/Overview

Design and implement comprehensive, integrated fire response plans for the FIAT areas and other Great Basin areas that prioritize protection of low resilience landscapes most at-risk to detrimental impacts of fire and invasive species.

These actions are required to further a risk-based, cross-boundary approach to rangeland fire response planning and preparedness. Rangeland fire suppression priorities identified by the Order will be incorporated into revised Fire Management Plans (FMPs) and updated computer-aided dispatch (CAD) systems; availability of technology and technology transfer to wildland fire managers will be increased; and initial attack capacity and capability in the FIAT designated states (Idaho, Nevada, Oregon, California, and Utah) will be enhanced. These longer-term actions build on those identified in the Initial Report for implementation during 2015 (see Appendix B).

Action Item #1

Update Fire Management Plans to enhance protection of the sagebrush-steppe from wildfire. Updated plans will include consideration of areas and suppression objectives identified in the FIAT process, as well as reflect land management objectives.

Responsibility:

Co-Leads: DOI Bureau Fire Executives

Support: Local Unit Fire Management Officers in BLM, NPS, BIA, and FWS

Target to Complete: Second Quarter 2016 for FIAT areas; Second Quarter 2017 outside FIAT areas

Action Item #2

Develop a national technology plan to increase the availability of technology and technology transfer to wildland fire managers. Develop a national plan, including implementation guidance, for improving access to real time maps, information, and data by local fire management organizations.

Responsibility:

Lead: Fire Management Board

Support: DOI and USFS Chief Information Officers (CIOs) and Bureau Assistant Directors for Information Resources (IR)

Target to Complete: Second Quarter 2016

Action Item #3

Strengthen rapid and long-term response capabilities and capacity in priority greater sage-grouse habitat, particularly in identified FIAT areas. Each bureau will conduct an assessment to identify the best mix of, and as needed, increases in firefighting assets including equipment such as dozers, engines and aircraft, and people, such as veteran fire crews. The first priority would be to increase initial attack capability, followed by increasing long-term capacity to address other rangeland fire management needs.

Responsibility:

Lead: DOI Bureau Fire Executives

Target to Complete: Second Quarter 2016

Action Item #4

Develop a long-term national plan for enhancing capability, capacity, and utilization of non-Federal wildland fire assets and organizations. This plan will include increasing the capability and capacity of tribal, state, and local agencies as well as rural or local fire departments and RFPAs, to enhance the ability of communities to provide local protection. This plan will also identify opportunities within existing and future Federal wildland fire management budgets to expand capacities and capabilities to support enhancing local efforts to reduce wildfire risk in priority sagebrush-steppe areas, with a goal to create fire-adapted communities and augment Federal protection responsibilities. Examples of expanded capabilities include mandatory training, equipment, and technical assistance.

Responsibility:

Co-Leads: Director, Office of Wildland Fire (OWF) and USFS Director, Fire and Aviation Management (FAM)

Support: **DOI** Bureau and USFS Fire Executives and USFA

Target to Complete: Second Quarter 2016

Section 7(b) ii. – Prioritization and Allocation of Resources

Issue Description/Overview

Provide clear direction on the prioritization and allocation of fire management resources and assets. These actions are required to improve utilization of fire management resources and assets in relation to rangeland fire, increase efficiency, and reduce costs. These actions build on those implemented during 2015, as identified in the Initial Report (see Appendix B).

Action Item #1

Identify and take actions to reduce administrative barriers that adversely affect the mobility of firefighting assets. Identify barriers (e.g., the lack of a travel credit card for fire crews limits the expeditious assignment and reassignment of fire personnel resources from one incident to another) and propose recommended solutions.

Responsibility:

Co-Leads: Director, OWF and Director, USFS (FAM)

Support: **DOI** Bureau Fire Executives, USFA; and National Association of State Foresters (NASF); DOI and USFS business and financial management offices

Target to Complete: Second Quarter 2016

Action Item #2

Enhance predictive services and fire intelligence capabilities to anticipate, plan for, and utilize firefighting resources and assets. Develop and enhance tools to determine and understand expected rangeland fire conditions (e.g., weather and fuels). Improve analytical ability to acquire, pre-position, and mobilize firefighting assets to effectively prepare for and respond to the increased threat from unwanted wildland fire, with priority given to rangeland areas.

Responsibility:

Co-Leads: Director, OWF and Director, USFS FAM

Support: Fire Management Board, National Weather Service, and non-federal partners, including states

Target to Complete: Second Quarter 2016, with additional enhancements in future years

Action Item #3

Engage international and Department of Defense (DOD) partners. Update and strengthen existing arrangements to utilize skills, assets, capabilities, and build capacity with international and DOD partners to supplement domestic Federal and non-federal wildland firefighting capabilities. Complete and implement updated international agreements with Mexico, Australia, and Canada. Review, update, and expand agreements and protocols with DOD to utilize a wide range of capabilities including information and intelligence gathering and analysis, ground and aviation assets, and personnel.

Responsibility:

Co-Leads: Director, OWF and Director, USFS FAM

Support: DOI International Affairs and USFS International Fire

Target to Complete:

- International Agreements: Fourth Quarter 2015
- DOD Agreements: Second Quarter 2016

Action Item #4

Review cooperative agreements between Federal, tribal, and state entities. Review, revise, and update, as necessary, the approach to cooperative wildland fire management agreements. Ensure the utility of those agreements to provide interagency wildland firefighting assets to address priorities including consideration of areas and suppression priorities identified in the FIAT process.

Responsibility:

Co-Leads: Director, OWF and Director, USFS FAM

***Support:* DOI** Bureau Fire Executives; Chair, Forest Fire Protection Committee, NASF

Target to Complete: Second Quarter 2016

Action Item #5

Improve management of the radio spectrum. Develop mechanisms for better management and allocation of radio spectrum during peak use.

Responsibility:

***Co-Leads*:** Director, OWF and Director, USFS FAM

Support: DOI and USFS CIOs, Bureau Assistant Directors for IR, DOI Bureau Fire Executives

Target to Complete: Second Quarter 2016

Action Item #6

Support efforts to identify responsibility for protecting all lands. Provide technical advice and other assistance to state and local governments to define responsibility for those lands that currently lack wildland fire protection.

Responsibility:

Co-Leads: Director, OWF and Director, USFS FAM

Support: Bureau state and regional Fire Management Officers

Target to Complete: Ongoing

Action Item #7

Develop mechanisms to capture and analyze data regarding allocation of firefighting assets and wildfire impacts to priority sagebrush-steppe ecosystems. Develop mechanisms to improve collection, analysis, and use of information to (1) allocate and prioritize firefighting resources and (2) understand the impacts of wildland fire on greater sage-grouse habitat and populations, in order to ensure appropriate prioritization and allocation of firefighting assets to mitigate these threats to critical natural resource values. This includes revisions to the existing Incident Status Summary (ICS 209) and the Incident Management Situation Report (SIT Report).

Responsibility:

Co-Leads: Director, OWF and Director, USFS FAM

Support: DOI Bureau and USFS Resource and Fire Executives, US Fire Administration, National Association of State Foresters, and Fire Management Board

Target to Complete: Second Quarter 2016

Section 7(b) iii. – Fuels

Issue Description/Overview

Improve targeting of fuels reduction opportunities and implementation. These actions are required to achieve efficiencies, promote collaboration, and eliminate existing barriers in fuels management actions. These actions support the need for increased capacity, staffing, and funding to continue to implement risk based projects at the local and landscape-scale that will ultimately lead to increased health of our Nation's sagebrush-steppe ecosystem. These actions build on those implemented during 2015, as identified in the Initial Report (see also Appendix B).

The following collaborative efforts that address fuel treatments serve as the building blocks for many of the proposed actions identified below: *The National Cohesive Wildland Fire Management Strategy*; DOI's Landscape Conservation Cooperatives [LCCs] and Resilient Landscapes [RL]; USFS's Collaborative Forest Landscape Restoration Program [CFLRP]; BLM's Healthy Lands and FIAT; and The Nature Conservancy's Fire Learning Networks

[FLNs]). The 2014 passage of The Farm Bill also includes the Good Neighbor Authority that provides for restoration work to occur across Federal and state boundaries.

Action Item #1

Identify fuels management priorities. Identify priority landscapes and fuels management priorities within landscapes. Land management agencies will collaboratively develop consistent criteria across jurisdictions to prioritize landscapes, and expedite planning and implementation of fuel treatments, particularly in the FIAT assessment areas.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning and Assistant Director for Fire and Aviation

Support: USFS, NRCS, FWS, state agencies, counties, and private landowners

Target to Complete: Third Quarter 2015, continued improvements in subsequent years

Action Item #2

Develop common interagency metrics to validate fuels management activities in sagebrush-steppe. Metrics should be (1) consistent with those developed for monitoring and evaluation of greater sage-grouse land use plans and implementation of adaptive management strategy; (2) science-based (see *Joint Fire Science Program (JFSP) Fuel Treatment Science Plan*); and (3) incorporated into fuels management effectiveness monitoring to understand how fuel treatments are influencing ecosystem structure, function, and resilience.

Responsibility:

Lead: Director, OWF

Support: Federal land management agencies, USGS, JFSP, interested tribes, and non-federal partners (e.g., states, NGOs, etc.)

Target to Complete: First Quarter 2016

Action Item #3

Review and update current best management practices (BMPs) for rangeland fuels treatments. Review and update BMPs for rangeland fuels treatments to better integrate resistance and resilience concepts, ecological resilience science, and to identify a specific suite of preferred design alternatives for fuel treatments in sagebrush-steppe. The BMPs will specifically consider tribal and cultural values and provide flexibility to adjust practices, as needed, prior to fuels treatments (particularly in pinyon-juniper).

Responsibility:

Lead: BLM Assistant Director for Fire and Aviation

Support: Agency fuels specialists (DOI agencies, USFS, and NRCS fuels managers, wildlife, range/vegetation, research scientists with fuel treatment experience), scientific community representatives, and non-federal partners (WAFWA, Western Governors' Association [WGA] representatives, other NGOs).

Target to Complete: Third Quarter 2016

Action Item #4

Coordinate the development of effective landscape-level fuels treatment plans.

Improvements are needed in: (1) developing better understanding of vegetation dynamics in non-forested systems, (2) developing better characterization of sagebrush-steppe and invasive annual grass fuels, treatment actions, effects, and associated changes in potential fire behavior, (3) linkages between fuels and habitat quality for key species, and (4) developing economic models (such as avoided cost) to describe the cost-effective return of investments. To ensure progress in this arena, develop new, integrated modeling systems, built off current systems or new ones.

a. Initiate a pilot project to test existing tools and/or prototype versions of new tools. An initial pilot project will occur to test Interagency Fuels Treatment – Decision Support System (IFT-DSS).

Responsibility:

Co-Leads: BLM Assistant Director for Fire and Aviation and USFS – Wildland Fire Management Research, Development, and Application (WFMRD&A) initiate pilot project to test Interagency Fuels Treatment – Decision Support System (IFT-DSS)

Support: NRCS, NWCG Interagency Fuels Committee

Target to Complete: Results from initial pilot project by Fourth Quarter 2015; initiate additional pilot project(s) in the First Quarter 2016.

b. Use results from pilot project(s) to make improvements in models and identify appropriate tools for developing strategies for future landscape-level fuel treatments in sagebrush-steppe ecosystems. Coordinate with other agencies and organizations that may develop and lead additional pilot projects.

Responsibility:

Co-Leads: BLM Assistant Director for Fire and Aviation and USFS (WFMRD&A)

Support: NRCS, DOI land management agencies, JFSP, and USFS - National Forest Systems (NFS); scientific and academic communities, NGOs

Target to Complete: Core capabilities developed by end of First Quarter 2016; review completed by end of Third Quarter 2016; and recommendations to the Fire Management Board by end of the First Quarter 2017.

Action Item #5

Implement a comprehensive knowledge transfer program to enhance the fuels management program's role in sagebrush-steppe management.

Develop an integrated fuels management knowledge transfer/training program applicable to interdisciplinary specialists. The program would include best management practices, and science-technology transfer components to increase probability for success.

Responsibility:

Co-Leads: BLM Assistant Director for Fire and Aviation and Assistant Director for Renewable Resources and Planning

Support: USFS and DOI Bureau Fire and Resource Executives working with JFSP and/or NGO/universities to develop training

Target to Complete: Develop training by the Second Quarter 2016 and deliver in 2017.

Action Item #6

Explore opportunities to provide support to livestock grazing permittees and private landowners to implement fuel treatment actions as part of strategic, landscape efforts to protect, conserve, and restore sagebrush-steppe habitats. The BLM (and other land management agencies) and NRCS will collaboratively identify priority landscapes where NRCS Sage-Grouse Initiative targets technical and financial assistance on private lands to complement public land fuel treatments to address threats effectively.

Responsibility:

Co-Leads: BLM Assistant Director for Renewable Resources and Planning and NRCS

Support: BLM Assistant Director for Fire and Aviation, USFS, Soil and Water Conservation Districts, private landowners, states, counties, and RFPAs

Target to Complete: Identify landscapes by the First Quarter 2016 and fund work for 2017.

Action Item #7

Explore incentives for livestock producers to implement targeted fuels and vegetation treatments.

In response to interest from private landowners and grazing permittees, work with livestock producers to implement fuels treatments on their lands and allotments. For example, development of Candidate Conservation Agreements with Assurances (CCAA) on private lands and the Candidate Conservation Agreements (CCA) for Federal lands that provides livestock grazers, where feasible, with the ability to implement actions (fuel treatments) to reduce threats to greater sage-grouse in sagebrush-steppe habitat voluntarily.

Responsibility:

Co-Leads: BLM Assistant Director for Renewable Resources and Planning and FWS Assistant Director for Ecological Services

Support: Private landowners, states, counties, and RFPAs

Target to Complete: Evaluate opportunities for livestock producer engagement in FIAT areas by First Quarter 2016. Expand assistance/incentives to producers and permittees in priority landscapes in 2016 – 2017.

Action Item #8

Use risk-based, landscape-scale approaches to identify and facilitate investments in fuels treatments in the Great Basin. Risk-based assessments will consider sagebrush-steppe values within priority greater sage-grouse habitat, particularly in FIAT identified areas, will incorporate adaptive management principles, and will be science-based.

a. DOI will use a risk-based approach to allocate program funds to Bureaus.

Responsibility:

Lead: Director, OWF

Support: DOI Bureau Fire Executives

Target of Complete: Complete by the Fourth Quarter 2015 for 2016 and 2017 Bureau funding

b. DOI agencies to apply a risk-based approach to allocate fuels management program funds to units.

Responsibility:

Lead: DOI Bureau Fire Executives

Target to Complete: By Fourth Quarter 2015 for 2016 and 2017 funding

Section 7b (iv). - Integrate Science into Project Design and Implementation

Issue Description/Overview

Use current and emerging traditional and scientific knowledge of ecological resistance and resilience in the development and implementation of fuels management and restoration actions. Use effective adaptive management to ensure that design practices and implementation strategies reflect both emerging scientific findings and knowledge gained from the analysis of past actions.

These actions outline the steps needed to integrate information known about the science of ecological resilience into habitat management plans, fine and coarse fuels management, invasive species control, and landscape restoration design in sage-steppe habitat and ensure the effective use of adaptive management.

Action Item #1

Develop a Conservation and Restoration Strategy for the sagebrush-steppe that considers emerging science, particularly ecological resistance, and resilience in habitat management, fuels treatment and restoration projects. The Conservation and Restoration Strategy (C&R

Strategy) will include a baseline assessment, conceptual models, and other components necessary to provide an overarching strategy for "on the ground" restoration actions in the sagebrush-steppe and provide a foundation for adaptive management and budget prioritization. The C&R Strategy will acknowledge risks to resource treatments and will incorporate geospatial tools and objectives.

The FIAT assessments, regional mitigation strategies, State Wildlife Action Plans, and other appropriately scaled conservation and restoration strategies are the building blocks in the development of the C&R Strategy. They should be used to create a more unified approach that identifies shared objectives and negotiates inconsistencies. The C&R Strategy should include consideration of multiple resource management objectives and change agents including, but not limited to, greater sage-grouse brood rearing habitat, riparian areas, cultural areas; and risks from climate change, fire, invasive species, development, and other change agents. The C&R Strategy will model possible options for implementation of how specific management activities could improve resilience for greater sage-grouse and other sagebrush obligate species at the site and landscape-scales.

Responsibility:

Co-Leads: BLM Assistant Director for Renewable Resources and Planning and Assistant Director Fire and Aviation

Support: Other DOI and USDA agencies, states, tribes, WAFWA, NGOs, and other partners in conservation science and development, and invite stakeholders to participate

Target to Complete: Fourth Quarter 2016

Action Item #2

Identify priority actions for conservation and restoration. The C&R Strategy will guide prioritization and implementation of multi-partner, multi-year restoration and conservation actions and activities, including plant materials development, monitoring, adaptive management, and science prioritization. The C&R Strategy will be coordinated with other ongoing prioritization efforts within the sagebrush-steppe and other elements of the Strategy required by Secretarial Order 3336 to identify priorities for action. These identified priorities will inform budget decisions in the DOI and DOI bureau programs that fund restoration, fuels reduction, invasive species management, habitat improvement, monitoring, and adaptive management. Additionally, these identified priorities may inform priorities for native plant materials development and science.

Responsibility:

Co-Leads: BLM Assistant Director for Renewable Resources and Planning and Assistant Director Fire and Aviation

Support: Other DOI and USDA bureaus, states, tribes, WAFWA, NGOs and other partners in conservation science and development, and invite stakeholders to participate

Target to Complete*:* Fourth Quarter 2016

Action Item #3

Incorporate traditional ecological knowledge into management practices. Review and consider indigenous peoples' historic fire management practices and the outcomes of those practices, particularly with regard to resilient ecosystems. Consult with appropriate tribal members to identify specific ecological changes due to current fire management practices and other factors, and to identify traditional ecological understandings of interest today. Work with the research community to investigate and improve the effectiveness of rangeland fire protection, conservation, and restoration treatments, incorporating traditional ecological knowledge, into the C&R Strategy. Develop measures of success for projects from multiple perspectives and knowledge systems. Define parameters of success from both western science and traditional ecological knowledge. Recognize contributions of tribal partners in final products, publications, and efforts to publicize projects.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Support: Other DOI and USDA bureaus, states, tribes, WAFWA, NGOs and other partners in conservation science and development, and invite stakeholders to participate

Target to Complete: Fourth Quarter 2016

Section 7(b) v. – Post-Fire Restoration

Issue Description/Overview

Review and update Emergency Stabilization and Burned Area Rehabilitation policies and programs to integrate with long-term restoration activities. These actions will address policy and program changes to existing DOI Emergency Stabilization (ES) and Burned Area Rehabilitation (BAR) policies to improve the allocation and utilization of funds to recognize sagebrush-steppe factors, to integrate ES and BAR funding with other bureau land and resource management funding and programs, to expedite funding, and to maximize success of restoration projects. These actions build on those identified for implementation during 2015, as identified in the Initial Report (see Appendix B). Since issuance of the Initial Report, an interagency team of ES/BAR and resource management program specialists developed proposals to revise, update, and integrate ES/BAR policies and programs and will present these proposals to interagency leadership for approval and implementation in the summer of 2015.

Action Item #1

Review, update, and resolve Emergency Stabilization (ES) and Burned Area Rehabilitation (BAR) policy, procedures, and allocation changes to meet the goals of the Order. Revise ES/BAR policies and program implementation to align with bureau land management and resource management programs and activities to promote long-term restoration and recovery, update prioritization criteria, and incorporate science to promote resistance and resilience.

Lead: Director, OWF

***Support*:** DOI Bureau Fire and Resource Executives

Target to Complete: Third Quarter 2015

Action Item #2

Integrate ES, BAR, and other restoration programs to adhere to ecologically based desired conditions, and develop processes for long-term restoration commitment and maintenance of ES and BAR treatments.

Conduct an assessment to determine how to best integrate ES, BAR, and restoration activities to obtain a desired ecologically based conditions .and revise and update program handbooks and other documents as necessary.

Lead: Director, OWF

***Support*:** DOI Bureau Fire and Resource Executives

Target: Second Quarter, 2016

Action Item #3

Conduct periodic reviews to test efficacy of ES and BAR programs. Conduct periodic reviews to evaluate and simplify processes in applying for, implementing and reporting on ES and BAR projects over time, including refining ES and BAR policies to align with best available ecological restoration science, while considering changes to timelines, funding, planning, prioritization criteria, and other factors.

Lead: Director, OWF

***Support*:** DOI Bureau Fire and Resource Executives

Target to Complete: Third Quarter 2016

Section 7(b) vi. – Commit to Multi-year Investments in Restoration

Issue Description/Overview

Support long-term strategies for the restoration of sagebrush-steppe ecosystems, including consistent long-term monitoring protocols and adaptive management for restored areas.

These actions will organize existing restoration activities better, implement the Conservation and Restoration Strategy, remove administrative and policy barriers to supporting long-term strategies for restoration, and reduce challenges to coordinating with partners. The DOI's commitment to long-term strategies related to restoration, monitoring, and adaptive management would be more meaningful when managed within a larger context of commitment to restoration in the sagebrush-steppe ecosystem.

Action Item #1

Identify, document and map current investments in restoration, monitoring, and adaptive management.

Compile a list of activities and programs that fund restoration, monitoring and adaptive management investments within the sagebrush-steppe ecosystem. Map "hot spots" of restoration activity or investment to help identify trends and opportunities for greater efficiency and leveraging of funds.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Support: BLM Assistant Directors for Energy, Minerals, and Realty and Fire and Aviation; OWF, other DOI and USDA agencies, states, tribes, WAFWA, and partners in conservation and development.

Target to Complete: First Quarter 2016

Action Item #2

Identify and initiate actions to reduce administrative barriers to fulfilling multi-year commitments to restoration, monitoring, and adaptive management and to collaborating across landscapes.

Review internal DOI and bureau policies that hinder multi-year commitments to restoration, monitoring, and adaptive management, including existing policy that no-year funds be applied to restoration and managed at the bureau or program-level on a single-year basis. Propose and implement changes to policies and procedures that would facilitate multi-year plans for restoration, monitoring, and adaptive management, including those that would facilitate treatment implementation when environmental conditions are favorable, and those that facilitate collaborating across landscapes.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Support: BLM Assistant Directors for Energy, Minerals, and Realty and Fire and Aviation; OWF, other DOI bureaus, USDA agencies, states, tribes, WAFWA, and partners in conservation and development

Target to Complete: Second Quarter 2016

Action Item #3

Describe lessons learned from existing multi-year investment programs and recommend procedural changes for funding multi-year plans for restoration, monitoring, and adaptive management.

To identify shared objectives and project priorities, aggregate funds, and/or issue contracts (e.g., Utah's Watershed Restoration Initiative), survey regional "brokers" or "coordinators." Review DOI and other Federal agencies for programs that allow for some form of multi-year plan or that fund particular projects through their duration (e.g., Construction and Deferred Maintenance Projects). Report the lessons learned and recommendations.

Responsibility:

Co-Leads: BLM Assistant Director for Renewable Resources and Planning

Support: Other DOI Bureaus and USDA agencies; invite tribes, partners, and stakeholders to participate.

Target to Complete Dates: First Quarter 2016

Action Item #4:

Develop a community of practice for restoration, monitoring, and adaptive management in the sagebrush-steppe ecosystem. Facilitate and support a cross-jurisdictional consortium of agencies, organizations and partners dedicated to implementation of restoration, monitoring, and adaptive management activities leading to a healthy ecosystem.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Support: BLM Assistant Directors for Energy, Minerals, and Realty and Fire and Aviation; OWF, other DOI bureaus, USDA agencies, states, tribes, WAFWA, and partners in conservation and development

Target to Complete: Fourth Quarter 2016

Action Item #5:

Develop comprehensive policies and consistent funding to implement the Conservation and Restoration Strategy.

Develop a multi-partner, multi-year program of work to implement the C&R Strategy, including monitoring and adaptive management. Include plans to increase continuity of support for specific treatment areas or programs, e.g., Emergency Stabilization (ES) projects and invasive species treatments.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning and Assistant Director for Fire and Aviation

Support: BLM Assistant Director for Energy, Minerals, and Realty; OWF, other DOI bureaus, USDA agencies, states, tribes, WAFWA, and partners in conservation and development

Target to Complete: Fourth Quarter 2016

Section 7(b) vii. – Large-scale Activities to Remove Invasive Non-native Grasses

Issue Description/Overview

Implement large-scale experimental activities to remove cheatgrass and other invasive annual grasses through various tools.

These actions will result in large-scale activities to remove cheatgrass and other invasive annual grasses through various tools beginning in 2015 with full implementation in subsequent years. The goal of large-scale activities is the effective control and restoration of areas dominated by invasive, non-native annual grasses at a rate greater than the rate of the spread.

Action Item #1

Develop a framework for a national invasive species Early Detection and Rapid Response (EDRR) program.

This effort is in response to a directive in the President's Priority Agenda: *Enhancing the Climate Resilience of America's Natural Resources.* It will benefit agencies, states, tribes, and local entities working on EDRR. It will also provide recommendations to operationalize a national EDRR system. It will build on and aim to connect existing programs that identify potentially invasive species that could become abundant, conduct surveys to assess their extent, and take actions to limit their spread.

