

Final 4/15/2013

**Language to be Included into the Draft GRSG RMP Amendments and EISs**Chapter 3 – Affected Environment*Lands with Wilderness Characteristics*

The purpose and need of the National GRSG Planning Effort is limited to making land use planning decisions specific to the conservation of greater sage-grouse habitats. No decisions related to the management of LWCs will be made as part of this planning effort; therefore, management of LWCs is considered outside the scope of this plan amendment process. Impacts to LWCs from the alternatives being analyzed for this planning effort are presented in section [REDACTED].

As part of the original FLPMA Section 603-mandated inventories, inventories that were conducted during past RMP revisions and amendments efforts, and through other various LWC inventory updates that have recently taken place, inventories for wilderness characteristics were conducted between [REDACTED] and [REDACTED] and reflect the most up-to-date LWC baseline information for this planning area. For inventories that were conducted after 2011, findings were documented following guidance in *IM 2011-154, Requirement to Conduct and Maintain Inventory Information for Wilderness Characteristics and to Consider Lands with Wilderness Characteristics in Land Use Plans*, which is now encompassed in BLM Manuals 6310 and 6320. LWC inventories will be updated for any site-specific project NEPA analyses that are conducted in the planning area to determine if a project will have impacts to LWCs identified through previous or updated inventory efforts.

Include a brief summary and reference the findings from the most recent LWC inventories that were conducted in the planning area (regardless of how old these inventories are). In many cases, this information can be derived from the existing RMPs that this plan amendment will be amending.

Chapter 4 – Environmental Consequences*Lands with Wilderness Characteristics*

In any format consistent with the structure of the plan amendment EIS's chapter 4, analyze the impacts to LWCs for all of the alternatives analyzed in this document. Please use the baseline information for the most recent LWC inventories that were summarized in chapter 3.

## Lands with Wilderness Characteristics (LWC)

Section 201 of FLPMA requires the BLM to maintain on a continuing basis an inventory of all public lands and their resources and other values, which includes wilderness characteristics. It also provides that the preparation and maintenance of the inventory shall not, of itself, change or prevent change of the management or use of public lands. Regardless of past inventory, the BLM must maintain and update as necessary, its inventory of wilderness resources on public lands. In some circumstances conditions relating to wilderness characteristics may have changed over time, and an area that was once determined to lack wilderness characteristics may now possess them. The BLM determines when it is necessary to update its wilderness characteristics inventory.

Under the following circumstances, the BLM considers whether to update a wilderness characteristics inventory or conduct a wilderness characteristics inventory for the first time:

1. The public or the BLM identifies wilderness characteristics as an issue during the National Environmental Policy Act (NEPA) process.
2. The BLM is undertaking a land use planning process.
3. The BLM has new information concerning resource conditions, including wilderness characteristics information submitted by the public that meets the BLM's minimum standard described in the Wilderness Characteristics Inventory Process section of this policy.
4. A project that may impact wilderness characteristics is undergoing NEPA analysis.
5. The BLM acquires additional lands.

There also may be other circumstances in which BLM will find it appropriate to update its wilderness characteristics inventory.

The primary function of an inventory is to determine the presence or absence of wilderness characteristics.

BLM has completed LWC inventory in the Four Rivers, Bruneau, Jarbidge, Pocatello, and Upper Snake Field Offices. Partial inventories have been completed in Owyhee, Shoshone, Burley, Challis and Salmon Field Offices.

Pocatello and Upper Snake Field Offices inventory found those offices have no lands with wilderness characteristics.

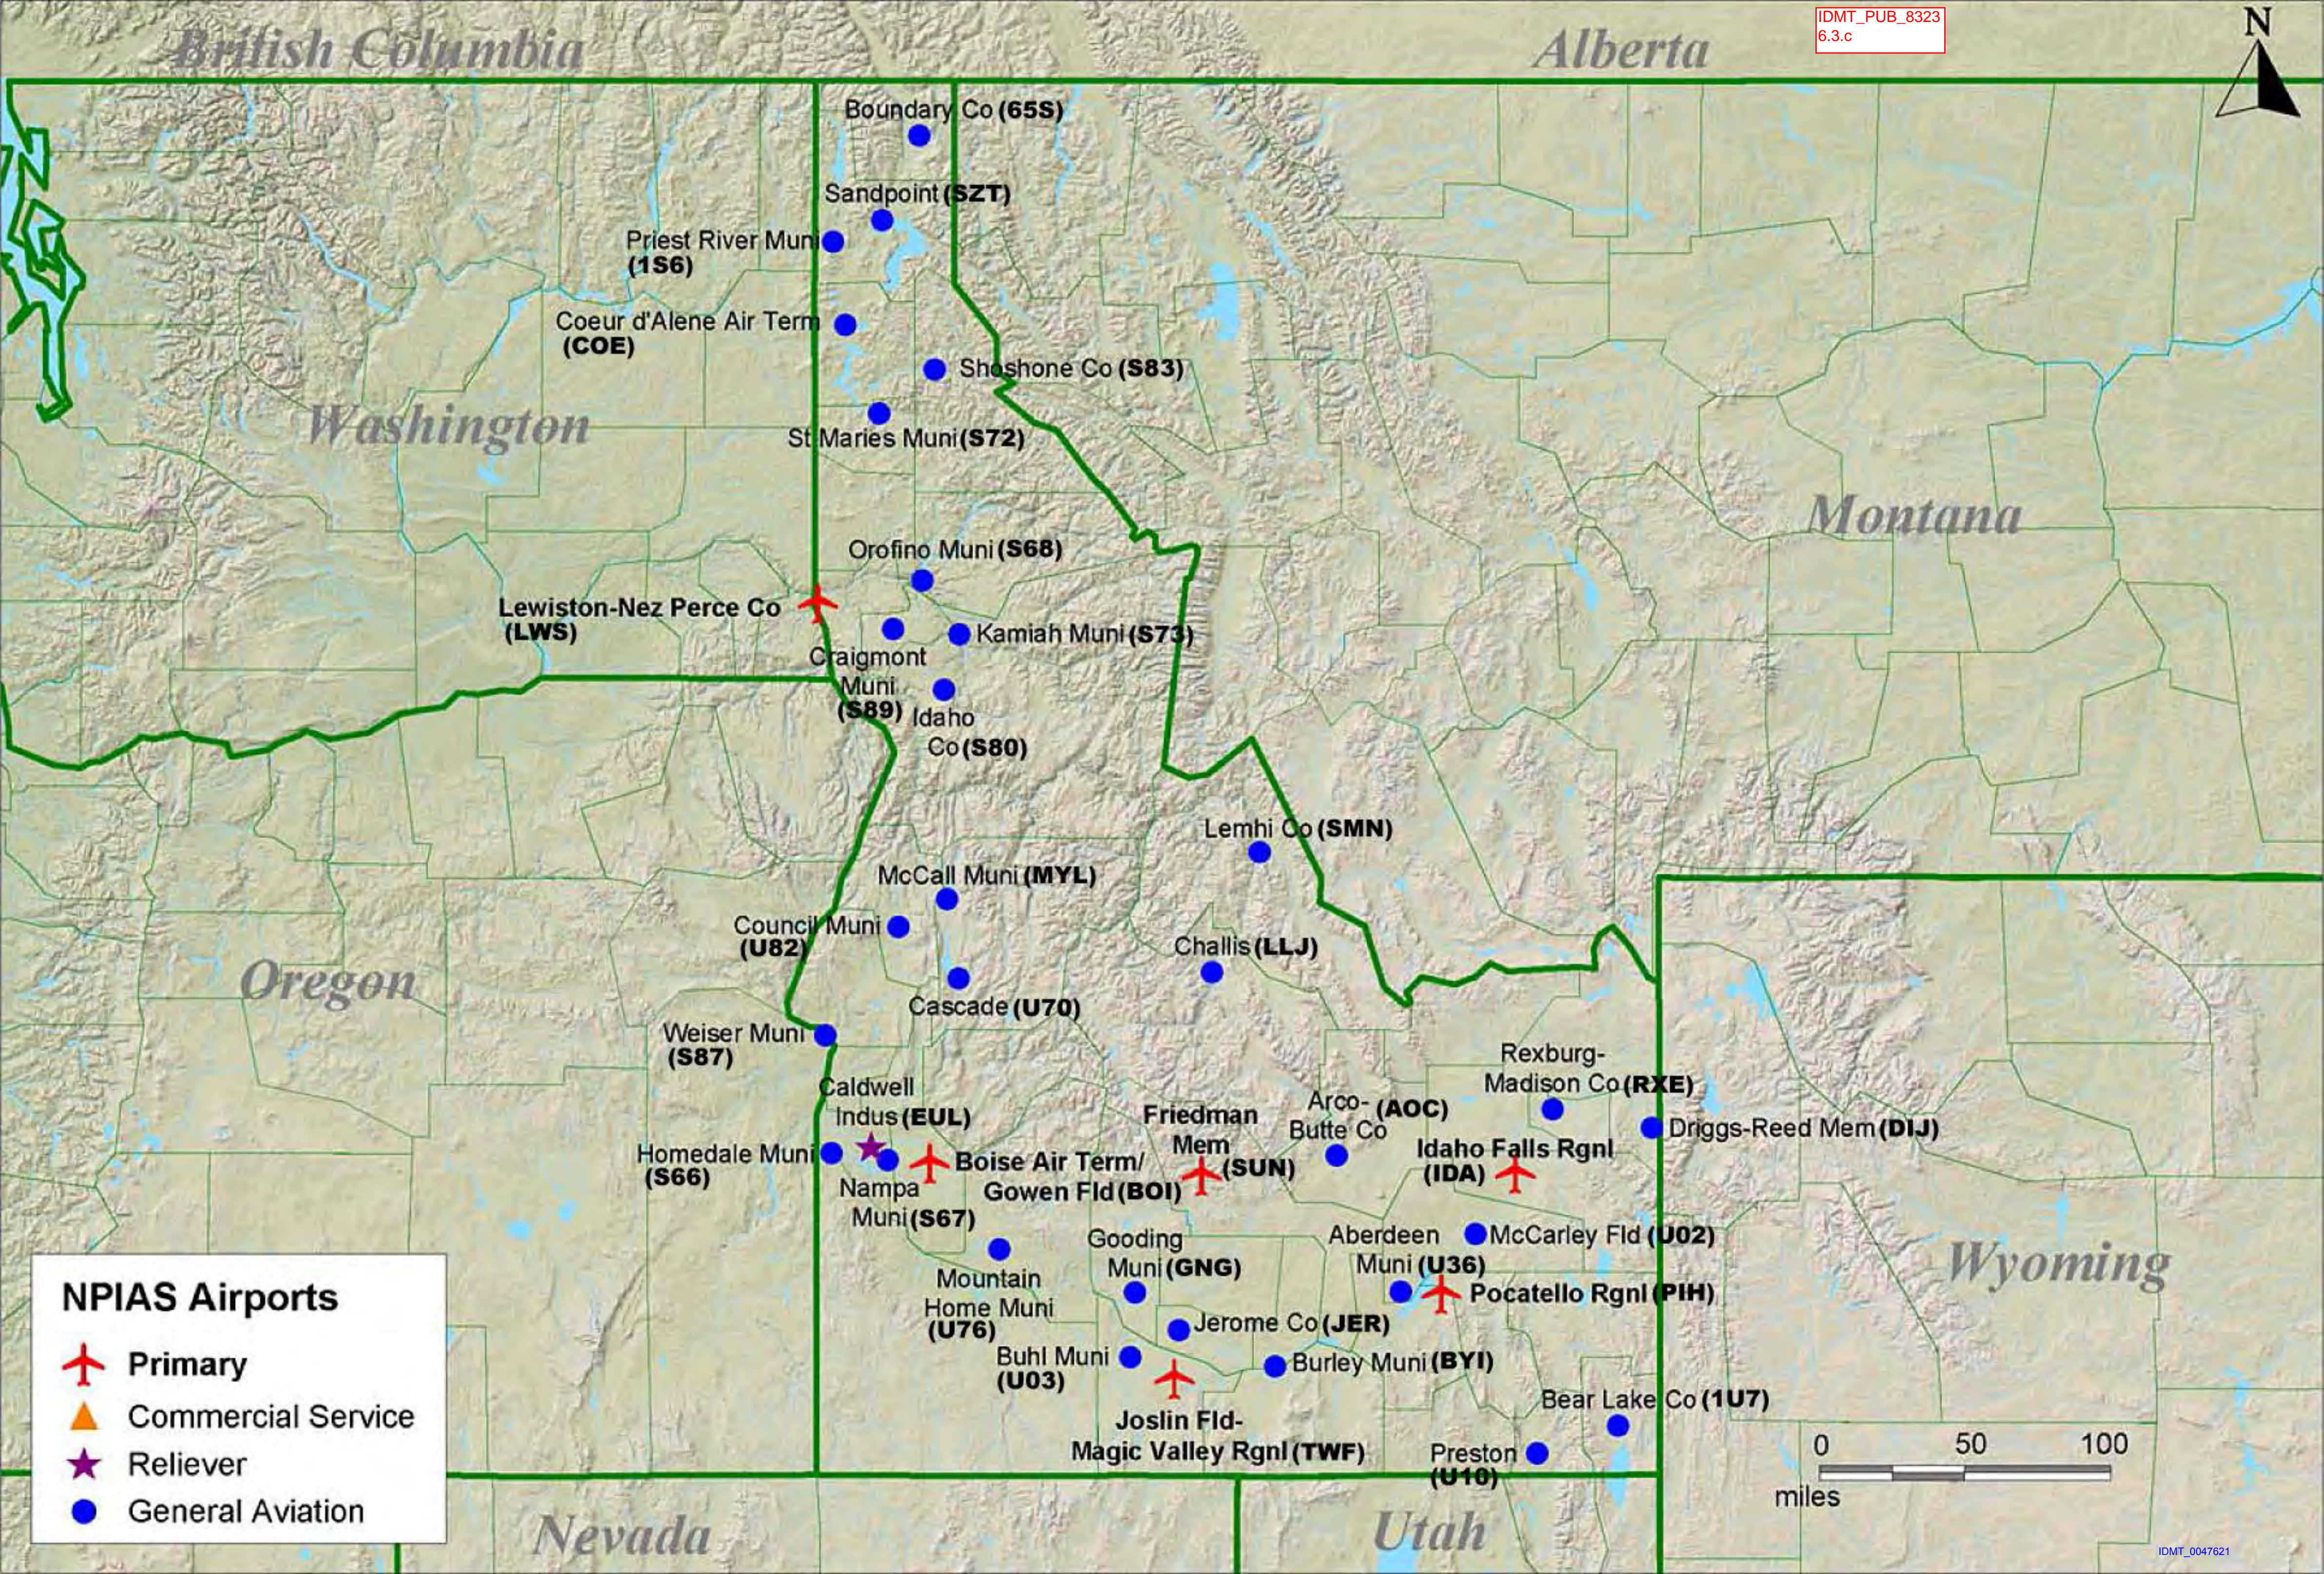

Four Rivers, Bruneau, and Jarbidge inventories found areas that do contain lands with wilderness characteristics.

Owyhee, Shoshone, Burley, Challis and Salmon Field Offices do not have final inventory reports.

There are XX,000 acres of lands with wilderness character within the planning area boundary.

## Predation

The greater sage-grouse is potential prey to a variety of predator species, such as the golden eagle (*Aquila chrysaetos*), ferruginous hawk (*Buteo regalis*), common raven (*Corvus corax*), American badger (*Taxidea taxus*), coyote (*Canis latrans*), red fox (*Vulpes vulpes*), weasels (*Mustela* spp.) and others (Schroeder et al. 1999, Coates 2007) but none specialize in the species (Hagen 2011). Adults are susceptible to predation while on leks or nests, and eggs are vulnerable as well (Schroeder et al. 1999, Coates 2007, Hagen 2011). Predation is the most commonly identified cause of direct mortality for sage-grouse during all life stages (USFWS 2010 citing others) but numerous studies since the 1970's suggest that nest predation is not a widespread problem and generally high survival rates of adults and older juveniles suggests that on average, predation is not limiting populations (Connelly et al. 2000, Hagen 2011). As a result, there is little scientific support for predator management over broad geographic or temporal scales (Hagen 2011).

In areas where habitat is not limited and of good quality, predation is not a threat to the persistence of the species (USFWS 2010). However, in fragmented habitats or areas with subsidized predator populations, such as where landfills or other human factors attract and concentrate scavengers (Coates 2007), or where electrical transmission or other man-made structures facilitate nesting and perching by avian predators such as ravens (Howe 2012), predation may limit population growth (Hagen 2011).

In the context of the Idaho/Southwestern Montana sage-grouse conservation strategy, direct predator control at the broad-scale is outside of the scope of BLM and FS decision space. Rather, such control efforts would be under the purview of the states of Idaho and Montana, and/or USDA APHIS Wildlife Services, in cooperation with the USFWS.

As land-management agencies, the primary role of the BLM and FS is the management of habitats and land uses and associated authorizations. Therefore, the amelioration of predation effects on sage-grouse in this conservation strategy is best accomplished through 1) the appropriate management, improvement or restoration of sagebrush habitats and 2) the siting and design of anthropogenic structures in a way that eliminates or reduces risk from predators that may utilize them to their advantage.

## Ecoregional Context and Landscape Approach

Public lands are undergoing complex environmental challenges that go beyond traditional management boundaries. In response, the BLM is instituting a landscape-scale management approach which evaluates large areas to better understand the ecological values, human influences, and opportunities for resource conservation. This approach frequently allows identification of environmental changes that might not be apparent in smaller areas.

The BLM's landscape approach includes Rapid Ecoregional Assessments (REAs) which provide a framework for integrating science and management. REAs evaluate landscape scale ecoregions, which are large areas with similar environmental characteristics. The BLM has initiated fourteen REAs since 2010. The Nevada-NE California Sub-Region lies within the Central Basin and Range (CBR) and the Northern Basin and Range (NBR) ecoregions.

REAs synthesize the best available broad-scale information data to examine the current status of ecological values, conditions, and trends within the ecoregion conservation elements and change agents, and provide geospatial responses to a defined set of management questions. Assessments of these larger areas provide land managers additional information and tools to use in subsequent resource planning and decision-making.

REAs describe and map conservation elements, which are areas of high ecological value, ecoregionally important resources, and e habitat types, and species, or species assemblages of management concern. REAs look across all lands in an ecoregion to identify regionally important habitats for fish, wildlife, and species of concern. REAs then gauge the potential of these habitats to be affected by four overarching environmental *change agents*: climate change, wildfires, invasive species, and development (both energy development and urban growth). REAs also help identify areas that do not provide essential habitat, that are not ecologically intact or readily restorable, and where development activities may be directed to minimize impacts to important ecosystem values. provide a coarse-grain look at the areas where impacts from change agents are concentrated, and areas that are still relatively intact, or have opportunities for restoration or protection.

In the Nevada-NE California Sub-Region, the Central Basin and Range REA (CBR REA) has been completed while the Northern ~~Basin and Range~~ Great Basin REA is underway nearing completion. The CBR REA will be used to inform and enhance the quality of resource management and environmental analysis at the landscape level. The REA information is considered in the development of management objectives that can be adapted to the changing environment. This REA will aid in identifying priority areas for conservation and development, including important areas for wildlife habitat and migration corridors, and help inform finer-scale information and assessments at the local level.

Nevada is a vast land and the BLM and USFS are responsible for managing approximately 70% of the state. In order to effectively manage it, the BLM and USFS are taking a cohesive management approach based on partnerships, built on the principle of conserving or improving natural resources across the landscape. The landscape level REAs allow the BLM and USFS to collaborate beyond the usual jurisdictional boundaries with the goal of conserving the native ecological communities, traditional uses, and helping to maintain the rural Nevada culture that makes it so unique.

For additional information about BLM's Landscape Approach website at [http://www.blm.gov/wo/st/en/prog/more/Landscape\\_Approach.html](http://www.blm.gov/wo/st/en/prog/more/Landscape_Approach.html)

As REAs are completed the information about each REA is posted on the REA website. The website includes published REA reports and the REA Data portal. The data portal provides access to an interactive map and downloadable data.

### Central Basin and Range REA Citation:

**Commented [LD1]:** Also recreation, minerals, exurban, and agriculture

**Commented [LD2]:** The NGB REA also looks at grazing as a change agent, maybe there is a way to incorporate that

**Commented [LD3]:** Final from contractor expected in May 2013

**Commented [LD4]:** Will both REAs be used, or just the CBR?

**Commented [LD5]:** I think this should go up at the top

Kutner. 2012. *Central Basin and Range Rapid Ecoregional Assessment Report*. Prepared for the U.S. Department of the Interior, Bureau of Land Management. 168 pp + Appendices

## Paleontological Resources (Gregory Liggett, BLM MT State Paleontologist)

Paleontological resources (fossils) have long been recognized for their scientific, educational, and recreational value. A fossil is any evidence of past life, and includes body fossils such as shells and bones, as well as trace fossils such as footprints, burrows, trails, or other evidence of an organism's presence. Fossils are preserved in rocks and are usually discovered when they are eroding out of the rock at the surface, or during ground-disturbing activity such as road grading or trenching. Most individual organisms that lived in the past did not die in such a way as to have their remains fossilized, and fewer still will be collected and studied before they erode away. Therefore fossils are considered rare and nonrenewable.

All fossils contain information about past life, but not all fossils are significant. Significant fossils are those that are unique, unusual, or rare, are diagnostic, stratigraphically important, and add to the existing body of knowledge. In order to determine a fossil's significance, an assessment must be made by someone who is experienced in the field of paleontology, and who possesses a sufficient mastery of the existing body of knowledge to understand how a given fossil contributes to our overall understanding.

The Bureau of Land Management (BLM) has managed fossils as a valued resource for many years. Legal authority to manage fossils comes from a variety of laws, executive orders, and policies. The laws include the National Environmental Policy Act of 1969 (NEPA) and the Federal Land Policy and Management Act of 1976 (FLPMA). More recently, the Paleontological Resources Preservation subtitle of the Omnibus Public Land Management Act of 2009, also known by its popular name, the Paleontological Resources Preservation Act (PRPA), directs land managers within the Department of the Interior Agencies and the U.S. Department of Agriculture, but not including either Indian or Military (Department of Defense) lands, to manage and protect fossils using scientific principles and expertise. PRPA does not make a distinction between the types of organism preserved; therefore, all fossil resources, plants, invertebrates, and vertebrates that are determined to be scientifically significant are to be actively managed.

As mentioned, fossils are found in rocks. The rocks that we see today were formed over millions, and sometimes billions, of years. When the animal or plant that we find today as a fossil was alive, the environmental conditions of that location were significantly different. For example, the rock that fossils are found in today may have been formed by sediments at the bottom of an ocean, or along the edge of a tropical river or lake. By using the evidence preserved in the rocks, and by examining fossils, scientists can piece together the history of the Earth, its changing environmental conditions, and its changing life forms.

Given that most fossils are preserved in sediments from past environments that have been changed into rocky outcrops, understandably, most fossils are found in sedimentary rocks. The other major categories of rocks, igneous and metamorphic, are much less likely to preserve fossils—however it is not impossible.

Igneous rocks are those that are related to volcanic activity, wherein the rock is formed by the cooling of magma or lava, or during a volcanic eruption. While those environments are not generally suitable for living things, there are on rare occasions fossils associated with igneous rocks. For example, an animal may be killed by lava that surrounded it, but the cooling rocks might preserve an impression of the animal as a mold. Such a mold is a fossil—evidence of past life. Entire herds of rhinos have been preserved under ash deposits resulting from distant volcanic eruptions. And the development of caves or fissures in these otherwise unfossiliferous rocks could produce extensive collections of fossils.

Metamorphic rocks are those that have been changed by extremes of heat and pressure. Fossils that occur in the rocks prior to undergoing metamorphic change can be preserved as long as the metamorphism is low grade and not extreme enough to alter them beyond recognition. Such might be the case in a limestone with fossils that gets altered to a low grade metamorphic marble with fossils still visible.

Geologists have mapped the rocks exposed at the Earth's surface. Rocks that are similar in character, usually due to how they formed, are organized into mappable units called formations. Formations are formal units and are given names consisting generally of a place name and the word "formation," or the characteristic rock type. Examples include the Sixmile Creek Formation and the Aspen Shale. The place name is generally derived from the region in which the formation is first recognized.

Given that the environment in which a formation forms will strongly influence its likelihood of preserving fossils, and not all formations are equally likely to have fossils, the BLM uses a coding system to rank a formation's probability of containing significant fossils. This system is the Potential Fossil Yield Classification (PFYC), a numerical ranking from 1 (low potential) to 5 (very high potential). This system allows land managers to predict where significant fossils will occur in order to make informed planning decisions with regard to fossil resources.

Several important points should be kept in mind. Fossils are not evenly distributed throughout a formation, and so even highly ranked formations may produce only occasional fossils in a given locality. And, that a code of 1 does not mean that a geologic formation has no chance to produce significant fossils. Indeed, the discovery of a fossil in a class 1 rock unit might be all the more significant given its

unexpected occurrence. The system is just designed to help in planning, and cannot replace detailed analysis on a case-by-case basis by trained personnel.

### Indicators

- Number of paleontological sites within the planning area
- Extent of rock outcrops and their PFYC values
- Number of permits issued to work on the resource

### Existing Conditions

#### Conditions of the Planning Area

The geology of the planning area is diverse, and includes several physiographic regions: 1) Basin and Range; 2) Snake River Plain; 3) Owyhee Plateau; 4) Challis Volcanics; 5) Idaho Batholith; and 6) Columbia River Plateau (Figure 1). These regions are created by their fundamental geologic character. Fossiliferous formations can be found throughout the entire planning area, but it is to be expected that some regions have more fossil-rich rock than others.

**Figure 1. Map showing the relationships of the physiographic regions of Idaho.**

Areas expected to be generally more fossil-rich include the Basin and Range and Snake River Plain. Within the Basin and Range of both Montana and Idaho various intermontane basins have many known fossil localities (Hanneman, 1989;

Hanneman and Wideman, 1991). Additionally, Mesozoic and Paleozoic rocks are exposed that often contain fossils in this region.

The Snake River Plain contains extensive sedimentary deposits, particularly from the last several million years and have produced a wide array of fossils such as the American Falls Reservoir faunas (Pinsof, 1998) and the older Hagerman Horse Quarry (Bjork, 1970; McDonald, 1993). Even basalt flows (formed by lava) in the Snake River Plain have formed many caves in the form of lava tubes and blisters, and most contain extensive fossil accumulations (Winterfeld and Rapp, 2009d).

**Figure 2. A sample of some vertebrate fossils from Idaho. A) *Equus simplicidens* from the Hagerman Horse Quarry, ~3.5 million years old; B) *Bison latifrons*, a very large-horned species from the Ice Age, ~100,000 years ago; C) *Cymbospondylus*, a large marine reptile from the ichthyosaur group, ~ 220 million years old; D) the enigmatic tooth whorl of the Paleozoic shark *Helicoprion*, ~310 million years.**

### Conditions on BLM-Administered Lands

A number of resources are available to characterize the paleontological resources on BLM administered land in the planning area. However, statements made must remain generalized due to the nature of the data available at this time.

For example, for the Montana portion of the planning area information was gathered from a georeferenced database of localities at the Montana State Office.

That locality information was compiled from BLM-funded inventories of fossil resources (Nichols and Hanneman, 2000), localities reported to BLM by permittees, and localities reported in scientific literature. However, compilation of this information is still ongoing. Even so, there are 227 known fossil localities on BLM land within the planning area in Montana.

Most of the compiled information on Idaho can be found in reports on the fossil resources of Idaho (Winterfeld and Rapp, 2009a; Winterfeld and Rapp, 2009b; Winterfeld and Rapp, 2009c; Winterfeld and Rapp, 2009d; Winterfeld and Rapp, 2009e). In those overviews, localities were tallied by 7.5 minute quadrangle maps for each District in Idaho. From those summaries the total number of quadrangles with documented localities and that contain BLM lands were counted, and the approximate number of localities was summed. From these various sources, it can be estimated that over 1,800 fossil localities could be on BLM land within the planning area. The details are presented in Table 1.

**Table 1. Summary of data from various sources on the approximate number of paleontological localities on BLM land within the planning area. The numbers for Idaho come from commissioned reports on the paleontology of that state. That information was summarized by 7.5 minute quadrangles, with approximate number of localities given for each quad. Here is presented the count of quadrangles and the sum of localities within those quadrangles that included BLM land. Montana data is compiled from the locality database at the Montana State Office.**

District	Quadrangles with Localities	Localities
Boise	53	1,022
Twin Falls	32	418
Idaho Falls	63	190
Western Montana		227
<b>Total</b>		<b>1,857</b>

## Trends

With the passage of PRPA the paleontology program of the BLM is slowly being able to take on more active management of paleontological resources. The resources are managed in collaboration with BLM partners such as universities and museums across the country, as it is those parties that provide much of the work done on collecting, studying, storing, and providing meaning to our fossil resources. Additionally, BLM and our partners strive to educate the public about the value of this natural heritage.

In general, the desired outcomes for the paleontological resource is to: 1) protect the resource from unnecessary damage, theft, or vandalism; 2) ensure that the resource is responsibly collected by qualified individuals working to benefit the public through their actions; 3) utilize the resource in educational programs for the general public; and 4) teach the public about BLM's role in the management of this important resource.

The impact to fossils from the management of other resources on BLM land can be negligible to deleterious, depending up on nature of those actions. However, by maintaining best practices for the identification of resources and the mitigation of damage, the paleontological resources should continue to remain an invaluable part of the national trust.

## Wildland Fire Management

The wildland fire management program encompasses the full range of hazardous fuels, an appropriate preplanned response to unplanned ignitions of wildland fires, and the rehabilitation of lands affected by these unplanned ignitions.

The wildfire suppression program utilizes a coordinated effort to respond to all unplanned ignitions (wildfire) with a preplanned, appropriate response. Each response is guided by resource management plan and fire management plan direction. As the severity and number of wildfires escalates, the further response and prioritization of fire suppression resources becomes a collaborative effort between field, district, and state managers working closely with interagency partners.

Analyzing fire occurrence and drawing any direct or indirect correlation between supplied data is a far from perfect science. Some generalizations can be roughly interrupted such as an average length of fire season in days for current districts, the number of fires that could be reasonably expected annually, and the number of acres that are burned on an average year.

Trend analysis of fire starts and acres burned in the sage steppe ecosystem is very general and dependent predominately upon weather and fuels conditions. The relative fuel conditions of live fuel moistures and fine fuel loadings coupled with weather conditions such as relative humidity, wind speed, and days since last rainfall drive large fire growth in the grass fuel type.

Fire occurrence is weighed towards human causes, especially around urban centers and along major highway corridors. (insert/provide ID BLM fire occurrence map, showing both human and lightning starts??) However, lightning is the major contributor to multiple large fire days and high numbers of BLM acres burned. Lightning storms generally track from Southwestern towards Eastern Idaho, leaving successive lightning starts across all three southern districts, often times in remote or difficult to reach areas. These lightning events are commonly associated with strong winds which contribute to rapid large fire growth. Summer storms commonly lack significant rainfall. It should be reasonably expected that the majority of large fire days correspond to high percentile BI days.

Since 2006, emphasis upon the protection of sage-grouse habitat during suppression actions has taken center stage in planning and operational discussions. High numbers of PPH and PGH acres were burned in 2007 and 2012. XXX PPH and XXX PGH acres have been burned from 2006 through 2012. Again, the majority of these acres were burned during corresponding high BI days or periods.

Burning Index (BI)--A number related to the contribution of fire behavior to the effort of containing a fire. The BI is an index that rates fire danger related to potential flame length over a fire danger rating area.

<b>Historical Large Fires (300 Acres and Greater) 1980 to 2012</b>

## Fire Regime Condition Class:

### Natural Fire Regime:

A natural fire regime is a general classification of the role fire would play across a landscape without

modern human mechanical intervention.<sup>1,2</sup> The five natural fire regimes are classified based on average

number of years between fires (fire frequency) combined with the severity of the fire on the dominant

overstory vegetation (amount of vegetation replacement). These five regimes include:

I – 0 to 35 year frequency and low (surface fires most common) to mixed (less than 75% of the dominant overstory vegetation replaced) severity;

II – 0 to 35 year frequency and high severity (greater than 75% of the dominant overstory vegetation replaced);

III – 35 to 100+ year frequency and mixed severity (less than 75% of the dominant overstory vegetation replaced);

IV – 35 to 100+ year frequency and high severity (greater than 75% of the dominant overstory vegetation replaced);

V – 200+ year frequency and high severity (greater than 75% of the dominant overstory vegetation replaced).

### Fire Regime Condition Class (FRCC):

A fire regime condition class (FRCC) is a classification of the amount of change in fire

frequency and severity from the natural fire regime.<sup>3</sup> The three classes are based on low (FRCC

1), moderate (FRCC 2), and high (FRCC 3) change from the natural fire regime.<sup>4,5</sup> The change in natural fire regime results from changes to one or more of the following fire regime attributes:

Vegetation characteristics (i.e., species composition, structural stages, stand age, canopy closure, and mosaic pattern); Fuel composition; Fire frequency, severity, and pattern; and Other associated disturbances (e.g., insect and diseased mortality, grazing, and drought).

Characteristic vegetation and fuel conditions are considered to be those that occurred within the natural fire regime. Uncharacteristic conditions are considered to be those that did not occur within the natural fire regime. Examples of uncharacteristic conditions include invasive species (e.g. weeds, insects, and diseases) or excessive vegetation removal. The amount of change is based on comparison of the fire regime attributes as identified above to the natural fire regime. The amount of change is then classified to determine the FRCC.

### **Current Conditions:**

The Hazardous Fuels Reduction Program (HFR) involves a variety of treatments to modify vegetation to provide for firefighter safety, reduce the potential of wildfire spread, reduce the detrimental effects of wildfire on a landscape, protect private holdings and infrastructure, and decrease the costs of rehabilitation efforts after a wildfire has occurred. Depending on the specifics of the overall project, multiple treatment types may be involved over several years to obtain the specifications for the project. One example of this would be: For an annual grass dominated area, prescribed fire will be used to remove existing layers of the annual grass and reduce the seed source. Chemical application(s) would be utilized to further reduce the seed source and the resulting new annual grass plants. Mechanical seeding(s) of perennial (native or non-native, grass/shrub/forb) mixtures would occur, pending the most successful time of year for application(s).

### ***Examples of treatment types:***

**Prescribed Fire (Treatment)** – An HFR Treatment Category for any fire ignited by management actions to meet specific objectives and to achieve Fire Management Plans.

**Mechanical (Treatment)** – An HFR Treatment Category that describes work that manually or mechanically removes or modifies fuel load structures to achieve Fire Management Plans.

**Other (Treatment)** – An HFR Treatment Category that describes work involving the use of chemicals and biological methods to achieve Fire Management Plans.

In Idaho, the HFR Program has been in place since the start of the 2000 National Fire Plan identified the need and funding source to develop and maintain the program. Within the last 5 years, which would represent the most current treatments on the existing landscape, the following acreage and types of treatments are shown below. The prescribed fire acreages have decreased from historical levels due to multiple large scale wildfires accomplishing the removal of undesirable vegetation in areas planned for future projects. Mechanical treatments have increased in, both, seeding and mechanical reductions of conifer encroachment throughout PPH and PGH areas. The use of chemical or “Other” types of treatments has grown to increase the probability of success of seeding(s) of perennial (native or non-native, grass/shrub/forb) mixtures by removing the dominance and competitiveness of the undesirable annual grass and weed species. Biological or “Other” treatments (insects, goat, specific pathogens) have recently been of interest in very specific areas due to the “high risk” in areas that may have significant values should accidents occur during implementation of mechanical treatments (rocks, windows, etc.).

## **Trends:**

### **Treatment type and acreages over the past 5 years:**

**Prescribed Fire:** 2008-11,199 acres, 2009- 8,647 acres, 2010- 7,189 acres, 2011- 6,398 acres, 2012- 3,021 acres.

**Mechanical:** 2008- 46,073 acres, 2009- 38,992 acres, 2010- 33,975 acres, 2011- 30,987 acres, 2012- 30,725 acres.

**Other:** 2008- 59,003 acres, 2009- 47,991 acres, 2010- 36,500 acres, 2011- 39,895 acres, 2012- 71,666 acres.

Over the past few years, the focus of the HFR program was to treat acreages within the Wildland Urban Interface (WUI). This was specific to protecting private in-holdings in the attempt to decrease the detrimental effects of wildfire to human structures and the associated infra-structure for the communities. Direction was to focus the majority of expenditures in the WUI and expend minimal amounts on landscape level treatments. Budgetary erosion and increased costs are forcing decisions in the fire management arena to decrease the capability of the proactive HFR program to maintain the reactive suppression and rehabilitation efforts. If this trend continues it is forecasted that the HFR program will be non-existent by 2018. The side effects of this trend is that areas, regardless of ownership, would be left untreated or maintained and landscapes will have minimal treatments to: Reduce fire growth in areas of conifer encroachment, invasive annual grasses and weeds, habitats of concerned species, watersheds of communities and fuel breaks to compartmentalize fire growth.

## Emergency Stabilization and Rehabilitation (ESR)

Alteration to the historic fire regime has substantially reduced the sagebrush steppe communities of the Sub Unit and the larger Great Basin. The exclusion of wildfire within the upper elevations shrub steppe communities (primarily mountain big sagebrush) has converted approximately XXX acres of sage-grouse habitat into juniper woodland.

The greatest loss of sage-grouse habitat however has been from cheatgrass proliferation and wildfire within the lower elevation sagebrush communities (primarily Wyoming big sagebrush). Historically, wildfire was not a common occurrence within the Wyoming big sagebrush sites. Current literature estimates the fire interval at approximately 100 years. When these sites did burn, the discontinuous fuels of the scattered native bunch grasses likely resulted in small, discontinuous fires. Conversely, cheatgrass is highly flammable due to its uniform fine fuels which dry out early in the growing season. Each recurring fire set the stage for further cheatgrass expansion, resulting in an ever increasing cheatgrass/fire cycle and loss of sage-grouse habitat. On many of these sites, fire-return intervals have been shortened to between two and four years (Whisenant 1990).

Most lower elevation shrub steppe communities within the subunit (even those containing minimal cheatgrass understories) will cross a threshold into fire maintained cheatgrass dominated communities unless they are successfully rehabilitated within the first couple years following wildfire. Such areas are also highly susceptible to noxious weed invasions. Therefore, successfully reestablishing perennial vegetation within this narrow time frame is essential for reducing the loss of low elevation sage-grouse habitat.

Fire rehabilitation consists of mitigating damaging effects from wildfire and in restoring vegetative structure and function to recently burned fire damaged areas which cannot recover on their own. These efforts consist of seeding perennial grasses, shrubs, and forbs. The seeding technique is based largely on seed size. Most grasses (which have relatively large seeds) are drill seeded to effectively cover the seed, whereas sagebrush and many forbs (which consist of small seeds) are most successful broadcast seeded.

Drought and invasive annual grass competition are the two biggest challenges to reestablishing perennial vegetation following wildfire on the low elevation sites. Seedlings are most successful during years of adequate precipitation and on sites where cheatgrass competition is minimal such as recently burned sagebrush stands in good condition, or sagebrush stands with cheatgrass in the understory which burned hot enough consume cheatgrass seed lying on the soil surface underneath the sagebrush canopy. Accordingly, the higher the density of sagebrush cover prior to the burn, the greater the likelihood for seedlings success. Because sagebrush fires burn hotter and slower than grassland fires, the cheatgrass seed lying on the soil surface underneath the sagebrush canopy is usually consumed, whereas the seed laying outside of the sagebrush canopy or other shrub free areas (such as previously burned cheatgrass dominated sites) is not consumed and remains viable. Accordingly, the areas underneath the burned sagebrush canopy create a cheatgrass free "clean" seedbed which allows seeded species to establish relatively free of cheatgrass competition. Although the areas

outside of the canopies will remain dominated by cheatgrass, the established plants underneath the former sagebrush canopy will usually outcompete the adjacent cheatgrass over time. However, strong wind driven fires often prevent consumption of cheatgrass seed, thereby require cheatgrass control. Seeding previously burned cheatgrass-dominated sites devoid of a brush overstory, is not usually successful because these rapid cheatgrass driven fires do not provide enough heat to consume cheatgrass seed lying on the soil surface.

Herbicides have proven to be the most effective and noninvasive method for controlling annual grasses prior to seeding. Before 1991, the use of herbicides to control invasive annual grasses was prohibited on public land. Therefore, various tilling methods such as plowing and disking were the only available options. Unfortunately, these treatments obliterated remaining native vegetation and biologic soil crusts, increased site susceptibility to wind erosion and often resulted in seed being drilled too deeply, thereby opening the site for total cheatgrass domination when seedings were unsuccessful. Prescribed fire was used in attempts to kill cheatgrass seed while still on the plant. Although such fires kill some seed still on the plant, they do not burn hot enough to kill cheatgrass seed on the soil surface.

Intensive livestock grazing is often suggested for controlling cheatgrass competition. Although targeted grazing may have some applications for fuels management, it is not effective in reducing cheatgrass competition. During the short time when cheatgrass is highly palatable in the spring, a sufficient number of livestock cannot be concentrated on a small enough area to reduce the cheatgrass seed significantly or reduce cheatgrass seed lying on the soil surface. In addition, this type of grazing can be detrimental to remaining perennial grasses which opens the site up for further cheatgrass expansion in the future.

BLM is authorized to use various approved contact and pre-emergent herbicides for controlling invasive annual grasses. Both types of herbicides have their advantages and shortcomings.

Contact herbicides such as Glyphosate which has been widely and successfully used within the Twin Falls District. These herbicides must be applied during the short period that cheatgrass is actively growing, and before seed development occurs. When numerous cheatgrass crops occur on a given year, repeated applications are required. Additionally, application rates must be tuned to minimize damage to existing perennial plants while effectively controlling the invasive annuals. Glyphosate is quickly absorbed into the soil and therefore has no potential for offsite non-target damage from moving soil particles

Preemergent herbicides such as imazapic and sulfometuron methyl are highly effective in controlling invasive annual grasses while having minimal impacts to most established perennial species. They are also classified as nontoxic to fish and wildlife. These herbicides do not require the specific application timing needed with glyphosate, and their residual action in the soil controls annual grasses whenever they happen to germinate. The residual action lasts from 1 to three years, depending on soil moisture, pH, and temperature. In addition to controlling invasive annual grasses prior to seeding, these herbicides could be used to help maintain and protect existing native plant communities which have been invaded with annual grasses. Such treatments would allow the natives to gain a competitive advantage over the

exotic annuals, and the associated reduction in annual grass fuels would reduce the site's risk to wildfire. A limitation of these herbicides is their potential to damage crops at extremely low concentrations. Accordingly, these herbicides cannot be used near agricultural areas or on unstable soils.

Recent research on naturally occurring fungi and bacteria for controlling cheatgrass is encouraging and may prove to be an effective future control method.

Selecting plant materials which can establish and persist in these arid cheatgrass competitive environments is essential for restoring sagegrouse habitat lost through wildfire. Prior to 1986, fire rehabilitation funds could not be used for sagebrush seeding. Since that time, sagebrush is included in most fire rehabilitation seedings on its respective ecological sites. Occasionally, during busy fire years, sagebrush seed shortages restrict its use to priority burned sage-grouse habitat.

Native grasses and forbs are preferred over introduced species when they can meet the above requirements. Historically, few adapted native grass seed was available which could persist in these desert environments, thereby requiring the use of durable introduced species such as crested wheatgrass. Over time, selections of native blue bunch wheatgrass, basin wildrye, Snake River wheatgrass, squirreltail, Indian ricegrass, and Sandberg bluegrass have become increasingly available and are now used extensively in fire rehabilitation seedings for areas that receive at least 10" of annual precipitation in recently burned sagebrush communities. For the past ten years, BLM has been funding the interagency Great Basin Native Plant Selection and Increase Project for increasing native seed availability, especially native forbs important to sage-grouse, and to improve the success of land managers in establishing native plants (<http://www.fs.fed.us/rm/boise/research/shrub/greatbasin.shtml>)

However, some important native grasses (such as Thurber's Needlegrass) are still not widely available and or effective in competing with cheatgrass in the harshest environments. In these areas, durable introduced species as Siberian wheatgrass and Russian wild rye are still the only viable option. Even those species are often unsuccessful on those sites. Additionally, restoring native plant communities in repeatedly burned annual dominated grasslands has proven largely unsuccessful. Considerable speculation and research has attempted to understand why. A lack of mycorrhiza, soil nutrients, and other changes to the soil environment from years of invasive annual grass domination is believed to be at least partially responsible.

The theory of "assisted succession" is suggested as a method for ultimately restoring these areas by first vegetating with resilient introduced species to break the fire cycle, removing annual grass dominance and deplete annuals' seed source, and restore soil characteristics which may in time make the site more hospitable to restoring the native community, followed by eventual seeding with natives. Accordingly, this is a long term costly process which cannot begin to be implemented until the fire cycle has been broken. Until the majority of annual grass dominated landscapes can be rehabilitated to less fire prone species in the long-term, these short fire cycles will result in a continual loss of these investments, and in the remaining native sagebrush steppe communities.

Seeded areas require rest from livestock use to become fully established, followed by livestock management which will maintain plant health and vigor. BLM policy traditionally prescribes a minimum of growing season rest period (from livestock grazing), and until plant establishment objectives are met. Depending on moisture and other site conditions, longer rest is often needed grazing can be resumed. However a true native restoration could require years of rest from grazing to become successfully established (depending on plant materials used and site characteristics). Such large scale treatments could have significant repercussions to grazing permittees, and may also necessitate more restrictive management to maintain the native seeded species over the long term.

The ability to protect these areas from recurring wild fire is crucial to maintaining the reestablished sagebrush component. Successful fire rehabilitation seeding contributes partially to this goal by changing the fuels from highly flammable annual grasses with high fuel continuity, into less fire prone perennial bunch grasses which stay greener longer and which provide much less fuel continuity. Accordingly, when fire does return to these rehabilitated areas, the fires are often spotty which leave substantial unburned sagebrush islands and a seed source for naturally reestablishing sagebrush. Additionally, the burned perennial grasses quickly re-sprout and compete effectively with annual weeds.

Also needed is a system of effectively managed fuels breaks consisting of durable fire resistant vegetation (such as forage kochia) placed primarily along roads to reduce the wildfire size, and provide lines of defense for fire suppression efforts.

The Omnibus Act of 2009 limited recreational mechanized and motorized travel on public lands within Owyhee County to legally established routes as the the date of enactment. The area affected by that portion of the Act includes the entire Owyhee and Bruneau Field Offices, and the XXacres of the Jarbidge Field Office. Generally, individual Travel Management Plans follow Land Use Plan revisions within five years of the signing of a ROD. Current Bureau policy effectively requires the reallocation (open/limited/closed) of vast open acreage to limited with the exception of smaller manageable polygons, e.g. dunes, etc.

## Appendix A: Non-Market Valuation Methods

This appendix addresses economic valuation of three categories of non-market resources that are present in the study area and could potentially be affected by the alternatives. These three categories of non-market value are recreation, values of sage grouse to households in the intermountain west, and value of the ranching tradition to the ranchers themselves and residents as well as visitors to the region. Recreation is included because actions that promote the conservation of sage-grouse habitat may result in changes in recreation opportunities, such as increasing the amount of habitat for other wildlife species that may be hunted or viewed that depend on public lands, roads open or closed for recreation access, and the quality of the recreation experience.

At the outset it should be noted that the economic non-market values described in this appendix are not directly comparable to regional economic indicators commonly used to describe how natural resources on public lands contribute to the regional economic indicators such as output/sales, labor income, and employment. These indicators provide valuable information to the local public as well as to regional government agencies for purposes of public service and infrastructure planning. These impacts or contributions are often referred to as distributional effects as they describe the effects to the region. However, these indicators do not represent net economic value. For example, in economic terms, labor income associated with mineral production would actually be considered a cost to the producer. Similarly, expenditures by a recreation visitor associated with a visit to public lands would be viewed by the recreationist as a cost. One last example would be the total sales generated by the sale of minerals extracted from Federally-owned minerals – the total sales do not reflect the net economic value since the costs associated with the extraction are not accounted for (including labor income, supplies, equipment as well as potentially non-market costs such as those cost associated with pollution). This section considers the economic value of the non-market outputs – a concept described below.

### ***Total Non-market Economic Value***

Many of the multiple uses in the study area are not bought and sold in competitive markets. For instance, many recreational visitors to public lands pay no or low admission fees, and the presence of wild animals such as sage grouse have no “market price”, yet both have value to people. In some cases people gain value from *using* these non-market resources, such as recreation on public lands; in other cases, protection of some natural resources provides both a use value (e.g., wildlife viewing) as well as a non-use value (e.g., the value some people hold for knowing that a specific natural resource exists and is protected even if they never intend to “use” or visit it).

Economists call the sum of these two values Total Economic Value. Use values typically can be for consumptive uses (e.g., hunting) and/or non-consumptive uses, such as viewing or being present on site (e.g., camping, hiking, etc.). In contrast, non-use values occur off-site to people who derive enjoyment from knowing a natural environment,

habitat or species exists in its natural state, either for themselves (existence value) and/or future generations (bequest value). Krutilla (1967) documents the conceptual origins of these two elements of non-use value, and Freeman (2003) provides a rigorous theoretical treatment.

Non-use or existence values can potentially be enjoyed by millions if the good or service (e.g., the presence of a specific wild species such as wild salmon or rare bird species) is of widespread interest. Thus, while the non-use value per household may much lower than a value per day received by a visitor, in total, non-use values may be quite large.

### ***Recreation Values***

Economists measure the net economic use and non-use values as “Consumer Surplus”. At its most basic level, consumer surplus is the maximum amount a person would pay minus the amount they actually have to pay. Consumer surplus, which is also sometimes referred to as “net willingness to pay,” is a measure of benefit has been used by economists and federal agencies for decades (e.g., see U.S. Water Resources Council, 1983; USEPA, 2009, 2010).

For public land recreation, especially on BLM and USFS recreation sites, entrance fees are typically very low or non-existent, so the value people place on these public land recreation opportunities is not fully measured simply by the entrance fees they pay. In economic terms, there is not a competitive market or a “market clearing price” for access to public recreation sites. Therefore, there can be a substantial difference between what people pay to visit a recreation site (e.g., entrance fees plus travel costs, including the value of time) and the maximum amount they would pay.

A common non-market valuation method used for recreation is the travel cost method (TCM). In this method, economists survey visitors to a recreation site and collect data on their frequency of trips, travel distance and costs incurred to access the site. Because the survey uses information from actual visitors, the TCM is a “revealed preference” method of valuation; economists use the travel costs as a proxy to determine the value that people gain from using the site. Variations in the travel cost across visitors, along with their respective number of trips, allow economists to statistically estimate a relationship between travel cost and quantity of trips – an aggregate demand curve for the recreation site, much like a demand curve for goods and services that are sold in competitive markets. This aggregate demand curve will tend to show that individuals with a relatively high travel cost take fewer trips on average, while individuals with a lower cost take more trips on average. From this aggregate demand curve, economists can calculate consumer surplus. Many of the consumer surplus values for recreation in the literature (e.g. Loomis, 2005) and recently developed by the USFS (e.g. Bowker et al., 2009) rely upon TCM.