Responsibility:

Lead: DOI Invasive Species Coordinator

Support: BLM Assistant Director for Renewable Resources and Planning; FWS, NPS, USGS, USFS, NRCS, U.S. Department of Commerce (DOC), Environmental Protection Agency (EPA), and the National Invasive Species Council (NISC), WGA, state agencies, tribes, and NGOs.

Target to Complete: First Quarter 2016

Action Item #2

Conduct large-scale research and demonstration projects for control of cheatgrass and other invasive annual grasses to identify and advance effective strategies for preventing the spread of invasive species and support large-scale rangeland restoration. Researchers and managers locate and coordinate installation of long-term studies and subsequent monitoring to test the efficacy of large-scale application of integrated pest management programs that include chemical, mechanical, biological, newly registered biocides, and subsequent restoration practices. The program of work would identify suitable locations and process to solicit and review proposals.

Responsibility:

Co-Leads: BLM Assistant Director for Renewable Resources and Planning and Assistant Director for Fire and Aviation; and USGS Associate Director for Ecosystems

Support: FWS, BIA, NPS, USFS, NRCS, ARS, NGOs, tribes, and GBLCC

Target to Complete: Third Quarter 2016

Action Item #3

Complete the Vegetation Treatments Programmatic Environmental Impact Statement (PEIS). The PEIS serves as the working document for the use of herbicides, chemical pesticides, and biocides on lands managed by BLM.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Target to Complete: Fourth Quarter 2016

Action Item #4

Develop a process to coordinate with the Animal and Plant Health Inspection Service (APHIS) and EPA on registration and labeling of new invasive annual grass biological and chemical control agents, as applicable. A structured and scheduled interaction with both APHIS and EPA would occur to discuss options associated with the management of invasive annual grasses. This would allow the agencies to keep current on the options available for consideration in the management of invasive annual grasses.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Support: USGS, USFS, APHIS, Agricultural Research Service (ARS), and EPA

Target to Complete: Fourth Quarter 2015

Action Item #5

Develop scalable and adaptive grazing management plans for reducing invasive annual grass and other fine fuels through targeted livestock grazing methods to diminish fire risk in priority greater sage-grouse areas to meet greater sage-grouse habitat goals. For example, during seasons with above-normal winter and spring rainfalls, utilize more targeted grazing methods to reduce fine fuels adjacent to priority habitats. Targeted grazing would be a cooperative engagement on both private and Federal lands.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Support: NRCS, FWS, USFS, ARS, states, counties, grazing permittees, and private landowners

Target to Complete: Agreements and standards in place for use by Third Quarter 2017

Section 7(b) viii. – Science and Research

Issue Description/Overview

Commit to multi-year investments in science and research.

Although a large body of scientific information exists for the sagebrush-steppe ecosystem, key gaps in knowledge remain. A multi-year plan for science and research will provide a basis for an integrated approach to identifying, prioritizing, and funding science and research activities necessary to support this Strategy. The plan will include approaches to ensure science and research is synthesized and accessible for use by managers and contributes to a comprehensive and landscape-level understanding of the sagebrush-steppe ecosystem. Focus areas for science will include:

- Resistance and resilience concepts and thresholds
- Effective and efficient landscape-scale restoration methods, considering regional and site-specific conditions, degree of degradation, major threats, and other factors
- Native and appropriate non-native seeds and plant materials
- Vegetation treatment techniques and effectiveness monitoring (e.g., fuels management, grazing, restoration, invasive annual grass control)
- Wildland fire impacts to native plant communities
- Implications of climate change, grazing and other land uses

Action Item #1

Develop and maintain an inventory of research commitments and capacity. In order to have a better understanding of ongoing research commitments and capacity, Federal agencies will maintain an annual, ongoing inventory of funded research beginning in FY 2015.

Responsibility:

Lead: DOI Science Advisor

Support: USGS, BLM, FWS, NPS, USFS, NRCS, ARS, JFSP, and GBLCC

Target to Complete: Third Quarter 2015 and ongoing

Action Item #2

Review existing research prioritization and strategy efforts to identify science needs for the Great Basin. In the past two years, Federal and state agencies made considerable strides in identifying and prioritizing science needs. These needs included (1) suppressing rangeland fire and controlling invasive plants, and (2) restoring sagebrush-steppe for the benefit of the greater sage-grouse and other priority wildlife species (e.g., USGS Greater Sage-Grouse National Research Strategy; USFS draft Sage-Grouse Conservation Science Strategy; JFSP Fuel Treatment Science Plan; and WAFWA reports: Fire and Fuels Management Contributions to Sage-Grouse

Conservation, Wildfire and Invasive Species in the West: Challenges that Hinder Current and Future Management and Protection of the Sagebrush-steppe Ecosystem—A Gap Report, and Invasive Plant Management and Greater Sage-grouse Conservation Report,). These completed and ongoing efforts will serve as the foundation to identify information gaps and extract science needs focused on fire and invasive plants.

Responsibility:

Lead: USGS Associate Director for Ecosystems

Support: Appropriate Federal agencies, JFSP, and GBLCC

Target to Complete: Fourth Quarter 2015

Action Item #3

Develop an actionable science plan of prioritized research needs. Building on the science needs in Action Item #2, develop a science action plan that prioritizes science needs, and identifies specific research efforts and associated costs and timelines.

Responsibility:

Co-Leads: USGS Associate Director for Ecosystems and USFS Deputy Chief for Research and Development

Support: Interagency team of appropriate Federal, state, tribal, academic, JFSP, and GBLCC representatives

Target to Complete: Third Quarter 2016

Action Item #4

Develop or identify a primary online science delivery system to allow easier access to published science products and other science information. The Great Basin Fire Science Exchange (GB Exchange) funded by the Joint Fire Science Program (JFSP), will be expanded to serve as the primary delivery system for science information for the management and science community. The GB Exchange will compile relevant scientific information, identify gaps in archived information, update and maintain existing websites, provide active links (e.g., GBLCC, GBRMP) to facilitate transfer of relevant scientific information, and develop science syntheses, tools, and services (e.g., training) to increase understanding and use of science in management decisions.

Responsibility:

Co-Leads: JFSP/GBLCC

Support: Other information providers, affected Federal and state agencies, tribes, and NGOs.

Target to Complete: Fourth Quarter 2015

Action Item #5

Identify available funding sources to support the action plan and implement new research in 2017 and beyond. As part of a comprehensive science action plan, DOI and bureaus will plan for its implementation through a commitment to long-term strategies to support science priorities. These priorities include field-based testing and adaptive management and monitoring in ensuring the durability of the action plan.

Responsibility:

Lead: DOI Science Advisor

Support: Other Federal agencies, tribes, GBLCC, JFSP, and DOI Science Coordinator

Target to Complete: Third Quarter 2016 for budget plan development, re-occurring for out-year budget requests

Action Item #6

Conduct periodic reviews and updates of the science action plan. These reviews, conducted at least once every three years, will identify emerging science and determine if new technological innovations have arisen to support management priorities.

Responsibility:

Lead: USGS Associate Director for Ecosystems

Support: Interagency team of appropriate Federal, state, tribal, academic, JFSP, and GBLCC representatives

Target to Complete: Re-occurring with first update in 2019

Section 7(b) ix. – Seed Strategy

Issue Description/Overview

Develop a comprehensive strategy for acquisition, storage, and distribution of seeds and other plant materials. These actions will facilitate the development of a reliable supply of genetically appropriate and locally adapted seed, as well as seeding technology and equipment for successful and expanded effective restoration of the sagebrush-steppe ecosystem, including both native and non-native materials. These longer-term actions build on those identified for implementation during 2015, as identified in the Initial Report (see also Appendix B).

Action Item #1

Complete and issue the National Seed Strategy and Implementation Plan (2015 – 2020) to increase production, storage capacity, acquisition, and use of genetically appropriate and locally adapted seed.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Support: BIA, FWS, NPS, and USGS; USDA (USFS, NRCS, ARS, National Institute of Food and Agriculture [NIFA]); DOT Federal Highway Administration (FHWA); Smithsonian; and U.S. Botanical Garden

Target to Complete: Fourth Quarter 2015

Action Item #2

Implement the National Seed Strategy. This includes developing a budget and business plan to accomplish the strategy, providing training for managers when making decisions about the selection of genetically appropriate plant materials and technologies for vegetation restoration, propagation, and conservation of culturally important (first food) species, establish pilot training/demonstration projects and solicit scientific research as needed.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning in coordination with the Federal Native Plant Conservation Committee of the Plant Conservation Alliance

Support: BIA, FWS, NPS, and USGS; USDA (USFS, NRCS, ARS, NIFA); DOT FHWA; Smithsonian; U.S. Botanical Garden; and private entities

Target to Complete: Fourth Quarter 2016

Action Item #3

Increase the availability of native seed and plant materials by ensuring the collection, production, storage, and distribution of commercial seed for long-term rangeland conservation in collaboration with private partners. Collect native seed from across the distribution of the species for use in developing commercial seed and for long-term seed banking to ensure conservation of germplasm to promote climate resilience and long-term rangeland health.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Support: BIA, FWS, NPS, and USGS; USDA (USFS, NRCS, ARS, NIFA); DOT FHWA; Smithsonian; U.S. Botanical Garden; and private parties

Target to Complete: Fourth Quarter 2015 and ongoing

Action Item #4

Coordinate and collaborate across agencies on climate trend data as it relates to seeds. Understand the trends in climate, across the Western United States with a focus on sagebrush-steppe and pinyon-juniper ecosystems.

Responsibility:

Lead: USGS Associate Director for Climate Change and Land Use

Support: DOI and USDA agencies; state agencies, tribes, scientific and academic institutions, and NGOs

Target to Complete: Fourth Quarter 2015 and ongoing

Action Item #5

Increase the availability of native seed and plant materials for the Great Basin. Increase seed production and the grow-out of genetically appropriate native plant species for the restoration of the sagebrush-steppe ecosystem within the Great Basin, which will provide necessary structure and habitat, as well as dietary and other benefits for the greater sage-grouse.

Responsibility:

Lead: BLM Assistant Director for Renewable Resources and Planning

Support: BIA, FWS, NPS; USDA (USFS, NRCS, ARS, NIFA), and Great Basin Native Plant Project

Target to Complete: Fourth Quarter 2015 and ongoing

Action Item #6

Work with tribal and agency plant material specialists to improve efficiencies in rangeland seeding operations for restoration that includes Emergency Stabilization (ES) and Burned Area Rehabilitation (BAR). Agencies will work with rangeland plant material specialists and research to determine how to improve treatment efficiencies while improving monitoring and evaluation of treatment effectiveness, including the National Seed Strategy and Implementation Plan (2015-2020) once final, adaptive management, and engaging research.

Responsibility:

Lead: USGS Associate Director for Ecosystems on developing design and monitoring protocols; Implementation by DOI bureaus

Target to Complete: Fourth Quarter 2016

Action Item #7

Expand efforts to utilize native and non-native seed and vegetation plantings, where appropriate, to accelerate efforts to improve and restore post-fire rangeland health. The Post-Wildfire Handbook and other restoration guidance will incorporate concepts from the National Seed Strategy and Implementation Plan (2015-2020) when completed to identify opportunities to improve rangeland health.

Responsibility:

Lead: Interagency Burned Area Emergency Rehabilitation Team

Support: DOI Bureaus

Target to Complete: Second Quarter 2016

Appendix B – Table of Action Items[7]

A Total Set of Action Items

Initial Report Action Items (Short-Term)

INITIAL REPORT ACTION ITEMS (SHORT TERM)		
Action Item	**Responsible Party/Parties**	**Target to Complete**
Develop and share a geospatial tool that highlights areas of concern in the Great Basin and includes, at a minimum, focal, Fire and Invasives Assessment Tool (FIAT) and Priority Habitat Management areas.	BLM/USGS	May 1, 2015
7(b) i Integrated Response Plans		
#1. Increase the capabilities of rural/volunteer fire departments and RFPAs and enhance the development and use of veterans crews.	OWF/Agency Fire Leadership	June 1, 2015
#2. Ensure local, MAC groups function, and MAC plans are updated.	MAC groups working with local Federal wildland fire suppression agencies, tribes state fire suppression agencies, RFPAs, local fire departments, and other cooperators	May 1, 2015

---

[7] Quarters are defined as calendar year (e.g., first quarter ends March 31; second quarter ends June 30; third quarter ends September 30, and fourth quarter ends December 31 each year).

INITIAL REPORT ACTION ITEMS (SHORT TERM)

Action Item	Responsible Party/Parties	Target to Complete
#3. Develop and implement minimum draw down level and step up plans to ensure availability of resources for protection in priority greater sage grouse habitat.	Federal local unit FMOs, in coordination with cooperators and reviewed by Federal state/regional FMOs	May 1, 2015
#4. Apply a coordinated risk based approach to wildfire response to assure initial attack response to priority areas.	Local MAC groups and unit FMOs, with review by Federal regional/state FMOs	May 1, 2015
#5. Develop a standardized set of briefing materials.	Geographic Area Coordinating Groups (GACGs) and local MACs	May 1, 2015
#6. Review/update local plans and agreements for consistency and currency to ensure initial attack response to priority greater sage grouse areas.	Federal local unit FMOs in coordination with cooperators and with review by Federal regional/state FMOs	May 15, 2015
#7. Develop supplemental guidance for use of "severity funding."	DOI OWF in coordination with BLM	May 15, 2015
#8. Evaluate the effectiveness of action plans.	DOIOWF and Federal Agency Fire Directors	May 30, 2015
#9. Increase the availability of technology and technology transfer to fire management managers and suppression resources.	DOI national bureau leadership; DOI state/ regional and local unit managers	June 1, 2015
#10. Improve the description and awareness of critical resource values threatened in various stages of the fire response process including large fire management.	NMAC Group, National Interagency Coordination Center, and Geographic Area Coordination Centers	June 1, 2015

INITIAL REPORT ACTION ITEMS (SHORT TERM)

Action Item	Responsible Party/Parties	Target to Complete
#11. Ensure compliance and evaluation of the implementation plan action items.	Local Unit FMO and Federal regional/ state FMOs	July 1, 2015
7(b) ii Prioritization and Allocation of Resources		
#1. Communication Plan	National Agency Fire Leadership (DOI Bureaus and USFS)	April 1, 2015
#2. Review and update the delegation of authority for the NMAC Group.	National agency leadership (DOI Bureaus/USFS/NASF)	May 1, 2015
#3. Issue national level "Leaders' Intent."	National agency leadership (DOI Bureaus/USFS/NASF)	May 1, 2015
#4. Engage GMAC Groups.	National agency leadership (DOI/USFS/NASF)	May 1, 2015
#5. Develop "Delegation of Authority" template for use by local line officers.	NMAC	May 1, 2015
#6. Engage line officers to communicate Leaders' Intent and expectations.	Federal agency leadership (USFS/DOI Bureaus)	June 1, 2015

INITIAL REPORT ACTION ITEMS (SHORT TERM)

Action Item	Responsible Party/Parties	Target to Complete
7(b) v Post Fire Recovery		
#1. Review and update ES and BAR policy guidance to address rating and evaluation criteria, project design to promote the likelihood of treatment success, cost containment, monitoring, and continuity and transition to long term restoration activities and treatments.	I-BAER/OWF/IFEC/FEC/Federal Fire Policy Council	June 1, 2015
#2. Address acquisition, financial management, and other procedures that pose challenges to timely project implementation.	OWF/Bureau Designated Representatives	July 1, 2015
#3. Accelerate schedule approving BAR projects consistent with the guidelines established for the 2015 fire season.	IBAER/DOI Bureaus	June 1, 2015
#4. Identify non fire programs and activities that will fund treatments and restoration activities for the long term in conjunction with BAR and ES policy and program review to be conducted in 2015.	All Affected DOI Bureaus	June 1, 2015
#5. Identify requirements for NFPORS capabilities.	IBEAR/DOI Bureau	June 1, 2015

INITIAL REPORT ACTION ITEMS (SHORT TERM)

Action Item	Responsible Party/Parties	Target to Complete
7(b) ix Seed Strategy		
#1. Develop the draft National Seed Strategy and Implementation Plan (2015 2020)	BLM (lead agency) BIA, FHA, USFS, FWS, NPS, ARS, NRCS, NIFA, and USGS (support agencies)	April 2015
#2. Identify a forum to discuss and highlight current native seed and restoration techniques and research.	BLM and USFS	April 2015
#3. Provide an opportunity to discuss current research, case studies, and tools that inform applied restoration opportunities in the Great Basin.	BLM and USFS Great Basin Native Plant Project, Society for Ecological Restoration, and Fire Science Exchange	May 2015

Final Report Actions (Longer Term)

FINAL REPORT ACTION ITEMS (LONGER-TERM)		
Action Item	**Responsible Party/Parties**	**Target to Complete**
Cross Cut Items		
#1. Develop interagency capability and functionality to provide ongoing coordination, oversight, and accountability to ensure timely and appropriate implementation of the Strategy and the supporting action items.	Rangeland Fire Task Force (Lead)	Third Quarter 2015; Ongoing
#2. Develop and share a geospatial tool that highlights areas of concern and priority habitats in the Great Basin, including within priority greater sage grouse habitat, particularly in areas identified using the Fire and Invasives Assessment Tool (FIAT).	USGS Associate Director for Core Science Systems (Lead) BLM AD for Fire and Aviation Dept. Geospatial Information Officer BLM AD for Renewable Resources and Planning (Support)	Third Quarter 2016

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
#3. Establish an interagency framework with protocols, standards, and capacity to conduct long and short term monitoring at all appropriate scales, of the sagebrush steppe ecosystem condition and the effectiveness of fire prevention, fire suppression, and habitat restoration. Use adaptive management to respond to changing conditions, guide new science, and adjust management practices and policy.	USGS AD for Ecosystems for development of monitoring framework and BLM AD for Renewable Resources and Planning for field implementation of monitoring (Co-Leads) and USFS and other appropriate Federal and state agencies and tribes	Fourth Quarter 2016
#4. Develop and implement efficient and appropriate National Environmental Policy Act (NEPA) and other environmental compliance processes.	Office of the Secretary – Assistant Secretary – Policy, Management, and Budget and Assistant Secretary – Land and Minerals Management (Co-Leads) Support: BLM, FWS, BIA, NPS, and other supporting agencies	Third Quarter 2015 to develop process, including schedule for implementation

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
#5. Develop multi year resource and action plan to implement the Strategy and supporting actions and develop tools to facilitate integrated budget development and track implementation.	Assistant Secretary – Policy, Management, and Budget (Lead) DOI Assistant Secretaries and Bureau Directors, in coordination with USDA (Support)	Ongoing
#6. Enhance Funding Leverage and Collaboration with Partners.	Assistant Secretary – Policy, Management, and Budget (Lead) DOI Assistant Secretaries and Bureau Directors, in coordination with USDA (Support)	Ongoing
7(b) i. Integrated Response Plans		
#1. Update Fire Management Plans to enhance protection of the sagebrush steppe from wildfire.	DOI Bureau Fire Executives (Co-Leads) Local Unit Fire Management Officers – BLM, NPS, BIA, and FWS (Support)	Second Quarter 2016 for FIAT Areas Second Quarter 2017 outside FIAT Areas
#2. Develop a national technology plan to increase the availability of technology and technology transfer to wildland fire managers.	Fire Management Board (Lead) DOI and USFS Chief Information Officers (CIOs) and Bureau ADs for Information	Second Quarter 2016

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
	Resources (IR) (Support)	
#3. Strengthen rapid and long term response capabilities and capacity in priority greater sage grouse habitat, particularly in identified FIAT areas.	DOI Bureau Fire Executives (Lead)	Second Quarter 2016
#4. Develop a long term national plan for enhancing capability, capacity, and utilization of non federal wildland fire assets and organizations.	Director, Office of Wildland Fire (OWF); Director, USFS Fire and Aviation Management (FAM) (Co-Leads) DOI Bureau and USFS Fire Executives; USFA (Support)	Second Quarter 2016
7(b) ii. Prioritization and Allocation of Resources		
#1. Identify and take actions to reduce administrative barriers that adversely affect the mobility of firefighting assets.	Director, OWF; Director, USFS FAM (Co-Leads) DOI Bureau Fire Executives, USFA, and NASF; DOI and USFS business and financial management offices (Support)	Second Quarter 2016
#2. Enhance predictive services and fire intelligence capabilities to anticipate, plan for, and utilize firefighting resources and assets.	Director, OWF; Director, USFS FAM (Co-Leads) Fire Management Board, National Weather Service, and non-federal partners, including states	Second Quarter 2016, with additional enhancements in future years

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
	(Support)	
#3. Engage international and Department of Defense (DOD) partners.	Director, OWF; Director, USFS FAM (Co-Leads) DOI International Affairs and USFS International Fire (Support)	International Agreements: Fourth Quarter 2015 DOD Agreements: Second Quarter 2016
#4. Review cooperative agreements between Federal, tribal, and state entities.	Director, OWF; Director, USFS FAM (Co-Leads) DOI Bureau Fire Executives; Chair, Forest Fire Protection Committee, NASF (Support)	Second Quarter 2016
#5. Improve management of the radio spectrum.	Director, OWF; Director USFS FAM (Co-Leads) DOI and USFS CIOs, Bureau ADs for IR, DOI Bureau Fire Executives (Support)	Second Quarter 2016
#6. Support efforts to identify responsibility for protecting all lands.	Director, OWF; Director USFS FAM (Co-Leads) Bureau state and regional Fire Management Officers (Support)	Ongoing
#7. Develop mechanisms to capture and analyze data regarding allocation of firefighting assets and wildfire impacts to priority sagebrush steppe ecosystems.	Director, OWF; Director, USFS FAM (Co-Leads) DOI Bureau and USFS Resource and Fire Executives, USFA, and NASF; and Fire Management Board (Support)	Second Quarter 2016

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
7(b) iii. Fuels		
#1. Identify fuels management priorities.	BLM ADs for Renewable Resources and Planning and Fire and Aviation (Co-Leads) USFS, NRSC, FWS, state agencies, counties and private landowners (Support)	Third Quarter 2015, continued improvements in subsequent years
#2. Develop common interagency metrics to validate fuels management activities in sagebrush steppe.	Director, OWF (Lead) Federal land management agencies, USGS, JFSP, interested tribes, and non-federal partners (e.g., states, NGOs, etc.) (Support)	First Quarter 2016
#3. Review and update current best management practices (BMPs) for rangeland fuel treatments.	BLM AD for Fire and Aviation (Lead) Agency fuels specialists (DOI, USFS, NRCS), wildlife, range/vegetation, research scientists with fuel treatment experience, scientific community representatives, and non-federal partners (WAFWA, WGA representatives, and other NGOs) (Support)	Third Quarter 2016

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
#4. Coordinate the development of effective landscape level fuel treatment plans. ***4a. Initiate a pilot project to test existing tools and/or prototype versions of new tools. An initial pilot project will occur to test Interagency Fuels Treatment Decision Support System (IFT DSS).***	BLM AD for Fire and Aviation; USFS Wildland Fire Management Research, Development, and Application (WFMRD&A) (Co-Leads) NRCS, NWCG Interagency Fuels Committee (Support)	Results from initial pilot project by Fourth Quarter 2015; initiate additional pilot project(s) in the First Quarter of 2016
4b. Use results from pilot project(s) to make improvements in models and identify appropriate tools for developing strategies for future landscape level fuel treatments in sagebrush steppe ecosystems. Coordinate with other agencies and organizations that may develop and lead additional pilot projects.	BLM AD Fire and Aviation and USFS WFMRD&A (Co-Leads) NRCS, DOI land management agencies, JFSP, and USFS National Forest Systems (NFS); scientific and academic communities, NGOs (Support)	Core capabilities developed by the end of the First Quarter 2016; Review completed by end of Third Quarter 2016; and Recommendations to the Fire Management Board by the end of the First Quarter 2017
5. Implement a comprehensive knowledge transfer program to enhance the fuels management program's role in sagebrush steppe management.	BLM AD for Fire and Aviation and BLM AD for Renewable Resources and Planning (Co-Leads) USFS and DOI Bureau Fire and Resource Executives working with JFSP and/or NGO/universities to develop training (Support)	Develop training by Second Quarter 2016; Deliver training in 2017

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
6. Explore opportunities to provide support to livestock grazing permittees and private landowners to implement fuel treatment actions as part of strategic, landscape efforts to protect, conserve, and restore sagebrush steppe habitats.	BLM AD for Renewable Resources and Planning and NRCS (Co-Leads) BLM AD for Fire and Aviation, USFS, Soil and Water Conservation Districts, private landowners, states, counties, and RFPAs (Support)	Identify landscapes by the First Quarter 2016; Fund work for 2017
7. Explore incentives for livestock producers to implement targeted fuel and vegetation treatments.	BLM AD for Renewable Resources and Planning and FWS AD for Ecological Services (Co-Leads) Private landowners, states, counties, and RFPAs (Support)	Evaluate opportunities for livestock producer engagement in FIAT areas by First Quarter 2016; Expand assistance/incentives to producers and permittees in priority landscapes in 2016 – 2017.