Figure A-1 provides an illustration of a demand curve for recreation on a particular site. In Figure A-1, the aggregate demand is shown on an average basis, that is, for an

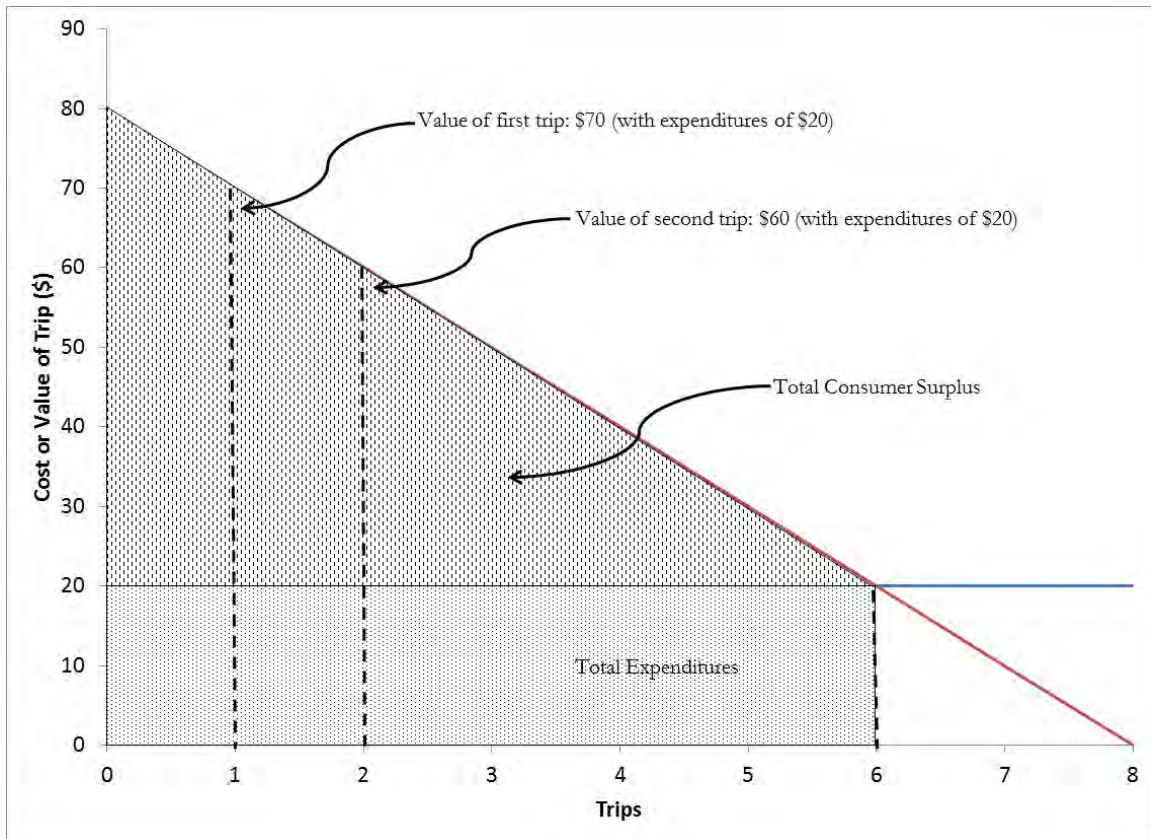

average individual consumer. The downward-sloping diagonal line in Figure A-1 represents the relationship between the travel cost and quantity of trips demanded by this average consumer. In the figure, the value of the first several trips is relatively high (\$70 for the first and \$60 for the second trip), while the value of the sixth trip is lower (\$20 in the figure). In a TCM study, these values are statistically derived from the aggregate demand calculated for the entire population. The downward slope of the demand curve corresponds to declining value associated with each trip, which is typical for most goods and services.<sup>1</sup> It also corresponds to the fact that visitors will take fewer trips to areas with a higher travel cost.

Each visitor receives a net benefit from each trip, which is measured by the difference between what they had to pay and the maximum amount they would pay for each trip. In Figure A-1, the net benefit for the average visitor is the difference between their actual expenditures of \$20 per trip and the maximum amount they would pay for each trip. As shown, the first trip has a net benefit of \$50 (\$70 of value less \$20 in expenditures), the second trip \$40 (\$60 less \$20), and so on until the sixth trip. At the sixth trip the visitor's cost is the same as their benefit, and hence there is no net benefit from further trips. Thus, this gain to the visitor over and above what they spend is their "consumer surplus."

**Figure A-1. Consumer Demand Curve and Consumer Surplus for Recreation Trips**

---

<sup>1</sup> Note that for some types of recreation use, users may gain increased value over a portion of the number of trips; for example, mountain bikers may experience increased enjoyment of subsequent trips to a single location as their trail-specific skills and knowledge increase with repeat visits. Climbers and other users may also experience similar gains over repeat visits. However, even these users will likely hit a point where the marginal value begins to decrease with more trips.

Given the large range and diversity of sites in the study area, BLM and the USFS did not perform original TCM analysis of visitation in the study area. Rather they relied upon transferring existing recreation values from TCM studies such as Bowker et al. (2009) and other recreation values from the existing literature (Loomis, 2005; Loomis and Richardson, 2007; USFWS, 2009) to the recreation activities in the study area, focusing on existing studies in the Rocky Mountain and Great Basin area (Idaho, Montana, Utah, Colorado, Wyoming, Arizona, New Mexico, and Nevada). This approach, known as “Benefit Transfer,” is well-developed in academic and policy literature and has been used by federal agencies including the USEPA (see Griffiths et al., 2012 for a recent listing of economic studies where benefit transfer was used), U.S. Army Corps of Engineers, Bureau of Reclamation, USFS (U.S. Forest Service, 1991; also see Ervin et al., 2012 for a recent application of benefit transfer to the Mount Hood NF), and other agencies. Benefit transfer is widely used in academic applications as well; see Wilson and Hoehn (2006) for a series of journal articles on benefit transfer.

BLM measures recreation activity in various units, including a “visitor hour”, which represents the presence of one or more persons in an area for continuous or simultaneous periods of time aggregating one hour (e.g., one person for one hour or two persons for 30 minutes each). A “visitor day” as defined by BLM represents twelve

visitor hours (BLM, 2003). The BLM Recreation Management Information System provides data on recreation visitor days (RVDs); to be compatible with these units, BLM identified non-market values for various recreation activities in units of dollars per RVD. Values from economic literature, based on primary research conducted on various recreation sites, were matched to BLM and USFS recreation activity classifications. Table A-1 provides a listing of the values per day representing the study area of Idaho and southwest Montana.

**Table A-1. Consumer Surplus for Recreation Activities**

<b>Recreation Activity Category</b>	<b>Consumer Surplus per Visitor Day (2012 dollars)</b>
Backpacking	36.48
Camping	31.73
Cross Country Skiing	36.32
Fishing	66.00
Floatboating/Rafting/Canoeing	82.28
General Recreation	42.96
Hiking	107.16
Hunting	65.51
Motorboating	65.24
Mountain Biking	175.21
Off-Road Vehicle Driving/Off-Highway Vehicle	51.35
Other Recreation	47.69
Picnicking	52.27
Pleasure Driving	71.65
Rock Climbing	61.32
Sightseeing	41.33
Snowmobiling	51.75
Swimming	35.10
Waterskiing	69.23
Wildlife Viewing	37.00
Sources: Rosenberger, 2012; Loomis, 2005; Loomis and Richardson, 2007; Bowker et al., 2009; USFWS, 2009.	

Consistent with the description above of consumer surplus and the TCM, readers should interpret the values in Table A-1 as the consumer surplus or the amount of value that the average visitor derives from a full day of recreation beyond their actual expenditures. Thus, a typical off-highway vehicle user would pay an average value of \$51.35 more than their trip cost to have the opportunity to participate in a typical day of driving off road vehicles.

Table A-2 shows the total consumer surplus associated with recreation activities on BLM and USFS managed lands for the sub-region, including the BLM Field Offices of Bruneau, Burley, Butte, Challis, Dillon, Four Rivers, Jarbidge, Owyhee, Pocatello, Salmon, Shoshone, and Upper Snake, as well as the Beaverhead-Deerlodge, Boise, Salmon-Challis, Sawtooth, and Caribou-Targhee National Forests (note that NVUM does not

provide recreation data for the Curlew National Grassland). RVDs on BLM lands presented in Table A-2 are calculated directly from Report 26 from the BLM RMIS (Report 26 provides RVDs based on recorded visitor hours – defined above – and dividing by twelve). For this analysis, BLM used average RVDs per year over the period 2008-2012. RVDs on National Forests are calculated from the most recent available data (ranging from FY2005 to FY2009 for the forests noted) from the USFS National Visitor Use Monitoring (NVUM) report (USFS, 2013). RVDs for National Forest lands were calculated based on the total number of site visits, the “main activity” reported by recreators, and the number of hours per day reported engaging in that activity, with the number of RVDs equal to the number of hours divided by twelve. Note that conservation measures for sage grouse may only affect specific types and fractions of the public lands that contributed to the visitor days used to estimate the surplus values in Table A-2.

<b>Table A-2. Total Consumer Surplus for Recreation in Idaho/Montana Sub-Region</b>		
<b>Recreation Activity</b>	<b>Average RVDs Per Year</b>	<b>Total Consumer Surplus (millions of 2012 dollars)</b>
Backpacking	168,100	\$6.1
Big Game Hunting	602,123	\$39.4
Camping	2,463,485	\$78.2
Cross Country Skiing	104,161	\$3.8
Fishing	896,544	\$59.2
Floatboating/Rafting/Canoeing	327,189	\$26.9
General Recreation	90,222	\$3.9
Hiking	484,388	\$51.9
Hunting – Other	755,614	\$49.5
Motorboating	189,607	\$12.4
Mountain Biking	80,562	\$14.1
Off Road Vehicle Driving/ Off-Highway Vehicle	445,795	\$22.9
Other Recreation	594,560	\$28.4
Picnicking	268,400	\$14.0
Pleasure Driving	354,478	\$25.4

***Values associated with populations of sage-grouse***

Economists have long recognized that wildlife species, especially rare, threatened and endangered species, have economic values beyond just viewing. This is supported by a

series of legal decisions and technical analyses. The U.S. Court of Appeals in 1989 first clarified that the U.S. Department of Interior, in assessing damages in Natural Resource Damage Assessment (NRDA) cases, should include what it termed as “passive use values”, that is, existence values provided to non-users of the species – as a compensable value in addition to any use value. These passive use values are also included in Oil Pollution Act (OPA) damage assessments as well. The term passive values is interchangeable with the term non-use values defined previously. This ruling and subsequent analysis for NRDA and OPA assessments are consistent with well-established economic theory showing that people derive value from passive use or non-use as well as active uses of resources (Krutilla, 1967). Economists have devoted a great deal of conceptual and empirical work to refining concepts and developing methods to measure these passive use values.

The dominant methods are “stated preference” methods, of which the most prominent is the Contingent Valuation Method (CVM). The basic element of this method is to use a survey to construct or simulate a market or referendum for protection or improvement of a natural environment, habitat or species, and then having the respondent indicate whether or not they would pay for an increment of protection, and if so how much they would pay. While the method has developed a great deal of sophistication that has increased the validity of the willingness to pay (WTP) responses, there is admittedly a degree of bias that can result in stated WTP exceeding actual WTP by a factor averaging 2-3 (Loomis, 2011; Murphy et al., 2005; List and Gallet, 2001). While not a perfect estimator of WTP, CVM provides a useful means for estimating the public’s passive use values.

Numerous academic papers and even entire books have been written on CVM. Mitchell and Carson (1989) was one of the first, while Alberini and Kahn (2006) is a more recent treatment. To date there have been about 7,500 CVM studies in over 130 countries (Carson, 2011). A number of federal agencies have used or referenced stated preference methods, including the Bureau of Reclamation, Environmental Protection Agency, National Park Service, and state agencies such as the California Department of Fish and Game, Idaho Fish and Game, and Montana Fish, Wildlife and Parks. The USFWS commissioned an original CVM study of the economic values the public receives from reintroduction of wolves in the areas of Idaho, Montana and Wyoming, and used those values in an EIS on wolf reintroduction (USFWS, 1994). The Bureau of Reclamation, National Park Service, and Lower Elwha S’Klallam Tribe commissioned a CVM study on the value of removal of the Elwha and Glines Canyon Dams (Meyer et al., 1995). The U.S. Bureau of Reclamation also commissioned an original CVM study on the values of providing stable river flows to benefit riparian vegetation, endangered species and cultural resources. That study was cited by then-Secretary of Interior Bruce Babbitt as a factor in selecting the more protective flow regime from Glen Canyon Dam despite it having more foregone hydroelectricity (Babbitt, 1996).

BLM and USFS conducted a literature search to demonstrate the potential range of values that could be associated with species that are candidates for listing as threatened or endangered, such as sage-grouse populations. Analysts first verified there are no existing studies on TEV or non-use valuation specific to the sage-grouse. This is not an uncommon occurrence, as there are dozens of rare or potentially threatened species which have not been valued despite the very high policy relevance of the species and the large magnitude of economic value at stake in these policy decisions.

BLM and USFS used three criteria to identify studies that are most applicable to the current analysis: (1) whether the species valuation study was located in the same geographic region as the sage-grouse habitat; (2) whether the species was listed or not listed as a threatened or endangered species; (3) whether the species was hunted or not (implying a mix of use and non-use values).

The primary database of articles was the recent peer reviewed journal article by Richardson and Loomis (2009), which is a compilation of the economic values of threatened, endangered and rare species. A literature review was also conducted to determine if there had been any recent studies on sage grouse or closely related species. Unfortunately, there is not a perfect match in the literature in terms of geographic region (intermountain) and a species that is both hunted and rare. Table A-3 provides a summary of the studies with features most similar to the sage-grouse species.

**Table A-3. Existing Estimates of Annual Total Economic Value of Protecting Habitat for Species Similar to Sage-Grouse**

Region	Species	Listed	Hunted	Annual Value per Household <sup>b</sup>	Change valued
Four Corners (AZ, CO, NM, UT)	Mexican Spotted Owl	Yes	No	\$58.49	Avoid extinction in 15 years in Four Corners region
New England	Wild Turkey	No	Yes	\$16.72 <sup>a</sup>	Avoid extinction in New England
Texas (also L.A., NYC, Chicago, Atlanta)	Whooping Crane	Yes	No	\$43.69 <sup>a</sup>	Avoid extinction
Maine	Peregrine Falcon	Yes	No	\$32.37 (one time)	Restore self-sustaining population
South Carolina & Rest of U.S.	Red-Cockaded Woodpecker	Yes	No	\$14.69	Restore habitat to increase chance of survival to 99%
<p>Sources: Loomis and Ekstrand, 1997 (Mexican spotted owl); Stevens et al., 1991 (New England wild turkey); Bowker and Stoll, 1988 (whooping crane); Kotchen and Reiling, 2000 (peregrine falcon); Reaves et al., 1999 (red-cockaded woodpecker). All of these sources are as cited in Richardson and Loomis (2009).</p> <p>Notes:</p> <ul style="list-style-type: none"> <li>a. Average of estimates from the study.</li> <li>b. As noted in the text, these stated preference values for household may have a degree of hypothetical bias that could overstate the actual monetary amount households would pay by a factor of 2-3.</li> </ul>					

As can be seen in Table A-3, there is one study with a geographic region overlapping the sub-region (Mexican spotted owl), and one study on a species that was hunted at the time (wild turkey). At the time of the study, the Mexican Spotted Owl was a threatened species under the Endangered Species Act, and respondents were told in the survey that it was a threatened species. The whooping crane, red-cockaded woodpecker peregrine falcon studies involved an endangered species.

All of these studies used the CVM method in a mail survey. Households were asked whether they would pay a specific dollar amount, with that amount varying across individuals in the sample (i.e., the valuation questions were “closed-ended”, although the wild turkey study and red-cockaded woodpecker also used an open-ended valuation question for some respondents). Researchers used the closed-ended valuation questions to generate a statistical valuation function. This valuation function exhibited internal validity: the higher the dollar amount households were asked to pay, the lower the percentage of them that would pay that dollar amount.

With the exception of the peregrine falcon study, which asked respondents to commit to a one-time payment, each survey asked respondents to pay annually to accomplish the stated goal (typically, preventing the species from going extinct in the region of interest, although this varied by study as the table shows). For the peregrine falcon and red-cockaded woodpecker, households were told that their payment would restore a self-sustaining population (i.e., one that would not go extinct).

The original wild turkey study provided an estimate of three values (in 1990 dollars) which were averaged and then adjusted to 2012 dollars using the CPI, resulting in a value of \$16.72 per household per year. The same procedure was used to update the 1996 dollar values of the Mexican Spotted Owl to 2012, resulting in values of \$58.49 per household per year. The higher values for the Mexican Spotted Owl may be due to the large area of habitat (4.6 million acres stated in the survey and shown on a map) that would be protected in the Four Corners area by paying, and the fact the species was not a hunted species. The whooping crane values are fairly large at \$43.69 per household per year; this value represents a Total Economic Value, including both use and non-use value, as some of the sample included people who actively “used” the species (as wildlife viewers).

The study values in Table A-3 demonstrate that many people, or segments of the public, hold substantial value for protecting threatened and endangered species, which may carry over to the sage-grouse. However, additional studies would be needed to identify values specifically for sage-grouse protection. Given that protection is a public good available to all households in the intermountain west, the aggregate or intermountain regional value could be substantial.

#### ***Values associated with grazing land***

Public lands managed for livestock grazing provides both market values (e.g., forage for livestock) and non-market values. Many ranchers themselves value the ranching lifestyle in excess of the income generated by the ranching operations. This is evident in some ranch sales transaction data which suggests some ranch properties have sold for more than the market value of the public land forage (Bartlett et al., 2002; Taylor, 2006). One of the primary reasons public lands ranchers indicate they own land is for the “tradition, values and culture” rather than primarily for profit (Tanaka et al., 2005). Many public land ranchers work elsewhere part-time and rely on the ranch for only 20 percent of

their income (Hanus, 2011), relying instead on outside jobs or other savings to support their ranching lifestyle. Land appreciation has also provided increased value and therefore served as an economic resource for ranchers (Tanaka et al., 2005; Torell et al., 2005). As several of these authors note, changes in public land grazing that reduce the profitability of grazing may not directly translate to withdrawal from ranching, due to the fact that economic factors are not necessarily the primary motivation for public land ranching.

Some studies have found non-market values of ranching associated with use values to residents (Mangun et al., 2005) and tourists in the form of open space and western ranch scenery (Ellingson et al., 2006). However, some others see non-market opportunity costs associated with livestock grazing that may, depending on management methods and other variables, reduce native plant species and forage for wildlife (Todres et al., 2003). The potential exists for other residents or visitors to prefer lifestyles or have lifestyle needs that are not consistent with grazing or ranching lifestyles or landscapes.

Methods available to measure the use values to residents and tourists associated with grazing land include stated preference methods similar to contingent valuation (Ellingson et al., 2006; Mangun et al., 2005). Methods for attempting to isolate any amenity values that ranchers themselves may hold include the hedonic price method. This method uses observed sale prices of ranch land as a function of the characteristics, including both conventional market factors (e.g., size of ranch, quantity of forage) but also amenity values (e.g., scenic views, presence of wildlife species, on-site fishing or hunting opportunities) that may be provided by the ranch (Torell et al., 2005). The additional value that ranchers pay for the amenity values of the ranch provide some indication of how much they value these amenities. Using the hedonic price method to estimate a “lifestyle value” separate from the market and amenity values has yet to be done in the literature. This may be due to the fact that lifestyle values attributed to living on a ranch or ranching is present on nearly all ranch properties sold. As such, statistically it is difficult to isolate the contribution of ranching lifestyle to differences in ranch property values as ranching lifestyle is a common feature of nearly all ranch properties sold.

<sup>1</sup> Non-labor income includes dividends, interest, and rent and personal current transfer receipts.

<sup>2</sup> Personal current transfer receipts are benefits received by persons for which no current services are performed. They are payments by government and business to individuals and institutions, such as retirement and disability insurance benefits.

<sup>3</sup> Residence adjustment represents the net inflow of the earnings of inter-area commuters. A positive number indicates that, on balance, area residents commute outside to find jobs; a negative number indicates that, on balance, people from outside the area commute in to find jobs.

<sup>4</sup> Contributions for government social insurance consist of payments by employers, employees, the self-employed, and other individuals who participate in the following government programs: Old-age, Survivors, and Disability Insurance; Medicare; unemployment insurance; railroad retirement; pension benefit guarantee; veterans' life insurance; publicly-administered workers' compensation; military medical insurance; and temporary disability insurance.

<sup>5</sup> Earnings by place of work differs from total personal income by the exclusion of dividends, interest, and rent, as well as adjustments to account for net transfer payments (e.g., unemployment benefits and Social Security taxes and payments) and the residential adjustment.

<sup>6</sup> (D) Not shown to avoid disclosure of confidential information, but the estimates for this item are included in the totals.

<sup>7</sup> (L) Less than \$50,000, but the estimates for this item are included in the totals.

<sup>8</sup> "Related activities" includes hunting and trapping, as well as agricultural services such as custom tillage.

<sup>1</sup> Ada, Bannock, Boise, and Canyon Counties in Idaho and Deer Lodge and Park Counties in Montana constitute a secondary study area, as documented in the Chapter 3 text.

<sup>2</sup> Non-labor income includes dividends, interest, and rent and personal current transfer receipts.

<sup>3</sup> Personal current transfer receipts are benefits received by persons for which no current services are performed. They are payments by government and business to individuals and institutions, such as retirement and disability insurance benefits.

<sup>4</sup> Residence adjustment represents the net inflow of the earnings of inter-area commuters. A positive number indicates that, on balance, area residents commute outside to find jobs; a negative number indicates that, on balance, people from outside the area commute in to find jobs.

<sup>5</sup> Contributions for government social insurance consist of payments by employers, employees, the self-employed, and other individuals who participate in the following government programs: Old-age, Survivors, and Disability Insurance; Medicare; unemployment insurance; railroad retirement; pension benefit guarantee; veterans' life insurance; publicly-administered workers' compensation; military medical insurance; and temporary disability insurance.

<sup>6</sup> Earnings by place of work differs from total personal income by the exclusion of dividends, interest, and rent, as well as adjustments to account for net transfer payments (e.g., unemployment benefits and Social Security taxes and payments) and the residential adjustment.

<sup>7</sup> (D) Not shown to avoid disclosure of confidential information, but the estimates for this item are included in the totals.

<sup>8</sup> (L) Less than \$50,000, but the estimates for this item are included in the totals.

<sup>9</sup> "Related activities" includes hunting and trapping, as well as agricultural services such as custom tillage.

<sup>1</sup> Non-labor income includes dividends, interest, and rent and personal current transfer receipts.

<sup>2</sup> Personal current transfer receipts are benefits received by persons for which no current services are performed. They are payments by government and business to individuals and institutions, such as retirement and disability insurance benefits.

<sup>3</sup> Residence adjustment represents the net inflow of the earnings of inter-area commuters. A positive number indicates that, on balance, area residents commute outside to find jobs; a negative number indicates that, on balance, people from outside the area commute in to find jobs.

<sup>4</sup> Contributions for government social insurance consist of payments by employers, employees, the self-employed, and other individuals who participate in the following government programs: Old-age, Survivors, and Disability Insurance; Medicare; unemployment insurance; railroad retirement; pension benefit guarantee; veterans' life insurance; publicly-administered workers' compensation; military medical insurance; and temporary disability insurance.

<sup>5</sup> Earnings by place of work differs from total personal income by the exclusion of dividends, interest, and rent, as well as adjustments to account for net transfer payments (e.g., unemployment benefits and Social Security taxes and payments) and the residential adjustment.

<sup>6</sup> (D) Not shown to avoid disclosure of confidential information, but the estimates for this item are included in the totals.

<sup>7</sup> (L) Less than \$50,000, but the estimates for this item are included in the totals.

<sup>8</sup> "Related activities" includes hunting and trapping, as well as agricultural services such as custom tillage.

<sup>1</sup> Ada, Bannock, Boise, and Canyon Counties in Idaho and Deer Lodge and Park Counties in Montana constitute a secondary study area, as documented in the Chapter 3 text.

## CHAPTER 3

### 3.1. SOCIAL AND ECONOMIC CONDITIONS (INCLUDING ENVIRONMENTAL JUSTICE)

Due to the nature of social, economic, and environmental justice conditions, the social and economic analysis is based on a somewhat different area for analysis than is used for other resources. Specifically, the Socioeconomic Study Area is made up of counties within the Idaho-Southwest Montana sub-region that contain greater sage-grouse habitat and within which social and economic conditions might reasonably be expected to change based on alternative management actions. In addition, BLM reviewed the need to include additional counties within a secondary study area that may not contain greater sage-grouse habitat but are closely linked from an economic and/or social perspective to counties that do contain habitat. This latter category includes what are sometimes called “service area” counties, or counties from which businesses operate that regularly provide critical economic services, such as recreational outfitting or support services for the livestock grazing sector, within the counties that contain habitat (METI Corp / Economic Insights of Colorado, 2012). Including service area counties is important because a change in economic activity in a county containing habitat may result in changes in economic activity within service area counties as well.

The Socioeconomic Study Area contains twenty-seven counties in Idaho: Adams, Bear Lake, Bingham, Blaine, Bonneville, Butte, Camas, Caribou, Cassia, Clark, Custer, Elmore, Fremont, Gem, Gooding, Jefferson, Jerome, Lemhi, Lincoln, Madison, Minidoka, Oneida, Owyhee, Payette, Power, Twin Falls, and Washington; and four counties in Montana: Beaverhead, Gallatin, Madison, and Silver Bow. Each of these counties contains sage-grouse habitat, either Preliminary Priority Habitat (PPH) or Preliminary General Habitat (PGH). A secondary study area is included that contains an additional four counties in Idaho: Ada, Bannock, Boise, and Canyon; and two counties in Montana: Deer Lodge and Park. All of these counties are included in the secondary study area because of identified links to the primary area based on commuter patterns (OMB, 2009; U.S. Census Bureau, 2012b).<sup>1</sup>

Table I shows the share of workers employed in a given county of the Primary and Secondary Socioeconomic Study Areas and that reside in the same county. It also shows other counties that provide labor to the selected primary or secondary study area.