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
#8. Use risk based, landscape scale approaches to identify and facilitate investments in fuel treatments in the Great Basin. ***a. DOI will use a risk based approach to allocate program funds to Bureaus.*** ***b. DOI agencies to apply a risk based approach to allocate fuels management program funds to units.***	8a. Director OWF (Lead) DOI Bureau Fire Executives (Support) 8b. DOI Bureau Fire Executives (Co-Leads)	8a. Complete by Fourth Quarter of 2015 for 2016 and 2017 8b. By Fourth Quarter 2015 for 2016 and 2017 funding
7(b) iv. Integrate Science into Project Design and Implementation		
#1. Develop a Conservation and Restoration Strategy for the sagebrush steppe that considers emerging science, particularly ecological resistance, and resilience in habitat management, fuels treatment and restoration projects.	BLM ADs for Renewable Resources and Planning and Fire and Aviation (Co-Leads) Other DOI and USDA agencies, states, tribes, WAFWA, NGOs, and other partners in conservation science and development, and invite stakeholders to participate (Support)	Fourth Quarter 2016

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
#2. Identify priority actions for conservation and restoration.	BLM ADs for Renewable Resources and Planning and Fire and Aviation (Co-Leads) Other DOI and USDA agencies, states, tribes, WAFWA, NGOs, and other partners in conservation science and development, and invite stakeholders to participate (Support)	Fourth Quarter 2016
#3. Incorporate traditional ecological knowledge into management practices.	BLM AD for Renewable Resources and Planning (Lead) Other DOI and USDA agencies, states, tribes, WAFWA, NGOs, and other partners in conservation science and development, and invite stakeholders to participate (Support)	Fourth Quarter 2016
7(b) v. Post Fire Restoration		
#1. Review, update, and resolve Emergency Stabilization (ES) and Burned Area Rehabilitation (BAR) policy, procedures, and allocation changes to meet the goals of the Order.	Director, OWF (Lead) DOI Bureau Fire and Resource Executives (Support)	Third Quarter 2015

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
#2. Integrate ES, BAR, and other restoration programs to adhere to ecologically based desired conditions, and develop processes for long term restoration commitment and maintenance of ES and BAR treatments.	Director, OWF (Lead) DOI Bureau Fire and Resource Executives (Support)	Second Quarter, 2016
#3. Conduct periodic reviews to test efficacy of ES and BAR programs.	Director, OWF (Lead) DOI Bureau Fire and Resource Executives (Support)	Third Quarter 2016
7(b) vi. Commit to Multi year Investments in Restoration		
#1. Identify, document and map current investments in restoration, monitoring, and adaptive management.	BLM AD for Renewable Resources and Planning (Lead) BLM ADs for Energy, Minerals, and Realty Management and Fire and Aviation; OWF; other DOI and USDA agencies, states, tribes, WAFWA, and partners in conservation and development (Support)	First Quarter 2016

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
#2. Identify and initiate actions to reduce administrative barriers to fulfilling multi year commitments to restoration, monitoring, and adaptive management and to collaborating across landscapes.	BLM AD for Renewable Resources and Planning (Lead) BLM ADs for Energy, Minerals, and Realty Management and Fire and Aviation; OWF; other DOI and USDA agencies, states, tribes, WAFWA, and partners in conservation and development (Support)	Second Quarter 2016
#3. Describe lessons learned from existing multi year investment programs and recommend procedural changes for funding multi year plans for restoration, monitoring, and adaptive management.	BLM AD for Renewable Resources and Planning (Lead) Other DOI Bureaus and USDA agencies Invite tribes, partners, and stakeholders to participate (Support)	First Quarter 2016
#4. Develop a community of practice for restoration, monitoring, and adaptive management in the sagebrush steppe ecosystem.	BLM AD for Renewable Resources and Planning (Lead) BLM ADs for Energy, Minerals, and Realty Management and Fire and Aviation; OWF; other DOI and USDA agencies, states, tribes, WAFWA, and partners in conservation and development (Support)	Fourth Quarter 2016
#5. Develop comprehensive policies and consistent funding to implement the Conservation and Restoration Strategy	BLM AD for Renewable Resources and Planning and Fire and Aviation (Co-Leads) BLM ADs for Energy, Minerals, and Realty	Fourth Quarter 2016

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
	and Fire and Aviation; OWF; other DOI and USDA agencies, states, tribes, WAFWA, and partners in conservation and development (Support)	
7(b) vii. Large scale Activities to Remove Invasive Non native Grasses		
#1. Develop a framework for a national invasive species Early Detection and Rapid Response (EDRR) program.	DOI Invasive Species Coordinator (Lead) BLM AD for Renewable Resources and Planning; FWS, NPS, USGS, USFS, NRCS, DOC, Environmental Protection Agency (EPA), and National Invasive Species Council (NICS), WGA, state agencies, tribes, and NGOs (Support)	First Quarter 2016
#2. Conduct large scale research and demonstration projects for control of cheatgrass and other invasive annual grasses to identify and advance effective strategies for preventing the spread of invasive species and support large scale rangeland restoration.	BLM ADs for Renewable Resources and Planning and Fire and Aviation; USGS AD for Ecosystems (Co-Leads) FWS, BIA, NPS, USFS, NRCS, ARS, NGOs, tribes, and GBLCC (Support)	Third Quarter 2016

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
#3. Complete the Vegetation Treatments Programmatic Environmental Impact Statement.	BLM AD for Renewable Resources and Planning (Lead)	Fourth Quarter 2016
#4. Develop a process to coordinate with the Animal and Plant Health Inspection Service (APHIS) and EPA on registration and labeling of new invasive annual grass biological and chemical control agents, as applicable.	BLM AD for Renewable Resources and Planning (Lead) USGS, USFS, ARS, APHIS, and EPA (Support)	Fourth Quarter 2015
#5. Develop scalable and adaptive grazing management plans for reducing invasive annual grass and other fine fuels through targeted livestock grazing methods to diminish fire risk in priority greater sage grouse areas to meet greater sage grouse habitat goals.	BLM AD for Renewable Resources and Planning (Lead) NRCS, FWS, USFS, ARS, states, counties, grazing permittees, and private landowners (Support)	Agreements and standards in place for use by Third Quarter 2017
7(b) viii. Science and Research		
#1. Develop and maintain an inventory of research commitments and capacity.	DOI Science Advisor (Lead) USGS, BLM, FWS, NPS, USFS, NRCS, ARS, JFSP and GBLCC (Support)	Third Quarter 2015 and Ongoing
#2. Review existing research prioritization and strategy efforts to identify science needs for the Great Basin.	USGS AD for Ecosystems (Lead) Appropriate Federal agencies, JFSP, and GBLCC (Support)	Fourth Quarter 2015

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
#3. Develop an actionable science plan of prioritized research needs.	USGS AD for Ecosystems and USFS Deputy Chief for Research and Development (R&D) (Co-Leads) Interagency team of appropriate Federal, state, tribal, academic, JFSP, and GBLCC representatives (Support)	Third Quarter 2016
#4. Develop or identify a primary online science delivery system to allow easier access to published science products and other science information.	JFSP and GBLCC (Co-Leads) Other information providers, affected Federal and state agencies, tribes, NGOs (Support)	Fourth Quarter 2015
#5. Identify available funding sources to support the action plan and implement new research in 2017 and beyond.	DOI Science Advisor (Lead) Other Federal agencies, tribes, GBLCC, JFSP, and DOI Science Coordinator (Support)	Third Quarter 2016 for budget plan development, re-occurring for out-year budget requests
#6. Conduct periodic reviews and updates of the science action plan.	USGS AD for Ecosystems (Lead) Interagency team of appropriate Federal, state, tribal, academic, JFSP, and GBLCC representatives (Support)	Re-occurring with first update in 2019

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
7(b) ix. Seed Strategy		
#1. Complete and issue the National Seed Strategy and Implementation Plan (2015 2020) to increase production, storage capacity, acquisition, and use of genetically appropriate and locally adapted seed.	BLM AD for Renewable Resources and Planning (Lead) BIA, FWS, NPS, and USGS; USDA (USFS, NRCS, ARS, National Institute of Food and Agriculture [NIFA]); DOT Federal Highway Administration (FHWA); Smithsonian; and U.S. Botanical Garden (Support)	Fourth Quarter 2015
#2. Implement the National Seed Strategy.	BLM AD for Renewable Resources and Planning (Lead) BIA, FWS, NPS, and USGS; USDA (USFS, NRCS, ARS, National Institute of Food and Agriculture [NIFA]); DOT Federal Highway Administration (FHWA); Smithsonian; U.S. Botanical Garden; and private entities (Support)	Fourth Quarter 2016
#3. Increase the availability of native seed and plant materials by ensuring the collection, production, storage, and distribution of commercial seed for long term rangeland conservation in collaboration with private partners.	BLM AD for Renewable Resources and Planning (Lead) BIA, FWS, NPS, and USGS; USDA (USFS, NRCS, ARS, National Institute of Food and Agriculture [NIFA]); DOT Federal Highway Administration (FHWA); Smithsonian; U.S. Botanical Garden and private parties	Fourth Quarter 2015 and ongoing

FINAL REPORT ACTION ITEMS (LONGER-TERM)

Action Item	Responsible Party/Parties	Target to Complete
	(Support)	
#4. Coordinate and collaborate across agencies climate trend data as it relates to seeds.	USGS Associate Director for Climate Change and Land Use (Lead) DOI and USDA agencies; state agencies, tribes, scientific and academic institutions, and NGOs (Support)	Fourth Quarter 2015 and ongoing
#5. Increase the availability of native seed and plant materials for the Great Basin.	BLM AD for Renewable Resources and Planning (Lead) BIA, FWS, NPS; USDA (USFS, NRCS, ARS, National Institute of Food and Agriculture [NIFA]), and Great Basin Native Plant Project (Support)	Fourth Quarter 2015 and ongoing
#6. Work with tribal and agency plant material specialists to improve efficiencies in rangeland seeding operations for restoration that includes Emergency Stabilization (ES) and Burned Area Rehabilitation (BAR).	USGS AD for Ecosystems on developing design and monitoring protocols; Implementation by DOI bureaus (Lead)	Fourth Quarter 2016
#7. Expand efforts to utilize native and non native seed and vegetation plantings, where appropriate, to accelerate efforts to improve and restore post fire rangeland health.	IBAER (Lead) DOI Bureaus (Support)	Second Quarter 2016

Appendix C – Fire and Invasive Assessment Tool (FIAT)

Overview of the FIAT

Greater Sage-Grouse Wildfire, Invasive Annual Grasses & Conifer Expansion Assessment (Fire and Invasive Assessment Tool, June 2014; (Prepared by Fire and Invasive Assessment Team (Appendix 5), 44 pages).

Introduction and Background

The purpose of the Fire and Invasive Assessment Tool (FIAT) is to identify priority habitat areas and management strategies to reduce the threats to greater sage-grouse resulting from impacts of invasive annual grasses, wildfires, and conifer expansion. The Conservation Objectives Team (COT) report (USFWS 2013) and other scientific publications identify wildfire and conversion of sagebrush habitat to invasive annual grass dominated vegetative communities as two of the primary threats to the sustainability of greater sage-grouse (*Centrocercus urophasianus*, hereafter sage-grouse) in the western portion of the species range. For the purposes of this assessment protocol, invasive species are limited to, and hereafter referred to, as invasive annual grasses (e.g., primarily cheatgrass (*Bromus tectorum*)). This assessment also addresses the Conifer expansion (also called encroachment).

The development of the FIAT process was in response to FWS' need for an assurance that DOI would strategically address fire and invasive species on the landscape and tied to the Conservation Objectives Team (COT) Report (FWS 2013). The concept of the FIAT was first presented to the National Policy Team (NPT) at a September 2013 Federal agency meeting. The decision by the NPT from that meeting was to conduct the FIAT (Fire and Invasive Assessment Team) assessments and commissioned a team led by Mike Pellant, BLM, Great Basin Restoration Initiative Coordinator. The final FIAT process report was completed in June 2014, and then the Fire and Invasives Assessment *Teams* evolved into a Fire and Invasives Assessment *Tool* (or Process). Evolution was completed after issuance of BLM Instruction Memorandum (IM) 2014-134 from BLM Assistant Director Resources, and Planning, on August 28, 2014.

The initial analysis is limited to Western Association of Fish and Wildlife Management Agencies' (WAFWA) Management Zones III, IV, and V (roughly the Great Basin region) because of the significant issues associated with invasive annual grasses, conifer expansion, and the high occurrence of wildfires in this region. An interagency team of wildland fire and resource management specialists and research ecologists from BLM, USFS Rocky Mountain Research Station, ARS, USGS, FWS, and NRCS developed the FIAT protocol to specifically incorporate resistance to invasive annual grasses and resilience to disturbance principles into the assessment protocol.

The cornerstone of the FIAT protocol is recent scientific research on resistance and resilience of Great Basin ecosystems (Chambers et al. 2014a). The Western Association of Fish and Wildlife Agencies (WAFWA) assembled an interdisciplinary team to address the issues of wildfires and invasive annual grasses. This interagency collaboration between rangeland scientists, fire specialists, and sage-grouse biologists resulted in the development of a strategic, multi-scale approach for employing ecosystem resilience and resistance concepts to manage threats to sage-grouse habitats from wildfire and invasive annual grasses (Chambers et al. 2014b). This paper, published as a Forest Service Rocky Mountain Research Station General Technical Report RMRS-GTR-326, serves as the reference and basis for the FIAT protocol. A paper derived from this GTR is being developed for peer-reviewed publication in a scientific journal.

FIAT Process

The assessment process included two steps with sub-elements:

Step 1

First, important Priority Areas for Conservation (PACs) and focal habitats are identified (Step 1a). Second, potential management strategies are identified to conserve or restore important focal habitats threatened by wildfires, invasive annual grasses, and conifer expansion (primarily pinyon pine and/or juniper species; Step 1b) within focal habitats. Focal habitats are the portions of a PAC with important habitat characteristics that support viable populations of greater sage-grouse, and are at risk due to threats (e.g., wildfires, invasive annual grasses, and conifer expansion). Soil temperature and moisture regimes are used to characterize capacity for resistance to invasive annual grasses and resilience to disturbance (primarily wildfires) within focal habitats and to assist in identifying appropriate management strategies.

Step 2

Step 2 is conducted by local management units to address wildfire, invasive annual grasses, and conifer expansion in or near focal habitat areas. The geospatial data from Step 1 are integrated with more refined local data in Step 2 of the assessment process. By integrating regional findings, refined local data, and resistance/resilience concepts, FIAT step 2 produces a suite of potential treatments and management strategies for sage-grouse conservation. Specifically, these include management opportunities for fuels management, habitat restoration, fire operations, and post-fire rehabilitation. These opportunities are developed in concert with State and Federal partners, and involve management across ownerships.

The Science That Supports FIAT

Greater sage-grouse are considered a landscape species that require very large areas to meet their annual life history needs. Greater sage-grouse are highly clumped in their distribution (Doherty et al. 2010), and the amount of landscape cover in sagebrush is an important predictor of greater sage-grouse persistence in these population centers (Knick 2011). FIAT used data sets that were available across the three management zones as an initial step for prioritizing five large PACs and several smaller adjacent PACs for the first round of FIAT assessments.

Priority Areas for Conservation (PACs) and Breeding Bird Density (BBD)

PACs were developed in the COT Report (USFWS 2013) based on greater sage-grouse habitat requirements and population data and served as the first filter for the assessment. Greater sage-grouse breeding bird densities (BBD) developed by Doherty et al. (2010) were used to identify greater sage-grouse population concentration centers. While this coverage strongly reflects breeding habitats, it also serves as the best regional dataset for portraying greater sage-grouse population abundance. Finer scale seasonal habitat use data was incorporated at local levels (where available) to ensure management actions encompassed all seasonal habitat requirements.

For this assessment, FIAT chose to use the 75 percent BBD as an indicator of high bird density areas and focused management activities in or near these areas in the PACs selected for assessments. Note that breeding density areas displayed in Doherty et al. (2010) were identified using best available information in 2009. Where available, more current BBD data provided by State game and fish agencies were incorporated into FIAT Step 2 assessments. Subsequent analysis should use the most current information available. In addition, BBD areas should not be viewed as rigid boundaries but rather as a means to prioritize landscapes regionally where step down assessments and actions should be implemented quickly to conserve the most birds.

Soil Temperature and Moisture Regimes

In cold desert shrublands, vegetation community resistance to invasive annual grasses and resilience following disturbance is strongly influenced by soil temperature and moisture regimes. Generally, colder soil temperature regimes and moister soil moisture regimes are associated with more resilient and resistant vegetation communities. While vegetation productivity and ability to compete and recover from disturbance increase along a moisture gradient, cooler temperatures limit invasive annual grass growth and reproduction (Chambers et al. 2007; Chambers et al. 2014a). Conversely, warm and dry soil temperature and moisture regimes and to a lesser degree cool and dry soil temperature and moisture regimes, are linked to less resistant and resilient communities that are more likely to be invaded by invasive annual grasses. These relationships can be used to prioritize management actions within sage-grouse habitat using broadly available data.

To capture relative resistance and resilience to disturbance and invasive annual grasses across the landscape, soil temperature and moisture regime information (described in detail in Chambers et al. 2014b) were obtained from the NRCS Soil Survey Geographic Database (SSURGO) data. Where gaps in this coverage existed, the NRCS US General Soil Map (STATSGO2) data were used (Soil Survey Staff 2014a, b).

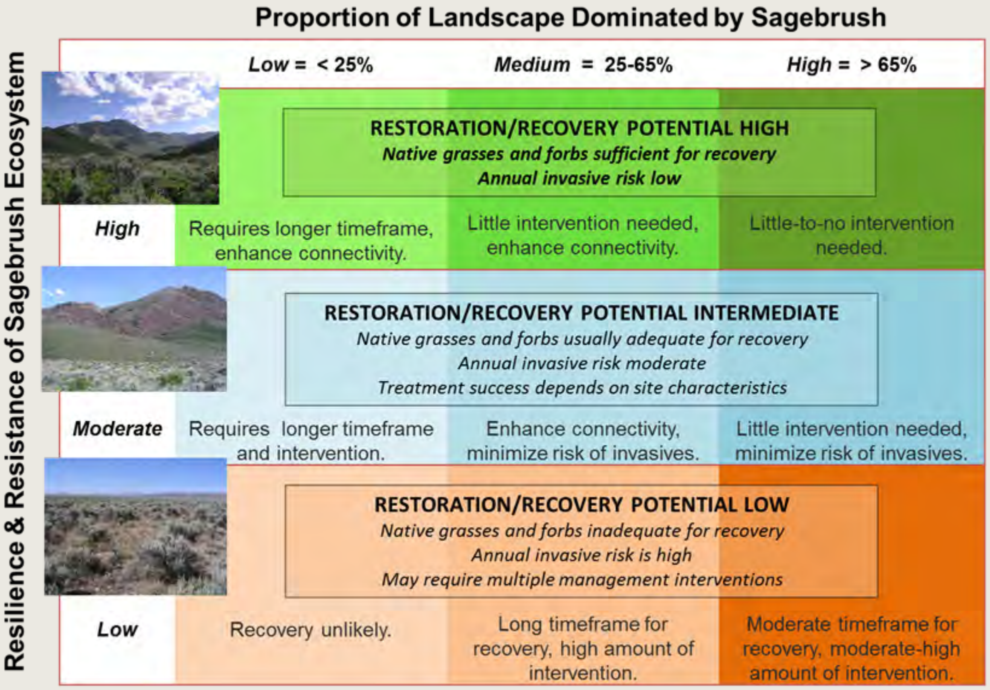
Sagebrush Landscape Cover

The amount of the landscape in sagebrush cover is closely related to the probability of maintaining active sage-grouse leks, and is used as one of the primary indicators of sage-grouse habitat potential at landscape-scales (Aldridge et al. 2008; Wisdom et al. 2011; Knick et al. 2013). For purposes of prioritizing landscapes for sage-grouse habitat management, FIAT used less than or equal to 25 percent sagebrush landscape cover as a level below which there is a low probability of maintaining sage-grouse leks, and greater than or equal to 65 percent as the level above which there is a high probability of sustaining sage-grouse populations with further increases of landscape cover of sagebrush (Aldridge et al. 2008; Wisdom et al. 2011; Knick et al. 2013). FIAT then grouped the percentage of landscape sagebrush cover into each of the selected categories (0 to 25 percent, 25 to 65 percent, and 65 to 100 percent). These thresholds were used to inform the development of management opportunities in the FIAT assessments.

Putting it All Together: Sage-Grouse Habitat Matrix

The key to the FIAT Assessment is the Sage-Grouse Habitat Matrix (below) which assists managers in prioritizing management activities based on the resistance and resilience of the landscape and the amount of sagebrush landscape cover. Combined with the 75% Breeding Bird Density, managers have the information needed to prioritize areas for fire operations, fuels management, post-fire rehabilitation and habitat restoration and recovery.

Figure C-1. *Matrix designed to link ecosystem resilience and resistance with potential species habitat for sagebrush ecosystems and greater sage-grouse in the western portion of sage-grouse's range. The rows provide information on the restoration/recovery potential of ecological types with relatively high, moderate, and low resilience and resistance and are illustrated here by mountain big sagebrush/mountain brush, mountain big sagebrush, and Wyoming sagebrush, respectively. The columns provide information on the amount of time and types of intervention required to increase sagebrush cover, and the probability of sage-grouse persistence for areas with low (< 25%), medium (25-65%) and high (> 65%) land cover of sagebrush. The management objective is to move from left to right within each resilience and resistance category and increase contiguous land cover of sagebrush (adapted from Chambers et al. 2014b).*



Proportion of Landscape Dominated by Sagebrush

Resilience & Resistance of Sagebrush Ecosystem

	Low **= < 25%**	***Medium*** **= 25-65%**	***High*** **= > 65%**
	RESTORATION/RECOVERY POTENTIAL HIGH ***Native grasses and forbs sufficient for recovery*** ***Annual invasive risk low***		
High	Requires longer timeframe, enhance connectivity.	Little intervention needed, enhance connectivity.	Little-to-no intervention needed.
	RESTORATION/RECOVERY POTENTIAL INTERMEDIATE *Native grasses and forbs usually adequate for recovery* *Annual invasive risk moderate* *Treatment success depends on site characteristics*		
Moderate	Requires longer timeframe and intervention.	Enhance connectivity, minimize risk of invasives.	Little intervention needed, minimize risk of invasives.
	RESTORATION/RECOVERY POTENTIAL LOW *Native grasses and forbs inadequate for recovery* *Annual invasive risk is high* *May require multiple management interventions*		
Low	Recovery unlikely.	Long timeframe for recovery, high amount of intervention.	Moderate timeframe for recovery, moderate-high amount of intervention.

Status of FIAT Assessments

The BLM was the lead agency for the FIAT Step 2 assessments, which were completed on March 27, 2015.

Additional partners contributing to the assessments include USFWS, U.S. Forest Service, Rocky Mountain Research Station, NRCS, and state game and fish agencies. In total, five FIAT assessments are complete for highly valued landscapes, as identified in FIAT step 1. These landscapes correspond to PACs, as outlined in the COT Report (USFWS 2013):

- Central Oregon
- Northern Great Basin
- Snake/Salmon/Beaverhead
- Southern Great Basin
- Western Great Basin / Warm Springs Valley NV, Western Great Basin

In each of these areas, FIAT teams applied guidance from Chambers et al. (2014b), the COT report (USFWS 2013), and additional science to identify management strategies and potential treatments, which ameliorate threats to greater sage-grouse. These management opportunities include fuel breaks, which complement fire suppression efforts; removal of conifer species expanding into greater sage-grouse habitats; treatment of invasive annual grasses and native plant reestablishment; identifying areas for highest fire suppression priority; and prioritizing landscapes for rehabilitation practices when wildfires occur. In addition to the written assessments, spatial data depictions of the location and extent of management opportunities were developed.

In the years ahead, BLM and partner agencies will implement these potential treatments and management strategies, contributing to sage-grouse conservation through habitat improvement, efficient fire suppression, effective post-fire recovery, and projects, which improve firefighter success.

Appendix D – Wildland Fire Management Overview

An Overview of Wildland Fire Management

Terminology

Wildland fire is any non-structure fire that occurs in vegetation or natural fuels. Wildland fire includes prescribed fire and wildfire. Rangeland fire is wildland fire occurring in rangelands. The term Fire Management includes all activities for the management of wildland fires to meet land management objectives. Fire management includes the entire scope of activities from planning, prevention, fuels or vegetation modification, prescribed fire, hazard mitigation, fire response, rehabilitation, monitoring and evaluation.

Wildland Fire Organizations

The DOI, United States Forest Service, state, tribes, counties, and local governments maintain operational wildland fire organizations. These are supplemented by volunteer organizations such as volunteer fire departments and rangeland protection associations. In DOI, the operational fire organizations reside in Bureau of Land Management (BLM), National Park Service (NPS), U.S. Fish and Wildlife Service (FWS), and Bureau of Indian Affairs (BIA). Other organizations such as US Fire Administration (in Department of Homeland Security) and U.S. Geological Survey (USGS) have fire expertise that supports and partners with the operational fire organizations. The Office of Wildland Fire (OWF) at DOI provides budget and policy coordination, leadership, and oversight for the operational programs within DOI.