<sup>1</sup> Other counties considered but excluded from the secondary area were: (a) Valley County, ID, which has its main commuter tie to Ada County, ID, a secondary area county; (b) Franklin County, ID, which has its main commuter tie to Cache County, UT, a county outside of the Socioeconomic Study Area; (c) Teton County, ID, which has its main commuter tie to Teton County, MT, a county outside of the Socioeconomic Study Area; (d) Jefferson and Broadwater Counties, MT, both of which have their main commuter ties to Lewis and Clark County, MT, a county outside of the Socioeconomic Study Area; (e) Ravalli County, MT, which has its main commuter tie outside the primary study area, is linked to the Salmon Challis NF or the Beaverhead Deerlodge NF, but is less likely to be affected by sage grouse habitat management alternatives because sage grouse habitat is concentrated in the southeast of Lemhi County, ID, at a distance from Ravalli County; and finally, (d) the counties of Missoula, Granite and Powell (all in MT) were not included in the secondary study area because the Beaverhead Deerlodge NF areas potentially affected by sage grouse habitat management alternatives are located considerably to the south of those counties.

1

**Table I. Commuter Patterns in the Socioeconomic Study Area, 2010**

<b>Geographic Area of Employment</b>	<b>Live in Same Area of Employment</b>	<b>Other Counties Where Considerable Share of Workers Live</b>
Primary Socioeconomic Study Area		
Adams County, ID	69.4%	Valley (7.3%), Idaho (6.7%), Washington (3.5%)

Because any effects on the secondary study area would be indirect and sometimes focused on specific sectors, this chapter focuses primarily on the social and economic conditions of the Socioeconomic Study Area and provides what is necessary to convey appropriate context for the impact analysis. The impact analysis in the next chapter will document potential effects on both the primary and the secondary study areas.

Table 2 shows the planning documents that may be altered by the Idaho-Southwest Montana sub-region sage-grouse planning process and the counties containing sage-grouse habitat within the area encompassed by those plans.

RMP Resource Management Plan

USFS U.S. Forest Service

1 Because of the nature of the Socioeconomic Study Area, the socioeconomic  
2 resources section has a slightly different format than the other resource  
3 analyses in the EIS. Rather than proceeding by Field Office and National Forest,  
4 the section provides information for the entire Socioeconomic Study Area  
5 except where the relevant information or data is tabulated for the specific  
6 geographic area of Field Office or National Forest. In addition, the analysis  
7 presents information about existing conditions and trends within the same  
8 section, because that is the common practice for analysis of social and economic  
9 conditions.

### 10 3.1.1. Indicators

11 Many of the indicators used to characterize social and economic conditions are  
12 quantitative, including population, demographics (e.g., age and gender  
13 breakouts), local industry (e.g., recreation, mineral development), employment,  
14 personal income, and presence of minority and low-income populations. Other  
15 indicators, especially for social conditions, are qualitative.

### 16 3.1.2. Existing Conditions and Trends

#### 17 *Social Conditions*

18 Social conditions concern human communities, including towns, cities, and rural  
19 areas, and the custom, culture, and history of the area as it relates to human  
20 settlement, as well as current social values.

#### 21 Population and Demographics

22 Table 3 shows current and historic populations in the Socioeconomic Study  
23 Area.

9

Since 1990, the population in Idaho has increased by 55.7 percent, more than doubling the United States population growth rate (24.1 percent) during the same time period. In contrast, Montana's population has grown 23.8 percent, more similar to that of the United States as a whole. Both states experienced a higher percentage of population growth from 1990 to 2000 than they did from 2000 to 2010. The Socioeconomic Study Area population growth also outpaced the United States, growing 36 percent between 1990 and 2010.

1 Twin Falls, Idaho, with a population of 44,125 (U.S. Census Bureau, 2010b) is  
 2 the largest city in the Socioeconomic Study Area and the seventh largest city in  
 3 the State of Idaho. It is the county seat and largest city in Twin Falls County  
 4 (NACO, 2012). It is also the principal city of the Twin Falls, ID Micropolitan  
 5 Statistical Area, which includes Jerome and Twin Falls Counties. Twin Falls is the  
 6 hub community of the eight-county south-central Idaho region known as Magic  
 7 Valley (City of Twin Falls, 2012).

8 Bozeman, Montana, with a population of 37,280 (U.S. Census Bureau, 2010b), is  
 9 the largest city in the Montana portion of the Socioeconomic Study Area, and  
 10 the fourth largest city in the State of Montana. It is the county seat of Gallatin  
 11 County (NACO, 2012). Bozeman is home to Montana State University, which is  
 12 also the city's largest employer. Bozeman is served by the Bozeman Yellowstone  
 13 International Airport, and it serves as a gateway community to Yellowstone  
 14 National Park.

15 Butte, Montana, with a population of 33,525 (U.S. Census Bureau, 2010b) is the  
 16 county seat of Silver Bow County. In 1977, the city and county governments  
 17 consolidated to form the sole entity of Butte-Silver Bow. Butte has a long  
 18 history as a mining town, dating back to 1864 when prospectors first struck gold  
 19 in Silver Bow Creek (Butte Montana CVB, 2012). It is home to one of the  
 20 nation's largest National Historic Landmark Districts with over 4,000 historic  
 21 structures (Mainstreet Uptown Butte, 2012). Butte is also the location of one  
 22 of the country's largest Superfund sites, Upper Clark Fork River.

23 Rexburg, Idaho, with a population of 25,484 (U.S. Census Bureau, 2010b), is the  
 24 county seat and largest city in Madison county (NACO, 2012). It is also the  
 25 principal city of the Rexburg, ID Micropolitan Statistical Area. Rexburg is a hub  
 26 for commerce for most communities in the Upper Snake River Valley. Rexburg  
 27 is also well known as the host of the Idaho International Dance and Music  
 28 Festival and the home of Brigham Young University-Idaho (City of Rexburg,  
 29 2012).

30 The "Communities of Place" section below provides more information about  
 31 additional cities and towns in the Socioeconomic Study Area, as well as the  
 32 character and history of the counties. Table 4 shows age and gender  
 33 characteristics of the population in each county of the Socioeconomic Study  
 34 Area.

35 **Table 4. Demographic Characteristics, Share in Total Population**  
 36 **(percent), 2010**

Geographic Area	Women	20 to 64 Years of Age	Under 20 Years of Age	65 Years of Age or Older
Adams County, ID	48.7	58.2	21.0	20.8

United States	50.8	60.1	26.9	13.0

Source: U.S. Census Bureau, 2010b.

The Socioeconomic Study Area, Idaho, Montana, and the United States all generally follow the same trend in gender, with approximately half of the population being female. Of the counties within the Socioeconomic Study Area, Clark County, ID (44.7 percent) and Custer County, ID (46.9) have the lowest percentages of women. And only one county, Madison County, ID (51.6 percent) has a higher percentage of women than the nation.

Idaho and the Socioeconomic Study Area have a younger population than the nation: each having 57 percent of the population between 20 and 64 years of age compared to 60 percent of the national population, and more than 30 percent

1 of the population less than 20 years of age compared to only 27 percent of the  
2 national population. In contrast, Montana has a slightly older population than the  
3 nation, having nearly 15 percent of the population being 65 years or older  
4 compared to only 13 percent of the national population. Of the counties within  
5 the Socioeconomic Study Area, Bingham County, ID, Cassia County, ID,  
6 Jefferson County, ID, Jerome County, ID, Lincoln County, ID, Madison County,  
7 ID, and Power County, ID have the highest percentages of residents under the  
8 age of 20, all at least 7 percentage points higher than the national average (60.1  
9 percent). In contrast, Adams County, ID, Lemhi County, ID, Washington  
10 County, ID, and Madison County, MT have the highest percentages of residents  
11 over the age of 65, all at least 7 percentage points higher than the national  
12 average (13 percent).

#### 13 Interest Groups and Communities of Place

14 There is a range of interest groups in the Socioeconomic Study Area, including  
15 groups that focus advocacy on resource conservation and others that focus  
16 advocacy on resource uses such as livestock grazing. There are also groups that  
17 represent coalitions of interest groups. A list of interest groups that have  
18 requested to receive a copy of the DEIS are provided in Chapter XX. The types  
19 of interest groups identified within the Socioeconomic Study Area include the  
20 following: federal agencies, state agencies, county agencies, local agencies,  
21 congressional representatives, local representatives, academic institutions, civic  
22 organizations, local chambers of commerce, environmental groups, land  
23 conservation groups, outdoors groups, local school boards, farm associations,  
24 Native American groups and Tribal Governments, and various business groups.  
25 Specific types of business interest groups identified include the following: real  
26 estate, tourism, mineral extraction, farms/ranches, textile manufacturers,  
27 livestock growers, and news media.

28  
29  
30 The Socioeconomic Study Area includes various communities of people who are  
31 bound together because of where they reside, work, visit, or otherwise spend a  
32 continuous portion of their time. Stakeholder groups currently benefitting from  
33 BLM- and FS-managed lands within the Socioeconomic Study Area include those  
34 associated with agriculture and livestock production; forest products; mining;  
35 travel, tourism, and recreation; and local residents (see, for example, BLM,  
36 2005b; BLM, 2008; BLM, 2010; USFS, 2003).

37 A common perception is that there is a dichotomy of values and attitudes  
38 between stakeholder groups in the Study Area between individuals or groups  
39 who feel that resource conservation and non-consumptive uses of public lands  
40 are more important than benefits derived from consumptive type uses, such as  
41 livestock grazing, timber harvesting, and mining. At a more nuanced scale,  
42 however, personal attitudes, interests, and values are quite complex, and these  
43 groupings are not mutually exclusive. The high value that residents and visitors  
44 place on small town character, private property rights, low population density,  
45 scenery and landscape, outdoors and open space, the rural lifestyle, fishing, and  
46 hunting are commonly held throughout the Study Area (see, for example, BLM,  
47 2005b; BLM, 2008; BLM, 2010; USFS, 2003). These values are also commonly  
48 expressed within individual county land use plans, and were also expressed by

1 attendees at both scoping meetings and the Economic Strategies Workshop that  
2 BLM and FS held in Twin Falls, ID, in June 2012.

3 A unifying theme expressed by residents of the Socioeconomic Study Area –  
4 including in previous planning processes – is the concern for the preservation of  
5 rural characteristics and values. For example, a shift toward larger, more  
6 mechanized agricultural operations, as well as the increasing diversification of  
7 local economies, have challenged traditional ways of life in many communities.  
8 These changes are evident in the declining number of mid-sized farms and the  
9 number of workers employed in agriculture and agriculture-based industries  
10 (Blaine County, 1994; Power County, 2009; Headwaters Economics, 2012; U.S.  
11 Department of Commerce, 2012a). Nevertheless, farming and ranching remain  
12 important parts of the economy, society and culture across the Socioeconomic  
13 Study Area.

14 In some areas, particularly those with scenic and recreational amenities,  
15 farmlands and ranches are being sold and used for recreation purposes or  
16 subdivided for homesites. This phenomenon is part of a larger trend in which  
17 many rural communities in the western United States have witnessed "migration  
18 turnaround," a reversal of the rural-to-urban migration that characterized much  
19 of the United States prior to the 1970s. Many rural areas are now experiencing  
20 a significant increase in population after decades of stability or decline (BLM,  
21 2005b). In response to recent commercial and industrial expansion and the  
22 associated demand for affordable, diversified housing, many counties are  
23 encouraging infill development and other strategies to prevent the loss of  
24 agricultural lands and maintain the rural character of their communities  
25 (Caribou County, 2006; Silver Bow County, 2008).

26 Despite population increases across most of the study area, some rural areas  
27 continue to lose population (Idaho Department of Labor, 2011). This is due, in  
28 part, to the out-migration of young people and aging of the population (BLM,  
29 2010; Idaho Commerce & Labor, 2005). In contrast to communities where in-  
30 migration is occurring, residents of these communities may be more concerned  
31 about the economic survival of their communities. Multiple use management of  
32 and access to public lands, which comprise a large portion of lands in many  
33 counties, are cited as paramount concerns in these areas (BLM, 2005b).  
34 Residents expressed some similar themes during public scoping and the June  
35 2012 Economic Strategies Workshop for this planning effort (BLM and USFS,  
36 2012; BLM, 2012d). Comments received from these outreach efforts came from  
37 non-profit or citizen groups; local, state and Federal governments; the  
38 commercial sector and members of the general public. These comments  
39 strongly supported maintaining or expanding access to public lands for grazing  
40 and recreational purposes. Many expressed concern that placing additional  
41 constraints on these activities might create economic hardship within their  
42 communities and alter traditional cultural values and lifestyles. Additionally,  
43 some argued that constraints on livestock grazing would exacerbate existing

1 trends of conversion of ranch lands to agricultural and residential uses, perhaps  
2 with the unintended consequence of decreasing open space and wildlife habitat.  
3 Other issues of concerns cited by residents include the management of invasive  
4 species, fire and fuels, and whether public lands should be opened to wind  
5 energy development.

6 Economic activity and land use patterns in the Socioeconomic Study Area have  
7 been strongly influenced by the region's dramatic geography. Agriculture,  
8 timber harvesting, and mining have historically defined the character and lifestyle  
9 of much of the Study Area. Within the past two decades, however, increasing  
10 urbanization and the growth of service sector industries, including retail trade,  
11 local government, and health care, have been powerful agents of change on the  
12 landscape and local cultures (Headwaters Economics, 2012; U.S. Department of  
13 Commerce, 2012a).

14 The rolling hills and valleys of the Northern Basin and Range, which stretches  
15 across much of southern Idaho, provide ample opportunities for livestock  
16 grazing with occasional croplands, and contains all or substantial parts of  
17 Caribou, Cassia, Oneida, Owyhee, Power, and Twin Falls Counties (McGrath et  
18 al., 2002). The region is still heavily dependent on agriculture and agriculture-  
19 based industries, despite stagnant or declining employment in these sectors  
20 (Headwaters Economics, 2012; U.S. Department of Commerce, 2012a). Twin  
21 Falls is the most populous city in the Socioeconomic Study Area, and serves as  
22 the major commercial and industrial hub of south-central Idaho's Magic Valley  
23 region, so named due to the transformation of the basin into productive  
24 farmland through the construction of extensive irrigation systems in the early  
25 1900s.

26 The broad Snake River Plain that arcs just north of Idaho's Basin and Range  
27 region contains all or substantial parts of Ada, Adams, Bingham, Canyon,  
28 Elmore, Gem, Gooding, Jefferson, Jerome, Lincoln, Madison, Minidoka, Payette,  
29 and Washington Counties. Potatoes, sugar beets, alfalfa, grains, and vegetables  
30 are grown in areas where irrigation and soil depth are suitable for crop  
31 production (McGrath et al., 2002). Other prominent land uses include livestock  
32 grazing, cattle feedlots, and dairy operations. The barren, lava-field landscape of  
33 Craters of the Moon National Monument is a popular visitor attraction  
34 showcasing the region's unique geologic history. Upward trends in population  
35 growth, fueled by expansion in the retail trade and small manufacturing sectors  
36 over the past decade, have left some school districts and governmental service  
37 struggling to provide maintain adequate levels of service (Jefferson County,  
38 2005).

39 Butte, Camas, Clark, Custer, and Lemhi Counties are located in Idaho's Rocky  
40 Mountain region, which rises sharply from the northern edge of the Snake River  
41 Plain. Here, timber harvesting, grazing, and recreation are the predominant land  
42 uses (McGrath et al., 2002). The counties of Bonneville, Butte, Caribou, and

1 Fremont in Idaho and Beaverhead, Silver Bow, Madison, and Gallatin in  
2 southwestern Montana also offer abundant opportunities for outdoor  
3 recreation. Popular activities include fishing, hunting, hiking, horseback riding,  
4 OHV use, skiing, and sightseeing, which attract residents, as well as visitors  
5 from all areas of the United States (BLM, 2005b; BLM, 2008). In many  
6 communities, such as Butte, MT, growth in tourism and recreation industries  
7 has largely outpaced historical land uses. The in-migration of residents who  
8 purchase smaller ranches or farms, but do not depend on the economic return  
9 from these activities as their primary source of income, has created conflict with  
10 long-time rural residents (BLM, 2008).

11 Bear Lake County, which occupies the far southeastern corner of Idaho and the  
12 Wasatch and Uinta Range, has remained largely rural, but serves also as an  
13 important destination for tourists and recreationists.

#### 14 County Land Use Plans

15 BLM/USFS-administered and other federal land in the Socioeconomic Study  
16 Area is intermingled with State and private lands. County governments have  
17 land use planning responsibility for the private lands located within their  
18 jurisdictions. County level land use plans (also referred to as Comprehensive  
19 plans or Growth Policies) were identified for twenty-eight of the thirty-one  
20 counties within the Socioeconomic Study Area (Adams County, 2006; Bingham  
21 County, 2005; Blaine County, 1994; Bonneville County, 2004; Camas County,  
22 2006; Caribou County, 2006; Cassia County, 2006; Clark County, 2010; Custer  
23 County, 2006; Elmore County, 2004; Fremont County, 2008; Gem County,  
24 2010; Gooding County, 2010; Jefferson County, 2005; Jerome County, 2006;  
25 Lemhi County, 2007; Lincoln County, 2008; Madison County, 2008; Minidoka  
26 County, 2001; Owyhee County, 2010; Payette County, 2006; Power County,  
27 2009; Twin Falls County, 2008; Washington County, 2010; Beaverhead County,  
28 2009; Gallatin County, 2005; Madison County, 2006; Silver Bow County, 2008).  
29 Of the counties with identified land use plans, all had some form of economic  
30 development component, such as promotion of specific industrial sectors and  
31 natural resource use.

#### 32 ***Economic Conditions***

33 Economic analysis is concerned with the production, distribution, and  
34 consumption of goods and services. This section provides a summary of  
35 economic information, including trends and current conditions. It also identifies  
36 and describes major economic sectors in the Socioeconomic Study Area that  
37 can be affected by management actions. Most likely affected would be those  
38 economic activities that rely or could rely on public lands, such as recreation  
39 and livestock grazing.

#### 40 Economic Sectors, Employment, and Personal Income

The distribution of employment and income by industry sector within the Socioeconomic Study Area is summarized in Table 5 and Table 6 below. See Appendix X for equivalent data by county.

**Table 5. Employment by Sector within the Socioeconomic Study Area**

Socioeconomic Study Area	Absolute			Percentage of total		Percent Change 2001-2010
	2001	2010	Change 2001-2010	2001	2010	
<b>Total Employment (number of jobs)</b>	<b>352,752</b>	<b>395,236</b>	<b>42,484</b>	<b>100.0%</b>	<b>100.0%</b>	<b>12.0%</b>
<b>Non-services related</b>	<b>87,102</b>	<b>82,972</b>	<b>-4,129</b>	<b>24.7%</b>	<b>21.0%</b>	<b>-4.7%</b>
Farm	29,597	26,909	-2,688	8.4%	6.8%	-9.1%
Forestry, fishing, & related activities	4,615	4,704	89	1.3%	1.2%	1.9%
Mining (including oil and gas)	1,431	2,046	615	0.4%	0.5%	43.0%
Construction	25,636	25,897	262	7.3%	6.6%	1.0%
Manufacturing	25,822	23,416	-2,407	7.3%	5.9%	-9.3%
<b>Services related</b>	<b>200,014</b>	<b>243,372</b>	<b>43,358</b>	<b>56.7%</b>	<b>61.6%</b>	<b>21.7%</b>
Utilities	1,213	1,546	333	0.3%	0.4%	27.4%
Wholesale trade	13,480	13,871	391	3.8%	3.5%	2.9%
Retail trade	41,426	43,618	2,192	11.7%	11.0%	5.3%
Transportation and warehousing	9,619	11,215	1,596	2.7%	2.8%	16.6%
Information	4,381	5,095	714	1.2%	1.3%	16.3%
Finance and insurance	9,319	13,699	4,381	2.6%	3.5%	47.0%
Real estate and rental and leasing	11,339	18,249	6,909	3.2%	4.6%	60.9%
Professional and technical services <sup>1</sup>	23,409	27,865	4,455	6.6%	7.1%	19.0%
Management of companies and enterprises	792	778	-14	0.2%	0.2%	-1.8%
Administrative and waste services	12,976	16,229	3,253	3.7%	4.1%	25.1%
Educational services	2,217	3,618	1,401	0.6%	0.9%	63.2%
Health care and social assistance	21,187	31,292	10,105	6.0%	7.9%	47.7%
Arts, entertainment, and recreation	6,331	8,435	2,103	1.8%	2.1%	33.2%
Accommodation and food services	24,261	26,417	2,157	6.9%	6.7%	8.9%
Other services, except public administration	18,065	21,446	3,382	5.1%	5.4%	18.7%
<b>Government</b>	<b>54,242</b>	<b>57,046</b>	<b>2,804</b>	<b>15.4%</b>	<b>14.4%</b>	<b>5.2%</b>
Federal	12,456	12,265	-191	3.5%	3.1%	-1.5%
State	9,884	10,537	653	2.8%	2.7%	6.6%
Local	31,052	33,807	2,755	8.8%	8.6%	8.9%

1 Sources: Headwaters Economics, 2012; U.S. Department of Commerce, 2012a.

2 <sup>1</sup>Professional and technical services activities require a high degree of expertise and training. Example activities  
3 include: legal advice and representation; accounting, bookkeeping, and payroll services; architectural,  
4 engineering, and specialized design services; computer services; consulting services; research services;  
5 advertising services; photographic services; translation and interpretation services; and veterinary services.

6 With respect to employment by industry sector, the services related sector  
7 accounted for the largest share (61.6 percent) of total employment in the  
8 Socioeconomic Study Area in 2010. This reflects a growth rate of 21.7 percent  
9 from 2001 (compared to an overall employment growth rate for all sectors of  
10 12.0 percent from 2001). Compared to the services related sector, the non-  
11 services related sector and the government sector represented lower levels of  
12 employment, 21.0 percent and 14.4 percent, respectively. At the industry level,  
13 retail trade (11.0 percent) accounted for the largest share of employment of all  
14 industries in the Socioeconomic Study Area in 2010, followed by local  
15 government (8.6 percent), health care and social assistance (7.9 percent), and  
16 professional and technical services (7.1 percent). Although mining contributed a  
17 relatively small share of total employment within the study area in 2010, a  
18 notable proportion of total employment within Caribou County (7.2 percent)  
19 and Clark County (4.1 percent) came from the mining industry. The industries  
20 that demonstrated the largest growth between 2001 and 2010 were educational  
21 services, with an increase of 63.2 percent; real estate rental and leasing, with an  
22 increase of 60.9 percent; and health care and social assistance, with an increase  
23 of 47.7 percent. The only industries to decrease in employment levels from  
24 2001 to 2010 were management of companies and enterprises (decrease of 51.3  
25 percent) and farming (decrease of 9.2 percent).

26 **Appendix X** provides county-level employment figures. The greatest difference  
27 in industry sector proportion between counties in 2010 was in the professional  
28 and technical services industry. Professional and technical services contributed a  
29 low 1.5 percent of total employment in Power County, Idaho but a much larger  
30 percentage in Butte County, Idaho (83.8 percent). Other industries also showed  
31 large variation in shares of employment across counties, including the farm  
32 industry (from 0.7 percent in Silver Bow County, Montana to 25.6 percent in  
33 Gooding County, Idaho) and the manufacturing industry (from 0.6 percent in  
34 Butte County, Idaho to 24.8 percent in Power County, Idaho). Other counties  
35 identified as having relatively high employment shares in the farming industry  
36 include Lincoln County, Idaho (22.5 percent), Oneida County, Idaho (22.6  
37 percent), and Owyhee County, Idaho (25.3 percent). The federal government  
38 industry also showed a high level of variation in shares across counties (from 1.0  
39 percent in Blaine County, Idaho to 35.5 percent in Elmore County, Idaho).  
40 However, in 26 of the 31 counties included in the Socioeconomic Study Area,  
41 the federal government contributed less than 5 percent of employment).  
42 Recreation-related economic activity, including the arts, entertainment and  
43 recreation; retail trade; and accommodation and food services industries, varied  
44 across the counties (by 8.4 percentage points, 12.7 percentage points, and 16.7  
45 percentage points, respectively). Note that these sectors are influenced not only

by recreation but also by many other industries. See Appendix X for individual county detail.

**Table 6. Labor Income by Sector within the Socioeconomic Study Area (2010 dollars)**

Socioeconomic Study Area	Absolute (Millions)			Percentage of total <sup>1</sup>		Percent Change 2001-2010
	2001	2010	Change 2001-2010	2001	2010	
<b>Total Labor Earnings<sup>2</sup></b>	<b>\$12,847.6</b>	<b>\$15,018.5</b>	<b>\$2,171.0</b>	<b>100.0%</b>	<b>100.0%</b>	<b>16.9%</b>
<b>Non-services related</b>	<b>\$3,633.4</b>	<b>\$3,899.2</b>	<b>\$265.8</b>	<b>28.3%</b>	<b>26.0%</b>	<b>7.3%</b>
Farm	\$1,103.1	\$1,241.9	\$138.8	8.6%	8.3%	12.6%
Forestry, fishing, & related activities	\$139.3	\$136.5	-\$2.8	1.1%	0.9%	-2.0%
Mining (including oil and gas)	\$126.5	\$367.2	\$240.7	1.0%	2.4%	190.3%
Construction	\$1,147.8	\$1,007.2	-\$140.6	8.9%	6.7%	-12.2%
Manufacturing	\$1,116.7	\$1,146.5	\$29.7	8.7%	7.6%	2.7%
<b>Services related</b>	<b>\$6,793.2</b>	<b>\$8,502.3</b>	<b>\$1,709.0</b>	<b>52.9%</b>	<b>56.6%</b>	<b>25.2%</b>

Sources: Headwaters Economics, 2012; U.S. Department of Commerce, 2012a. Values reported in 2001 dollars were converted to 2010 dollars using the Consumer Price Index (BLS, 2012a).

<sup>1</sup>Industry earnings are reported as a share of total labor earnings. Dividends, interest, and rent; personal current transfer receipts; and contributions to government social insurance are reported as a share of personal income.

<sup>2</sup>Total labor earnings are reported by place of work.

<sup>3</sup>Non-labor income includes dividends, interest, and rent and personal current transfer receipts.

<sup>4</sup>“Personal current transfer receipts” are benefits received by persons for which no current services are performed. They are payments by government and business to individuals and institutions, such as retirement and disability insurance benefits.

<sup>5</sup>“Contributions for government social insurance” consists of payments by employers, employees, the self-employed, and other individuals who participate in the following government programs: Old-age, Survivors, and Disability Insurance; Medicare; unemployment insurance; railroad retirement; pension benefit guarantee; veterans’ life insurance; publicly-administered workers’ compensation; military medical insurance; and temporary disability insurance (U.S. Department of Commerce, 2012b).

<sup>6</sup>Total personal income is reported by place of residence.

With respect to personal earnings, the services related sector accounted for the largest share (56.6 percent) of personal earnings in the Socioeconomic Study Area in 2010, followed by the non-services related sector (26.0 percent) and the government sector (19.1 percent). In 2010, the individual industries that generated the largest shares of personal earnings included the professional and technical services industry (11.3 percent), the local government industry (9.3 percent), and the health care and social assistance industry (8.7 percent). Mining, management of companies and enterprises, and healthcare and social assistance all showed strong trends of growth since 2001 (a percent change of 190.3 percent, 76.9 percent, and 63.1 percent, respectively); these were the highest growth rates between 2001 and 2010. During the same time period, the real estate, rental and and leasing industry and the construction industry experienced the largest decline in earnings of all the industry sectors (declines of 19.1 percent and 12.2 percent, respectively).

**Appendix X** provides county-level labor earnings figures. The county-by-county patterns are similar to those for employment, with relatively more variation in income from professional and technical services than from other industries; professional and technical services contribute the most to earnings in Butte County, Idaho at 93.5 percent. At the other end of the range, professional and

1 technical services accounts for only 1.2 percent of earnings in Elmore County,  
2 Idaho and only 1.3 percent in Power County, Idaho. Of the counties for which  
3 data are provided (22 of 31), only three earn more than 10 percent of income  
4 from the professional and technical services industry. Farm income varied from  
5 a low share of -2.1 percent of total earnings in Adams County, Idaho to highs of  
6 47.3 percent in Gooding County, Idaho, followed by 46.9 percent in Owyhee  
7 County, Idaho. Manufacturing income varied in proportion across the counties,  
8 from 0.2 percent of earnings in Butte County, Idaho to 32.9 percent in Power  
9 County, Idaho. Earnings from the mining sector are left undisclosed in 15 of the  
10 31 counties included in the Socioeconomic Study Area due to confidentiality  
11 requirements. Furthermore, mining sector earnings figures are not provided for  
12 nine of the 31 counties because the earnings amounted to less than \$50,000 in  
13 those counties. For the counties for which data are available, earnings from  
14 mining range from 0.1 percent in Twin Falls County, Idaho to a share of 12.7  
15 percent of total earnings in Caribou County, Idaho. Accommodation and food  
16 services contributes 0.1 percent of total earnings in Butte County, Idaho and up  
17 to 16.6 percent in Madison County, Montana. The other recreation and travel-  
18 related industries (i.e., retail trade and arts, entertainment, and recreation)  
19 contribute between 0.1 percent (arts, entertainment, and recreation in Elmore  
20 County, Idaho) and 16.2 percent (retail trade in Adams County, Idaho).

21 In addition to industry shares of labor earnings, another metric – residence  
22 adjustment – provides information about the economic conditions in the  
23 Socioeconomic Study Area. Residence adjustment represents the net inflow of  
24 the earnings of inter-area commuters. A positive number indicates that, on  
25 balance, area residents commute outside to find jobs; a negative number  
26 indicates that, on balance, people from outside the area commute in to find jobs.  
27 Jefferson County, Idaho’s residence adjustment represented 27.8 percent of its  
28 total personal income, the highest share of all counties in the Socioeconomic  
29 Study Area. Gem County, Idaho had the second highest share (25.8 percent).  
30 Residence adjustment accounted for the most lowest share of total personal  
31 income in Butte County, Idaho (-701.3 percent), followed by Caribou County,  
32 Idaho (-22.1 percent). See Appendix X for individual county detail.

33 In addition to the 31 counties of the Socioeconomic Study Area, **Appendix X**  
34 provides employment and earnings data for Ada and Canyon Counties in Idaho,  
35 which constitute a secondary study area as discussed in the introduction. In  
36 2010, overall employment in the two-county secondary study area (339,924)  
37 was only slightly smaller than overall employment levels in the 31-county  
38 primary socioeconomic study area (395,236). Earnings in the two-county  
39 secondary study area were \$15,021.40, approximately the same as the earnings  
40 in the primary socioeconomic study area (\$15,018.50). The economies of the  
41 Ada and Canyon Counties are relatively diversified, with no industry capturing  
42 more than 12.3 percent of the workforce. In Ada County, the health care and  
43 social assistance industry dominates, contributing 12.0 percent of total  
44 employment; the next largest contributors are retail trade (11.1 percent) and

administrative and waste services (8.9 percent). In Canyon County, retail trade contributes the largest share of employment (12.3 percent), followed by healthcare and social assistance (11.2 percent) and manufacturing (10.6 percent). Besides retail trade, other industries that are directly and indirectly affected by recreation (e.g., accommodation and food services; arts, entertainment, and recreation) do not contribute significantly to secondary study area counties. The impact analysis in the next chapter will document potential effects on the economy in the secondary study area, as well as for the 31 counties within the primary socioeconomic study area.

Table 7 presents the unemployment rates for each county in the Socioeconomic Study Area, as well as the rates for the counties aggregated and the States of Idaho and Montana. The data show that unemployment in the Socioeconomic Study Area matches or approximates that of the State for each of the years listed. At the county level, in 2011, the unemployment rates in the Socioeconomic Study Area ranged from a low of 5.0 percent in Owyhee County to a high of 17.3 percent in Adams County.

### Recreation

Approximately 34,430 jobs (17.2 percent of total employment in 2010) in the Socioeconomic Study Area are related to travel and tourism, which was 2.1 percentage points higher than the national average (15.1 percent) (Headwaters Economics, 2012). This estimate is based on data from the U.S. Census Bureau County Business Patterns and includes industrial sectors that, at least in part, provide goods and services to visitors, the local economy, and the local population. This estimate includes both full- and part-time jobs. Most of these jobs are concentrated in the “accommodation and food services” and “retail trade” sectors. Jobs related to travel and tourism are more likely to be seasonal and/or part-time and more likely to have lower average annual earnings than jobs in non-travel and tourism-related sectors. The average annual wage per travel or tourism related job was \$15,152 (2010 dollars) in the Socioeconomic Study Area in 2010, compared to \$32,425 for jobs not related to travel and tourism (Headwaters Economics, 2012).

Although much of the recreation use on BLM lands is dispersed and far from counting devices (e.g., trail registers, fee stations, or vehicle traffic counters), approximations of the number of visitors to BLM-administered lands can be obtained from the BLM Recreation Management Information Service (RMIS) database, in which BLM recreation specialists provide estimated total visits and visitor days to various sites within their field office boundaries. Table 8 summarizes BLM visitation data in each field office area for fiscal year (FY) 2011 (i.e., the year ending September 30, 2011), and USFS visitation data from Round 2 of the National Visitor Use Monitoring program (NVUM).

**Table 8. Estimated Annual Visits by Planning Unit**

NF National Forest

Source: BLM data from BLM (2012c); FS data from USFS (2012b).

<sup>1</sup>Based on national averages for all National Forests. White and Gooding (2012).

<sup>2</sup>Non primary means incidental visits where the primary purpose of the trip was other than visiting the National Forest being surveyed.

<sup>3</sup>Includes Curlew National Grassland

Visitor expenditures can be approximated by using the RMIS and NVUM visitation data in conjunction with data from USFS, which has constructed recreation visitor spending profiles based on years of survey data gathered through the USFS NVUM. Although the data are collected from National Forest visitors, the analysis that follows is based on the NVUM profiles because the BLM has no analogous database. The profiles break down recreation spending by type of activity, day use versus overnight use, local versus non-local visitors, and “non-primary” visits (i.e., incidental visits where the primary purpose of the trip was other than visiting public lands). Table 9 summarizes individual and party visits and expenditures by trip type and estimated direct expenditure.

**Table 9. Visitor Spending from Recreation on BLM and USFS Land in Socioeconomic Study Area, FY 2011**

Trip Type	Percent of Visits <sup>1</sup>	Estimated Number of Individual Visits	Average Party Size <sup>1</sup>	Estimated Number of Party Visits	Party Spending Per Visit (2010 \$) <sup>1</sup>	Estimated direct expenditure (Millions \$)
Non-local Day Trips	10	1,245,469	2.5	498,188	\$63.68	\$31.7
Non-local Overnight on Public Lands	9	1,120,922	2.6	431,124	\$237.27	\$102.3

NA Not Applicable

<sup>1</sup>Visits on BLM land estimated using the national average distribution of trip types for all national forests, from White and Gooding (2012). Visits on USFS land by trip type are provided in NVUM (USFS, 2012b). Party spending per visit was converted from 2009 to 2010 dollars using the Consumer Price Index (BLS, 2012a).

As Table 9 shows, the estimated total visitor spending on BLM and USFS lands in the Socioeconomic Study Area was about \$868.83 million in FY 2011. It is important to note that this includes expenditures from local residents and from visitors whose use of public lands was incidental to some other primary purpose.

#### Grazing

Farming employed approximately 26,909 people in the Socioeconomic Study Area in 2010, accounting for 6.8 percent of total employment. The average annual wage for a farm job in the Study Area was \$27,448 in 2010. This was lower than the average annual wage for a non-farm job (\$29,268) (Headwaters Economics, 2012).<sup>2</sup>

Table 10 presents the proportion of personal income originating from farm earnings and the farm cash receipts from livestock received throughout the Socioeconomic Study Area and Idaho and Montana as a whole. As shown in Table 10, agricultural services are an important contribution in several counties; however, in some counties the data are not released for confidentiality reasons.

Sources: Headwaters Economics, 2012; U.S. Department of Commerce, 2012a. Values reported in 2001 dollars were converted to 2010 dollars using the Consumer Price Index (BLS, 2012a).

<sup>1</sup>This division is the finest resolution of data provided by the U.S. Department of Commerce's Bureau of Economic Analysis that includes agricultural services.

<sup>2</sup>(D) indicates that the value is not shown to avoid disclosure of confidential information.

Table 10 shows the relative contribution of farm earnings across the counties in the Socioeconomic Study Area. Farm earnings constitute the largest share of total earnings in Camas, Cassia, Clark, Gooding, Jefferson, Jerome, Lincoln, Minidoka, Oneida, Owyhee and Twin Falls Counties. Both livestock and crops provide substantial cash receipts, with some variations across the counties. Though approximately 61.8% of farm cash receipts in the Socioeconomic Study Area come from livestock, many counties have significant percentages of farm cash receipts from crops, including Camas, Caribou, Clark, Gem, Madison, Minidoka, Oneida, Power and Silver Bow Counties.

Table 11 provides information on active and billed Animal Unit Months (AUMs) on BLM and USFS land, for each of the BLM Field Offices and National Forest areas. The estimated gross receipts in the table are calculated from data from the USDA Economic Research Service (ERS), which publishes annual budgets for cow-calf operations for different production regions across the country (USDA ERS, 2012). BLM calculated a ten-year inflation-adjusted average gross receipt per cow-calf operation from the ERS budgets, then converted that information to a per-AUM figure based on average forage requirements for a cow including other livestock (e.g., bulls and replacement heifers) that are needed to support the production from the cow (Workman, 1986). Southwest Montana falls into the Basin and Range region, whereas southern Idaho is in the ERS's Fruitful Rim region. BLM's calculations resulted in a ten-year average gross receipt in the Basin and Range region of \$50.24 per AUM (2010 dollars), and in the Fruitful Rim region of \$30.29 per AUM (2010 dollars). However, BLM used the higher value for both regions, both to err on the side of conservative analysis and because the characteristics of livestock grazing in southern Idaho seem more like those in southwest Montana (and across southeast Oregon, Nevada, and

Utah, which are also in ERS's Basin and Range region) than like those in the remainder of the Fruitful Rim (e.g., much of the California coast, western Oregon, and Washington State).

Thus, the table below reflects a gross receipt value of \$50.24 per AUM, and the last column of the table represents annual gross receipts in the region from livestock operations in 2010 dollars.

**Table 11. Active and Billed Animal Unit Months**

NM National Monument

Sources: BLM, 2012a; USFS, 2012a; USFS, 2012c; Workman, 1986; USDA ERS, 2012.

Gross receipts are calculated based on active AUMs and ten-year average gross receipts, as described in the text.

The data in the table help to demonstrate the importance of livestock grazing throughout the Socioeconomic Study Area. It is important to remember, as

well, that the data are only for forage values on BLM/USFS-administered land; forage on other public lands, and private lands, contribute additional values to the Socioeconomic Study Area. The economic analysis of the alternatives, presented in Chapter 4, addresses additional indirect contributions of livestock grazing (as well as other resource uses) to the regional economy, comparing the alternatives to one another.

Forestry and Wood Products

Approximately 1,972 jobs (1.0 percent of total employment in 2010) in the Socioeconomic Study Area came from timber-related industries, which is 0.3 percentage points higher than the national average of 0.7 percent (Headwaters Economics, 2012). This estimate is based on data from the U.S. Census Bureau County Business Patterns. The proportion of employment associated with timber-related industries varied by county, with a low of zero percent in Butte, Camas, Caribou, Clark, Lincoln, Minidoka, and Power Counties and highs of 23.9 percent in Adams County, 13.7 percent in Washington County, 9.1 percent in Payette County, and 6.7 percent in Owyhee County. These estimates include both full- and part-time jobs and reflect three timber-related industries: “growing and harvesting,” “sawmills and paper mills,” and “wood products manufacturing.”

Average annual earnings for timber-related jobs tend to be higher than for non-timber jobs. The average annual wage per timber-related job in the Socioeconomic Study Area in 2010 was \$33,530 (2010 dollars), compared to \$29,105 for non-timber jobs.<sup>3</sup>

Mining and Minerals

The data in Table 12 show that within the thirty-one counties included in the Socioeconomic Study Area, mining industries employed 1,727 people in 2010 or approximately 0.8 percent of total employment, which is 0.3 percentage points higher than the national average (Headwaters Economics, 2012). Mining industries include “oil and gas extraction,” “coal mining,” “metals mining,” “nonmetallic minerals mining,” and “mining related” industries. The proportion of employment associated with mining industries varied by county, from zero percent in twelve of the counties up to 30.4 percent of total employment in Custer County and 22.7 percent of total employment in Caribou County. The average annual earnings per mining-related job in the Socioeconomic Study Area are higher than non-mining jobs. The average annual wage per job in this sector was \$69,476 (2010 dollars) in the Socioeconomic Study Area in 2010, compared to \$29,763 for non-mining jobs (Headwaters Economics, 2012).

1 Phosphate mining in Caribou County for BLM-administered phosphate raw ore  
2 produced 4.2 million units for a sales total of \$167.4 million in 2011 (ONRR,  
3 2012). Although some of the richest silver-producing regions in the U.S. are in  
4 the northern Idaho panhandle (outside the Socioeconomic Study Area), the  
5 study area does produce some silver, along with industrial minerals such as  
6 molybdenum (Idaho Mining Association, 2010).

1 Other Values

2 Public lands provide a range of goods and services that benefit society in a  
3 variety of ways. Some of these goods and services, such as timber and minerals,  
4 are bought and sold in markets, and hence have a readily observed economic  
5 value (as documented in the sections above); others have a less clear connection  
6 to market activity, even though society derives benefits from them. In some  
7 cases, goods and services have both a market and a non-market component  
8 value to society. This section provides an overview of several “non-market”  
9 values described through a qualitative and quantitative economic valuation  
10 analysis.

11 The non-market values associated with public lands can be classified as values  
12 that derive from direct or indirect use (e.g., recreation) and those that do not  
13 derive from use, such as existence values held by the general public from self-  
14 sustaining populations of sage grouse. This section and the related appendix  
15 describe the use and non-use economic values associated with recreation,  
16 populations of sage-grouse, and land that is currently used for livestock grazing  
17 and ranch operations. The sections that follow discuss each of these values in  
18 turn. Appendix A provides more discussion of the concepts and measurement  
19 of use and non-use non-market values. It is important to note that these non-  
20 market values are not directly comparable to previous sections that describe  
21 output (sales or expenditures) and jobs associated with various resource uses  
22 on BLM and USFS administered lands (see Appendix A for more information).

23 *Values associated with recreation*

24 Actions that promote the conservation of sage-grouse habitat may result in  
25 changes in recreation activity, by changing opportunities or access for different  
26 recreational activities. Opportunities for some activities such as wildlife viewing  
27 may increase as the amount of habitat may increase for species that depend on  
28 public lands including sage grouse. The Environmental Consequences analysis  
29 (Chapter 4) addresses this issue for each of the management alternatives. This  
30 section documents baseline non-market values visitor receive associated with  
31 recreation activities. This is measured by what economists call consumer  
32 surplus, which refers to the additional value that visitors receive over and above  
33 the price they pay. Appendix A provides an explanation of consumer surplus.  
34 Fees to use public lands for recreation are typically very low or non-existent, so  
35 the value people place on public land recreation opportunities is not fully  
36 measured simply by the entrance fees people pay.

37 Economists estimate the consumer surplus from recreation by measuring how  
38 the variation in visitors’ travel costs corresponds to the number of visits taken.  
39 This “travel cost method” has been developed extensively in academic literature  
40 and is used by federal agencies in economic analyses; the method is explained  
41 more fully in Appendix A. Conducting original travel cost method studies can be  
42 time-consuming and expensive; for this project BLM and USFS relied on

1 estimates of consumer surplus from prior recreation studies in the same  
2 geographic region, using an established scientific method called “benefit  
3 transfer.” Based on the studies reviewed and cited in Appendix A, visitors to  
4 natural areas, such as lands managed by BLM and USFS, gain values (in excess of  
5 their direct trip cost) ranging from approximately \$32 per day for camping, to  
6 about \$175 per day for mountain biking.

7 To calculate the aggregate “consumer surplus” value of recreation in the study  
8 area, BLM multiplied this per-day value of recreation by the estimated number  
9 of visitor days associated with each activity type. Visitation estimates by activity  
10 are derived based on the BLM Recreation Management Information System  
11 (RMIS) database and the USFS National Visitor Use Monitoring program  
12 (NVUM) for the study area.

13 Accounting for the value per day and the number of days, the total non-market  
14 value of recreation on BLM and USFS lands in the study area was estimated to  
15 be about \$515 million per year (see Appendix A for details). Based on the  
16 quantity of recreational trips and the economic value of each type of activity, the  
17 largest annual non-market values are associated with hunting, camping, fishing,  
18 hiking, sightseeing, floatboating/ rafting/ canoeing, and pleasure driving. These  
19 categories omit downhill skiing, because there is little or no overlap between  
20 sage-grouse habitat and lands used for downhill skiing. The Environmental  
21 Consequences section (Chapter 4) discusses how recreational visits and total  
22 non-market value for recreation may change under the alternatives being  
23 considered.

#### 24 *Values associated with populations of sage-grouse*

25 The existence and perseverance of the Endangered Species Act and similar acts  
26 reflects the values held by the American public associated with preventing  
27 species from going extinct. Economists have long recognized that rare,  
28 threatened and endangered species have economic values beyond those  
29 associated with active “use” through viewing. This is supported by legal  
30 decisions and technical analysis (see Appendix A for details), as well as a number  
31 of conceptual and empirical publications that refine concepts and develop  
32 methods to measure these non-use or existence values.

33 The dominant method uses surveys to construct or simulate a market or  
34 referendum for protection of areas of habitat, or changes in populations of  
35 species. The survey asks the respondent to indicate whether they would pay for  
36 an increment of protection, and if so how much they would pay. Economists  
37 have developed increasingly sophisticated survey methods for non-use value  
38 over the last two decades to improve the accuracy of this method. Appendix A  
39 offers an in-depth discussion of this method of value estimation.

40 Original surveys to estimate non-use values are complex and time-consuming;  
41 rather than perform a new survey, BLM and USFS reviewed existing literature

1 to determine if there were existing non-use value studies for sage-grouse. No  
2 existing studies on valuation specific to the sage-grouse were found. However,  
3 there are several studies published in peer-reviewed scientific journals for bird  
4 species that BLM judged to have similar characteristics with sage-grouse,  
5 including being a candidate for listing as threatened or endangered and being a  
6 hunted species. These studies find average stated willingness to pay of between  
7 \$15 and \$58 per household per year in order to restore a self-sustaining  
8 population or prevent regional extinction (see Appendix A for details). These  
9 values represent a mix of use and non-use values, but the non-use components  
10 of value are likely to be the majority share, since the studies primarily address  
11 species that are not hunted. Since sage-grouse protection is a public good  
12 available to all households throughout the intermountain west, if similar per-  
13 household values apply to the species the aggregate regional existence value  
14 could be substantial.

15 *Values associated with grazing land*

16 Public land managed for livestock grazing provides both market values (e.g.,  
17 forage for livestock) and non-market values, including open space and western  
18 ranch scenery, which provide value to some residents and outside visitors, and  
19 may also provide some value to the non-using public (e.g., the cultural icon of  
20 the American cowboy). Many people who ranch for a living or who otherwise  
21 choose to live on ranches value the ranching lifestyle in excess of the income  
22 generated by the ranching operations. This could be seen as a non-market value  
23 associated with livestock grazing. On the other hand, some residents and  
24 visitors perceive non-market opportunity costs associated with livestock  
25 grazing. Although some scholars and policy makers have discussed non-market  
26 values associated with livestock grazing, the process for incorporating these  
27 values into analyses of net public benefits remains uncertain, and BLM and USFS  
28 did not attempt to quantify these values for the present study.

29 Furthermore, some of the lifestyle value of ranching is likely to be captured in  
30 markets, such as through the property values of ranches adjacent to public lands  
31 with historic leases or permits for grazing on public land. Economists typically  
32 use a method called the hedonic price method to estimate values associated  
33 with particular amenities; this method may be used to explain the factors that  
34 influence the observed sale prices of ranch land. **Appendix A** provides more  
35 information about this method, as well as additional information to address  
36 potential non-market values associated with grazing.

37 **Fiscal**

38 Most of Idaho's tax revenue comes from three sources: income, sales and use,  
39 and property taxes (U.S. Census Bureau, 2010d). The Idaho State Tax  
40 Commission collects income tax and sales and use tax, while property taxes  
41 fund local governments and are imposed and collected by the county where the  
42 property is located. Idaho imposes a sales and use tax of 6 percent, a corporate

1 net income tax of 7.6 percent, and an individual income tax rate that ranges  
 2 from 1.6 percent to 7.8 percent. In addition, Idaho imposes a severance tax  
 3 rate of two percent of the market value of oil and gas produced or sold in the  
 4 state. It also imposes a mine license tax of one percent of the value of ores  
 5 mined or extracted, which accounted for approximately \$2.5 million in tax  
 6 revenue in 2011 (Idaho State Tax Commission, 2011).

7 Idaho's counties receive most of their revenue from property taxes, charges for  
 8 local services and redistribution of State and Federal sources. In 2009/2010,  
 9 Idaho counties received approximately 25% of their revenues from property  
 10 taxes, 25% from charges and 40% from State government intergovernmental  
 11 transfers (U.S. Census Bureau, 2010e). Major sources of state funds received by  
 12 counties include state liquor revenues, highway user taxes and fees, sales taxes  
 13 and education funds and endowments (Idaho Association of Counties, 2011).  
 14 Public elementary and secondary schools received, in 2008-09, approximately  
 15 67% of their resources from State sources, 10% from Federal funds and 23%  
 16 from local funds, mostly property taxes (National Center for Education  
 17 Statistics, 2012).

18 The largest source of revenue in Montana is the individual income tax. The  
 19 second largest source is severance and other taxes (U.S. Census Bureau,  
 20 2010d), although most of the mineral production in Montana is outside the  
 21 Socioeconomic Study Area for this sub-region. Two-thirds of the severance and  
 22 other taxes category is made up of an oil and gas production tax, with the  
 23 remainder of the category being composed of mining taxes and other  
 24 miscellaneous taxes. While it is collected at the state level, about half of the oil  
 25 and gas tax is distributed to local governments and school districts. Montana  
 26 does not have a general sales tax, but selective sales taxes account for about  
 27 14% of state tax revenue (Montana Department of Revenue, 2010).

28 In Montana, local government and school district tax collections come almost  
 29 entirely from property taxes. Local jurisdictions also collect a coal gross  
 30 proceeds tax, a local severance tax that imposes a flat tax on the value of  
 31 production so that all mines pay the same rate (Montana Department of  
 32 Revenue, 2010).

33 The primary government revenues that are directly linked to BLM and USFS  
 34 lands are Payments in Lieu of Taxes (PILT), which are federal government  
 35 payments based on the presence of all federal lands (not just BLM lands) within  
 36 each county. Table 13 shows the PILT payments each county received in 2010.  
 37 The non-taxable status of federal lands is of interest to local governments,  
 38 which must provide public safety and other services to county residents. BLM  
 39 revenue-sharing programs provide resources to local governments in lieu of  
 40 property taxes because local governments cannot tax federally owned lands the  
 41 way they would if the land were privately owned.