Wildland Fire Governance

A number of chartered interagency groups exist to provide coordination and consistency among the widland fire organizations to ensure policy and operational consistency and interoperability. Among these are:

- Wildland Fire Leadership Council – policy level coordination and leadership among Federal, state, tribal, and local organizations
- Federal Fire Policy Council – policy leadership among Federal agency heads
- Forest Fire Protection Committee, National Association of State Foresters - policy and program coordination among states
- Fire Executive Committee – policy direction and oversight among Federal fire senior executives
- Fire Management Board – program management and coordination among Federal fire program directors

- National Wildfire Coordinating Group – intergovernmental development of interoperability standards for adoption by individual agencies
- National Multi-Agency Coordination Group – national level intergovernmental allocation and prioritization of firefighting assets
- Geographic Area Multi-Agency Coordination Group – geographic level intergovernmental allocation and prioritization of firefighting assets

Firefighting Assets

Firefighting assets consistent of all those items necessary to conduct wildland fire management activities, including: personnel (permanent, seasonal, contract, agency employees), owned and leased vehicles and equipment (engines, dozers, radios, and so on), owned and leased aircraft (fixed wing, helicopters), supplies, and facilities (fire stations, warehouses, tanker bases, and so on). Each firefighting organization acquires and manages assets within its operational fire program.

Preparedness assets (those already paid for) are placed at locations determined by each organization based on workload, complexity, risk, and similar factors. Assets in excess of immediate local need are available for re-assignment (these are identified in the system as "available"). Re-assignment may be a one-time assignment of an asset to support an incident in a different location or re-assignment could be the relocation of an asset to another area once the height of fire season has passed at their home base.

Contract, leased, and purchased assets are acquired by the incident team as needed. These can include heavy equipment (dozers, water tenders, and so on), aviation, supplies, and contract or short-term employees.

Guiding Principles for Sharing Firefighting Assets

Firefighting assets are shared as needed – no single agency or unit has enough assets to meet peak needs. As assets are shared, four guiding principles are used:

- Total mobility – all assets can move if not needed
- Interoperability – all assets are interchangeable – training, organization, functionality, etc.
- Closest forces – use available assets that are closest, regardless of ownership
- Local control and direction of incidents – objectives, strategies, tactics are set by local unit manager (owner)

Fighting Fire

Initial Attack (95-98% of all fires): Initial attack on an incident uses local unit assets. Assets are deployed based on pre-planned dispatch ("run cards") that specify response based on conditions (time of year, location, values at risk, environmental conditions, weather, etc.) Additional "mutual aid" support from nearby units is used if needed.

Extended Attack: When an incident (fire) need additional assets the local ("zone") interagency dispatch fills "resource orders" from within the geographic extent of the dispatch area using the principles total mobility and closest forces. If sufficient assets are not available within that dispatch zone Geographic Areas will fill resource orders across dispatch boundaries. During extended attack, local forces may largely return to initial attack responsibilities.

Large Fires: For sustained large fires, a separate (temporary) fire organization established for that incident. An incident management team under the jurisdiction and authority of the local manager manages the incident. Requests for assets (resource orders) placed in the same manner described above. Local firefighting forces return to initial attack duty.

Setting Priorities

Broad national priorities are set in policy and articulated through Leaders' Intent documents from senior agency leadership. Specific priorities are set at multiple levels – to accomplish incident management objectives, to ensure efficient and cost-effective use of assets, and to adjudicate scarce assets:

- At the incident – through objectives for the incident
- Locally – among fires in a local area
- Geographically – among fires in the Geographic Areas
- Nationally – among Geographic Areas

The responsibility for setting priorities lies with agency administrators, on interagency/ intergovernmental basis as necessary. Dispatch centers and fire management staffs execute those priorities.

At the local, initial attack local multi-agency coordinating (MAC) groups of local managers set scale priorities. General priorities are set pre-season through mobilization guides and pre-planned dispatch, based on values to be protected, weather parameters, and other factors. During incidents, specific priorities are set to manage scarce assets and meet management objectives.

At the Geographic Area, level Geographic Area MAC groups of regional-level managers set priorities. Priorities are set through mobilization guides similar to local units – based on values to be protected and other parameters. During the season, priorities are established to manage scarce assets and meet management objectives. Geographic Areas set priorities among fires, not on individual fires.

At the national level, the National MAC group sets pre-season priorities through a national mobilization guide based on national policy direction. During the season, priorities are set to manage scarce assets and meet management objectives on a national scale. At the national level, priorities are set among Geographic Areas, not on individual fires. The national MAC group pays particular attention to the management of scarce and expensive "national resources/assets" (e.g. air tankers, Type 1 teams, Type 1 crews) among Geographic Areas.

Appendix E – Secretarial Order 3336

Rangeland Fire Prevention, Management, and Restoration

ORDER NO. 3336

Subject: Rangeland Fire Prevention, Management and Restoration

Sec. 1 **Purpose**. This Order sets forth enhanced policies and strategies for preventing and suppressing rangeland fire and for restoring sagebrush landscapes impacted by fire across the West. These actions are essential for conserving habitat for the greater sage-grouse as well as other wildlife species and economic activity, such as ranching and recreation, associated with the sagebrush-steppe ecosystem in the Great Basin region. This effort will build upon the experience and success of addressing rangeland fire, and broader wildland fire prevention, suppression and restoration efforts to date, including the National Cohesive Wildland Fire Management Strategy, and ensure improved coordination with local, state, tribal, and regional efforts to address the threat of rangeland fire at a landscape-level.

Sec. 2 **Background**. The Department of the Interior is entrusted with overseeing the management of Federal lands for the benefit of current and future generations as well as the protection and recovery of imperiled species of flora and fauna and the ecosystems upon which they depend. Rangeland fires in the Great Basin of the Western United States have increased in size and intensity in recent years. The accelerated invasion of non-native annual grasses, in particular cheatgrass and medusahead rye, and the spread of pinyon-juniper across the sagebrush-steppe ecosystem, along with drought and the effects of climate change, have created conditions that have led to the increased threat of rangeland fires to the sagebrush landscape and the more than 350 species of plants and animals, such as mule deer and pronghorn antelope, that rely on this critically important ecosystem. As a result, the increasing frequency and intensity of rangeland fire also poses a significant threat to ranchers, livestock managers, sportsmen, and outdoor recreation enthusiasts who use the sagebrush-steppe ecosystem, and puts at risk their associated economic contributions across this landscape that support and maintain the American way of life in the West.

In 2010, the U.S. Fish and Wildlife Service (USFWS) found that the invasion of annual grasses and the loss of habitat from fire in the Great Basin is a significant threat to the greater sage-grouse in that portion of its remaining range. The USFWS is now considering whether protections under the Endangered Species Act are warranted. In response to this finding, the Bureau of Land Management (BLM) and the U.S. Forest Service are currently undertaking land use plan revisions and amendments to incorporate appropriate conservation measures to conserve, enhance, and restore greater sage-grouse habitat by reducing, eliminating, or minimizing threats to that habitat. More targeted actions to reduce the likelihood and severity of fire, to stem the spread of invasive species, and to restore the health and resilience of the landscape are necessary to preserve, protect, and restore greater sage-grouse habitat in the sagebrush-steppe ecosystem, and address important public safety, economic, cultural, and social concerns. This includes enhanced coordination and collaboration with partners and stakeholders, including rangeland fire protection associations.

Sec. 3 **Authorities**. This Order is issued under the authority of Section 2 of Reorganization Plan No. 3 of 1950 (64 Stat.1262), as amended. Other statutory authorities related to this Order include and are not limited to the following:

a. National Environmental Policy Act (NEPA), 42 U.S.C. 4321 *et seq.*

b. The Endangered Species Act (ESA), 16 U.S.C. 1531 *et seq.*

c. The Migratory Bird Conservation Act, 16 U.S.C. 715 *et seq.*

d. The National Fish and Wildlife Foundation Establishment Act, 16 U.S.C. 3701 *et seq.*

e. The Fish and Wildlife Coordination Act, 16 U.S.C. 661 *et seq.*

f. The Federal Land and Policy Management Act (FLPMA), 43 U.S.C. 1701 *et seq.*

g. The Federal Land Assistance Management and Enhancement Act of 2009, Title V of Division A of P.L. 111-88.

Sec. 4 **Policy**. Protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, greater sage-grouse habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department. Allocation of fire management resources and assets before, during, and after wildland fire incidents will reflect this priority, as will investments related to restoration activities.

Sec. 5 **Developing an Enhanced Fire Prevention, Suppression, and Restoration Strategy**. To accomplish protection, conservation, and restoration of greater sage-grouse habitat the Department, through the Rangeland Fire Task Force established in accordance with Section 6, will:

a. Work cooperatively and collaboratively with other Federal agencies, states, tribes, local stakeholders, and non-governmental organizations on fire management and habitat restoration activities, including: (i) Enhancing the capability and capacity of state, tribal, and local government, as well as non-governmental, fire management organizations, including rangeland fire protection associations and volunteer fire departments, through improved and expanded education and training; and (ii) Improving coordination among all partners involved in rangeland fire management to further improve safety and effectiveness.

b. Utilize risk-based, landscape-scale approaches to identify and facilitate investments in fuels treatments, fire suppression capabilities, and post-fire stabilization, rehabilitation, and restoration in the Great Basin.

c. Seek to reduce the likelihood, size, and severity of rangeland fires by addressing the spread of cheatgrass and other invasive, non-native species.

d. Commit wildland fire management resources and assets to prepare for and respond to rangeland fires.

e. Advance the development and utilization of technologies for identifying areas of high ecological and habitat value in sagebrush-steppe ecosystems to enhance fire prevention and sage-grouse habitat protection efforts.

f. Apply science and research to improve the identification and protection of resistant and resilient sagebrush-steppe landscapes and the development of biocontrols and other tools for cheatgrass control to improve capability for long-term restoration of sagebrush-steppe ecosystems.

g. To the extent practicable, utilize locally-adapted seeds and native plant materials appropriate to the location, conditions, and management objectives for vegetation management and restoration activities, including strategic sourcing for acquiring, storing, and utilizing genetically-appropriate seeds and other plant materials native to the sagebrush-steppe ecosystem.

h. Encourage efforts to expedite processes, streamline procedures, and promote innovations that can improve overall rangeland fire prevention, suppression and restoration efficiency and effectiveness.

i. Explore opportunities to pilot new strategies to reduce the threat of invasive, non-native plant species and rangeland fire to sagebrush-steppe ecosystems and greater sage-grouse conservation, including enhanced use of veteran fire crews and youth conservation teams, and efforts to further public-private partnerships to expand capacity for improved fire management.

j. Establish protocols for monitoring the effectiveness of fuels management, post-fire and long-term restoration treatments and a strategy for adaptive management to modify management practices or improve land treatments when necessary.

Sec. 6 **Rangeland Fire Task Force**. A Rangeland Fire Task Force (Task Force) is hereby established and is chaired by the Deputy Secretary. Members of the Task Force shall include: Assistant Secretary – Policy, Management and Budget, Assistant Secretary – Land and Minerals Management, Assistant Secretary for Fish and Wildlife and Parks, Assistant Secretary – Water and Science, and Assistant Secretary – Indian Affairs. The Task Force will do the following:

a. Develop a science-based strategy to reduce the threat of large-scale rangeland fire to habitat for the greater sage-grouse and the sagebrush-steppe ecosystem through effective rangeland management (including the appropriate use of livestock), fire prevention, fire suppression, and post-fire restoration efforts at a landscape-scale.

b. Conduct a comprehensive review of the existing programs, policies, and practices associated with current efforts to prevent, suppress, and restore rangeland fire-impacted sagebrush-steppe, including the outcomes of the recent rangeland fire conference *The Next Steppe: Sage-grouse and Rangeland Fire in the Great Basin*, and utilize the experience of the conference participants; and the expertise of the practitioners and senior policy groups in this effort.

c. Seek input from the U.S. Geological Survey and individual Bureau Fire Directors in the Department; the U.S. Forest Service and the Natural Resources Conservation Service in the Department of Agriculture; various state wildland fire agencies and programs; the offices of the governors in the states most threatened by rangeland fire, including California, Oregon, Nevada, Utah, and Idaho, as well as the Western Governors' Association; affected American Indian tribes; scientists; and local, community-based fire organizations such as the rangeland fire protection associations, weed collaboratives, native seed production organizations, soil and water conservation districts, and various stakeholder groups with interest and expertise in rangeland fire prevention, suppression, and rangeland restoration.

Sec. 7 **Implementation Plan, Deliverables and Report**.

a. No later than February 1, 2015, the Task Force will provide a detailed plan for implementing this Order that includes a process for tribal consultation.

b. The Task Force will provide to the Secretary two reports that outline actions that can be accomplished prior to the onset of the 2015 Western fire season, actions that can be accomplished prior to the onset of the 2016 Western fire season, and actions that will require a longer period for implementation. At a minimum, these actions are to include the following:

(i) Design and implement comprehensive, integrated fire response plans for the Fire and Invasives Assessment Tool evaluation areas in the Great Basin subject to fire and invasive species;

(ii) Provide clear direction on the prioritization and allocation of fire management resources and assets; (iii) Expand the focus on fuels reduction opportunities and implementation; (iv) Fully integrate the emerging science of ecological resilience into design of habitat management, fuels management, and restoration projects; (v) Review and update emergency stabilization and burned area rehabilitation policies and programs to integrate with long-term restoration activities;

(vi) Commit to multi-year investments for the restoration of sagebrush-steppe ecosystems, including consistent long-term monitoring protocols and adaptive management for restored areas; (vii) Implement large-scale experimental activities to remove cheatgrass and other invasive annual grasses through various tools; (viii) Commit to multi-year investments in science and research; and (ix) Develop a comprehensive strategy for acquisition, storage, and distribution of seeds and other plant materials.

c. No later than March 1, 2015, the Task Force will present its initial report on actions that will be implemented prior to the 2015 Western fire season. Individual bureaus are also encouraged to take immediate action to implement improvements within their respective areas of responsibility before the initial report is issued.

d. No later than May 1, 2015, the Task Force will present its final report on activities that will be implemented prior to the 2016 Western fire season, and longer term actions to implement the policy and strategy set forth in this Order, including to ensure continued implementation of approved actions associated with the strategy.

Sec. 8 **Implementation**. The Deputy Secretary is responsible for implementing all aspects of this Order. This responsibility may be delegated as appropriate. This Order does not alter or affect any existing duty or authority of individual Assistant Secretaries or bureaus.

Sec. 9 **Effect of the Order**. This Order is intended to improve the internal management of the Department. This Order and any resulting report or recommendations are not intended to, and do not, create any right or benefit, substantive or procedural, enforceable at law or equity by a party against the United States, its departments, agencies, instrumentalities or entities, its officers or employees, or any other person. To the extent there is any inconsistency between the provisions of this Order and any Federal laws or regulations, the laws or regulations will control.

Sec. 10 **Expiration Date**. This Order is effective immediately. It will remain in effect until its provisions are converted to the Departmental Manual, or until it is amended, superseded or revoked, whichever occurs first.

/s/ Sally Jewel

Secretary of the Interior

Date: January 5, 2015

This Page is Intentionally Blank

Appendix F – Glossary of Terms

Burned Area Rehabilitation (BAR)

The post-fire activities prescribed and implemented to rehabilitate and restore fire-damaged lands.

Draw Down Level

The minimum level of personnel and equipment resources needed (at either the local or national level) without compromising response capability.

Emergency Stabilization (ES)

Planned actions to stabilize and prevent unacceptable degradation to natural and cultural resources, to minimize threats to life or property resulting from the effects of a fire, or to repair/ replace/construct physical improvements necessary to prevent degradation of land or resources.

Initial Attack

A prepared response to wildfire given the wildfire's potential. Initial attack may include size up, patrolling, monitoring, holding action, or suppression.

Medusahead Rye

Medusahead rye is a type of annual grass.

Multi-Agency Coordinating Group (MAC Group)

A national, regional, or local management group for interagency planning, coordination, and operations leadership for incidents. Provides an essential management mechanism for strategic coordination to ensure incident resources are managed efficiently and appropriately in a cost-effective manner.

National Environmental Protection Act (NEPA)

The NEPA process ensures that information on environmental impacts is considered in the decisionmaking process undertaken by Federal agencies. The Act establishes national environmental policy, including a multidisciplinary approach to considering environmental effects in Federal Government agency decisionmaking.

Organizational Owner

Organization owner is the organization (Federal, state, or local) that funds the resource or resources.

Rangeland Fire

Any wildfire located on rangelands.

Section 106

Requires Federal agencies to consider the effects of projects they approve, fund, or carryout on historic properties.

Resilient Ecosystems

Resilient ecosystems have the capacity to regain their fundamental structure, processes, and functioning when altered by stressors like drought and disturbances, inappropriate livestock grazing, 21 and altered fire regimes.

Resistant Ecosystems

Resistant ecosystems have the capacity to retain their fundamental structure, processes, and functioning when exposed to stresses, disturbances, or invasive species.

Severity Funding

Suppression funds used to increase the level of pre-suppression capability and fire preparedness when predicted or actual burning conditions exceed those normally expected, due to severe weather conditions.

Step Up Plans

Step up plans (also called staffing plans) are designed to direct incremental preparedness actions in response to increased fire danger.

Wildfire

An unplanned, unwanted wildland fire including unauthorized human-caused fires, escaped wildland fire use events, escaped prescribed fire projects, and all other wildland fires where the objective is to put the fire out.

Fact Sheet
For Tribal Consultation
Greater Sage-grouse Plan Amendment (PA)

- **Why are the BLM/Forest Service Undertaking this Plan Amendment Effort**
  1. In 2010, the Fish and Wildlife Service (FWS) determine that the Sage –grouse was warranted for listing under the Endangered Species Act. They determined that based on higher priorities for listing, Sage-grouse would be "Precluded" from listing at that time.
  2. FWS listed "lack of regulatory mechanism" for protection of the Greater Sage-grouse as one reason for their "warranted for listing" determination.
  3. FWS was sued regarding "precluded determinations" and a Settlement Agreement reached that stated FWS will issue proposed listing decision(s) on Greater Sage-grouse by 2015.
  4. BLM and Forest Service decided they needed to amend their Land Use Plans to provide for conservation of sage grouse and will need to be completed prior to the FWS issuance of their proposed rule on Sage-grouse.
  5. BLM identified as lead federal agency and Forest Service as Cooperating Agency. One Environmental Impact Statement (EIS) will be prepared for each sub-region.
  6. BLM and the Forest Service will issue separate decisions, based upon the EIS
  7. Current Resource Management Plan (RMP) revisions by the BLM (Battle Mountain and Carson City) will incorporate the Plan Amendments into the RMP revisions.
- **Decision(s) to be Made**
  1. Identification of "priority" habitat for the sage grouse. Current definition is (defined in IM). Decision will establish:
     - Criteria
     - Current location
     - How adjusted
  2. Identification of actions that will provide for the conservation of the Greater sage-grouse.
     - By Resource program
     - By Species Management
- **Questions for Tribes**
  1. Are there areas that need protection for sage-grouse?
  2. Are there conservation actions that the BLM/FS should consider?
- **Area Included in the Analysis (Should have maps)**
  1. Greater Sage-grouse analysis divided into two Regions; Rocky Mountain Region (Eastern) and Great Basin Region (Western)
  2. Greater Basin Region further divided into sub-regions. Four (4) Sub-regions; Idaho, Oregon, western Utah, and NE California and Nevada. Our focus is on decisions for the CA/NV sub-region.
  3. Bi-State Sage-grouse population (NW Nevada/SE California) not included in this Plan Amendment effort.
- **Time Line for NEPA process**
  1. Starting Public Scoping 12/2011 and ending March 23, 2012. Scoping Report summarized public comments including list of Tribes that have stated that they wish to be have Cooperative Agency status with the BLM.
  2. Tentative list of Alternatives to be identified by mid-July
  3. Draft EIS to be issued April 2013
  4. Final EIS to be issued In February 2014
  5. Record of Decision signed by August, 2014
- **Draft Alternatives.** The following is a list of tentative range of alternatives:
  1. Current PPH and PGH with conservation actions identified in NTT report
  2. Conservation Alternatives based on information submitted by conservation groups during public scoping period
  3. BLM/FS adjustments of PPH/PGH and NTT conservation action items
  4. Governor's State Alternatives
     - Governor Sandoval establish working group that will propose 1) core sage-grouse habitat and 2) conservation action. Goal of alternative is to provide for conservation of sage-grouse and not eliminated local economic growth.

    - Tribal Representative on Group is Beverly Harry of Nixon, Nevada
  5. Additional Alternative based upon scoping, local issues.
- **Background**
  1. **National Technical Team (NTT) Report**
     - Report, developed by experts on sage-grouse, identified conservation actions for sage grouse management. Report issued in December 2012.
  2. **BLM IM for Planning and Current Projects-(Should have IM as handouts)**
     http://www.blm.gov/wo/st/en/info/regulations/Instruction_Memos_and_Bulletins/national_instruction/2012/IM_2012-043.html
     http://www.blm.gov/wo/st/en/info/regulations/Instruction_Memos_and_Bulletins/national_instruction/2012/IM_2012-044.html
     - In December 2011, the BLM WO issued two (2) Instructional Memorandums regarding their sage grouse efforts. One dealt with this Plan Amendment effort and one discusses proposed project planning and approval until such time as the Plan Amendments are approved.
     - Required the identification of Preliminary Priority Habitat (PPH) and Preliminary General Habitat (PGH). BLM (and Forest Service) identified PPH and PGH based on sage-grouse classification map produced by the Nevada Department of Wildlife (NV). CA map is in the process of being developed. (Have maps as handouts)
     - Forest Service has not issued a similar document (called Interim Directive), but is currently reviewing a draft based on the BLM IM.
  3. **PPH/PGH definition in IM**
     - **PPH-** Preliminary Priority Habitat (PPH): Areas that have been identified as having the highest conservation value to maintaining sustainable Greater Sage-Grouse populations. These areas would include breeding, late brood-rearing, and winter concentration areas.
     - **PGH**- Areas of occupied seasonal or year-round habitat outside of priority habitat.

  4. **Governor's 2004 Conservation Strategy**
     - In 2004, Nevada issued a Conservation Strategy (primarily focused on habitat restoration actions and species inventories) that was based on information developed by local working groups for each identified sage-grouse Population Management Units (PMU). The agencies will use that plan to assist identification of conservation actions.
  5. **Biological (species information)**
     - Discuss with local biologist for specific information in your area.

- **Contacts (for internal use only)**
  1. **BLM-**
     - Plan Amendment Issues: Raul Morales, Joe Tague, Brian Amme
     - Tribal Consultation Issues: Bryan Hockett, Brian Amme
  2. **Forest Service**
     - Plan Amendment Issues; Stephanie Phillips, Randy Sharp
     - Tribal Consultation Issues: Fred Frampton

Hi All –

This is a great tool for all of us to use for the QA/QC data CEQ call to the NOC. Matt put this together and is going to have the Rocky Mountain side use this. I would ask that we all use it and that you would forward the signed copy of this to me (via e-mail) prior to my review beginning on February 11.

Please share with your GIS specialists.

Thank-you!

Lauren

Administrative Draft Proposed Plan Allocation Data Submission Worksheet

Please scan and email this form to your designated regional project coordinator once completed.

QA/QC Step	Completed (initial by ASD or DSD)
Data Development	
Data has been clipped to the EIS area boundaries submitted by the planning leads.	
Data has been clipped to where the BLM/FS has management authority.	
Data has NOT been clipped to habitat (priority, general). *Decision data must cover your entire planning areas. The NOC will clip data to display it only within habitat management types.*	
Data should not overlap between decision categories within a program area (e.g. the four fluid mineral (oil and gas) decision categories do not overlap).	
Data errors that were discovered in the past few months have been corrected.	
Data related to wilderness areas, ACECs, and coal have not been submitted.	
Data associated with buffer distances are only displayed if they are tied to a land use planning allocation decisions (specifically for fluid mineral allocations/stipulations)	
Data associated with subsurface areas are included in the fluid mineral, locatable mineral and other mineral categories, if available.	
Data Map Verifications	
Folder structure, naming conventions, and categories that the Data Management Team agreed to have been used and there are no variations of names and additional categories.	
Data layers already submitted to the NOC that have NOT changed have been noted in the tracking spreadsheet.	
The following Proposed Plan PDF maps have been emailed to our Regional Project Coordinator (Lauren Mermejo, Great Basin and Matthew Magaletti, Rocky Mtn) before COB February 10, 2015: habitat delineations, land tenure, ROWs (major only), utility corridors, wind, solar, fluid, geothermal, locatable, salable, non-energy, and trails and travel management.	

I affirm that the follow steps identified above have been completed for our sub-region.

Associate State Director or Deputy State Director

Hi Frank,

We have completed and consolidated the maps for the G.B. Rollup meeting. They can be accessed in the following folder: T:\OC\Wildlife\Transfers\Frank\Proposed_Data\GreatBasin.

The permissions are set to allow authenticated active directory users access, so clicking or pasting the folder link above into Windows Explorer should get everyone into the location. Each individual map as well as a consolidated pdf are in there. I printed out the consolidated version and it came out clear and crisp. If you would like Shannon to add your table of contents to this compiled PDF just provide her the file and she will get it updated.

The updated population summary table is attached and linked below for reference.