PILT Payment in Lieu of Taxes

Includes payments received from BLM, USFS, Bureau of Reclamation, National Park Service, and Fish and Wildlife Service.

Other Federal payments to States, counties and public schools associated to the presence of Federal lands include Forest Service revenue transfers and Federal mineral royalties. Since 2008, the Forest Service pays 25% of its receipts to staets for use on roads and schools in the counties where national forests are located. The decline in the sale of timber from Federal lands over time has led to the decline in these payments. However, Secrue Rural Schools and Community Self-Determination Act of 2000 has attempted to limit this decline (Congressional Research Service, 2012). Idaho and Montana also receive Federal mineral royalties from mining activities on federal land. In Idaho, 90% of these receipts are distributed to the Public School Income Fund and the other 10% are distributed to the general fund of the counties where the revenue was generated. In Montana, 25% of Federal mineral royalties are distributed to counties (Headwaters Economics, 2011). Other revenues from Federal lands includes fees for grazing, recreation and rents of rights-of way.

BLM Expenditures and Employment

BLM offices provide a direct contribution to the economy of the local and surrounding area. BLM operations and management make direct contributions

### **Environmental Justice**

Environmental justice pertains to the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment means that no group of people, including racial, ethnic, or socioeconomic groups, should bear a disproportionate share of the adverse environmental consequences resulting

1 from industrial, municipal, and commercial operations or the execution of  
2 federal, state, local, and Tribal programs and policies (BLM, 2005a; USDA,  
3 1997). BLM and USFS incorporate environmental justice into its planning  
4 process, both as a consideration in the environmental effects analysis and by  
5 ensuring a meaningful role in the decision-making process for minority and low-  
6 income populations.

7 Executive Order 12898 requires federal agencies to “identify and address the  
8 disproportionately high and adverse human health or environmental effects of  
9 its programs, policies, and activities on minority populations and low-income  
10 populations.” The BLM Land Use Planning Handbook (BLM, 2005a) reiterates  
11 BLM’s commitment to environmental justice – both in providing meaningful  
12 opportunities for low-income, minority, and Tribal populations to participate in  
13 decision-making, and to identify and minimize any disproportionately high or  
14 adverse impacts on these populations. Similarly, the U.S. Department of  
15 Agriculture’s Departmental Regulation on Environmental Justice (USDA, 1997)  
16 provides direction to agencies for integrating environmental justice  
17 considerations into USDA programs and activities, including those of USFS.  
18 Specifically, the Departmental Regulation on Environmental Justice calls for the  
19 identification, prevention, and/or mitigation of disproportionately high and  
20 adverse human health or environmental effects of USDA programs and activities  
21 on minority and low-income populations and provision for the opportunity for  
22 minority and low-income populations to participate in planning, analysis, and  
23 decision making that affects their health or environment.

24 According to the Council on Environmental Quality (CEQ) Environmental  
25 Justice Guidance Under the National Environmental Policy Act (CEQ, 1997),  
26 “minority populations should be identified where either: (a) the minority  
27 population of the affected region exceeds 50 percent or (b) the minority  
28 population percentage of the affected region is meaningfully greater than the  
29 minority population percentage in the general population or other appropriate  
30 unit of geographic analysis.” The same document states that “In identifying low-  
31 income populations, agencies may consider as a community either a group of  
32 individuals living in geographic proximity to one another, or a set of individuals  
33 (such as migrant workers or Native Americans), where either type of group  
34 experiences common conditions of environmental exposure or effect.”

35 Additionally, the same guidance (CEQ, 1997) advises that “In order to  
36 determine whether a proposed action is likely to have disproportionately high  
37 and adverse human health or environmental effects on low-income populations,  
38 minority populations, or Indian tribes, agencies should identify a geographic  
39 scale, obtain demographic information on the potential impact area, and  
40 determine if there is a disproportionately high and adverse effect to these  
41 populations. Agencies may use demographic data available from the Bureau of  
42 the Census to identify the composition of the potentially affected population.

1 Geographic distribution by race, ethnicity, and income, as well as a delineation  
2 of tribal lands and resources, should be examined.”

3 Minority Populations

4 Table 15 summarizes the percentage of the population made up of ethnic  
5 minority groups in each county of the Socioeconomic Study Area and in the  
6 State of Idaho, the State of Montana, and the United States as a whole.

<sup>1</sup> Individuals who identify themselves as Hispanic or Latino might be of any race; the sum of the other percentages under the “Percent of Total Population” columns plus the “Hispanic or Latino” column therefore does not equal 100 percent, and the sum of the percentages for each racial and ethnic category does not equal the percentage of “total minorities”.

<sup>2</sup> The total minority population, for the purposes of this analysis, is the total population for the geographic unit analyzed minus the non-Latino /Hispanic white population.

Of the 27 Idaho counties in the Socioeconomic Study Area, 14 have a higher minority population than Idaho as a whole, while none of the four Montana counties in the Socioeconomic Study Area have a higher minority population than Montana as a whole. The percentage of minorities among counties ranges from a low of 4.6 percent in Madison County, Montana, to a high of 42.9 percent in Clark County, Idaho. Several Idaho counties have a Hispanic or Latino population greater than 25 percent, with the highest being Clark County (41 percent). Additionally, Montana as a whole has a high percentage of Alaska Native or American Indian residents (6.3 percent), though none of the Montana counties included in the study area have higher than two percent of its population in this minority group.

#### Low-income Populations

Table 16 summarizes the percentage of the population below the poverty line in each county of the Socioeconomic Study Area and in Montana, Idaho, and the United States as a whole. Following the Office of Management and Budget’s Directive 14, the Census Bureau uses a set of money income thresholds that vary by family size and composition to detect what part of the population is considered to be in poverty (U.S. Census Bureau, 2012a).

Source: U. S. Census Bureau, 2010c.

Of the 27 Idaho counties in the Socioeconomic Study Area, 14 have a higher percentage of residents below the poverty line than Idaho overall (13.6 percent), and two of the four Montana counties have a higher percentage of residents below the poverty line than Montana as a whole (14.5 percent). Both Idaho and Montana have a higher percentage of residents above the poverty line than the United States as a whole (13.8 percent). The percentage of residents

1 below the poverty line range from a low of 8.4 percent in Caribou County,  
2 Idaho to a high of 32.2 percent in Madison County, Idaho.

3 Tribal Populations

4  
5 Five Indian reservations in the State of Idaho are home to federally recognized  
6 tribes. These reservations comprise almost two million acres in trust. The  
7 Shoshone-Bannock Tribe of the Fort Hall Indian Reservation (Bannock, Bingham,  
8 Caribou, and Power Counties) and Shoshone-Paiute Tribe of the Duck Valley  
9 Indian Reservation (Owyhee County) are located within the Socioeconomic  
10 Study Area. Other tribes outside the Socioeconomic Study Area include Coeur  
11 d'Alene in Benewah and Kootenai Counties; Kootenai in Boundary County; and  
12 Nez Perce in Clearwater, Idaho, Latah, Lewis, and Nez Perce Counties  
13 (Rodríguez, 2011).

14 Several major tribes live in Montana: the Blackfeet nation, the Confederated  
15 Salish, the Pend d'Oreille, the Kootenai, the Assiniboine, the Sioux, the  
16 Northern Cheyenne, the Crow Nation, the Gros Ventre, and the Little Shell  
17 Chippewa (Montana Office of Indian Affairs, 2011). However, none of these  
18 tribes' reservations are located in or near the Socioeconomic Study Area.

## Soil Resources

Many resources and resource uses, including livestock grazing, wildlife habitat, riparian habitat, special status species, fisheries, recreation, water quality and forestry, depend on suitable soils. Consequently, soil attributes and conditions are important to BLM management decisions.

Soils are defined by the processes that form them. Through time, these processes form unique soil types and influence what plants may grow upon them. Soil surveys indicate that climate and topography are the primary influences on soil formation (NRCS 2000). Soil development processes, such as rock weathering, decomposition of plant materials, accumulation of organic matter, and nutrient cycling, are controlled largely by climate. Soil moisture and temperature strongly affect the rates of addition, removal, translocation, and transformation of material within the soil. Topography influences site conditions, such as precipitation amounts and effectiveness, drainage, runoff, erosion potential, and temperature.

Soils play an integral part in vegetation community development. Plants use soil as an anchor, a means to provide water for growth, and a storehouse for the nutrients needed for growth. Plant communities are most noticeably influenced where soil texture and thickness of soil horizons change, depth to restrictive layers including abrupt soil horizon boundaries exist, and by soil drainage, moisture holding capacity, or depth to water table. Native plant communities require management considerations that include the ability of the soil to produce a healthy ecosystem over the long term. Reducing the risk of erosion from water and air processes, limiting compaction from traffic source or grazing, and allowing the water to infiltrate at a normal rate for the given soil texture will allow vegetative communities to thrive and further protects the soil resources.

The Natural Resources Conservation Service (NRCS) provides soil mapping for individual counties across the United States. Soil information and mapping from the NRCS are provided below under existing conditions to describe soil resources.

## Indicators

Indicators vary by resource and include measureable factors that are used to describe resource conditions. The indicators used to describe current conditions are the same indicators that are used to forecast the potential effects that could result from implementation of any of the proposed alternatives described in Chapter 2. The following indicators for soil resources will be used to characterize soil resources and determine the relative effects on soil resources from management actions proposed by the different alternatives:

- Declining soil surface health, with soils either unable to support vegetation and rusts or not up to the potential for a particular ecological site (e.g., vegetation type, diversity, density, and vigor); and
- The inability to meet Standards for Public Land Health.

Land uses strive to conform to Standards for Public Land Health, which describe conditions needed to sustain public land health and relate to all uses of the public lands.

## Existing Conditions

### Conditions of the Planning area

#### Soil Productivity

Soil productivity within the planning area varies widely due to the diversity of soils and site characteristics, specifically differences in elevation and slope gradient. The soil types in the planning area occur from \_\_\_\_\_ feet above mean sea level in the area of \_\_\_\_ to \_\_\_\_ feet above mean sea level in the higher elevations. The planning area landscape varies greatly from broad valleys to mountains.

The average annual precipitation and temperature in the project area vary greatly by elevation and aspect. Some of the most productive soils are found in well drained valley bottoms, toe-slopes, benches, and broad ridge tops. On uplands where rainfall is moderate to low, medium textured soils may produce favorable conditions, depending on land uses such as livestock grazing. Soils that feature shallow clay pans, hardpans, or salts pose substantial constraints to land use and management

Management practices affect the ability of soils to maintain productivity by influencing disturbances such as displacement, compaction, erosion, and alteration of organic matter and soil organism levels. When soil degradation occurs in semiarid, high desert regions, natural processes are slow to return site productivity. Prevention of soil degradation is far more cost-effective and time effective than remediation or waiting for natural processes. Management practices, such as proper stocking rates for livestock, rotation of grazing, periodic rest from grazing, improved design, construction and maintenance of roads, selective logging, rehabilitation of unneeded surface disturbance, restricting vehicles to roads and trails, rehabilitating mined areas, and control of concentrated recreational activities, have reduced erosion effects and improved soil conditions.

#### Soil Erosion

Erosion is a continuing natural process that can be accelerated by human disturbances. Factors that influence soil erosion include soil texture, structure, length and percent of slope, vegetative cover, and rainfall or wind intensity. Soils most susceptible to erosion by wind or water are typified by bare or sparse vegetative cover, non-cohesive soil particles with slow infiltration rates, and moderate to steep slopes. Wind erosion processes are less affected by slope angle but are highly influenced by wind intensity.

The semi-arid planning area has between \_\_\_\_ and \_\_\_\_ percent natural plant community ground cover, allowing the soils to erode naturally in wind and during infrequent rain events. In addition, management actions affect the rate at which soil erodes. Activities that remove vegetative cover increase the erosion rate. Some soils are particularly vulnerable to soil erosion.

The potential for soil erosion increases with increasing slope. Approximately \_\_\_\_ acres exceed 40 percent slope within the planning area. Steep slopes are concentrated in the areas of \_\_\_\_ within the planning area.

NRCS soil map unit descriptions rate soils in the planning area according to their susceptibility to water and wind erosion. Wind erosion is particularly a hazard when surface litter and vegetation are removed by fire or other disturbances. Soils in the planning area were screened based on several relevant characteristics that indicate potentially fragile soils or high erosion hazards. These characteristics include:

- Soils rated as highly or severely erodible by wind or water, as described in NRCS soil survey reports;
- Landslide areas as identified in NRCS soil survey reports; and
- Soils on slopes greater than 35 percent

Within the planning area, \_\_\_ acres were mapped as fragile soils. Most fragile soils occur in the areas of \_\_\_ within the planning area.

### Soil Types

When making land management decisions based on soil related hazards or limitations, the BLM evaluates soil surveys available from the NRCS. Soils mapped according to the boundaries of major land resource areas, which are geographically associated land resource units that share common characteristics related to physiography, geology, climate, water resources, soils, biological resources, and land uses. Each soil survey describes the specific properties of soils in the area surveyed and shows the location of each kind of soil on detailed maps. BLM evaluates soil map units to make management decisions that would likely affect soils. Each soil survey applicable to the planning area describes soil map units by the individual soil or soils that make up the unit. These descriptions indicate the limitations and hazards inherent in each unit. Descriptions include soil depth, range of elevation, origin, climate, physical properties, runoff capabilities, erosion hazard, associated native vegetation, wildlife habitat use, and capability for community development and other uses.

Third order soil surveys, provided by the NRCS, cover most of the planning area. The NRCS maps over \_\_\_ soil map units in the planning area, making summarization complex.

Soil can be classified in many ways according to a whole host of parameters. For the generalization of soils in the planning area, the taxonomy of soil order is a convenient starting place. Most of the soils in the planning area are part of the largest soil order, Mollisols. This order encompasses approximately \_\_\_ percent of the Greater Sage-Grouse core habitat acres. The Aridisols correspond to \_\_\_ and the Alfisols \_\_\_ percent of the area. The remaining areas are composed of similar young developmental soils in the Inceptisol, Entisol, and Andisol orders with a very small amount of Histisols and Vertisols that have particular properties that may be of importance.

Soil properties can provide information why certain plants may grow in one area and not another, or why erosion occurs by wind and not water. The NRCS provides a suite of risk rating, interpretations, and basic soil data that describes soils resources. The soil texture for most soils across the planning area is a loam as composed of the representative percent of sand, silt and clay. Some greater or lesser amounts of these percentages produce clayey loams and silty loams for the most part. The soils have very low amounts of organic matter (2%), low available moisture contents in the top 10 inches (3.3 inches) and are conserved well drained. The risk to

erosion from water is slight, except in those very steep canyons and exposed bedrock ridges that have a severe to very severe rating. The overall majority of the planning area is considered to be of slight risk for \_\_\_\_\_. The soils are prone to degradation when soil is removed in excess of the ability to rebuild it. In this area of the state, the amount of loss can be significant with wind exposure or increased erosion from water. Only 1 to 2 tons of soil per acre per year needs to be removed in approximately half of the planning area to have a loss of long term productivity. A quarter of the area has the highest level of soil that can be removed (5 tons/acre/year) with the remaining quarter in the middle groups.

When it comes to infiltration of water into the soil surfaces, these soils will take in water very well. The silty and clay nature of the soils cause them to percolate water more slowly than a sandy soil or rocky soil would. But for most of the planning area, percolation rates do not cause standing water to form. The majority of the soils convey water at rates greater than 1 inch per hour. Of particular note are those soils in the low wetland areas in the northwest part of the planning area. They allow infiltration to equal or exceed 2 inches per hour. This is correlated to those same soils that have the highest wind erosion rates across the planning area. Others within the planning area have a very low rate of loss per acre and, therefore, are at low risk to wind erosion.

Hydric (wet) soils, unique biological soil crusts, and prime agriculture land are key soil resources in the planning area.

**Hydric Soils.** Hydric soils constitute only a small portion of the planning area. Hydric soils are associated with riparian areas and wetlands. Riparian-wetland soils are found throughout the planning area along water courses, near springs, seeps, playas, and adjacent to reservoirs. Because of the presence of water, riparian-wetland soils have properties that differ from upland areas. For example, most upland soils are derived from in-place weathering processes and relatively little soil is derived from offsite sources. In contrast, riparian-wetland soils are constantly changing because of the influx of new material being deposited by different storm events and overland flow. As a result, great variability in soil types can occur in short distances. An inventory of these soils has not been completed. Due to the dynamic nature of these soils, they require intensive monitoring and management.

**Biologic Soil Crusts.** Biologic soil crusts (BSC) are made up of tiny living plants and bacteria that grow together on the soil surface. They help keep the soil from washing or blowing away, fix nitrogen from the atmosphere into the soil, help keep out weeds, and promote the health of plant communities. In areas where BSC have been lost, native vascular plants have been replaced by invasive species such as cheat grass or medusa head.

Based on research throughout the west, parameters for the ecology and management of biological soil crusts have been developed by the Department of the Interior. Factors found affecting presence, density, cover, and species diversity of macrobiotic crusts include elevation, soils, and topography, disturbances, timing of precipitation, vascular plant community, ecological gradients and microhabitats.

## Trends

Soil resources change slowly unless catastrophic or larger scale disturbance events such as landslides, floods, volcanoes, or wildfires occur. Then, erosion or deposition would change the ground cover at one point or many. Thus, the degree of change in the planning area would be considered low or insignificant, with the direction of change being the most likely to occur naturally over time. There have been larger wildfire events and to some degree restoration activities that have altered the vegetation communities where juniper has been invading sagebrush communities.

The overall trend for soil resources is to maintain or improve the ability of the soil to support vegetation and allow water and nutrients to be cycled by either macro or microorganisms, all of which promote and improve the health of the land. Degradation by excessive grazing, erosion or land developments will cause a reduction in soil function as one or perhaps many of the soil properties are changed thereby affecting the functions necessary for healthy soils. In the planning area, impacts on soil resources have resulted from energy development, grazing recreation, natural processes, and other activities. The potential for maintaining or restoring these communities and conserving the soil resource depends on the specific soil types and how resource programs are managed.

## Visual Resources

Visual quality of western landscapes is an increasingly sensitive issue. Impacts to visual resources are identified as a significant issue to address in Resource Management Plans, Forest Plans and major EISs such as the renewable energy and transmission programmatic environmental impact statements (PEIS). The general public's increasing awareness of the vertical scale, footprint, character and visible prominence associated with utility scale renewable energy and transmission line development has increasing the need for Visual Resource Management (VRM).

### Bureau of Land Management

BLM manages scenic values using the visual resource management (VRM) program. VRM policy was initially launched in 1976 in response to both NEPA requirements placed on Federal land management, and FLPMA requirements for scenery resource inventory and management. The BLM developed the current VRM policy manual (M-8400) and handbooks (H-8410-1, H-8431-1) in the mid-1980's to guide the Field Offices through an objective and systematic program for managing scenery resources.

Visual resource management requires that BLM Field Offices complete a visual resource inventory of the lands under their management control. The visual resource inventory is a systematic process for determining the visual values on the public lands. The inventory process has three parts: scenic quality evaluation, sensitivity level analysis and delineation of distance zones. Based on the combinations of the three, BLM lands can then be categorized as Class I (most valued and highest quality of scenery) down to Class IV (areas of low scenic quality and sensitivity at most or all distance zones). These inventory classes represent the existing visual resources.

VRM provides a way to inventory and classify visual resources, describe characteristic landscapes, determine contrasts from proposed actions, and potential mitigation from impacts to visual resources.

BLM Handbook 8410 describes the three basic landscape characteristics used to indicate visual resources in VRM: 1) scenic quality; 2) sensitivity levels; and 3) distance zones. Scenic quality is a measure of the visual appeal of a tract of land. Areas can be sub-divided into Scenic Quality Rating Units (SQRU) of similar visual character on the basis of like physiographic characteristics, similar visual patterns, texture, color, variety, etc.; and areas which have similar impacts from man-made modifications. The size of the SQRU may vary from several thousand acres to 100 or less, depending on landscape feature similarities, and the desired inventory detail. Seven key factors determine the scenic quality of a unit: landform, vegetation, water, color, adjacent scenery, scarcity, and cultural modifications. Resource specialists consider these factors when ranking units for scenic quality (A = high, B = medium, C = low).

Visual sensitivity is a measure of public concern for scenic quality. Public lands are assigned high, medium, or low sensitivity levels by analyzing various indicators of public concern, such as: type of user, amount of use, public interest, adjacent land uses, and special areas.

Sensitivity level rankings are not available for the Planning Area.

Landscapes can be divided into three distance zones based on relative visibility from travel routes or observation points. They are foreground-middleground, background, and seldom seen. The foreground-middleground zone includes areas seen from highways, rivers, or other viewing locations that are less than five miles away. The background zone is generally between five and 15 miles away. The seldom-seen zone includes areas usually hidden from view.

During the resource management planning process, BLM determines how the visual landscape will be managed in the future. The VRM decisions that are made in the planning process result in areas being assigned a VRM management class. VRM management classes determine how much change will be allowed in the landscape. VRM Class I areas are managed to preserve the existing character of the landscape and allow for limited management activity. Class II allows for low levels of landscape change that do not attract attention of the casual observer. Class III allows for moderate changes to the landscape that may attract attention but are not dominant and Class IV areas allow for high levels of landscape change.

The BLM uses a VRM contrast rating system that addresses form, line, color and texture of the landscape to determine if proposed projects are in compliance with the designated visual resource management class.

These management classes are separate from the visual resource inventory classes and guide management irrespective of the underlying visual resource i.e. areas that have an inventory class II could be designated and managed as a VRM management class IV to allow for major changes in the landscape.

In the past, especially in older management framework plans, BLM Field Offices would often adopt the VRM inventory classes as the management class. In some plans, BLM did not make any decisions regarding the VRM management classes. In such cases, the VRM inventory class has generally been used as the management class. A majority of the BLM managed lands within the planning area do not have a current visual resource inventory.

BLM Visual Resource Management Class Acres  
(approximate for offices with designated VRM classes)

VRM Class	Class I	Class II	Class III	Class IV
Acres	510,924	2,058,432	3,983,572	2,052,936

#### US Forest Service Visual Management System

Forest Service Manual 2380.3 requires the agency to “inventory, evaluate, manage, and, where necessary, restore scenery as a fully integrated part of the ecosystems of National Forest System lands through the land and resource management and planning process. Scenery must be treated equally with other resources. The US Forest Service (Forest Service) developed a visual management system to provide a mechanism for inventory and analysis of landscape resources and the effects of land management activities on those resources.

The Forest Service established the VMS in 1974 to inventory, evaluate, and manage scenic resources. The VMS is described in Agriculture Handbook No. 462, National Forest Landscape Management (USFS 1974). Using an established physiographic character type as a frame of reference, the VMS determines the inherent scenic quality based on the different degrees of landscape variety within an area.

Inherent scenic quality is a measure of the natural landscape's scenic beauty based on attributes, such as landform, vegetation, water features, and rock formations. The basic assumption of the VMS is that all landscapes have some inherent value, but those with the most variety or diversity have the greatest potential for "high scenic value." Three variety classes, designated "A", "B," and "C", represent inherent scenic quality.

Sensitivity levels are identified in the VMS and are defined as the measure of people's concern for the scenic quality of the landscape. Basically, all viewed landscape is rated for a level of sensitivity. Sensitivity levels are overlaid with distance zones to identify all the viewed and unseen landscape within a given area. The VMS defines distance zones—that is, the distance from which a landscape is viewed—as foreground, middleground, and background. Distance zones are important in evaluating how change is perceived in the landscape because the closer the features in the landscape are to the viewer, the more pronounced they appear and the more detail is observed.

Visual quality objectives (VQOs) are determined in the VMS by combining the sensitivity levels and scenic quality. VQOs are assigned to the landscape to describe the degree of acceptable alteration of the natural landscape. The VQO classifications are Preservation, Retention, Partial Retention, Modification, and Maximum Modification. Preservation allows for ecological changes only, while Maximum Modification allows for landscape changes that may dominate the natural landscape character.

#### Scenery Management System

The VMS process has been updated as the Scenery Management System (SMS), which is being incorporated into respective Forest Management Plans. SMS is described in Landscape Aesthetics: A Handbook for Scenery Management (USFS 1995). Adoption of the SMS is to occur as each National Forest revises its land management plan and RMP. For National Forests not currently undergoing the forest-plan revision process, or for those requiring extensive time for revision, application of the SMS will occur at the subforest or Project level.

In general, the SMS differs from the VMS in that it is integrated with ecosystem management and addresses landscape character, constituent preferences, scenic integrity, and landscape visibility as key aesthetic considerations. Landscape character describes the visual patterns of form, line, color, texture, dominance, scale, and diversity of elements in the landscape and the cultural attributes that make the landscape identifiable and give it a "sense of place." Constituent preferences convey the aesthetic experience of forest visitors, communities, and tourists and the significance of scenic quality to these user groups.

Scenic management criteria are described below.

The SMS entails identifying the landscape character, visual sensitivity, and scenic integrity. The SMS provides an overall framework for the orderly inventory, analysis, and management of

scenery. It is a tool for integrating the benefits, values, desires, and preferences regarding aesthetics and scenery for all levels of land management planning. The SMS also considers Concern Levels, which are a categorization of the importance of scenic resources to forest visitors.

Three concepts of the SMS are of key importance: (1) Scenic Attractiveness, (2) Landscape Character, and (3) Scenic Integrity. These concepts and landscape character are defined below:

Scenic Attractiveness is the primary indicator of the scenic importance of a landscape based on human perceptions of the intrinsic beauty of landforms, rock outcrops and forms, waterforms, vegetation patterns, and cultural features. It reflects varying visual perception attributes of variety, unity, vividness, intactness, coherence, uniqueness, harmony, balance, and pattern. The frame of reference for scenic attractiveness (generally at the section scale) is landscape character. Three levels of scenic attractiveness are identified during the scenery inventory process: (A) Distinctive, (B) Common or Typical, and (C) Undistinguished (Forest Service Manual [FSM] 2380 – Landscape Management).