T:\ProjectsNational\GRSG\CEA\GRSG_Analysis\GRSG\GRSG_Tier_II\Proposed_Data\ManagementZoneProcessing\Final_Excel_Outputs\Proposed_RollUp_Meeting\HabitatByPAC_and_PopulationSummary_Final_Tables.xlsx

So, we're looking for something that covers an area like this image: http://www.fs.fed.us/rm/boise/research/gis/maps/GreatBasinMap.jpg

I can't read these files, but does the first entry "Great Basin Outline" on this page cover something like the area in the image link above? http://keck.library.unr.edu/datasets/gbgd.aspx

It looks like all the required files are in the ZIP folder so the only thought I have is that there somehow is a discrepancy between the number of records in the table (the .dbf appears to be empty). As soon as possible, could you check the shapefile on your end and if it works please re-zip and send it to me (Robin Sell is on leave). I am also trying to get IT to help me install a Shapefile Repair Tool that may fix the problem

Alisa will have to convert the 2 shapefiles to the following her state review/data clean-up, but the folders for additional documents looks good. We will attach the rangewide spatial data for other projects.

Alisa may find additional info during the final help a lot.

Arlene
Attached is the Land Tenure as discussed with Randy today.
I took your CA Lands Disposal and ran it against the PHMA/GHMA layer and removed those areas.
Then put it back with the NV Disposal layer for a complete Lands_Unavailable_Proposed

Please take a look at it and again your approval to this email will let Lauren know that it is complete.

If I missed the mark call me in the am. I will be in at 6am.

Thank you

Memorandum

To: Director, Bureau of Land Management
Chief, U.S. Forest Service

From: Director

Subject: Greater Sage-Grouse: Additional Recommendations to Refine Land Use Allocations in Highly Important Landscapes

Pursuant to our October 1, 2014 leadership discussion regarding the federal land management planning process for greater sage-grouse (sage-grouse) conservation and as a continuation of our ongoing coordination and advice regarding your land management plan revisions and amendments, we are providing recommendations to further assist your agencies in the important management decisions you are currently finalizing. During the ongoing coordination effort for the planning process, we have provided conservation advice in the form of the 2013 Conservation Objectives Team final report (COT report), our comments on the draft federal plans including comprehensive analyses of alternatives, and the National Policy Team (NPT) Guidance, as well as other consultative activities.

This memorandum and associated maps respond to a request from the Bureau of Land Management (BLM) to identify a subset of priority habitat most vital to the species persistence, within which we recommend the strongest levels of protection. The areas we have identified on the attached map are a subset of the already identified Priority Habitat Management Areas (PHMA). The areas we have identified within PHMA represent recognized "strongholds" for the species that have been noted and referenced by the conservation community as having the highest densities of the species and other criteria important for the persistence of the species. For example, the Western Association of Fish and Wildlife Agencies' 2004 Conservation Assessment of Greater Sage-Grouse and Sagebrush Habitats (Connelly, et al., 2004; Figure 13.1, attached) included a similar geographic distribution of these stronghold areas for breeding populations of sage-grouse. In addition, in 2010, Doherty et al. produced the first sets of breeding density maps, which clearly illustrate high densities of breeding birds exist in very similar locations. Most recently, Chambers et al. (2014) produced maps of relative resilience and resistance to invasive species and wildfire impacts to sagebrush habitats that also align closely with the subset of priority habitats we have identified in the Great Basin region.

Strong, durable, and meaningful protection of federally administered lands in these areas will provide additional certainty and help obtain confidence for long-term sage-grouse persistence. To be clear, enhanced protections in the stronghold areas do not obviate the need to follow the NPT guidance in the entirety of PHMAs (and in PACs in those instances where gaps between PHMA and PACs exist) and in general habitat.

We have previously advised and continue to recommend that BLM and US Forest Service (Forest Service) land management plans be designed to meet the objectives outlined in COT report. The attached maps highlight areas where it is most important that BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species.

Criteria, Methodology and Rationale

We used the following criteria to identify areas within PHMAs in which the most conservative approach should be applied:

- Existing high-quality sagebrush habitat for sage-grouse;
- Highest breeding densities of sage-grouse;
- Areas identified in the literature as essential to conservation and persistence of the species (Knick and Hanser 2011); and,
- A preponderance of current federal ownership, and in some cases, adjacent protected areas that serve to anchor the conservation importance of the landscape.

In addition, we evaluated these areas against related efforts by partner organizations (NatureServe and Conservation Biology Institute) to determine relative agreement between analyses. Using Data Basin, a mapping and analysis platform, we verified our analysis is consistent with landscape-level sage-grouse conservation opportunities and needs, as defined by the above criteria as well as additional considerations, including the modeled "velocity" of climate change onset in various parts of the range and the potential for fire and invasive species impacts on sage-grouse habitat. In the process of this comparative exercise, we determined there was generally good spatial relationship between these areas and other important habitat conservation values in the sagebrush-steppe ecosystem, including shrub-steppe passerine birds (Hanser and Knick 2011) and mule deer winter range (identified by the Western Governors Association Crucial Habitat Assessment Tool.

Rangewide Map (Map 1)

See below for regional maps and individual unit descriptions.

Great Basin Region (Map 2)

- **Southern Idaho/northern Nevada**: This general area is comprised almost entirely of federal surface lands. The area contains five designated federal Wilderness areas, and protected areas for bighorn sheep conservation. Sage-grouse breeding densities are very high.

- **North-central Idaho**: This area is anchored by Craters of the Moon National Monument, is comprised of mostly federal surface land ownership, and has a high density of breeding sage-grouse.

- **Areas adjacent to the Sheldon-Hart Mountain National Wildlife Refuge Complex, Oregon and Nevada:** This area occurs predominately on federal surface lands, and includes several Wilderness Study Areas (WSAs). It contains some of the highest sage-grouse breeding densities in Oregon and both of these national wildlife refuges (NWRs) are actively managing for sage-grouse conservation.

- **Southeastern Oregon/north-central Nevada:** This area is predominately federal surface lands and contains five designated WSAs. Breeding densities of sage-grouse are high.

Rocky Mountain Region (Maps 3 and 4):

- **Southwestern/south-central Wyoming** (Map 3): This expansive area is predominately federal surface estate and represents some of the best remaining sage-grouse habitat within the entire range of the species. The area includes four currently designated WSAs, one federal Wilderness area, and several areas managed for historic and cultural resources (which exclude development). Seedskadee National Wildlife Refuge is in the vicinity.

- **Bear River Watershed** (Northeastern Utah/Southwestern Wyoming, Map 3): This area has a high density of breeding sage-grouse. Cokeville Meadows NWR is located nearby.

- **North-central Montana** (Map 4): This area comprises the highest breeding sage-grouse densities in Montana. It follows the Missouri River, is adjacent to Charles M. Russell NWR. This area also provides wintering habitat for sage-grouse migrating seasonally from Alberta, Canada, where the species listed as endangered under the Canadian Species at Risk Act.

NATIONAL SYSTEM OF PUBLIC LANDS
U.S. DEPARTMENT OF THE INTERIOR
BUREAU OF LAND MANAGEMENT

MISSION STATEMENT

The BLM manages more than 245 million acres of public land, the most of any Federal agency. This land, known as the National System of Public Lands, is primarily located in 12 Western states, including Alaska. The BLM also administers 700 million acres of sub-surface mineral estate throughout the nation. The BLM's mission is to manage and conserve the public lands for the use and enjoyment of present and future generations under our mandate of multiple-use and sustained yield. In Fiscal Year 2014, the BLM generated $5.2 billion in receipts from public lands.

[Insert BLM WO Letterhead]

In Reply Refer To:
(WO210)(1610)

Dear Reader:

Enclosed are the Record of Decision (ROD) and Approved Resource Management Plan Amendments (ARMPAs) for the Great Basin Region Greater Sage-Grouse (GRSG) Sub-Regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah).

This ROD approves the four Great Basin Region ARMPAs, which are part of the National GRSG Conservation Strategy that was initiated on December 11, 2011. The Bureau of Land Management (BLM) initiated the conservation strategy in response to the US Fish and Wildlife Service's (FWS's) March 2010 "warranted, but precluded" Endangered Species Act listing petition decision. In this decision, the FWS identified the inadequacy of regulatory mechanisms as a significant threat to GRSG. Resource management plan (RMP) conservation measures were identified as the BLM's principal regulatory mechanism.

Combined, the BLM and the Forest Service administer approximately 62 percent of the GRSG habitat across the remaining range of the species. The National GRSG Conservation Strategy has been coordinated under two administrative planning regions across this landscape: the Rocky Mountain Region and the Great Basin Region. The regions were drawn roughly to correspond with the threats that the FWS identified in the 2010 listing decision, along with the Western Association of Fish and Wildlife Agencies' Management Zones framework (Stiver et al. 2006; see **Figure 1-4**, Greater Sage-Grouse Priority Areas for Conservation, Populations, and WAFWA Management Zones, of this ROD).

Range-wide, the BLM prepared 15 environmental impact statements (EISs), with associated proposed land use plan amendments and revisions in the Rocky Mountain and Great Basin region[illegible]he Forest Service was involved in the development of five EISs: two in the Rocky Mountain Region and three in the Great Basin. Each agency prepared two RODs: one for the approval of land use plan revisions or amendments in each of the regions covered by the GRSG Conservation Strategy. Thus, the BLM and the Forest Service prepared a total of four RODs to implement the Federal GRSG conservation plans across the remaining range of the species.

This ROD applies to the BLM ARMPAs in the Great Basin Region. However, the complete strategy for GRSG conservation on BLM-administered and National Forest System lands across the remaining range of the species consists of this ROD (and associated plans), in conjunction with the BLM ROD for the Rocky Mountain Region and the two Forest Service RODs, one for each region.

The BLM's ARMPAs provide a landscape-level, science-based, coordinated, collaborative strategy for addressing threats to GRSG and its habitat. This strategy was designed to address threats identified in the FWS's 2010 "warranted, but precluded" decision. In addition, the strategy was guided by over a decade of research, analyses, and recommendations for GRSG conservation, including the Conservation Objectives Team Report and the BLM National Technical Team Report. These reports were developed through a collaboration of state and Federal biologists and scientists with extensive experience in GRSG management and research. Science-based decision-making and collaboration with the FWS, the US Geological Survey, the Forest Service, and state and other partners were fundamental to developing these ARMPAs.

It is important to note that this ROD and these ARMPAs apply only to BLM-administered lands, including BLM-administered subsurface mineral estate. Throughout the GRSG planning process, the Forest Service has been a cooperating agency on the Idaho and Southwestern Montana, the Nevada and Northeastern California, and the Utah planning efforts. These Draft RMPAs/EISs and Proposed RMPAs/Final EISs for the Great Basin sub-regions included proposed GRSG management direction for National Forest System lands in Idaho and Southwestern Montana, Nevada and Northeastern California, and Utah. As noted above, the Forest Service has completed two separate RODs and associated land and resource management plan amendments under its planning authorities.

The Federal Land Policy and Management Act requires that resource management plans for managing public lands be developed and maintained, and, as appropriate, revised. The National Environmental Policy Act requires Federal agencies to prepare an EIS for major Federal actions significantly affecting the quality of the human environment. In fulfilling these requirements, the Draft RMPAs/EISs were published in the fall of 2013. They incorporated analysis and input provided by the following:

- The public
- Local, State, and other Federal agencies and organizations
- Native American tribes
- Cooperating agencies
- BLM resource specialists

Ninety-day public comment periods ensued, with more than 4,990 substantive comments from 1,348 unique letters submitted on all four Great Basin Region Draft RMPAs/EISs. The BLM and Forest Service reviewed, summarized, and took into consideration these comments when preparing the Proposed RMPAs/Final EISs.

The Proposed RMPAs/Final EISs were made available on May 29, 2015, for a 60-day Governor's consistency review and 30-day protest period. The BLM received consistency review letters from governors of California, Idaho, Montana, Nevada, Oregon, and Utah in the Great Basin Region. The BLM has worked closely with these States to address their concerns and to resolve inconsistencies where possible. Across all four sub-regions in the Great Basin Region, 133 protest submission letters were received from government entities, private citizens, nongovernmental organizations, and other stakeholders; 124 of these submissions contained valid protest issues, pursuant to 43 Code of Federal Regulations 1610.5-2, and were addressed in the Director's Protest Resolution Reports. These reports are available on the Internet at http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

The BLM Director and the Assistant Secretary, Land and Minerals Management, now approve the attached RMPAs as the land use plans that will guide future land and resource management within GRSG habitat in the Great Basin Region for the life of the plan amendments. The ARMPAs will benefit GRSG and over 350 other species of wildlife that depend on healthy sagebrush-steppe landscapes, while maintaining multiple uses, including grazing and recreation.

Copies of the ROD and ARMPAs can be obtained from the BLM's National Greater Sage-Grouse internet website, http://www.blm.gov/wo/st/en/prog/more/sagegrouse.html.

The BLM extends special appreciation to the extensive public involvement and the involvement of groups, organizations, cooperating agencies; local, State, and other Federal agencies, and Native American tribal representatives who contributed to the completion of these ARMPAs. This participation informed and improved the planning process and the planning documents. Your continued involvement is encouraged as the ARMPAs are implemented.

Sincerely,

Neil Kornze
BLM Director

Enclosure:
1. Record of Decision and Approved Resource Management Plan Amendments

This page intentionally left blank.

SUMMARY

This Record of Decision (ROD) is the culmination of an unprecedented effort to conserve Greater Sage-Grouse (GRSG) habitat on public lands administered by the Bureau of Land Management (BLM). It is consistent with the BLM's multiple-use and sustained yield mission and the joint objective established by Federal and State leadership through the GRSG Task Force to conserve GRSG habitat on Federal, State, and private land such that additional protections under the Endangered Species Act may be avoided.

In response to a 2010 determination by the US Fish and Wildlife Service (FWS) that the listing of the GRSG under the Endangered Species Act was "warranted, but precluded" by other priorities, the BLM, in coordination with the US Department of Agriculture Forest Service developed a landscape-level management strategy, based on the best available science, that was targeted, multi-tiered, coordinated, and collaborative. This strategy offers the highest level of protection for GRSG in the most important habitat areas. It addresses the specific threats identified in the 2010 FWS "warranted, but precluded" decision and the FWS 2013 Conservation Objectives Team (COT) Report.

This ROD and Approved Resource Management Plan Amendments (ARMPAs) are for the Great Basin Region GRSG Sub-Regions of Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah. They include GRSG habitat management direction that avoids and minimizes additional disturbance in GRSG habitat management areas. Moreover, they target restoration of and improvements to the most important areas of habitat. Management under the ARMPAs is directed through land use allocations that apply to GRSG habitat. These allocations accomplish the following:

- Eliminate most new surface disturbance in the most highly valued sagebrush ecosystem areas identified as Sagebrush Focal Areas
- Avoid or limit new surface disturbance in Priority Habitat Management Areas, of which Sagebrush Focal Areas are a subset
- Minimize surface disturbance in General Habitat Management Areas

In addition to protective land use allocations in habitat management areas, the ARMPAs include a suite of management actions, such as establishing disturbance limits, GRSG habitat objectives, mitigation requirements, monitoring protocols, and adaptive management triggers and responses. They also include other conservation measures that apply throughout designated habitat management areas. The cumulative effect of these measures is to conserve, enhance, and restore GRSG habitat across the remaining range of the species in the Great Basin and to provide greater certainty that BLM resource management plan decisions in GRSG habitat in the Great Basin Region can lead to conservation of the GRSG and other sagebrush-steppe associated species in the region.

The targeted land use plan protections presented in this ROD and ARMPAs not only protect the GRSG and its habitat but also over 350 wildlife species associated with the sagebrush-steppe ecosystem. This is widely recognized as one of the most imperiled ecosystems in North America. In addition to protecting habitat, reversing the slow degradation of this valuable ecosystem will also benefit local economies and a variety of rangeland uses, including recreation and grazing. This also will safeguard the long-term sustainability, diversity, and productivity of these important and iconic landscapes.

This conservation strategy has been developed in conjunction with the 10 States in which the ARMPAs in the Great Basin and the plans in the Rocky Mountain Region apply. In combination with additional State and Federal actions underway and in development, the strategy represents an unprecedented coordinated collaboration among Federal land management agencies and the States to manage an entire ecosystem and associated flora and fauna. The goal is to achieve the COT Report objective of "conserv[ing] the sage-grouse so that it is no longer in danger of extinction or likely to become in danger of extinction in the foreseeable future." [Dan Ashe. Transmittal letter to COT Report. 2013].

CHAPTER 1
INTRODUCTION

This Record of Decision (ROD) approves the United States (US) Department of the Interior, Bureau of Land Management's (BLM's) attached approved resource management plan amendments (ARMPAs) for the Great Basin Region GRSG Sub-Regions (Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah). This ROD and the attached ARMPAs provide a set of management decisions focused on specific GRSG conservation measures across the Great Basin Region on BLM-administered lands.

The BLM prepared the ARMPAs under the authority of the Federal Land Policy and Management Act (FLPMA; 43 United States Code [USC], Section 1701 et seq.), BLM planning regulations (43 Code of Federal Regulations [CFR] Part 1600), and other applicable laws. The BLM prepared environmental impact statements (EISs) in compliance with the National Environmental Policy Act (NEPA; 42 USC, Sections 4321-4347), as amended, and the Council on Environmental Quality's (CEQ's) and the US Department of the Interior's regulations for implementing the procedural provisions of NEPA (40 CFR 1500.1 et seq. and 43 CFR 46.01 et seq., respectively).

Throughout the GRSG planning process, the Forest Service has been a cooperating agency on the Idaho and Southwestern Montana, Nevada and Northeastern California, and the Utah planning efforts. All three of these Draft RMPAs/EISs and Proposed RMPAs/Final EISs included proposed GRSG management direction for National Forest System lands. The Forest Service has completed two separate RODs with associated resource management plan amendments under their planning authorities, which are available at http://www.fs.usda.gov/r4/.

This ROD, in conjunction with the ARMPs and ARMPAs approved through the Rocky Mountain ROD, constitute BLM land use planning decisions to conserve the GRSG and its habitats throughout its remaining range that is administered by the BLM under authority of FLPMA. The efforts of the BLM, in coordination with the Forest Service on National Forest System lands within the remaining range of the species, constitute a coordinated strategy for conserving the GRSG and the sagebrush-steppe ecosystem on most Federal lands on which the species depends. These decisions complement those implemented by Federal agencies through *An Integrated Rangeland Fire Strategy: Final Report to the Secretary of the Interior*

(US Department of the Interior 2015) and the Sage Grouse Initiative, as well as those implemented by State and local governments, private landowners, and other partners.

1.1 GREAT BASIN REGION PLANNING AREA

The Great Basin Region Planning Area is composed of four sub-regions: the Idaho and Southwestern Montana, Nevada and Northeastern California, Oregon, and Utah.(see **Figure 1-1**, Great Basin Region Greater Sage-Grouse Sub-Regions). The BLM prepared a separate EIS for each of these sub-regions, and each sub-region conducted its own planning effort, with input from local cooperators, stakeholders, and members of the public. The sub-regional boundaries were constructed to align with BLM administrative offices, state boundaries, and areas that share common threats to GRSG and its habitat. The boundaries for these sub-regions largely coincide with zones III, IV, and V identified by the *Western Association of Fish and Wildlife Agencies (WAFWA) Greater Sage-Grouse Comprehensive Conservation Strategy* (Stiver et al. 2006) to delineate management zones (MZs) with similar ecological and biological issues.

The Great Basin Region Planning Area boundaries include all lands regardless of jurisdiction (see **Figure 1-2**, Great Basin Region Planning Area). **Table 1-1** outlines the amount of surface acres that are administered by specific Federal agencies, States, local governments, and privately owned lands in the four sub-regions that make up the Great Basin. The Planning Area also includes other BLM-administered lands that are not identified as habitat management areas for GRSG. The ARMPAs generally do not establish any additional management for these lands outside of GRSG habitat management areas, and they will continue to be managed according to the existing land use plans for these Planning Areas.