Landscape Character is a combination of physical, biological, and cultural images that gives an area its visual and cultural identity and helps to define a "sense of place." Landscape character provides a frame of reference from which to determine scenic attractiveness and to measure scenic integrity (FSM 2380 – Landscape Management).

Scenic Integrity Objectives, referred to as SIOs, define the degrees of deviation from the landscape character that occur at any given time by using the process described in Agriculture Handbook 701, Landscape Aesthetics: A Handbook for Scenery Management (FSM 2380 – Landscape Management). When discussing SIOs, the degree of alteration is measured in terms of visual contrast with the surrounding natural landscape. The objectives of each SIO classification are included below:

- Very High – Management activities, except for very low visual-impact recreation facilities, are prohibited. Allows for ecological changes only. The existing landscape character and sense of place is expressed at the highest possible level.
- High – Management activities are not visually evident to the casual observer. The landscape character appears intact. Deviations may be present but must repeat the form, line, color, texture, and pattern common to the landscape character so completely and at such scale that they are not evident. Changes in the qualities of size, amount, intensity, direction, pattern, etc., should not be evident.
- Moderate – Management activities remain visually subordinate to the characteristic landscape being viewed. Activities may repeat form, line, color, or texture common to the characteristic landscape but may not change in their qualities of size, amount, intensity, direction, pattern, etc.

- Low – Management activities begin to visually dominate the original characteristic landscape. However, activities of vegetative and landform alteration must borrow from naturally established form, line, color, or texture so completely and at such a scale that its visual characteristics are those of natural occurrences within the surrounding area or character type. Structures must remain visually subordinate to the proposed composition.

- Very Low – Management activities of vegetative and landform alterations may dominate the characteristic landscape. While alterations may not borrow from attributes such as size, shape, edge effect, and pattern of natural openings, vegetative type changes, or architectural styles within or outside the landscape being viewed, they must be shaped and blended with the natural terrain so that elements such as unnatural edges, roads, landings, and structures do not dominate the composition.

Forest Service Acres of Scenic Management

Visual Management Classes

For both BLM and USFS, where management decisions have been made to preserve and protect the visual characteristics of the landscape, these areas are likely to provide better habitat and protection for sage grouse.

## Water Resources

Water on public lands is regulated by the Clean Water Act, Safe Drinking Water Act, Public Land Health Standards, and other laws, regulations, and policy guidance at the federal, state, and local levels. Water resources in Idaho are regulated by the US Environmental Protection Agency (EPA) and the Idaho Department of Environmental Quality (DEQ).

The Idaho DEQ has granted designated management agency status to the BLM. As a designated management agency, the BLM must: (1) implement and enforce natural resource management programs for the protection of water quality on Federal lands under its jurisdiction; (2) protect and maintain water quality where it meets or exceeds applicable state and Tribal water quality standards; (3) monitor activities to assure that they meet standards and report the results to the State of Idaho; and (4) meet periodically to recertify water quality best management practices (BMPs). BMPs include methods, measures, or practices to prevent or reduce water pollution, including but not limited to structural and nonstructural controls, operations, and maintenance procedures. BMPs are applied as needed to projects.

## Indicators

Indicators vary by resource and include measurable factors that are used to describe resource conditions. The indicators used to describe current conditions are the same indicators that are used to forecast the potential effects that could result from implementation of any of the proposed alternatives described in Chapter 2. The following indicators for water resources will be used to characterize water resources and determine the relative effects on water resources from management actions proposed by the different alternatives:

- Alter the physical characteristics of water sources that influence Greater Sage-Grouse to a point in which these resources are not properly functioning or sustainable.
- Meet state and federal water quality standards for surface waters.
- Impair water quality to a degree that could affect the survival of Greater Sage-Grouse or aquatic/riparian species.
- Alter water resources habitat for mosquitoes

## Existing Conditions

The discussion of existing conditions includes a description of water resources for the planning area, regardless of land ownership. Where appropriate, it also includes a more detailed description of water resources for just BLM administered lands within the planning area. For this, the description is limited to describing water resources associated with Great Sage-Grouse and their habitat. Wetlands and livestock water developments are important sources of water that can influence Greater-Sage Grouse and their habitat.

## Conditions of the Planning Area

The BLM is the overwhelming land manager in the planning area. The Forest Service, US Fish and Wildlife Service, Bureau of Indian Affairs, and State of Idaho all have lands within the planning area that also contain a suite of water resources.

The average yearly precipitation for this area ranges from \_\_\_ to \_\_\_ inches. Within the planning area, the major water features, are streams, lakes, wetlands, playas, and dry lakes. Streams can be ephemeral, intermittent, or perennial. Ephemeral streams do not flow during an average water year, but do flow in response to large precipitation events. Intermittent streams flow during spring runoff for an average water year, but generally dry up later in the summer. Perennial streams contain some water all year for an average water year. Lakes can be permanent or temporary. Wetlands and floodplains vary in extent and depth throughout the year. Permanent waters can also be in the form of ponds and reservoirs developed for human or livestock consumption.

Stream channels and floodplains are important because their shape and condition affect how rapidly water flows through a river system, how much water is stored within the basins, the quality of the water, and how much erosion occurs. These functions, in turn, affect fish and wildlife habitat, agriculture, recreation, and the susceptibility of local communities and landowners to floods.

As early land management reduced vegetation in the watershed, overland flow of water increased and stream channels deepened to match the increased supply of water and sediment. Major flood events in the late 1800s were the likely immediate cause of the deepening channels. Channel incisions eventually lead to bank failures and subsequent channel widening. As channel widening and bank failures continued, new low flow channels began to form in the debris from bank failure. Many of the stream channels in the planning area were in the process of this initial buildup in the 1980s. The result of this process is that new channels are usually lower than pre-disturbance channels, and the old floodplain now functions primarily as a terrace. Some terraces may be the result of climatic variations and associated changes in flow and sediment supply. The final stage of channel evolution results in a new bankfull channel and active floodplain at a new, lower elevation. Many stream channels in the planning area have new, lower elevation channels and floodplains.

#### Surface Water

The United States is divided and sub-divided into successively smaller hydrologic units called regions, sub-regions, accounting units (basins), and cataloging units (sub-basins). Each hydrologic unit is identified by a unique hydrologic unit code (HUC) consisting of two to eight digits. The fourth level of classification (sub-basin) is represented by an 8 digit HUC.

Sub-basin Name	8 digit HUC	Sub-basin Size (acres)	Sub-basin size within planning area (acres)	BLM administered lands in sub-basin within planning area (acres)	Length of streams in sub-basin within planning area (miles)	Length of streams crossing BLM lands in sub-basin within planning area (miles)

--	--	--	--	--	--	--

The historic scarcity of stream flow in the planning area has led to increased flow regulation by the state of Idaho. Projects for irrigation, livestock, human use, and flood control have significantly altered natural flow regimes. This has changed habitat conditions, channel stability and timing of sediment and organic material transport. Stream flow has been altered by management activities such as water impoundments, water withdrawals, road construction, vegetation manipulation, grazing, fire suppression, and timber harvesting.

Most surface runoff in the planning area is from snowmelt or rainfall producing peak discharges in the spring and early summer. Many of the streams in the lower elevation semi-arid areas are either intermittent, with segments of perennial flow near springs, or ephemeral, with flow only during spring runoff and intense summer storms.

Water developments are also influential sources of water for Greater Sage Grouse. Water developments can function for multiple uses. They provide additional and alternative sources of water for wildlife and livestock, and can decrease use of riparian areas. Within the planning area, the BLM maintains \_\_\_ water developments, \_\_\_ of which are for Greater Sage Grouse.

#### Riparian Areas and Wetlands

Riparian areas are ecosystems that occur along rivers, streams or water bodies. These areas exhibit vegetation or physical characteristics reflective of a permanent surface or subsurface water influence. Typical riparian areas are land along, adjacent to, or contiguous with perennially and intermittently flowing rivers, streams, and shores of lakes and reservoirs with stable water levels. Excluded are such sites as ephemeral streams, or washes that do not exhibit vegetation dependent on free water in the soil. Wetlands are areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support and which under normal circumstances do support a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands include marshes, swamps, lake shores, lakeshores, sloughs, bogs, wet meadows, and riparian areas. Even though riparian and wetlands areas occupy only a small percentage of the planning area, these areas provide a wide range of functions critical to many different wildlife species, improve water quality, provide scenery, and recreational opportunities.

The BLM uses proper functioning condition (PFC) assessments for evaluating riparian-wetland areas and uses it to supplement existing stream channel and riparian area evaluations and assessments. Each riparian-wetland has to be judged against its capability and potential. The capability and potential of natural riparian-wetland areas are characterized by the interaction of hydrology, vegetation, and erosion/deposition. PFC is defined separately for lotic (moving water systems, such as rivers, streams, and spring and lentic (standing water systems, such as lakes, ponds, seeps, and wet meadows). If a riparian or wetland area is not in PFC, it is placed into one of three other categories; functional at risk, non-functional, or unknown.

The majority of BLM stream channels and floodplains within the planning area are not meeting the BLM standard of PFC. However relatively few stream channels are non-functioning. More

intermittent stream channels are in non-functioning condition than perennial streams but they also have more miles of stream at potential and PFC.

## Water Quality

Water quality as defined by the CWA, includes all the physical, biological, and chemical characteristics which affect existing and designated beneficial uses. The state of Idaho is required to identify which beneficial uses a water body currently supports or could support in the future. Water quality standards are established to protect the beneficial uses of the State's waters. Beneficial uses in planning area are public and private domestic water supplies, industrial water supply, irrigation, livestock watering, fish and aquatic life, and recreation.

The State of Idaho is required by section 303(d) of the CWA to identify waters which are water quality impaired because of failing to meet their designated beneficial uses. Section 303(d) requires that each state develop a list of water bodies that fail to meet water quality standards and delineate stream segments and listing criteria for all streams. The 303(d) list of impaired waters is updated biannually, and the State is required to develop a total maximum daily load allocation for each pollutant of concern.

Water quality is evaluated based on the ability of a water body to support beneficial uses of the water. Generally, key water qualities are those that support native fish and wildlife and support human uses such as agriculture, recreation, and domestic water supply.

The major water quality concern for streams in the planning area has been water temperature. These water temperature concerns correlate to the beneficial use of fish spawning and rearing habitat. Conditions that affect stream temperature can be summarized as amount of near stream vegetation, channel shape, and hydrology. Many of these conditions are interrelated and many vary considerably across the landscape. For example, channel width measurements can change greatly over even small distances along a stream. Some conditions vary daily and or seasonally. Stream orientation from a north-south to an east-west can change solar heating considerably when stream width and vegetation type remain the same.

Removal of riparian vegetation and the shade it provides contributes to elevated stream temperatures. Channel widening can similarly increase solar loading. The principal source of heat energy delivered to the water column is solar energy striking the stream surface directly. Exposure to solar radiation can cause an increase in stream temperature. The ability of riparian vegetation to shade the stream throughout the day depends on aspect and vegetation height, width, density, and position relative to the stream, as well as aspect the stream flows.

Causes of stream degradation are removal of riparian vegetation and destabilization of streambanks. The land use most commonly associated with these problems in the planning area is livestock grazing. Other land uses associated with degraded streams include roads, trails, water withdraw, reservoir storage and release, altered physical characteristics of the stream and wetlands alteration.

## Groundwater

Groundwater is used for irrigation, domestic use, and livestock use. The quality of the groundwater is a function of the chemical makeup of the underground formation containing the water. Most of the planning area contains good quality water but the water is usually hard and contains moderate amounts of dissolved minerals.

The BLM maintains \_\_\_ potable water wells in the planning area. These wells are monitored to ensure the State of Idaho requirements for public water systems are met.

Springs and seeps occur in areas where water from aquifers reaches the surface. Many springs begin in stream channels others flow into small ponds or marshy areas that drain into channels. Some springs and seep area form their own channels. That reach flowing streams, but other springs lose their surface expression and recharge alluvial fill material or permeable stratum.

Springs and seeps are important to aquatic habitats because of the perennial base flow they provide to a stream. The outflow from springs in summer usually helps to maintain lower water temperatures. In winter, especially in small streams, base flow helps to maintain an aquatic habitat in an otherwise frozen environment.

#### Water Quantity

Water balance across the United States is approximately 30% runoff and 70% evaporation. This may be different across the planning area due to higher temperatures and lower relative humidity in some areas.

There are numerous gauging stations within the planning area and the highest volumes of water are produced in \_\_\_\_\_. The peak flows are connected with the spring runoff and snow melt with a decrease to near base flow during the month of July. Stream flow is measured in cubic feet per second (cfs) or amount of flow required to pass one cubic foot of water in one second. The average annual flow across the planning area is \_\_\_\_\_. Seasons and years of low water yield are particularly crucial periods for most of the planning area's beneficial uses.

The annual flow patterns may have changed since the 19<sup>th</sup> century. Historical descriptions indicate that streams were relatively stable with good summer streamflow and good water quality and heavy riparian cover. Stream banks were covered with dense growths of aspen, poplar, and willow; cottonwood galleries were thick and wide; and beaver were abundant. Now peak flows are greater and late season flows are diminished. This may be the normal condition of larger flowing streams in the planning area. It is suspected that these effects are due to reduced rates of soil infiltration, reduced capacity for groundwater/riparian storage and loss of in channel storage in beaver ponds.

#### Trends

Demands on water resources have increased over the past few decades. Although most early water rights were established for irrigation and mining, today's demand includes municipal water supplies, commercial and industrial supplies, and maintenance of adequate streamflow for fish, recreation, and water quality.

The availability of water in much of the planning area is limited and may hamper additional developments that depend on water. Future water development for wildlife, recreation, and livestock would require a State of Idaho water right before project implementation could occur.

## Wild and Scenic Rivers

The National Wild and Scenic Rivers System was created by Congress in 1968 (Public Law 90-542; 16 U.S.C. 1271 et seq.) to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The Act is notable for safeguarding the special character of these rivers, while also recognizing the potential for their appropriate use and development. It encourages river management that crosses political boundaries and promotes public participation in developing goals for river protection.

*It is hereby declared to be the policy of the United States that certain selected rivers of the Nation which, with their immediate environments, possess outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historic, cultural or other similar values, shall be preserved in free-flowing condition, and that they and their immediate environments shall be protected for the benefit and enjoyment of present and future generations. The Congress declares that the established national policy of dams and other construction at appropriate sections of the rivers of the United States needs to be complemented by a policy that would preserve other selected rivers or sections thereof in their free-flowing condition to protect the water quality of such rivers and to fulfill other vital national conservation purposes. (Wild & Scenic Rivers Act, October 2, 1968)*

Rivers may be designated by Congress or, if certain requirements are met, the Secretary of the Interior. Each river is administered by either a federal or state agency. Designated segments need not include the entire river and may include tributaries. For federally administered rivers, the designated boundaries generally average one-quarter mile on either bank in the lower 48 states and one-half mile on rivers outside national parks in Alaska in order to protect river-related values.

### River Classification

Rivers are classified as *wild*, *scenic*, or *recreational*.

**Wild River Areas** – Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.

**Scenic River Areas** – Those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.

**Recreational River Areas** – Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Regardless of classification, each river in the National System is administered with the goal of protecting and enhancing the values that caused it to be designated. Designation neither prohibits development nor gives the federal government control over private property. Recreation, agricultural practices, residential development, and other uses may continue. Protection of the river is provided through voluntary stewardship by landowners and river users and through

regulation and programs of federal, state, local, or tribal governments. In most cases not all land within boundaries is, or will be, publicly owned, and the Act limits how much land the federal government is allowed to acquire from willing sellers. Visitors to these rivers are cautioned to be aware of and respect private property rights.

The Act purposefully strives to balance dam and other construction at appropriate sections of rivers with permanent protection for some of the country's most outstanding free-flowing rivers. To accomplish this, it prohibits federal support for actions such as the construction of dams or other instream activities that would harm the river's free-flowing condition, water quality, or outstanding resource values. However, designation does not affect existing water rights or the existing jurisdiction of states and the federal government over waters as determined by established principles of law.

The Forest Service manages two designated rivers within the planning boundary. The Middle Fork of the Salmon is wholly within the planning boundary whereas only a portion of the Salmon River is within the planning boundary.

The BLM manages 16 designated rivers that are wholly within the planning boundary. All of the 16 rivers are within wilderness areas. Where the wilderness policy is more restrictive than the Wild and Scenic Rivers policy regarding actions within wilderness, the wilderness policy takes precedence.

#### FS Managed Wild and Scenic Rivers

<b>Name</b>	<b>Classification</b>	<b>River Miles</b>

## Wilderness

In 1964, the Wilderness Act (the Act) established the National Wilderness Preservation System to be managed by the U.S. Forest Service, National Park Service, and U.S. Fish and Wildlife Service. In 1976, with the passage of the Federal Land Policy and Management Act (FLPMA), Congress made the Bureau of Land Management (BLM) the fourth agency with wilderness management authority under the Wilderness Act. Section 603(c) of FLPMA directed that for BLM lands “designated [by Congress] for preservation as wilderness, the provisions of the Wilderness Act that apply to national forest wilderness areas shall apply with respect to the administration and use of such designated area.”

Section 4(b) of the Act further sets forth the agencies’ responsibilities in administering wilderness areas and states that the preservation of wilderness character is the primary management mandate. In the relevant part, the Act states: “Except as otherwise provided in this Act, each agency administering any area designated as wilderness shall be responsible for preserving the wilderness character of the area.”

As set forth in Section 2(c) (“Definition of Wilderness”) of the Wilderness Act, wilderness character is composed of four mandatory qualities and a fifth, optional, quality. These are:

- i. *Untrammeled*. The Wilderness Act states that wilderness is “an area where the earth and its community of life are untrammeled by man.” A “trammel” is literally a net, snare, hobble, or other device that impedes the free movement of an animal. Here, used metaphorically, “untrammeled” refers to wilderness as essentially unhindered and free from modern human control or manipulation. This quality is impaired by human activities or actions that control or manipulate the components or processes of ecological systems inside wilderness.
- ii. *Natural*. The Wilderness Act states that wilderness is “protected and managed so as to preserve its natural conditions.” In short, wilderness ecological systems should be as free as possible from the effects of modern civilization. Management must foster a natural distribution of native wildlife, fish, and plants by ensuring that ecosystems and ecological processes continue to function naturally. Watersheds, water bodies, water quality, and soils are maintained in a natural condition; associated ecological processes previously altered by human influences will be allowed to return to their natural condition. Fire, insects, and diseases are allowed to play their natural role in the wilderness ecosystem except where these activities threaten human life, property, or high value resources on adjacent non-wilderness lands. Additional guidance on this is provided in section 1.6.C of this manual, which addresses the management of specific activities in wilderness. This quality may be affected by intended or unintended effects of human activities on the ecological systems inside the wilderness.
- iii. *Undeveloped*. The Wilderness Act states that wilderness is an area “of undeveloped Federal land retaining its primeval character and influence, without permanent improvements or human habitation,” “where man himself is a visitor who does not remain,” and “with the imprint of man’s work substantially unnoticeable.” Wilderness has minimal evidence of modern human occupation or modification. This quality is impaired by the presence of structures or installations, and by the use of motor vehicles, motorized equipment, or mechanical transport that increases people’s ability to

occupy or modify the environment. More detail on the activities that impair this quality is found in Section 1.6.B of this policy.

iv. *Solitude or Primitive and Unconfined Recreation.* The Wilderness Act states that wilderness has “outstanding opportunities for solitude or a primitive and unconfined type of recreation.” Wilderness provides opportunities for people to experience: natural sights and sounds; remote, isolated, unfrequented, or secluded places; and freedom, risk, and the physical and emotional challenges of self-discovery and self-reliance. Any one wilderness does not have to provide all these opportunities, nor is it necessary that they be present on every acre of a given wilderness. Where present, however, the preservation of these opportunities is important to the preservation of wilderness character as a whole. This quality is impaired by settings that reduce these opportunities, such as visitor encounters, signs of modern civilization, recreation facilities, and management restrictions on visitor behavior.

v. *Unique, Supplemental, or Other Features.* The Wilderness Act states that wilderness areas “may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.” Though these values are not required of any wilderness, where they are present they are part of that area’s wilderness character, and must be protected as rigorously as any of the four required qualities. They may include historical, cultural, paleontological, or other resources not necessarily considered a part of any of the other qualities. These values are identified in a number of ways: in the area’s designating legislation, through its legislative history, by the original wilderness inventory, in a wilderness management plan, or at some other time after designation.

Section 4(b) of the Wilderness Act states that: “Except as otherwise provided in this Act, wilderness areas shall be devoted to the public purposes of recreational, scenic, scientific, educational, conservation, and historical use.” In most cases the public purposes reflect one or more qualities of wilderness character and are administered so as to preserve the wilderness character of the area.

Section 4(c) of the Wilderness Act lists uses and activities that are specifically prohibited in wilderness: “Except as specifically provided for in this Act, and subject to existing private rights, there shall be no commercial enterprise and no permanent road within any wilderness area designated by this Act and, except as necessary to meet minimum requirements for the administration of the area for the purpose of this Act (including measures required in emergencies involving the health and safety of persons within the area), there shall be no temporary road, no use of motor vehicles, motorized equipment or motorboats, no landing of aircraft, no other form of mechanical transport, and no structure or installation within any such area.”

The BLM Wilderness Manual 6340 states: Wildlife management within wilderness is guided by all relevant laws, including the Wilderness Act, acts designating specific wilderness areas, the Endangered Species Act, the Migratory Bird Treaty Act, Native American treaty rights, 43 CFR 6300 (Management of Designated Wilderness Areas), 43 CFR 24 (Department of the Interior Fish and Wildlife Policy: State-Federal Relationships), and applicable State laws and policies regarding wildlife.

Many wilderness areas provide important habitat for federally listed threatened or endangered wildlife species. The BLM will manage wilderness areas to protect and recover known populations of federally listed threatened or endangered species and to aid in their recovery in previously occupied habitat.

To protect or recover threatened, endangered, or candidate species necessary actions, including habitat manipulation and special protection measures, may be implemented in wilderness to a degree greater than for unlisted species. Nevertheless, any wilderness-impairing actions must be necessary for the protection or recovery of the species and it must be demonstrated that the actions cannot be done as effectively outside wilderness. In coordination with the U.S. Fish and Wildlife Service and applicable State wildlife agencies, the BLM will use the Minimum Requirements Decision Guide to determine the actions that least impair wilderness character.

Threatened and endangered species may be transplanted into previously occupied habitat within wilderness. By policy, all transplants will require approval by the BLM in coordination with the applicable State wildlife agencies through the use of the Minimum Requirements Decision Guide and subsequent NEPA analysis. The BLM’s NEPA analysis will evaluate the impacts of the activity on wilderness character.

When alternative areas outside of wilderness offer equal or better opportunities for habitat improvement for species protection, recovery actions will be taken outside of wilderness first, in cooperation, as applicable, with the U.S. Fish and Wildlife Service and State wildlife agencies.

BLM has six wilderness areas within the planning boundary. These six areas are all within Owyhee County and were designated by Congress in 2009 through the Omnibus Public Lands Management Act.

<b><u>BLM Wilderness Name</u></b>	<b><u>Wilderness Acres</u></b>
Big Jacks Creek Wilderness	52,826
Bruneau-Jarbidge Rivers Wilderness	89,966
Little Jacks Creek Wilderness	50,929
North Fork Owyhee Wilderness	43,413
Owyhee River Wilderness	267,328
Pole Creek Wilderness	12,533
<i>Total BLM Wilderness</i>	<i>516,995</i>

A wilderness management plan for the six BLM wilderness areas will be released in draft in February 2013. A final plan should be completed by mid to late 2013.

#### US Forest Service

The Forest Service, National Park Service and BLM manage wilderness areas under the same legislation; the 1964 Wilderness Act. The agencies have similar objectives and policies related to wilderness. Below is text from the Forest Service wilderness manual.

Wilderness is a unique and vital resource. In addition to offering primitive recreation opportunities, it is valuable for its scientific and educational uses, as a benchmark for ecological studies, and for the preservation of historical and natural features.

Manage the wilderness resource to ensure its character and values are dominant and enduring. Its management must be consistent over time and between areas to ensure its present and future availability and enjoyment as wilderness. Manage wilderness to ensure that human influence does not impede the free play of natural forces or interfere with natural successions in the ecosystems and to ensure that each wilderness offers outstanding opportunities for solitude or a primitive and unconfined type of recreation. Manage wilderness as one resource rather than a series of separate resources (FSM 2300 sec. 2320.6).

## **Objectives**

1. Maintain and perpetuate the enduring resource of wilderness as one of the multiple uses of National Forest System land.
2. Maintain wilderness in such a manner that ecosystems are unaffected by human manipulation and influences so that plants and animals develop and respond to natural forces.
3. Minimize the impact of those kinds of uses and activities generally prohibited by the Wilderness Act, but specifically excepted by the Act or subsequent legislation.
4. Protect and perpetuate wilderness character and public values including, but not limited to, opportunities for scientific study, education, solitude, physical and mental challenge and stimulation, inspiration, and primitive recreation experiences.
5. Gather information and carry out research in a manner compatible with preserving the wilderness environment to increase understanding of wilderness ecology, wilderness uses, management opportunities, and visitor behavior.

## **Policy**

1. Where there are alternatives among management decisions, wilderness values shall dominate over all other considerations except where limited by the Wilderness Act, subsequent legislation, or regulations.
2. Manage the use of other resources in wilderness in a manner compatible with wilderness resource management objectives.
3. In wildernesses where the establishing legislation permits resource uses and activities that are nonconforming exceptions to the definition of wilderness as described in the Wilderness Act, manage these nonconforming uses and activities in such a manner as to minimize their effect on the wilderness resource.

4. Cease uses and activities and remove existing structures not essential to the administration, protection, or management of wilderness for wilderness purposes or not provided for in the establishing legislation.