Figure 1-1
Great Basin Region Greater Sage-Grouse Sub-Regions

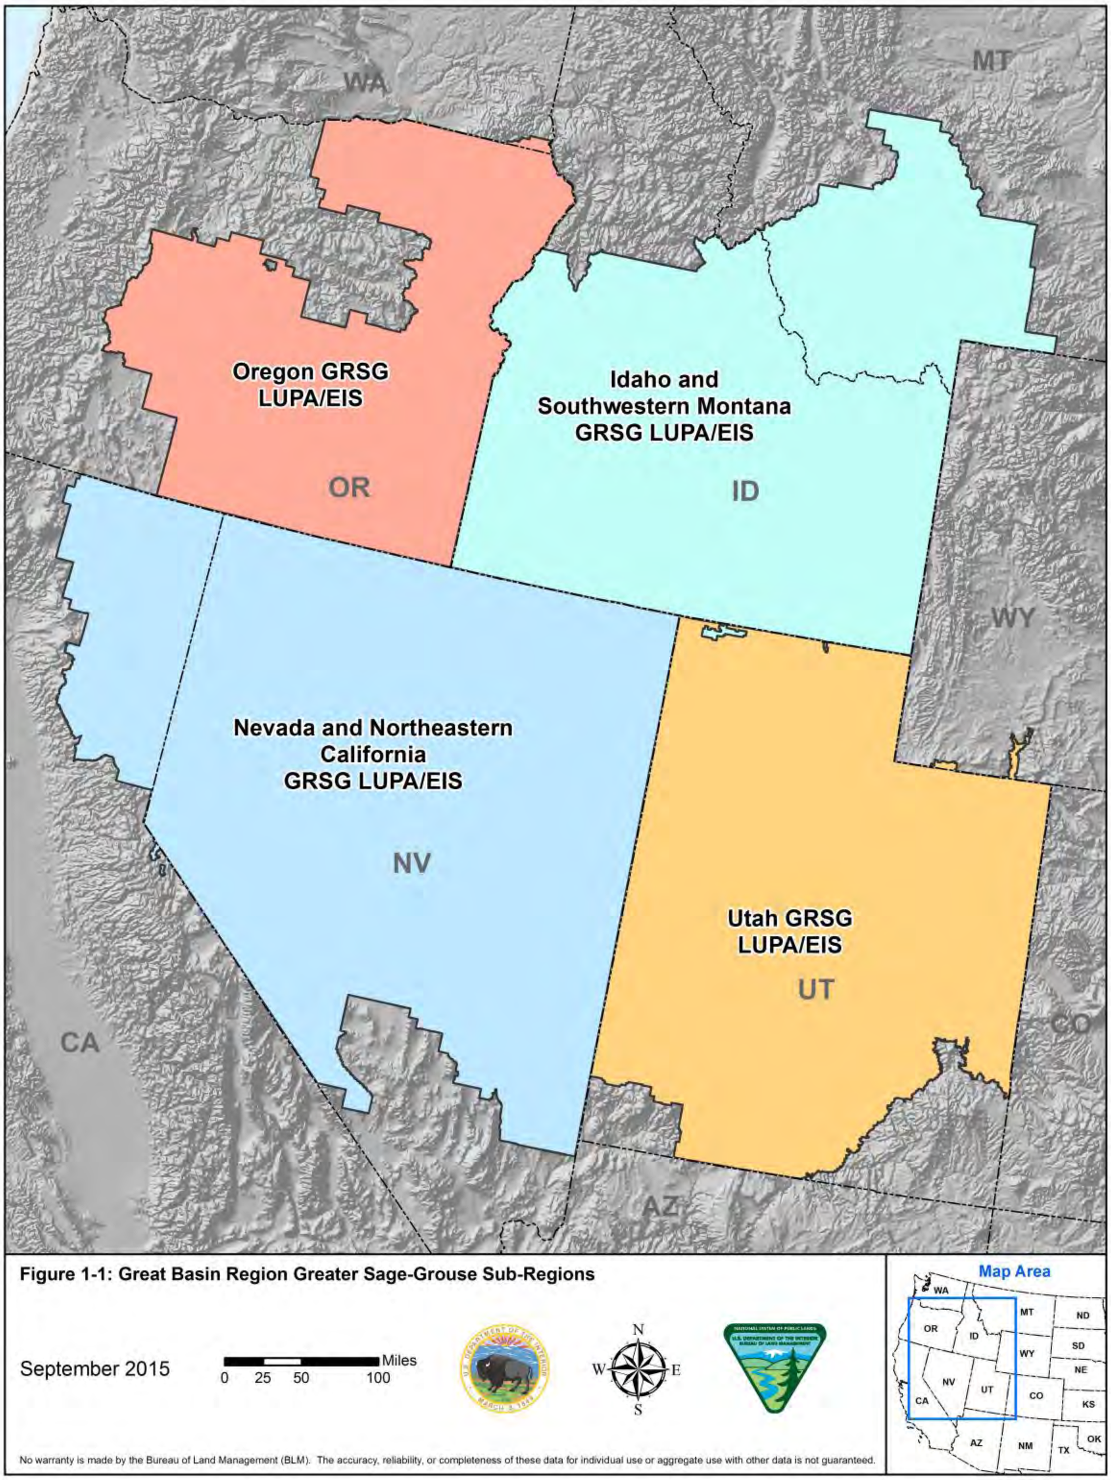

Figure 1-2
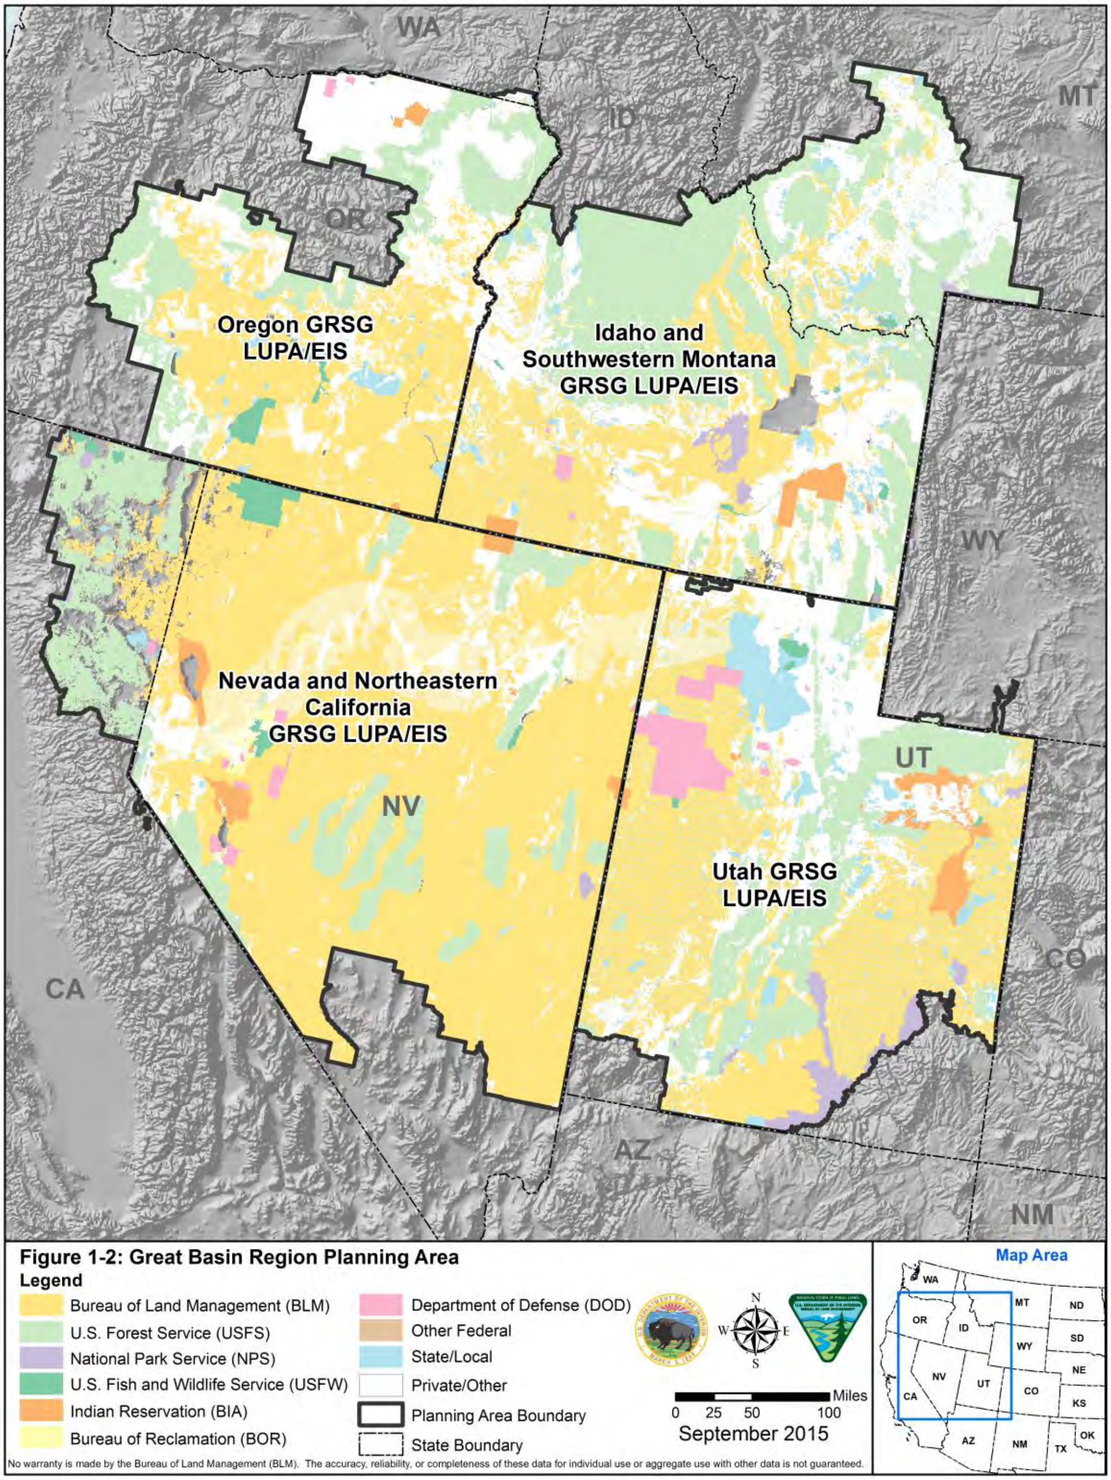
Great Basin Region Planning Area



The decision area for the Great Basin Region ARMPAs is BLM-administered lands in GRSG habitat management areas (see **Figure 1-3**, Great Basin Region Decision Area, Greater Sage-Grouse Habitat Management Areas [BLM-administered]), including surface and split-estate lands where the BLM has subsurface mineral rights. For a description of these habitat management areas, refer to **Section 1.5**.

1.2 EARLY GRSG CONSERVATION EFFORTS

Currently, GRSG occupy an estimated 56 percent of the historically occupied range. The BLM manages most of the GRSG habitat on Federal lands (i.e., the range of GRSG not including the Columbia Basin or Bi-State populations). The BLM and other wildlife conservation agencies and organizations have been conserving GRSG habitat for many years. This provides an important foundation for the GRSG conservation strategy that guides these plans.

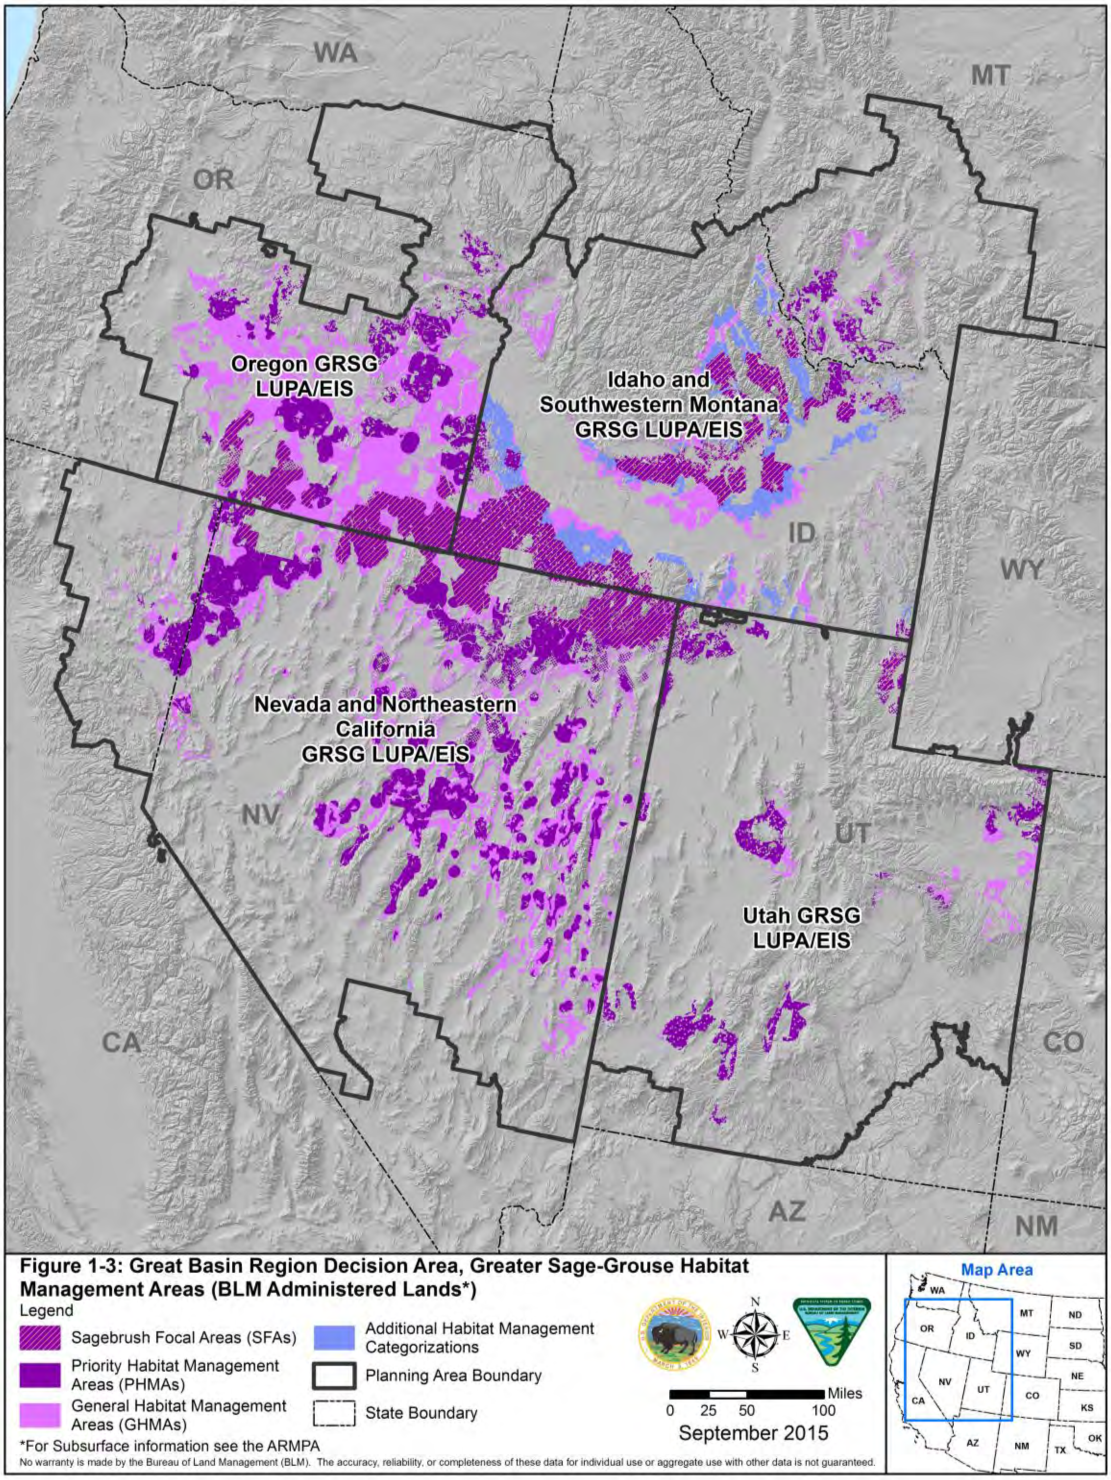
The WAFWA 2004 *Range-wide Conservation Assessment for Greater Sage-Grouse and Sagebrush Habitats* (Connelly et al. 2004) was the first range-wide assessment of GRSG using the vast amount of population data collected over the previous 60 years, habitat information spanning the previous 100 years, and literature dating back 200 years. The goal of the assessment, which includes contributions from the BLM, was to present an unbiased and scientific assessment of dominant issues and their effects on GRSG populations and sagebrush habitats.

In November 2004, the BLM released its *National Sage-Grouse Habitat Conservation Strategy*, which encouraged GRSG habitat conservation through consultation, cooperation, and communication with WAFWA, the US Fish and Wildlife Service (FWS), the Forest Service, the US Geological Survey (USGS), State wildlife agencies, local GRSG working groups, and various other public and private partners.

In 2006, WAFWA completed a *Greater Sage-Grouse Comprehensive Conservation Strategy* (Stiver et al. 2006), with the assistance of the BLM, the Forest Service, and other contributors. The overall goal of the strategy was to maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain those populations. The strategy outlined the critical need to develop the associations among local, State, provincial, tribal, and Federal agencies, nongovernmental organizations, and individual citizens to design and implement cooperative actions to support robust populations of GRSG and the landscapes and habitats that they depend on. The catalyst for this was widespread concern for declining populations and reduced distribution of GRSG. http://www.wafwa.org/documents/pdf/GreaterSage-grouseConservationStrategy2006.pdf

In 2008, the BLM created two national teams to investigate possible BLM management options for GRSG conservation and to summarize the BLM's ongoing conservation efforts. A product of this investigation was one of the first range-wide priority habitat maps for GRSG that referred to "key habitat." At the time, the primary purpose for the key habitat map was to inform and help prioritize fire suppression in GRSG habitat on BLM lands. An additional outcome of this team was the signing of a memorandum of understanding (MOU) by the WAFWA, the BLM, FWS, USGS in the US Department of the Interior, and the Forest Service and Natural Resources Conservation Service (NRCS) in the US Department of Agriculture. The MOU's purpose was to provide for cooperation among the participating State and Federal land managers and wildlife management and science agencies to conserve and manage GRSG sagebrush habitats and other sagebrush-dependent wildlife throughout the western United States.

Figure 1-3
Great Basin Region Decision Area, Greater Sage-Grouse Habitat Management Areas (BLM-administered Lands)



In 2010, the BLM commissioned a project to map and model breeding bird densities of GRSG across the West. It convened a conference with State wildlife agencies to coordinate the lek survey data needed for this project. Through an agreement with the FWS, this modeling project mapped known active leks across the West. This served as a standard starting point for all States to identify priority habitat for the species.

Error! Hyperlink reference not valid. In March 2010, the FWS published its *12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered* (75 FR 13910, March 23, 2010). In that finding, the FWS concluded that GRSG was "warranted, but precluded" under the Endangered Species Act (ESA). This finding indicates that, although the species meets the criteria for listing, immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, the species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

As part of its 2010 finding, the FWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. The FWS determined that Factor A, "the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG," and Factor D, "the inadequacy of existing regulatory mechanisms," posed "a significant threat to the GRSG now and in the foreseeable future" (75 FR 13910, March 23, 2010). In addition, the FWS found that existing local, State, and Federal regulatory mechanisms were not sufficient to address threats to the habitat. The FWS has identified for the BLM its resource management plans (RMPs) as the primary regulatory mechanisms; the BLM manages approximately 66 million acres of the remaining habitat for the species (see **Figure 1-4**, GRSG Priority Areas for Conservation, Populations, and WAFWA Management Zones).

1.3 THREATS TO GRSG IN THE GREAT BASIN REGION

In its 2010 finding, the FWS identified a number of specific threats to GRSG in the Great Basin Region. The primary threats are the widespread present and potential impacts of wildfire, the loss of native habitat to invasive species, and conifer encroachment. Other threats, some of which are more localized, are habitat fragmentation due to human disturbances associated with energy development, mining, infrastructure, recreation, urbanization, and sagebrush elimination, as well as impacts on habitat associated with free-roaming equids (horses and burros) and improper livestock grazing.

In 2011, the BLM established the GRSG National Technical Team (NTT), comprised of BLM, USGS, NRCS, and State specialists. The charge of the NTT was to identify science-based management considerations for the GRSG (i.e., conservation measures) to promote sustainable GRSG populations focused on the threats identified in the FWS listing determination (75 *Federal Register* [FR] 13910) in each of the regional WAFWA Sage-Grouse MZs (**Figure 1-4**). The NTT produced *A Report on National Greater Sage-grouse Conservation Measures* (NTT Report; NTT 2011) in which it proposed conservation measures based on habitat requirements and other life history requirements for GRSG. The NTT Report described the scientific basis for the conservation measures proposed within each program area. It also emphasized the importance of standardizing monitoring across the WAFWA GRSG MZs.

In 2012, the FWS, with the support of the Western Governors Association Sage-Grouse Task Force, convened the Conservation Objectives Team (COT), composed of State and Federal representatives. One of the team's tasks was to produce a peer-reviewed report identifying the principal threats to

GRSG survival. Another task was to determine the degree to which these threats need to be reduced or lessened to conserve the GRSG so it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The COT Report, released in March 2013, also identified Priority Areas for Conservation (PACs) and emphasized that "Maintenance of the integrity of PACs . . . is the essential foundation for sage-grouse conservation" (FWS 2013). Finally, the COT Report identified present and widespread, as well as localized threats by GRSG population across the West (**Table 1-2**). The BLM also identified and explained additional threats in the Final EISs that were published with proposed plans on May 29, 2015. **Figure 1-4** identifies the PACs, GRSG populations (and their names), and WAFWA MZs across the West.

A summary of the nature and extent of threats identified in the COT Report for each remaining identified population of GRSG in the Great Basin Region—as highlighted in the 2013 COT Report—is provided in **Table 1-2**.

1.4 NATIONAL GREATER SAGE GROUSE CONSERVATION STRATEGY

The BLM recognized the need to incorporate explicit objectives and concrete conservation measures into RMPs[1] to conserve GRSG habitat and provide robust regulatory mechanisms. This was based on the identified threats to the GRSG, especially inadequate regulatory mechanisms, and the FWS's timeline for making a decision on whether to propose this species for listing, In August 2011, the BLM charted a plan to revise and amend existing RMPs throughout the range of the GRSG. The intent was to incorporate management actions to conserve, enhance, and restore the species and the habitat on which it depends. Separate planning began that would address the conservation needs of the Bi-State populations in California and Nevada and the Washington State distinct population segment.

The BLM found that additional management direction and specific conservation measures on Federal public lands would be necessary to address the present and anticipated threats to GRSG habitat and to restore habitat where possible. This finding was in light of the 2010 "warranted" determination by the FWS, the recommendations of the NTT, and specific threats summarized in the COT Report. The BLM proposed to incorporate the management direction and conservation measures into its land use plans. The goals of incorporating these specific measures into BLM land use plans are to conserve, enhance, and restore GRSG and its habitat and to provide sufficient regulatory certainty such that the need for listing the species under the ESA may be avoided.

In December 2011, the BLM published a Notice of Intent to prepare EISs and a Supplemental EIS to incorporate GRSG conservation measures into land use plans across the range of the species.

The planning associated with the National GRSG Conservation Strategy has been coordinated under two administrative planning regions: the Rocky Mountain Region and the Great Basin Region. The regions were drawn roughly to correspond with the threats identified by the FWS in its 2010 listing decision, along with the WAFWA MZs framework (Stiver et al. 2006). Due to differences in the

---

[1] BLM land use plans prepared under the present regulations (see 43 CFR 1601.0-5[n]) are generally known as resource management plans. Some BLM land use plans, including ones predating the present regulations, are referred to by different names, including management framework plans. For purposes of this ROD, the BLM and Forest Service land use plan and resource management plan interchangeably refer to all BLM-administered land use plans.

Threats are characterized as Y = threat is present and widespread, L = threat present but localized, and U = unknown.

ecological characteristics of sagebrush across the range of the GRSG, WAFWA delineated seven MZs (MZs I to VII) based primarily on floristic provinces. Vegetation found within an MZ is similar, and GRSG and their habitats within these areas are likely to respond similarly to environmental factors and management actions.

The Rocky Mountain Region is composed of BLM planning efforts, including plan revisions and plan amendments, in Montana, North Dakota, South Dakota, Wyoming, Colorado, and portions of Utah. This region falls within WAFWA MZs I (Great Plains), II (Wyoming Basin) and a portion of VII (Colorado Plateau). The Great Basin Region is composed of planning efforts (plan amendments) in California, Nevada, Oregon, Idaho, and portions of Utah and Montana. That region falls within WAFWA MZs III (Southern Great Basin), IV (Snake River Plain), and V (Northern Great Basin).

Both the Rocky Mountain and Great Basin regions are further divided into sub-regions. The BLM began sub-regional planning efforts and associated EISs to analyze the alternatives developed for each of the Draft and Final RMPAs and ARMPs across the range of the species.[2] These sub-regions are based on the identified threats to GRSG and the WAFWA MZs from the FWS 2010 listing decision, with additional detail on threats to individual populations and sub-regions from the FWS COT Report.

---

[2] The National GRSG Conservation Strategy consisted of 15 separate EISs. For ease of implementation, the Bighorn Basin RMP has been split between the two field offices that make up the Bighorn Basin Planning Area, the Cody Field Office ARMP and the Worland Field Office ARMP. The Billings and Pompeys Pillar National Monument RMP has also been split between the Billings Field Office ARMP and Pompeys Pillar National Monument ARMP. This results in a total of 17 ARMPs and ARMPAs.

In the Rocky Mountain Region, some sub-regions correspond to BLM field and district office boundaries, specifically for planning that incorporates GRSG conservation measures through plan revisions that were that began before the start of the National GRSG Conservation Strategy in December 2011. **Figure 1-5** illustrates the regional and sub-regional Planning Area boundaries across the western United States.

The BLM used the best available science, including additional review and analysis from the USGS on specific issues that arose in developing the ARMPAs. Additionally, the BLM considered State GRSG conservation strategies where they existed, as well as State recommendations for measures to conserve GRSG on BLM-administered lands, where relevant, in its planning. These are reflected in the approved plans to the extent compatible with GRSG objectives to conserve, enhance, and restore GRSG habitat to address the threats identified in the FWS 2010 listing determination and the 2013 COT Report.

1.5 HOW THE ARMPAS ADDRESS THE IDENTIFIED THREATS TO THE CONSERVATION OF GRSG

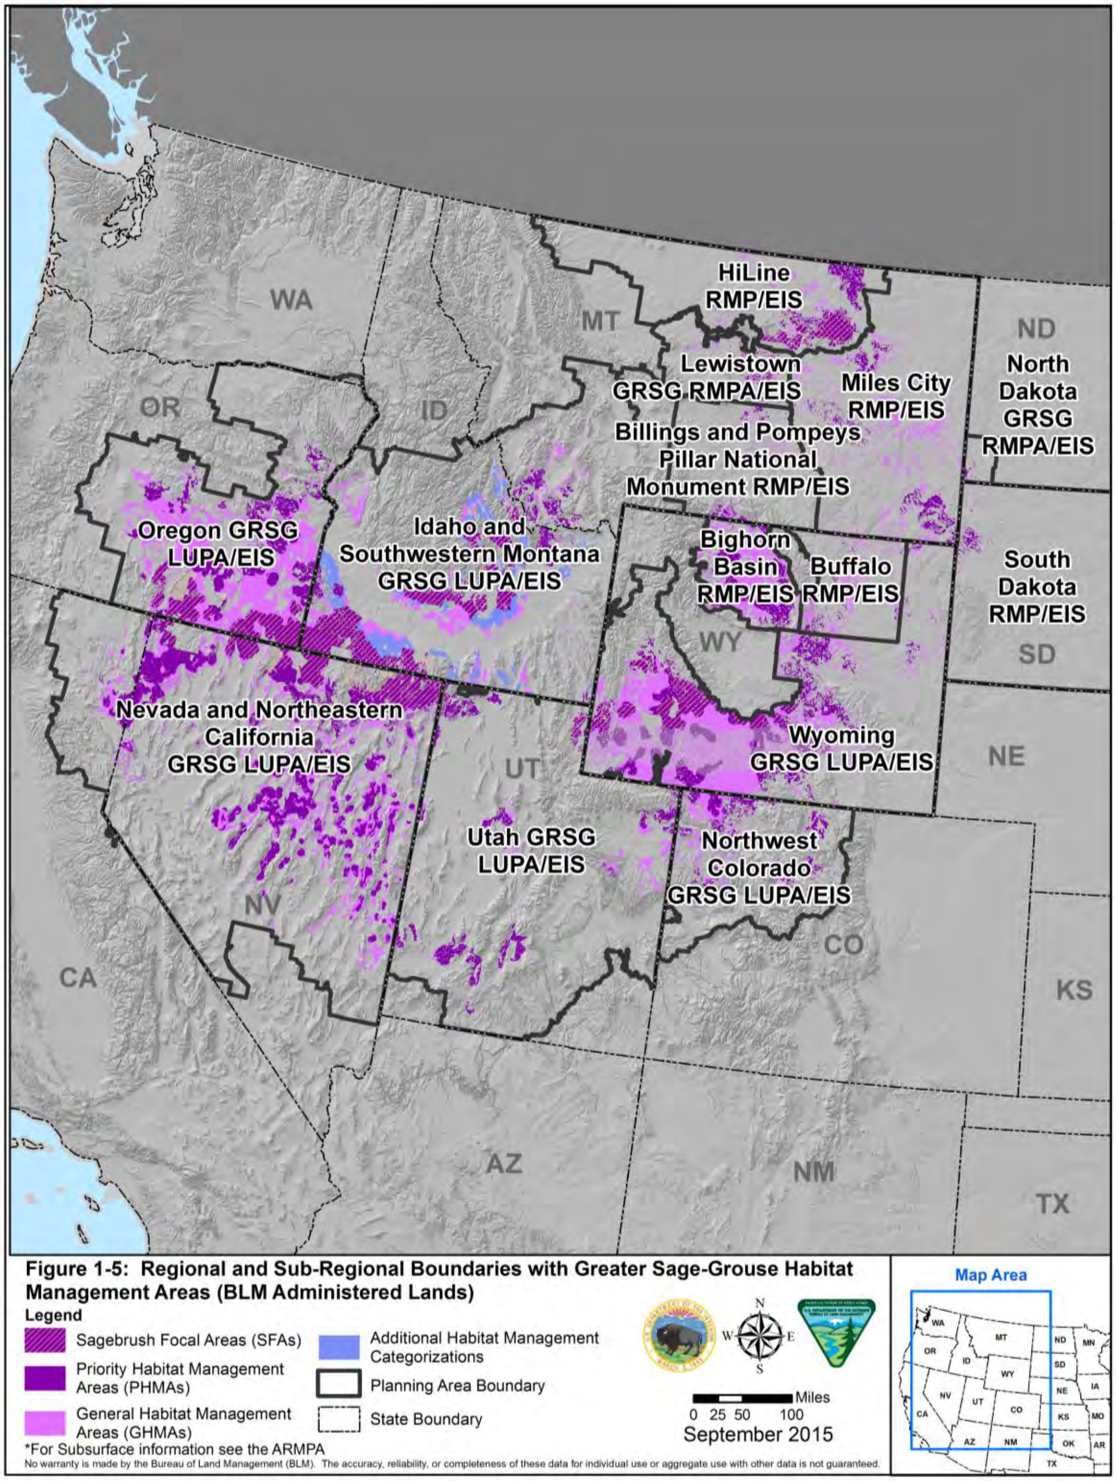
The 2006 WAFWA *Greater Sage-Grouse Comprehensive Conservation Strategy* stated goal for managing GRSG was to "maintain and enhance populations and distribution of GRSG by protecting and improving sagebrush habitats and ecosystems that sustain these populations" (Stiver et al. 2006). The NTT Report also endorsed this goal "as a guiding philosophy against which management actions and policies of BLM should be weighed" (NTT 2011).

In establishing the COT Report, with the backing of the Sage Grouse Task Force, the FWS Director affirmed the commitment to the goal for GRSG conservation originally articulated in the 2006 WAFWA report—reversing negative population trends and achieving a neutral or positive population trend—and emphasized the following:

> "The Service interprets this recommendation to mean that actions and measures should be put in place now that will eventually arrest what has been a continuing declining trend. Conservation success will be achieved by removing or reducing threats to the species now, such that population trends will eventually be stable or increasing, even if numbers are not restored to historic levels. (Stiver et al. 2006)"

The COT Report emphasized the need to avoid or minimize additional disturbance in GRSG habitat. Specifically, the COT Report stated, "[m]aintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation" (FWS 2013). To achieve this, the COT Report recommended "targeted habitat management and restoration" to be achieved by "eliminating activities known to negatively impact sage-grouse and their habitats, or re-designing these activities to achieve the same goal" (FWS 2013). The COT Report emphasized an "avoidance first strategy" and stressed those threats in GRSG habitat "must be minimized to the extent that population trends meet the objectives of the 2006 WAFWA Conservation Strategy" (FWS 2013).

Figure 1-5
Regional and Sub-Regional Boundaries with PHMAs and GRSG Habitat Management Areas (BLM-Administered Lands)



The plans were developed to address specific, identified threats to the species in order to conserve GRSG such that the need to list the species under ESA may be avoided. Across ten western states, the Great Basin and Rocky Mountain sub-regional ARMPs/ARMPAs contain land use plan direction on approximately 66 million acres of the remaining habitat for the species (see **Figure 1-5**). These plans are the product of extensive coordination between the BLM and the Forest Service and the active engagement of the FWS which informed the BLM and Forest Service land allocation and related management decisions. The plans also benefit from strong collaboration with the States and reflect the unique landscapes, habitats, priorities and approaches in each.

In order to protect the most important GRSG habitat areas, planning began with mapping areas of important habitat across the GRSG's range. In collaboration with State fish and wildlife agencies, the BLM identified areas as preliminary priority habitat (PPH) and preliminary general habitat (PGH). In Utah, all occupied GRSG habitat was identified as PPH. The draft land use plans used PPH and PGH to analyze the impacts of the decisions the BLM was proposing in the plans. PPH and PGH were identified as Priority Habitat Management Areas (PHMAs) and General Habitat Management Areas (GHMAs) in the Proposed RMPAs/Final EISs to identify the management decisions that apply to those areas (except for Nevada and Utah).

The designated GRSG Habitat Management Areas on BLM-administered lands in the decision area are PHMAs, which largely coincide with PACs identified in the COT Report;[3] GHMAs; Other Habitat Management Areas (OHMAs, applicable only to the Nevada and Northeastern California); and Important Habitat Management Areas (IHMAs, applicable only to Idaho). **Table 1-3** identifies surface acres of PHMAs, GHMAs, OHMAs, and IHMAs in the decision area for the Great Basin Region.

Habitat maps were based initially on State key habitat maps, which identified areas necessary for GRSG conservation. These areas were derived from breeding bird density maps and lek counts, nesting areas, sightings, and habitat distribution data. These data included occupied suitable seasonal habitats, nesting and brood-rearing areas, and connectivity areas or corridors. The BLM used this information to develop PPH and PGH maps and, subsequently, to identify PHMAs and GHMAs, respectively.

The COT Report preparers also used State key habitat maps as a basis for identifying PACs. The COT Report notes that there is substantial overlap between PACs and BLM PPH areas, with the exception of areas in Nevada and Utah (FWS 2013, p. 13). **Figure 1-5** illustrates the regional and sub-regional Planning Area boundaries, along with BLM-administered PHMAs and GHMAs across the western United States.

The BLM-administered surface and Federal mineral estate of each designation (in acres) in the Decision Area for the Great Basin Region are shown in **Table 1-3**; PHMAs, GHMAs, OHMAs, and IHMAs are defined below.

- **PHMA**—BLM-administered land identified as having the highest habitat value for maintaining sustainable GRSG populations. The boundaries and management strategies for PHMAs are derived from and generally follow the PPH boundaries. Areas of PHMAs largely

---

[3] Except for PACs in Nevada and Utah, as specified on page 13 of the COT Report; see **Figure 1-4**

coincide with areas identified as PACs in the COT Report (except for PACs in Nevada and Utah, as specified on page 13 of the COT Report).

Table 1-3
Surface Acres of PHMAs, GHMAs, OHMAs, and IHMAs in the Decision Area for the Great Basin Region

BLM-Administered Surface Acres	PHMAs	GHMAs	OHMAs	IHMAs
Idaho and Southwestern Montana	4,627,200	2,179,700	0	2,737,600
Utah*	2,023,400	502,500	0	0
Oregon	4,547,000	5,660,150	0	0
Nevada and Northeastern California	9,309,700	5,720,600	5,876,600	0
Total Acres	**20,507,300**	**14,062,950**	**5,876,600**	**2,737,600**

Source: BLM GIS 2015

*41,200 acres of National Forest System lands in the Anthro Mountain area of Utah would be managed as neither PHMAs nor GHMAs. These areas would be identified as "Occupied – Anthro Mountain." In the Utah ARMPA, these areas are considered split-estate, where the BLM administers the mineral estate.

- **GHMA**—BLM-administered GRSG habitat that is occupied seasonally or year-round and is outside of PHMAs. It is where some special management would apply to sustain GRSG populations. The boundaries and management strategies for GHMAs are derived from and generally follow the PGH boundaries.
- **OHMA**—BLM-administered land in Nevada and Northeastern California, identified as unmapped habitat in the Proposed RMP/Final EIS, that is within the Planning Area and contains seasonal or connectivity habitat areas. With the generation of updated modeling data (Spatially Explicit Modeling of Greater Sage-Grouse Habitat in Nevada and Northeastern California; Coates et al. 2014,) the areas containing characteristics of unmapped habitat were identified and are now referred to as OHMAs.
- **IHMA**—BLM-administered land in Idaho that provides a management buffer for and that connect patches of PHMAs. IHMAs encompass areas of generally moderate to high habitat value habitat or populations but that are not as important as PHMAs. These lands serve a critical role in the adaptive management strategy developed by the State of Idaho and adopted in the ARMPA.

The ARMPAs also identify Sagebrush Focal Areas (SFAs) on a portion of the landscape; they are a subset of PHMAs (see **Figure 1-3**). Across the Great Basin Region, there are 8,385,280 acres of BLM-administered SFAs. They correspond to the areas identified by the FWS as GRSG strongholds and represent "a subset of priority habitat most vital to the species persistence within which we recommend the strongest levels of protection" (FWS 2014a).

SFAs are areas of highest habitat value for GRSG and are managed to avoid new surface disturbance for the following reasons:

- They contain high-quality sagebrush habitat and the highest breeding bird densities
- They have been identified as essential to conservation and persistence of the species
- They represent a preponderance of current Federal ownership
- In some cases, they are next to protected areas that serve to anchor the conservation importance of the landscape

SFA management is consistent with the recommendations provided by the FWS that these are the areas "where it is most important that the BLM and Forest Service institutionalize the highest degree of protection to help promote persistence of the species" (FWS 2014a).

Remaining habitats in GHMAs and IHMAs (applicable only to BLM-administered lands in Idaho) would be managed consistent with the COT Report recommendation to recognize "that important habitats outside of PACs be conserved to the extent possible" (FWS 2013). Thus, land allocations in GHMAs and IHMAs provide for more flexibility for land use activities, while minimizing impacts on existing GRSG leks.

Major components of the attached ARMPAs that address the specific threats to GRSG and its habitat, as identified in the FWS 2010 listing decision and 2013 COT Report (many of which were also identified by the BLM's 2011 NTT Report), are listed and summarized in **Table 1-4**.

This tiered habitat management area framework, associated with the land use plan allocation decisions in the ARMPs and ARMPAs (explained more fully in **Section 1.6.2** of this ROD) provides a high degree of certainty that the integrity of PHMAs can be maintained through management decisions. This would be done to avoid or minimize additional surface disturbance. At the same time, it would recognize the potential importance of areas outside of PHMAs for maintaining connectivity between highly important habitats and their potential for addressing seasonal habitat needs, such as winter habitat areas not fully incorporated in PHMAs.[4]

Table 1-4
Key Responses from the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

---

[4] An analysis by Crist et al. (2015) highlights the importance of certain key "priority areas" across the species' range and the importance of connectivity between priority areas as a component of successful GRSG conservation. Generally, these priority areas coincide with PHMAs across the landscape. It is important to note that BLM-administered SFAs also coincide with a number of the areas identified by Crist et al. (2015) as important for maintaining connectivity between the network of conservation areas, essential PHMAs, that are of greatest importance to the integrity of the conservation strategy. In addition, to maintain connectivity between PHMAs across the remaining range, requirements were incorporated into most of the ARMPAs for the application of lek buffers. This is consistent with guidance provided by the USGS, mitigation to a net conservation gain, and the use of required design features for projects in GHMAs, described later in this document. These measures are specifically intended to provide benefits for GRSG in GHMAs that can provide added connectivity and habitat protection consistent with the Crist et al. (2015) findings.

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses from the Great Basin Region GRSG ARMPAs
All threats	• Implement an Adaptive Management Strategy, which allows for more restrictive management to be implemented if habitat or population hard triggers are met. • Monitor implementation and effectiveness of conservation measures in GRSG habitats in a consistent manner.
All development threats, including mining, infrastructure, and energy development	• PHMAs—Implement a human disturbance cap of 3 percent within the biologically significant unit (BSU) and proposed project analysis areas in PHMAs (slight variations to this management component in Nevada only). • PHMAs and IHMAs—Apply a disturbance density cap of 1 energy and mining facility per 640 acres (except in Nevada). • IHMAs—Implement the 3 percent disturbance cap. Apply Anthropogenic Disturbance Development Criteria (applicable to Idaho only). • Apply buffers based on project type and location to address impacts on leks when authorizing actions in GRSG habitat. • Apply required design features (RDFs) when authorizing actions in GRSG habitat. • Minimize the effects of infrastructure projects, including siting, using the best available science, updated as monitoring information on current infrastructure projects becomes available. • Consider the potential for the development of valid existing rights when authorizing new projects in PHMAs. • When authorizing third-party actions that result in habitat loss and degradation, require and ensure mitigation that provides a net conservation gain to the species.
Energy development—fluid minerals, including geothermal resources	• PHMAs—Open to fluid mineral leasing subject to a no surface occupancy (NSO) stipulation without waiver or modification and with limited exceptions. In SFAs, an NSO stipulation would be applied without waiver, modification, or exception. In Nevada only, in the portions of the PHMAs outside of SFAs, geothermal projects may be considered for authorization if certain criteria are met. • IHMAs—Open to fluid mineral leasing, subject to NSO stipulation without waiver or modification and with limited exception (applicable to Idaho only). • GHMAs—Open to fluid mineral leasing, subject to controlled surface use and timing limitation lease stipulations (except in Utah, where some portions of GHMAs are open with standard lease stipulations). • Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.
Energy development—wind energy	• PHMAs—Exclusion area (not available for wind energy development under any conditions, except in the southeastern counties of Oregon, where portions of PHMAs are avoidance areas). • IHMAs—Avoidance area (may be available for wind energy development with special stipulations; applicable to Idaho only). • GHMAs—Avoidance area (may be available for wind energy development with special stipulations, except in Utah and Idaho, where these areas are

Table 1-4
Key Responses from the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses from the Great Basin Region GRSG ARMPAs
	open to wind energy development).
Energy development—solar energy	• PHMAs—Exclusion area (not available for solar energy development under any conditions, except in southeastern counties in Oregon, where portions of PHMAs are avoidance areas). • IHMAs—Avoidance area (may be available for solar energy development with special stipulations; applicable to Idaho only). • GHMAs—Exclusion area (not available for solar energy development under any conditions, except in Oregon and Montana, where these areas are avoidance areas for solar energy development, and Idaho, where these areas are open to solar energy development).
Infrastructure—major rights-of-way (ROWs)	• PHMAs—Avoidance area (may be available for major ROWs with special stipulations). • IHMAs—Avoidance area (may be available for major ROWs with special stipulations; applicable to Idaho only). • GHMAs—Avoidance area (may be available for major ROWs with special stipulations, except in Utah, where GHMAs is open).
Infrastructure—minor ROWs	• PHMAs—Avoidance area (may be available for minor ROWs with special stipulations). • IHMAs—Avoidance area (may be available for minor ROWs with special stipulations; applicable to Idaho only).
Mining—locatable minerals	• SFAs—Recommend withdrawal from the Mining Law of 1872.
Mining—nonenergy leasable minerals	• PHMAs—Closed area (not available for nonenergy leasable minerals; however, expansion of existing operations could be considered if the disturbance is within the cap and subject to compensatory mitigation).
Mining—salable minerals	• PHMAs—Closed area (not available for salable minerals), with a limited exception (may remain open to free use permits and expansion of existing active pits if criteria are met).
Improper livestock grazing	• Prioritize the review and processing of grazing permits and leases in SFAs, followed by PHMAs. • Ensure that the NEPA analysis for renewals and modifications of grazing permits and leases includes specific management thresholds, based on the GRSG habitat objectives table, land health standards, and ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis. • Prioritize field checks in SFAs, followed by PHMAs, to ensure compliance with the terms and conditions of grazing permits.
Free-roaming equid (horses and burros) management	• Prioritize gathers in SFAs, followed by other PHMAs. • Manage herd management areas in GRSG habitat within established appropriate management level (AML) ranges to achieve and maintain GRSG habitat objectives.

Table 1-4
Key Responses from the Great Basin Region GRSG ARMPAs that Address the COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Management Responses from the Great Basin Region GRSG ARMPAs
	• Prioritize rangeland health assessment, gathers, and population growth suppression techniques, monitoring, and review and adjust AMLs and preparation of herd management area plans in GRSG habitat.
Range management structures	• Allow range improvements that do not impact GRSG or that provide a conservation benefit to GRSG, such as fences for protecting important seasonal habitats. • Remove livestock ponds built in perennial channels that are negatively impacting riparian habitats. Do not permit new ones to be built in these areas.
Recreation	• PHMAs and IHMAs—Do not construct new recreation facilities unless required for health and safety purposes or if the construction will result in a net conservation gain to the species. • Allow special recreation permits only if their effects on GRSG and its habitat are neutral or result in a net conservation gain. • PHMAs and GHMAs—Off-highway vehicle (OHV) use limited to existing routes (routes to be designated through future travel management planning). The Utah ARMPA does retain two areas as open to OHV use in PHMAs.
Fire	• Identify and prioritize areas that are vulnerable to wildfires and prescribe actions important for GRSG protection. • Restrict the use of prescribed fire for fuel treatments. • Prioritize post-fire treatments in SFAs, other PHMAs, IHMAs, and GHMAs.
Nonnative, invasive plant species	• Improve GRSG habitat by treating annual grasses. • Treat sites in PHMAs, IHMAs, and GHMAs that contain invasive species infestations through an integrated pest management approach.
Sagebrush removal	• PHMAs—Maintain all lands capable of producing sagebrush (but no less than 70 percent), with a minimum of 15 percent sagebrush canopy cover, consistent with specific ecological site conditions. • Ensure that all BLM use authorizations contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and juniper expansion	• Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat, in a manner that considers tribal cultural values.
Agricultural conversion and exurban development	• Retain GRSG habitat in Federal management, unless disposal (including exchanges) of the lands would provide a net conservation gain to GRSG or disposal (including exchanges) of the lands would have no direct or indirect adverse impact on conservation of GRSG.

1.6 KEY COMPONENTS OF THE BLM GRSG CONSERVATION STRATEGY

The ARMPAs were developed to meet the purpose and need to conserve, enhance, and restore GRSG and their habitat by eliminating or minimizing threats to GRSG habitat identified in the 2010 listing decision and highlighted in the Background and Purpose Section of the COT Report (FWS 2013). Consequently, consistent with guidance contained in the COT and NTT Reports, the BLM identified the following essential components of the GRSG conservation strategy:

- Avoiding or minimizing new and additional surface disturbances
- Improving habitat conditions
- Reducing threats of rangeland fire to GRSG and sagebrush habitat in the Great Basin
- Monitoring and evaluating the effectiveness of conservation measures and implementing adaptive management as needed

The land allocations and management actions included in the ARMPAs incorporate these components and are summarized below.

1.6.1 Avoid and Minimize Surface Disturbance

Land Use Allocations and Management Actions in SFAs, PHMAs, and GHMAs

The four Great Basin ARMPAs build on the designated habitat management areas described in **Section 1.5** by applying management actions to these areas to avoid and minimize disturbance associated with proposed projects, as described below and shown in **Table 1-4**. Land use plan allocations specify locations within the Planning Area that are available or unavailable for certain uses and also prioritize conservation and restoration management actions applied to habitat management areas.

The COT Report states that “maintenance of the integrity of PACs … is the essential foundation for sage-grouse conservation” (FWS 2013, p. 36). Areas of PHMAs largely coincide with areas identified as PACs in the COT Report. While surface disturbance associated with development in the Great Basin is not as significant a threat to GRSG and its habitat as rangeland fire and invasive species, the BLM ARMPAs include land allocations and management actions that avoid and minimize surface disturbance in PHMAs for identified threats (e.g., energy, mining, infrastructure, improper grazing, free-roaming horses and burros, recreation and urbanization). These land allocations and management actions are necessary because the location and extent of habitat loss to fire is difficult to predict, and much of the habitat, due to low precipitation in the Great Basin, is difficult to restore once lost. Further, even a small amount of development in the wrong place could have an outsized impact in these landscapes.

SFAs—The most restrictive allocations include requirements to avoid and minimize additional disturbance in SFAs, which are a subset of lands within PHMAs, with the highest habitat value for GRSG. Surface disturbance from fluid mineral development is avoided by imposing NSOs, without waiver, modification, or exception. In addition, these areas will be recommended for withdrawal to address the risk of disturbance due to mining.

PHMAs—In PHMAs outside of SFAs new fluid mineral leasing would be subject to NSOs, with no waivers or modifications. Exceptions would be granted only under two circumstances: if the proposed action would not have direct, indirect, or cumulative effects on GRSG or its habitat or if the action is proposed to be undertaken as an alternative to a similar action occurring on a nearby parcel, and it would provide a clear conservation gain to GRSG. This is fully consistent with guidance in the NTT Report, which states, "Do not allow new surface occupancy on federal lands within priority habitats" (NTT 2011, p. 23).

Similarly, PHMAs are closed to nonenergy and salable mineral development (this does not apply to locatable minerals governed under the 1872 Mining Law). An exception may be granted for free-use permits and the expansion of active pits for salable minerals and expansion of nonenergy leasable development under certain conditions. This exception is included because of the importance of these materials to local communities and their limited disturbance, which would be offset by the mitigation requirements.

Because there is no potential for coal development in the Great Basin Region outside of Utah, only the Utah ARMPA addresses the potential disturbance threat from coal development. In Utah, at the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is deemed unsuitable for all or certain coal mining methods, pursuant to 43 CFR 3461.5. PHMAs are essential habitat for maintaining GRSG for the purposes of suitability criteria set forth at 43 CFR 3461.5(o)(1).

All PHMAs will be managed as exclusion areas for commercial renewable energy development (solar and wind), with the exception of areas outside of SFAs in three counties in southeastern Oregon. The three counties in Oregon will be managed as avoidance areas, with priority placed on locating commercial-scale wind and solar energy development in nonhabitat areas first, that is, outside of PHMAs and GHMAs, before development in PHMAs is approved. New ROWs and development for transmission lines, pipelines, and related infrastructure would be avoided by restricting land use authorizations. In avoidance areas, exceptions would be granted only if it can be demonstrated that adverse impacts would be avoided or that residual impacts would be mitigated.

High voltage transmission lines will be avoided in PHMAs. A limited number of priority transmission lines (Transwest Express and portions that are collocated with Transwest Express) of Gateway South, Gateway West, and Boardman to Hemingway have been proposed to expand access to renewable sources of energy and to improve the reliability of the western grid. These projects have been underway for several years, and are currently being analyzed under separate authorization processes. As part of the decision-making process for those projects, conservation measures for GRSG are being analyzed in the project-specific NEPA processes, which should achieve a net conservation benefit for GRSG.

New recreation facilities would not be authorized in PHMAs, unless the development results in a net conservation gain to the GRSG or its habitat or unless required for health and safety purposes.

In PHMAs, travel is limited to existing routes until new routes are designated through the implementation travel management planning process. Travel management plans, including route inventories, NEPA analysis, and route designation will be completed in a subsequent public planning process.

A 3 percent human disturbance cap in PHMAs has been established in accordance with the recommendations contained in the NTT Report and peer-reviewed literature from the Great Basin (Knick 2013). Disturbance will be calculated at two scales: first at the BSU scale determined in coordination with the state and second for the proposed project area. BSUs are geographic units of PHMAs that contain relevant and important GRSG habitat. In Oregon, for example, BSUs are synonymous with PACs. These BSUs are used solely for the calculation of human disturbance caps and in some ARMPAs, the adaptive management habitat triggers.

If the 3 percent human disturbance cap is exceeded on lands (regardless of landownership) in PHMAs in any given BSU, no further discrete human disturbances (subject to valid existing rights) will be permitted on BLM-managed lands in that BSU until restoration of disturbed lands brings the BSU below the cap. If the 3 percent human disturbance cap is exceeded on all lands (regardless of landownership) within a proposed project analysis area in a PHMAs, then the BLM would permit no further human disturbance until disturbance in the area has been reduced to below the cap.

An exception to the 3 percent disturbance cap is provided in designated utility corridors for achieving a net conservation gain to the species. This exception is limited to projects that fulfill the use that the corridors were designated for (e.g., transmission lines and pipelines) and within the designated width of a corridor. This exception will concentrate future ROW surface disturbance in areas of existing disturbance and will avoid new development of infrastructure corridors in PHMAs, which is consistent with guidance in the COT Report. In addition, the Oregon and Nevada/Northeast California ARMPAs include variations to the disturbance cap. Oregon does not allow more than 1 percent new human disturbance per decade, not to exceed 3 percent disturbance at any time. In Nevada, the 3 percent disturbance cap can be exceeded at the BSU or project level provided that the outcome results in a net conservation benefit to the species with the concurrence of the BLM, the Nevada Department of Wildlife, and the FWS in each exception.

In the its Dillon Field Office in southwest Montana, the BLM will limit disturbance to 3 percent until the State institutes its Sage Grouse Plan's disturbance calculation method, at which time disturbance will be permitted up to a 5 percent cap. As with the Wyoming Core Area Strategy, this is to recognize the importance of the all-lands/all-disturbances strategy that Montana will institute for GRSG conservation (Montana Office of the Governor Executive Order No. 10-2014; State of Montana 2014). Appendix E of each of the attached ARMPAs includes additional information about the method for calculating human disturbance at the BSU and project scales.

The ARMPAs also incorporate a cap on the density of energy and mining facilities to encourage collocating structures to reduce habitat fragmentation in PHMAs. The limit is an average of one facility per 640 acres in PHMAs in a project authorization area. This is consistent with guidance contained in the NTT Report. If the disturbance density in the PHMAs in a proposed project area is, on average, less than 1 facility per 640 acres, the project can proceed through the NEPA analysis, incorporating mitigation measures into an alternative. If the disturbance density in the proposed project area is greater than an average of 1 facility per 640 acres, the proposed project will either be deferred until the density of energy and mining facilities is less than the cap or redesigned so facilities are collocated into an existing disturbed area, subject to applicable laws and regulations, such as the 1872 Mining Law and valid existing rights. The 1 facility per 640 density decision does not apply to Nevada, as described in **Section 1.7**.

GHMAs—While restrictions on future development in PHMAs are intended to avoid or minimize additional surface disturbance, restrictions on development in GHMAs are intended to allow disturbance but minimize any adverse effects of disturbance with restrictions on development activities to ensure compatibility with GRSG habitat needs. In addition, mitigation to avoid, minimize, and compensate for unavoidable impacts will be required for proposed projects in GHMAs, as will the application of the RDFs discussed below.

Disturbance associated with oil and gas development, for example, is subject to a controlled surface use and timing limitation stipulation rather than an NSO stipulation. (see **Table 1-4** for more details on GHMAs management decisions.) Any disturbance is subject to mitigation, with the objective of first avoiding and minimizing potential impacts on GRSG or its habitat and then compensating for unavoidable impacts on GRSG or its habitat, to a net conservation gain standard for the species. This is consistent with guidance in the COT Report which states: "Conservation of habitats outside of PACs should include minimization of impacts to sage-grouse and healthy native plant communities. If minimization is not possible due to valid existing rights, mitigation for impacted habitats should occur… If development or vegetation manipulation activities outside of PACs are proposed, the project proponent should work with federal, state or local agencies and interested stakeholders to ensure consistency with sage-grouse habitat needs" (FWS 2013).

These conservation measures are intended to ensure that areas of GHMAs that can provide connectivity between PHMAs may be important seasonal habitats not identified or incorporated into previously mapped areas of PHMAs or that they can provide important habitat to replace areas of important habitat lost to fire or human disturbance. This strategy is particularly important given the recent USGS report by Crist et al. (2015), *Range-Wide Network of Priority Aras for Grater Sage-Grouse—A Design for Conserving Connected Distributions or Isolating Individual Zoos*? For management decisions and allocations associated with IHMAs in Idaho, see **Table 1-4**.

Habitat Protection and Surface Disturbance Measures in PHMAs and GHMAs

The measures below are related to habitat protection and surface disturbance. They will be applied in both PHMAs and GHMAs.

Prioritization Objective—In addition to allocations that limit disturbance in PHMAs and GHMAs, the ARMPAs prioritize oil and gas leasing and development outside of identified PHMAs and GHMAs to further limit future surface disturbance and to encourage new development in areas that would not conflict with GRSG. This objective is intended to guide development to lower conflict areas and, as such, to reduce the time and cost associated with oil and gas leasing development. It would do this by avoiding sensitive areas, reducing the complexity of environmental review and analysis of potential impacts on sensitive species, and decreasing the need for compensatory mitigation.

Grazing—While improper livestock grazing can be a threat to GRSG habitat, grazing is not considered a discrete surface-disturbing activity for monitoring and calculating disturbance. The plans address grazing management to conserve GRSG and its habitat and is further described in **Section 1.6.2**.

Lek Buffers—In addition to any other relevant information determined to be appropriate, the BLM will further assess and address impacts from certain activities using the lek buffer distances, as identified in the USGS report, *Conservation Buffer Distance Estimates for GRSG – A Review* (Manier et al. 2014). Lek buffer distances will be applied at the project-specific level as required conservation measures to address the impacts on leks identified in the NEPA analysis. The lek buffer distances vary by type of disturbance, such as road, energy development, and infrastructure; justifiable departures may be appropriate, as fully described in Appendix B of the ARMPAs. In both PHMAs and GHMAs, impacts should be avoided first by locating the action outside of the applicable lek buffer-distances, as defined in the ARMPAs. In PHMAs, the BLM will ensure that any impacts within the buffer distance from a lek are fully addressed. In GHMAs, the BLM will minimize and compensate for any unavoidable impacts to the extent possible. This approach to determining relevant lek buffer distances is consistent with the COT Report recommendation that "conservation plans should be based on the best available science and use local data on threats and ecological conditions" (FWS 2013).

Required Design Features—RDFs are used for certain activities in all GRSG habitat, including oil and gas development, infrastructure, and other surface-disturbing activities and are fully described in Appendix C of the attached ARMPAs. RDFs establish the minimum specifications for certain activities to help mitigate adverse impacts on GRSG and its habitat from threats, such as those posed by standing water that can facilitate West Nile virus or tall structures that can serve as perches for predators. The applicability and overall effectiveness of each RDF, however, cannot be fully assessed until the BLM knows the project level, project location, and design. Because of site-specific circumstances, some RDFs may not apply to some projects, such as when a resource is not present on a given site) or may require slight variations, such as a larger or smaller protective area. In Nevada and Northeastern California, RDFs are also applied to identified OHMAs.

In summary, all forms of new development in PHMAs and GHMAs would either be closed, excluded, avoided, or developed only if the resultant effect were a net conservation gain to the GRSG or its habitat, ensuring that existing habitat would be protected and providing opportunities through compensatory mitigation.

1.6.2 Improving Habitat Condition

In addition to prescribing land use allocations and managing resource uses to minimize and avoid further surface disturbance, the ARMPAs identify management actions to restore and improve GRSG habitat.

Habitat Management—The ARMPAs contain an overall habitat management objective that "[i]n all Sagebrush Focal Areas and Priority Habitat Management Areas, the desired condition is to maintain all lands ecologically capable of producing sagebrush (but no less than 70 percent) with a minimum of 15 percent sagebrush canopy cover, consistent with specific ecological site conditions." To move toward this goal, the ARMPAs specify GRSG habitat objectives to be incorporated into land management programs, including wild horses and burros (WHBs), grazing, and habitat restoration. These habitat objectives were developed for each of the GRSG's life history stages within each ARMPA's sub-region. These objectives will be used to meet the applicable land health standard in GRSG habitats.

The ARMPAs also include specific decisions to improve habitat conditions and meet the habitat objectives by treating invasive annual grasses and removing encroaching conifers in SFAs, PHMAs, and GHMAs and by restoring degraded landscapes, including those impacted by fires (see **Section 1.6.3**.)

Livestock Grazing—The BLM recognizes that improper grazing can be a threat to GRSG and its habitat. Because grazing is the most widespread use of the sagebrush steppe ecosystem, the ARMPAs address improper grazing. The COT Report (FWS 2013) recommends conducting "grazing management for all ungulates in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage-grouse (e.g. shrub cover, nesting cover)." To ensure that grazing continues in a manner consistent with the objective of conserving the GRSG and its habitat, the Great Basin ARMPAs require incorporating terms and conditions informed by GRSG habitat objectives into grazing permits, consistent with the ecological site potential of the local areas, prioritizing reviewing and processing authorizations and field checks of grazing permits, and taking numerous actions to avoid and minimize the impacts of range management structures (see **Table 1-4**).

The BLM will prioritize reviewing and processing grazing authorizations, as well as field checking grazing permits in the habitat that is most important to GRSG populations: first in SFAs, then PHMAs, followed by GHMAs, focusing first on riparian and wet meadows. The decision to prioritize in this way does not indicate that grazing is more of a threat or is an incompatible use in any given area; rather it reflects a decision to prioritize resources to ensure that permittees and the BLM manage grazing properly in those areas most important to GRSG. If the BLM were to find that relevant habitat objectives are not being met due to improper grazing, it would work with the permittee to ensure progress toward habitat objectives.

Wild Horses and Burros—To address the localized threat due to negative influences of grazing by free-roaming WHBs, the BLM will focus on maintaining WHB herd management areas in GRSG habitat in established AML ranges. This is to achieve and maintain GRSG habitat objectives. It includes completing rangeland health assessments, prioritizing gathers and population growth suppression techniques, and developing or amending herd management area plans to incorporate GRSG habitat objectives and management considerations. The BLM will prioritize WHB management first in SFAs, then the remainder of PHMAs, and then GHMAs. In SFAs and PHMAs, the BLM will assess and adjust AMLs through the NEPA process within herd management areas when WHBs are identified as a significant factor in not meeting land health standards, even if current AML is not being exceeded.

Mitigation and Net Conservation Benefit—During the implementation of the ARMPAs, and consistent with valid existing rights and applicable law, in authorizing third-party actions that result in GRSG habitat loss and degradation, the BLM will require mitigation that provides a net conservation gain (the actual benefit or gain above baseline conditions) to the species. This will include accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for unavoidable impacts by applying beneficial conservation actions to offset remaining impacts associated with the action.

This standard is consistent with the recommendation in the *Greater Sage-Grouse Range-wide Mitigation Framework: Version 1.0* (FWS 2014b), which states that mitigation "should be strategically designed to result in net overall positive outcomes for sage-grouse." Mitigation will follow the regulations from the CEQ NEPA regulatory requirements (40 CFR 1508.20; e.g., avoid, minimize, and compensate). It would be implemented on BLM-administered lands in a manner consistent with Department of the Interior guidance for landscape mitigation, pursuant to Secretarial Order (S.O.) 3330. If impacts from BLM management actions and authorized third-party actions result in habitat loss and degradation that remain after avoidance and minimization measures are applied, then compensatory mitigation projects would be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation.

To help achieve the mitigation goal of net conservation gain across the range, the BLM will establish GRSG Conservation Teams, based on WAFWA MZs and including representatives from the respective

States, the Forest Service, FWS, and NRCS. These Conservation Teams will facilitate cross-state issues, such as regional mitigation and adaptive management monitoring and response. They will convene and respond to issues at the appropriate scale and will use existing coordination and management structures to the extent possible.

Climate Change—With regard to the threat of climate change, the ARMPAs set goals and objectives and describe actions intended to build resilience in the sagebrush steppe landscape to the impacts of climate change through habitat conservation and restoration measures. The coordinated landscape approach to addressing rangeland fire and invasive species described in the *Integrated Rangeland Fire Management Strategy: Final Report to the Secretary of the Interior* (US Department of the Interior 2015) will further these goals and objectives.

The Fire and Invasives Assessment Team (FIAT) assessments that informed the ARMPAs and supported the development of the Fire Strategy (US Department of the Interior 2015) were designed to identify landscapes of high resistance and resilience based on research by Chambers et al. (2014). Additionally, limiting or eliminating human surface disturbance, especially in the SFAs, would ensure the integrity of the PHMAs and would restore habitat through fuels management, post-fire restoration, and mitigation efforts. Connectivity and availability of sagebrush habitat would increase, thus contributing to increased climate resilience. The SFAs in particular were identified as key areas to conserve as the climate changes. The Oregon ARMPA commits to using climate change science concerning projected changes in species ranges and changes in site capability. This would be used to adjust expected and desired native species compositions as that information becomes available.

As identified by the FWS 2010 listing decision and the COT Report, climate change can impact efforts to conserve the GRSG and its habitat in a number of ways. While several ARMPAs acknowledge the potential impact of climate change on GRSG habitat and conservation, specific strategies to address the impacts of climate change are limited. The BLM and Forest Service, in coordination with the FWS, will continue to assess the potential impacts of climate change on GRSG and its habitat and will develop strategies to mitigate the anticipated effects on GRSG conservation efforts, as necessary and appropriate. Changes to management decisions will require a plan revision or amendment, as appropriate, recognizing the need to ensure that future management direction improves the resilience of habitat areas essential to the conservation of the species.

1.6.3 Reducing Threats of Rangeland Fire to GRSG and Sagebrush Habitat

The COT Report emphasized that "rangeland fire (both lightning-caused and human-caused fire) in sagebrush ecosystems is one of the primary risks to the greater sage-grouse, especially as part of the positive feedback loop between exotic invasive annual grasses and fire frequency" (FWS 2013). Recent USGS studies by Brooks et al. (2015) and Coates et al. (2015) reinforce the importance of a comprehensive management strategy to prevent and suppress rangeland fires in the western part of GRSG range and to aggressively restore habitat areas impacted by fire.

For this reason, the ARMPAs seek to improve efforts to strategically develop fuel breaks, in collaboration with GRSG biologists. This would be done to reduce potential habitat loss from rangeland fires, accelerate the restoration of fire-impacted landscapes to native grasses and sagebrush, and fight the spread of cheatgrass and other invasive species that increase the frequency and intensity of rangeland fires. However, prescribed fire will not be used in sagebrush steppe. The exception would be if the NEPA analysis for the burn plan were to provide a clear rationale for why alternative techniques were not selected as a viable option. The analysis also would need to explain how GRSG habitat management goals and objectives would be met by its use and how the COT Report objectives would be met. It would require a risk assessment to address how potential threats to GRSG habitat would be minimized.

Recent scientific research on resistance and resilience of Great Basin ecosystems (Chambers et al. 2014) provides the basis for improved targeting of fire management activities on BLM-administered lands. The BLM, the Forest Service, FWS, and other cooperating agencies agreed to incorporate this approach into the ARMPAs. This information is being used to identify and design projects to change vegetation composition and structure to modify potential fire behavior to improve fire suppression effectiveness and limit fire spread and intensity due to invasive grasses and conifer encroachment. The BLM *Greater Sage Grouse Invasive Annual Grasses and Conifer Expansion Assessment* (FIAT 2014) modeled conifer expansion for PACs to provide an initial stratification. It was done to determine where conifer removal would benefit important sagebrush habitats.

Consistent with this assessment, the BLM ARMPAs include management actions to remove invading conifers and other undesirable species and to prioritize vegetation treatments for the purpose closest to occupied GRSG habitats and near occupied leks.

In addition to and complementing the fire management measures in the ARMPAs described in this ROD, Secretarial Order 3336 on Rangeland Fire made clear that "**protecting, conserving, and restoring the health of the sagebrush-steppe ecosystem and, in particular, priority GRSG habitat, while maintaining safe and efficient operations, is a critical fire management priority for the Department**" (emphasis added; US Department of the Interior 2015).

Secretarial Order 3336 directed the development of the *Integrated Rangeland Fire Management Strategy* (Strategy) which places a Departmental priority on activities to prevent, suppress, and restore fire-impacted landscapes. It focused on priority GRSG habitat, including that identified by the FIAT for the Great Basin Region, using recent information derived from a report prepared by WAFWA to assist in addressing the threat of rangeland fire. The FIAT Assessments provide a critical guidance to conserve, enhance, and restore GRSG habitat consistent with best available science and identify highly resistant and resilient landscapes to target fire management in these most important lands.

A key element of the Strategy is a commitment to address the invasion and expansion of cheatgrass, medusahead rye, and other invasive grasses through expanded efforts to treat impacted acres. Efforts are underway to increase the acreages to be treated with chemical and biological agents to stem the spread of invasive species and to accelerate the registration of other biologicals useful in addressing the threat of cheatgrass invasion. In addition, recently adopted Department of the Interior guidance will allocate Emergency Stabilization and Burned Area Rehabilitation (ES&BAR) funds on a risk-based approach using historic acres burned to accelerate and expand the restoration of burned lands with native grasses and sagebrush seedlings. The BLM recently announced a Native Seed Strategy to accelerate and expand the production, storage, and allocation of seed for native vegetation and sagebrush. The strategy is to restore and rehabilitate burned areas and accelerate the improvement of the sagebrush ecosystem and habitat for GRSG.

Finally, by issuing a leaders' intent letter, signed by the Secretaries of Agriculture and the Interior, rangeland fire was identified as an "additional priority" for the firefighting community in making strategic decisions about firefighting resource allocation in 2015. Additional resources have been allocated and will be targeted at the following:

- Fuel treatments, including invasive species control
- Suppression, by positioning firefighting resources and training additional Rangeland Fire Protection Associations, local volunteer firefighters, and veteran fire fighters
- Restoring habitat in these areas

Firefighting assets (aircraft, firefighters, and related equipment) were positioned in advance of the 2015 fire season to improve capacity and reduce acres of rangelands lost to fire by improving the success of the initial attack. In future years, BLM firefighting assets will be located near PHMAs to limit habitat losses from rangeland fire.

1.6.4 Monitoring, Evaluation, and Adaptive Management

The COT Report preparers noted that "a monitoring program is necessary to track the success of conservation plans and proactive conservation activities. Without this information, the actual benefit of conservation activities cannot be measured and there is no capacity to adapt if current management actions are determined to be ineffective" (FWS 2013). The NTT further notes that "Monitoring is necessary to provide an objective appraisal of the effects of potentially positive conservation actions, and to assess the relative negative effects of management actions to sage-grouse populations and their habitats" (NTT 2011).

A range-wide monitoring and evaluation framework will be established and implemented, as described in the Monitoring Framework (Appendix D of each attached ARMPA). This monitoring strategy has two parts, as follows:

- Implementation monitoring (i.e., are decisions being implemented in a timely manner? are actions taken consistent with the plan decisions?)
- Effectiveness monitoring (i.e., are the decisions and implementation actions achieving the desired conservation goals?)

Through effectiveness monitoring, the BLM can determine how management decisions and actions implemented through the ARMPAs affect GRSG habitat. This would be to determine if the desired management objectives, such as avoiding and minimizing additional surface disturbance in PHMAs, have been achieved. Understanding the effectiveness and validating results of ARMPA management decisions is an essential part of the GRSG conservation strategy and provides the means for determining if desired outcomes are being achieved.

Monitoring that is applicable for evaluating management effectiveness can also be used to address a number of other critical habitat variables (e.g., location, condition, habitat loss or gain, and size of patches). Ideally, monitoring attributes of GRSG habitat, in coordination with population monitoring by State wildlife agencies and other partners, will allow real or potential habitat changes from both natural events and management actions to be linked to vital rates of GRSG populations. This analysis will enable managers to identify indicators associated with population change across large landscapes and to lessen the negative effects with appropriate conservation actions. The WAFWA Zone GRSG Conservation Teams (as described in **Section 1.6.2**) will also be used to advise regional monitoring strategies and data analysis, as described in the plans.

Each ARMPA includes an overarching adaptive management strategy that includes soft and hard triggers and responses. These triggers are habitat and population thresholds and are based on the two key metrics that are being monitored: habitat condition and population numbers. At a minimum, the BLM will assess annually whether hard and soft trigger thresholds have been met when the population or habitat information becomes available, beginning after this ROD is signed and issued.

Soft triggers represent an intermediate threshold indicating that management changes are needed at the implementation level to address habitat or population losses. If a soft trigger is tripped during the life of the ARMPAs, the BLM will implement more conservative or restrictive conservation measures on a project-by-project basis to mitigate for the specific cause in the decline of populations or habitats, taking into consideration local knowledge and conditions. In each ARMPA, a soft trigger begins a dialogue between the State, FWS, and the BLM to see if the cause can be determined and what implementation-level activities can be used to reverse any trend. These adjustments will be made to prevent tripping a hard trigger, which signals more severe habitat loss or population declines.

Hard triggers represent a threshold indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the BLM ARMPAs. In the event that a hard trigger were tripped, the BLM would implement plan-level decisions, such as allocation changes, to immediately institute greater protection for GRSG and its habitat. If a hard trigger were tripped in a PAC that crosses State boundaries, the WAFWA MZ GRSG Conservation Team would convene to discuss causes and identify potential responses.

In the event that new scientific information becomes available, demonstrating that the hard trigger response is insufficient to stop a severe deviation from GRSG conservation objectives set forth in the BLM ARMPAs, the BLM would immediately assess what further actions may be needed to protect GRSG and its habitat and to ensure that conservation options are not foreclosed. This could include a formal directive, such as an instruction memorandum (IM) or a plan amendment.

1.7 UNIQUE ASPECTS OF THE GREAT BASIN ARMPAS

The ARMPAs and their associated EISs were developed through four planning efforts across the Great Basin Region (as described in **Section 1.1**). To develop these plans, the BLM employed a landscape-scale approach to achieve a common set of management objectives across the range of GRSG recognizing. In particular, it implemented measures to limit anthropogenic disturbance in important habitats. Within this framework, management actions were developed and incorporated into the plans that are tailored to achieve these objectives and accommodate differences in resource conditions, severity of threats, and State-specific management approaches.

This flexible landscape approach provided the opportunity to incorporate recommendations resulting from collaboration with the States and local cooperators and from public comments in each Planning

Area. The plans and their future implementation are strengthened by the contributions of local partners and their knowledge, expertise, and experience.

Measures incorporated into the plans remain consistent with the range-wide objective of conserving, enhancing, and restoring GRSG habitat by reducing, eliminating, or minimizing threats to GRSG habitat, such that the need for additional protections under the ESA may be avoided.

Below is a brief description of the unique aspects of each of the Great Basin Region's ARMPAs.

Idaho and Southwestern Montana

The Idaho and Southwestern Montana ARMPA adopted specific aspects of the State of Idaho's Conservation Plan for GRSG. The most significant aspect adopted from the State's plan is a third category of habitat referred to as IHMAs. IHMAs are BLM-administered and National Forest System lands that provide a management buffer for PHMAs and connect patches of PHMAs. IHMAs encompasses areas of generally moderate to high conservation value habitat and/or populations.

In a landscape that is most threatened by fire and invasive species, this three-tiered approach allows land managers to focus suppression and restoration resources on those areas of highest importance. It also provides an acceptable additional level of flexibility in IHMAs and GHMAs because surface disturbance due to development is not as great a threat to habitat in the sub-region. The three tiers also are the foundation for an adaptive management approach that includes habitat and population hard and soft triggers. The adaptive management approach requires that when a hard trigger is reached, IHMAs will be managed as PHMAs to maintain sufficient PHMAs to support GRSG populations.

The Idaho portion of the Idaho and Southwestern Montana GRSG ARMPA also includes a unique approach to calculating disturbance to account for effective habitat. This is described in Appendix E of the attached Idaho and Southwestern Montana ARMPA, which the BLM developed in concert with the Idaho Department of Fish and Game, the Forest Service, and the FWS. The ARMPA also includes additional RDFs based on lek avoidance distances, which were developed in coordination with the Idaho Department of Fish and Game and the local FWS office. Examples are avoiding building new wire fences within 2 kilometers of occupied leks and placing new taller structures out of sightlines or at least one kilometer from occupied leks. The BLM will also work with the State of Idaho in setting priorities for reviewing and processing grazing permits and leases in SFAs, consistent with the method recommended by the State of Idaho in its proposed plan for managing BLM-administered lands in the State.

On August 7, 2015, the Sawtooth National Recreation Area and Jerry Peak Wilderness Act was signed into law (House Resolution 1138). In accordance with the Wilderness Act (16 USC, Section 1131 et seq.), certain Federal lands in the Challis National Forest and Challis District of the BLM in Idaho were designated as Wilderness, as a component of the National Wilderness Preservation System, known as the Jim McClure-Jerry Peak Wilderness. Approximately 12,430 acres of this Wilderness area is within BLM-administered SFAs. This area will now also be managed as Wilderness consistent with the Wilderness Act. As specified in the Sawtooth National Recreation Area and Jerry Peak Wilderness Act, a wilderness management plan will be developed within five years of the signing of the act and it will outline specific management guidance for the new wilderness area.

This act also released the Jerry Peak West, Corral-Horse Basin, and Boulder Creek Wilderness Study Areas and they are no longer subject to management, pursuant to Section 603(c) of the FLPMA. The acres of wilderness study areas released include approximately 71,194 acres of PHMAs, 11,923 acres of IHMAs, and 5,912 acres of GHMAs. The ARMPA decisions for these areas will not change as a result of the release.

Finally the Sawtooth National Recreation Area and Jerry Peak Wilderness Act also directed the BLM to convey certain public lands to Blaine County, Custer County, the City of Challis, the City of Clayton, and the City of Stanley. These conveyances include approximately 53 acres of PHMAs, 10 acres of IHMAs, and 828 acres of GHMAs that are reflected in the ARMPA as being administered by the BLM. Once conveyed, these lands will not be subject to the BLM management decisions outlined in the Idaho and Southwestern Montana GRSG ARMPA.

The decisions affecting Southwestern Montana in the ARMPA are consistent with the objectives of the Montana Sage Grouse Habitat Conservation Program (Montana Office of the Governor Executive Order No. 10-2014; State of Montana 2014) by establishing conservation measures and strategies to minimize disturbance and habitat loss, particularly as a result of surface disturbance from energy exploration and development.

The BLM plan will permit the disturbance limit to go from a 3 percent to a 5 percent disturbance cap, consistent with the Montana Plan when the process for implementing that State's disturbance calculation method is instituted and effective. Additionally, if the BLM finds that the State of Montana is implementing an effective GRSG habitat conservation program, the BLM would review their management actions to determine if additional GRSG-related management actions should be adjusted. This would be coordinated with the State of Montana and the FWS to achieve consistent and effective conservation across all lands, regardless of ownership.

Nevada and Northeastern California

The Nevada portion of the Nevada and Northeastern California ARMPA is unique from other Great Basin ARMPAs because of how the sub-regional habitat map was developed. The ARPMA uses the 2014 Coates Maps, developed locally using the best available science. The ARMPA included OHMAs, where RDFs will be applied at the project level. Decisions for BLM-administered lands in California include allocations and management direction that is generally similar to other ARMPAs in the Great Basin, while carrying forward some decisions identified in the Sage Steppe Ecosystem Restoration Final EIS (BLM 2008).

Decisions for BLM-administered lands in Nevada incorporate key elements of the *State of Nevada Greater Sage-Grouse Conservation Plan* (State of Nevada 2014), including consideration of the State of Nevada Conservation Credit System (Nevada Natural Heritage Program and Sagebrush Ecosystem Technical Team 2014) as the ARMPA is implemented and as projects are proposed within the Planning Area. This mitigation strategy focuses restoration on the key areas most valuable to the GRSG. The ARMPA adopts a disturbance management protocol to provide for a 3 percent limit on disturbance. The exception would be in situations where a biological analysis indicates a net conservation gain to the species, with concurrence from the BLM, the State of Nevada, and the FWS. The plan provides for this exception due to the development of mitigation tools in Nevada, including the Conservation Credit System, in collaboration with the FWS.