5. Because wilderness does not exist in a vacuum, consider activities on both sides of wilderness boundaries during planning and articulate management goals and the blending of diverse resources in forest plans. Do not maintain buffer strips of undeveloped wildland to provide an informal extension of wilderness. Do not maintain internal buffer zones that degrade wilderness values. Use the Recreation Opportunity Spectrum (FSM 2310) as a tool to plan adjacent land management.

6. Manage each wilderness as a total unit and coordinate management direction when they cross other administrative boundaries.

7. Use interdisciplinary skills in planning for wilderness use and administration.

8. Gather necessary information and carry out research programs in a manner that is compatible with the preservation of the wilderness environment.

9. Whenever and wherever possible, acquire non-Federal lands located within wildernesses, as well as non-Federal lands within those areas recommended for inclusion in the system.

The Forest Service manages eight wilderness areas that are either all or portions of within the planning area.

<u>FS Wilderness Name</u>	<u>Wilderness Acres</u>
Sawtooth	217,088 acres
Frank Church River of No Return	
Anaconda Pintler	
Gates of the Mountains	28,562 acres
Lee Metcalf	254,635 acres
Red Rock Lakes	32,350 acres
Absaroka Beartooth	

#### National Park Service

The following is from the National Park Service Wilderness Management Policy 2006: The National Park Service will manage wilderness areas for the use and enjoyment of the American people in such a manner as will leave them unimpaired for future use and enjoyment as wilderness. Management will include the protection of these areas, the preservation of their

wilderness character, and the gathering and dissemination of information regarding their use and enjoyment as wilderness. The purpose of wilderness in the national parks includes the preservation of wilderness character and wilderness resources in an unimpaired condition and, in accordance with the Wilderness Act, wilderness areas shall be devoted to the public purposes of recreational, scenic, scientific, educational, conservation, and historical use.

Craters of the Moon National Monument manages one wilderness area within the planning boundary.

NPS Wilderness Name	Wilderness Acres
Craters of the Moon National Wilderness	43,243 acres

## Wilderness Study Areas (WSAs)

Section 603 of FLPMA directed the BLM to carry out a wilderness review of the public lands. The wilderness inventory was conducted from 1978 to 1980, and excluded Alaska and Oregon and California Grant Lands Act of 1937 (O&C Act) lands managed primarily for timber production. The original inventory focused on roadless areas of public lands of 5,000 acres or more and on roadless islands, but also included areas of less than 5,000 acres that had wilderness characteristics in association with contiguous roadless lands managed by another agency, and areas of less than 5,000 acres that had wilderness characteristics and could practicably be managed to keep those characteristics in an unimpaired condition. Additional WSAs were designated through the BLM land use planning process under the authority of Sections 201,202, and 302 of FLPMA after the reports to Congress were completed in 1993

The inventory phase identified areas that were found to have the characteristics of wilderness enumerated by Congress in Section 2 (c) of the Wilderness Act of 1964:

"A wilderness... (1) generally appears to have been affected primarily by the forces of nature, with the imprint of man's work substantially unnoticeable; (2) has outstanding opportunities for solitude or a primitive and unconfined type of recreation; (3) has at least five thousand acres of land or is of sufficient size as to make practicable its preservation and use in an unimpaired condition; and (4) may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value." When these characteristics were found within a defined boundary, the presence of the wilderness resource was documented and the area was classified as a WSA.

During the study phase, all values, resources, and uses occurring within each WSA were analyzed, pursuant to the National Environmental Policy Act (NEPA), through legislative environmental impact statements. When the study was completed, recommendations as to the suitability or unsuitability of each WSA for designation as wilderness were submitted to the President through the Secretary of the Interior, and then from the President to Congress.

The BLM's management policy is to continue resource uses on lands designated as WSAs in a manner that maintains the area's suitability for preservation as wilderness. The BLM's policy will protect the wilderness characteristics of all WSAs in the same or better condition than they were on October 21, 1976 until Congress determines whether or not they should be designated as wilderness. When managers are in doubt as to a course of action in a WSA, this should serve as a guiding principle.

To keep WSAs suitable for wilderness designation, BLM manages them under the "non-impairment" standard. The non-impairment standard requires the BLM to review all proposals for uses and/or facilities within WSAs to ascertain whether the proposal would impair the suitability of the WSA for preservation as wilderness. While there are some exceptions, in

general, all uses and/or facilities must meet the non-impairment standard (i.e. must be both temporary and not create surface disturbance), as described in the following detailed criteria:

a. The use or facility is temporary. The use or facility is needed for a defined time period to respond to a temporary need, and would be terminated and removed prior to or upon wilderness designation. A chronic, repeated short-term use does not meet this definition of “temporary.” Uses, activities, or facilities that create a demand for uses that would be incompatible with wilderness management also do not meet the definition of temporary.

b. The use or facility will not create new surface disturbance. There is no new disruption of the rock, soil, or vegetation, including vegetative trampling, that would necessitate reclamation, rehabilitation, or restoration in order for the site to appear and function as it did prior to the disturbance. Uses or facilities that would require only passive natural restoration may still be considered surface disturbing. For example, cross-country vehicle use off boundary roads or existing primitive routes is surface disturbing because the tracks created by the vehicle leave depressions or ruts, compact the soils, and trample or compress vegetation. Landing fixed wing aircraft is considered surface disturbing unless it is on an existing airstrip or primitive route open to other motorized use (i.e. identified and documented to exist prior to passage of FLPMA). Certain activities allowed in wilderness areas, such as recreational hiking, use of pack stock, or domestic livestock grazing, are recognized as acceptable within a WSA, although, in the literal sense, they cause surface disturbance.

BLM currently manages approximately 770,000 acres of WSAs within the planning boundary. This includes 10 WSAs in the Dillon Field Office and 34 WSAs in the Idaho Field Offices.

There are XXX,000 acres of WSA within PPH.

BLM Manual 6330 Management of Wilderness Study Areas (2012)

## West Nile Virus Synopsis for NEPA Analyses

### Affected Environment:

West Nile virus (WNV) is a mosquito-borne flavivirus that can cause fatal disease in sage-grouse (Naugle et al. 2004) and many other bird species in North America (Kramer et al. 2008). Individual sage-grouse that do not die as a result of direct mortality may suffer persistent symptoms that reduce subsequent survival, reproduction, or both. The virus is replicated generally in a mosquito-bird-mosquito infection cycle. Local and regional population declines have been observed in sage-grouse and other bird species susceptible to the virus in North America.

WNV has acted as an important source of mortality for sage-grouse and the virus was an important relatively new source of mortality in low and mid-elevation sage-grouse populations range-wide from 2003–2007 (Naugle et al. 2004, 2005; Walker et al. 2004, 2007b; Aldridge 2005; Kaczor 2008; Walker 2008). The highest confirmed elevation at which sage-grouse have been infected with WNV is ~2,300 m (7,500 feet) in the Lyon-Mono population of eastern California (Naugle et al. 2005). Individual sage-grouse in populations exposed to the virus during July-August 2003 were 3.3 times more likely to die than birds in uninfected populations (Naugle et al. 2004). WNV mortality of sage-grouse has been documented as ranging from 5 to 44 percent with most mortality occurring in July and August (Walker and Naugle 2011). In Idaho, WNV has been documented in sage-grouse in Owyhee and Twin Falls counties in 2006 (USGS 2006). The sage-grouse hunting season was closed in western Owyhee County due to concerns of WNV impacts (Idaho Sage-grouse Advisory Committee 2008).

The long-term response of different sage-grouse populations to WNV is expected to vary markedly depending on factors that influence susceptibility including: (1) annual and seasonal temperature-precipitation profiles, (2) land uses that influence the distribution of surface water, (3) population size, (4) genetic diversity, and (5) connectivity with other populations. Small, isolated, or genetically depauperate populations and those on the fringe of the species' range as in eastern California, Washington, North and South Dakota, Alberta, and Saskatchewan, are likely at higher risk. WNV outbreaks in small populations are more likely to reduce population size below a threshold from which recovery is unlikely and the likelihood of demographic or genetic rescue by adjacent populations is low (Morris and Doak 2002). Large, intact, low- to mid-elevation populations affected annually by WNV in northern Nevada, southeastern Idaho, central Montana, may absorb impacts of WNV if the quality and extent of available habitat still supports positive population growth (Walker and Naugle 2011).

WNV infection has been documented in several genera of mosquitoes (*Culex*, *Aedes*, *Ochlerotatus*, *Culiseta*; (Goddard et al. 2002, Doherty 2007) and at least one other biting midge (*Culicoides sonorensis*) (Naugle et al. 2004), in sagebrush habitats of western North America. However, *Culex tarsalis* is the dominant vector of WNV in sagebrush habitats (Goddard et al. 2002, Naugle et al. 2004, Doherty 2007). This species of mosquito prefers sites with submerged vegetation on which to deposit eggs and warm, standing water that promotes rapid larval development, including ephemeral puddles, vegetated pond edges, and water-filled hoof prints

(Milby and Meyer 1986, Buth et al. 1990, Doherty 2007). Dense stands of emergent plants physically obstruct access to mosquitoes (larvae and pupae) by predators and hinder mosquito control efforts (Knight et al. 2003). Open water areas provide unsuitable habitats for mosquito larvae and pupae due to increased wave action and increased vulnerability to predation by native predators of mosquitoes (Laird 1988).

Mosquito larvae and pupae are subject to greater loss by direct solar radiation where there is little cover in water, resulting in fluctuating water temperatures. Larvae and pupae have been shown to be more sensitive to temperature fluctuations, so a habitat that provides a shady resting place from the heat of the day is more likely to have a higher survival rate of larvae/pupae than a habitat with little vegetation or little water. Open water environments without cover also provide increased availability of mosquito larvae to aquatic predators such as backskimmers (Laird 1988). Vegetation or debris provides shelter from predators, leading to a greater survival of mosquito larvae and a greater population of adults. These invertebrate predators can substantially impact mosquito populations by consuming high numbers of mosquito larvae, as well as reducing egg laying by adult female mosquitoes (Laird 1988).

Sage-grouse congregate in mesic habitats in mid- to late summer (Connelly et al. 2000) and often use ponds, springs, and other standing water sources during hot weather (Dalke et al. 1963, Connelly and Doughty 1989). *Culex tarsalis* uses these same habitats for breeding (Goddard et al. 2002, Doherty 2007) and the risk of exposure to WNV may be elevated at this time.

WNV transmission is also regulated by environmental factors, including temperature, precipitation, and distribution of anthropogenic water sources that support breeding mosquito vectors (Brust 1991, Dohm et al. 2002, Reisen et al. 2006a, Zou et al. 2006a, b). It has been suggested in ecosystems other than sagebrush that high temperatures associated with drought conditions increases West Nile virus transmission (Epstein and DeFilippo 2001, Shaman et al. 2005). Higher temperatures facilitate greater nocturnal host-seeking activity by mosquitoes, more rapid larval development, and shorter extrinsic incubation periods for the virus—the time it takes for the virus to replicate inside the mosquito and invade its salivary glands (Reisen et al. 2006a). Man-made water sources may also facilitate the spread of WNV within sage-grouse habitats (Zou et al. 2006b, Doherty 2007, Walker et al. 2007). All documented WNV-related mortality to sage-grouse has occurred from mid-May to through mid-September (Walker et al. 2007b, Walker 2008, Walker and Naugle 2011).

The addition of artificial water sources that increase the distribution and abundance of *Culex tarsalis* may contribute to the spread of WNV if they have attributes beneficial to *Culex tarsalis*. Man-made water sources known to support breeding *Culex tarsalis* in sage-grouse habitat include overflowing stock tanks, stock ponds, seep and overflow areas below earthen dams, irrigated agricultural fields, and ponds constructed for coal-bed natural gas development (Zou et al. 2006b, Doherty 2007). Also, habitat or range improvement projects that create mesic zones around stock tanks or ponds may inadvertently contribute to the WNV problem, because *Culex tarsalis* readily takes advantage of water-filled hoof prints around tanks and ponds for breeding (Doherty 2007).

## Affected Environment

This Page Intentionally Blank

## Chapter 3. Affected Environment

### 3.1 Introduction

This chapter documents the existing conditions and trends of resources in the planning area that may be affected by implementing any of the proposed alternatives described in **Chapter 2, Alternatives**. The affected environment provides the context for assessing potential impacts, which are described in **Chapter 4, Environmental Consequences**.

For this LUPA/EIS, the planning area is the entire sub-region within Idaho, southwestern Montana, and the portion of the Sawtooth National Forest within Utah. Specifically, the planning area is the sum of the GRSG population areas within this sub-region, regardless of landownership. **Table 3-1, Acres of GRSG Habitat by Surface Management**, provides a detailed breakdown of landownership status in the planning area. A map of the planning area is provided in **Chapter 1, Figure 1-3, Planning Area**.

The decision area includes the portions of the planning area that are composed of BLM, Forest Service, and Bankhead Jones surface estates, as well as the mineral estates administered by the BLM or Forest Service. Though the planning area includes private lands, ~~decisions made~~ direction provided in this LUPA only applies to BLM and Forest Service surface and minerals. Management direction and actions outlined in this EIS apply only to these BLM-administered and Forest Service-administered lands in the planning area and to federal mineral estate under BLM jurisdiction that may lie beneath other surface ownership. The federal government does not always own every type of mineral in a given acre of federal mineral estate. For example, in some areas, the federal government will only own the coal rights, while a private or state entity might own the oil and gas rights. For this reason, the federal mineral estate for any specific mineral type in the decision area is different than that for all other mineral types in the decision area.

While not a part of the planning area in the Idaho and Southwestern Montana GRSG Sub-Region, the Jarbidge and Bruneau Field Offices in Idaho will implement GRSG decisions on 77,800 acres of BLM-administered lands in Elko County, Nevada, located north of the Humboldt-Toiyabe National Forest and south of the Idaho-Nevada state line adjacent to the Bruneau and Jarbidge Field Offices in Idaho. For purposes of the GRSG plan amendments in Idaho and in Nevada, planning for these lands will occur through the Nevada and Northeastern California GRSG LUPA, and the regulatory measures and decisions that are put in place for the GRSG through the ROD will be implemented and administered by the Jarbidge and Bruneau Field Offices in Idaho. Due to their remoteness from other BLM-administered lands in Nevada, and because they are contiguous with major blocks of BLM-administered lands in Idaho, a Memorandum of Understanding (MOU) between BLM Nevada and BLM Idaho transfers administration of those lands to BLM Idaho.

To augment this planning document at a biologically meaningful scale for GRSG, the BER was produced by the USGS for the BLM and Forest Service (Manier et al. 2013). The BER is a science support document that provides information to put planning units and issues

<sup>1</sup> Butte Field Office-administered lands are not included as part of the analysis in this LUPA/EIS except as required in the cumulative effects analysis.

into the context of the larger WAFWA management zones. The BER examines each threat identified in USFWS' listing decision published on March 15, 2010. For each threat, the report summarizes the current scientific understanding of various impacts on GRSG populations and habitats. When available, patterns, thresholds, indicators, metrics, and measured responses that quantify the impacts of each specific threat are reported. Data from the BER are presented throughout this chapter to illuminate the location (e.g., PPH and PGH), magnitude, and extent of the threats within each WAFWA management zone that comprises the planning area.

Because the BER focuses on threats to GRSG at the WAFWA management zone (or range-wide) scale, it provides biologically meaningful data for larger-scale analyses, such as the cumulative effects analysis for GRSG in **Chapter 4**.

**Chapter 3** also presents data that are available at a finer scale than used in the BER's larger-scale, WAFWA management zone focus. These fine-scale, local data are incorporated into the affected environment discussion to complement the BER's biologically meaningful data, characterize the relative contributions of threats in the planning area versus the WAFWA management zones, and to set the stage for the cumulative effects analysis for GRSG (**Chapter 4**). However, it should be noted that the tables presented in the Regional Context discussions of each Chapter 3 resource and resource use discussion are from the BER (Manier et al. 2013) and extend outside of the planning area to WAFWA management zone boundaries. Those tables present information for the WAFWA management zones that would be affected by the [decisions made/direction provided](#) in this sub-regional EIS.

### 3.1.1 Organization of Chapter 3

Certain types of resources that may be present in the LUPA planning area, such as cave and karst resources, are not addressed in this LUPA because issues relating to the management of these resources were not identified during scoping by the public, or by the BLM or Forest Service as relevant to GRSG, or they are not included in the planning area (e.g., coal). Information from broad-scale assessments was used to help set the context for the planning area. The information and direction for BLM and Forest Service resources and resource uses has been further broken down into fine-scale assessments and information. The level of information presented in this chapter is commensurate with and sufficient to assess potential effects discussed in **Chapter 4**, based on the alternatives presented in **Chapter 2**.

The following resources and resource uses are specifically addressed in **Chapter 3** and **Chapter 4**, of the Idaho and Southwestern Montana Greater Sage-Grouse LUPA/EIS.

- Greater Sage-Grouse
- Vegetation (including noxious weeds; riparian and wetlands)
- Fish and wildlife
- Other special status species
- Wild horse and burro management

- Wildland fire ecology and management
- Livestock grazing
- Recreation
- Travel management
- Lands and realty
- Minerals
  - Leasable minerals
  - Locatable minerals
  - Salable minerals
  - Nonenergy leasable minerals
- Special Designations
  - Designated Wilderness/Wilderness Study Areas
  - Areas of Critical Environmental Concern
  - Research Natural Areas
  - Other special designations
- Soil resources
- Water resources
- Cultural resources and tribal interests
- Visual resources
- Lands with wilderness characteristics
- Air quality and climate change
- Social and economic conditions (including environmental justice)

Each resource section in this chapter contains a discussion of existing conditions, including trends.

- Existing conditions describe the location, extent, and current condition of the resource in the planning area in general, on BLM-administered and Forest Service-administered lands. Conditions for a resource can vary, depending on the resource. The Idaho and Southwestern Montana Sub-Region planning area contains 18,147,500 acres, regardless of land status. Within the Idaho and Southwestern Montana Sub-Region planning area, there are 15,260,200 acres of BLM-administered lands and 1,861,100 acres of Forest Service-administered lands that are managed according to the BLM and Forest Service plans being

amended by this LUPA/EIS. For each resource, a general description of the existing conditions is provided for the Idaho and Southwestern Montana Sub-Region planning area, regardless of land status. This is done to provide a regional context for the resource. More detailed discussion of the existing conditions on various scales may be provided depending on the resource topic. This is done to provide an area-specific description of the existing conditions for the resource. When possible, greater emphasis is placed on describing the existing conditions of the resource as it pertains to GRSG and their habitat.

- **Trends** identify the degree and direction of resource change between the present and some point in the past. Not all resource topics will have trends. For example, soil resources may not undergo notable resource change. If there is change, the degree and direction of resource change is characterized as moving toward or away from the current desired conditions, and the reasons for the change are identified. Trends can also be described in quantitative or qualitative terms. Identifying the trends is done to provide an understanding of how BLM and Forest Service management influences the desired condition of the resource over time. It can be difficult to analyze trends for certain resources, because changes to the resource often occur due to factors beyond the control of the BLM and Forest Service. For those resource topics that can be affected by climate change, a discussion of the effects from climate change on the resource is provided.

The BLM and Forest Service reviewed the LUPs being amended under this LUPA/EIS and other relevant information sources (such as other LUPAs, maps, and state GRSG conservation assessments) for existing conditions and trends for the resources listed above with respect to GRSG and their habitat. This affected environment information is summarized below and, where appropriate, noted when the information is incorporated by reference.

Acreage figures and other numbers used are approximate projections; readers should not infer that they reflect exact measurements or precise calculations. Acreages were calculated using Geographic Information Systems (GIS) technology, and there may be slight variations in total acres between resources.

## 3.2 Special Status Species – Greater Sage-Grouse

### 3.2.1 Conditions within the Planning Area

In 2006, the WAFWA used floristic characteristics to organize the diverse sagebrush habitat areas into seven GRSG management zones within the species' distribution (Stiver et al. 2006). The Idaho and Southwestern Montana Sub-Region contains portions of 2 of the 7 zones (MZs II and IV) (**Figure 3-1, ~~Western United States WAFWA Zones~~Western United States WAFWA Zones**). The vast majority of the Idaho and Southwestern Montana Sub-Region lies within WAFWA's GRSG MZ IV (Stiver et al. 2006); a small portion of southeastern Idaho occurs within MZ II and is associated with the Wyoming Basin population. Populations of GRSG in MZ IV are projected to decline by 55 percent from

Idaho and Southwestern Montana  
Draft LUPA/EIS

2007 to 2037 and by 66 percent in MZ II if current trends in populations and habitat activities continue (USFWS 2010a; Garton et al. 2011).

*Idaho and Southwestern Montana Sub-Region Greater Sage-Grouse LUPA/EIS*  
October 2013

Figure 3-1 Western United States WAFWA Zones

*Idaho and Southwestern Montana Sub-Region Greater Sage-Grouse LUPA/EIS*  
October 2013

*Chapter 3 – Affected Environment 3-7*

Within the sub-region, GRSG occupy all or portions of ten populations and eight subpopulations described in Connelly et al. (2004). Two large populations (Great Basin Core and Wyoming Basin) encompass portions of Oregon, Nevada, Utah, and Wyoming that extend beyond the sub-regional boundary.

Population estimates are not available for all GRSG populations due to limited data in some areas; however, Garton et al. (2011) estimated a minimum male GRSG population in 2007 of 9,114 for the Northern Great Basin population (analogous to the Great Basin Core population and inclusive of habitats in Idaho and associated portions of Nevada, Oregon, and Utah), and 5,457 for the Snake-Salmon-Beaverhead population. Estimates for the Bannack and Red Rocks Montana populations were 304 and 448 males, respectively. GRSG in southwestern Montana are migratory, moving between separate summer and winter areas. Migratory movements of GRSG also have been documented between eastern Idaho and southwestern Montana from the Bannack and Red Rock populations. Telemetry data from 1999 to 2012 show that seasonal movements (including both distance and duration) vary significantly between groups of GRSG.

***Availability of Sagebrush Habitat (Mid-Scale Indicator)***

The distribution of GRSG is closely aligned with the distribution of sagebrush-dominated landscapes (Schroeder et al. 2004). Occupancy by GRSG is strongly associated with measures of sagebrush abundance and distribution. Sagebrush area was the single best discriminator between occupied and extirpated ranges among 22 variables evaluated by Wisdom et al. (2011). In the sub-region, large expanses of sagebrush still occur in portions of southwestern and south-central Idaho, in association with the Northern Great Basin population shared with Nevada, Oregon, and Utah, as well as in portions of the Snake-Salmon-Beaverhead population north of the Snake River.

In 2012, the BLM completed the range-wide delineation of PPH and PGH in cooperation with respective state wildlife agencies (see **Figure 1-4**). The BLM national office Instruction Memorandum 2012-043 defined PPH as GRSG habitat having the highest conservation value to maintaining sustainable GRSG populations. PGH includes areas of occupied seasonal or year-round habitat outside of priority habitat.

At finer scales, PPH and PGH encompass areas of intact sagebrush suitable for GRSG habitat needs as well as areas of conifer encroachment and perennial grass-dominated areas, generally occupied by GRSG or potentially suitable for future restoration.

In Idaho, PPH and PGH were identified by the BLM and Forest Service based on a model incorporating GRSG breeding bird density and lek connectivity models, informed with additional ancillary broad-scale habitat data, seasonal habitat maps, connectivity information/expert opinion, population persistence model, local priority areas, and agriculture/conifer filters (Makela and Major 2012).

In general, GRSG habitats in Idaho and the portion of the Sawtooth National Forest in northern Utah are composed of a variety of species and subspecies of sagebrush, including mountain big sagebrush, Wyoming big sagebrush, Great Basin big sagebrush, low sagebrush,

black sagebrush, three-tip sagebrush, and early sagebrush. Conifer encroachment into GRSG habitats, mainly from Utah juniper and western juniper, occurs primarily in south-central and southwestern Idaho and in northern Utah, although encroachment of Douglas-fir and other conifers also occurs at higher elevations. Large areas of native, introduced, or mixed native/introduced perennial grasslands as well as annual grasslands are also present in portions of the Snake River Plain in southern Idaho as a result of recent wildfires and associated rehabilitative efforts or from other rangeland seeding efforts during the 20<sup>th</sup> century.

In Montana, PPH was delineated based on MFWP prior modeling of GRSG Core Areas using a lek-centric model based on male lek attendance and refined with seasonal habitat, telemetry, connectivity information, and field review. Documentation for the Montana Core area analysis is summarized at:

[http://www.mt.nrcs.usda.gov/technical/ecs/biology/sagegrouse/sagegrouse\\_attachments/appendix1.html](http://www.mt.nrcs.usda.gov/technical/ecs/biology/sagegrouse/sagegrouse_strategy_attachments/appendix1.html).

Montana PGH was mapped based on the Schroeder et al. (2004) GRSG distribution map.

Sagebrush steppe habitat across southwest Montana consists of diverse species and multiple successional stages, providing for all life stages. Species or subspecies composition consists primarily of mountain big sagebrush, Wyoming big sagebrush, three-tip sagebrush, basin big sagebrush, and low sagebrush, as well as multiple other species at lower densities. These occur in mixed as well as pure stands throughout southwestern Montana. Tilling and aerial spraying over 12,000 acres in the 1960s and early 1970s (about 1 percent of BLM-administered lands in the Dillon Field Office) reduced sagebrush canopy on large areas of BLM-administered, mostly in the area inhabited by the Bannack Population. These areas were reseeded with nonnative herbaceous species that further altered natural communities. Sagebrush canopy has recovered, but the herbaceous understory composition is a mix of native species and nonnative wheat grasses. Large areas of sagebrush in the Dillon Field Office appear to provide suitable habitat for GRSG but are unoccupied.

To facilitate analysis for the Idaho and Southwestern Montana LUPA/EIS, the GRSG population areas were clipped to the Idaho and Southwestern Montana Sub-regional boundary to eliminate portions occurring outside the sub-region. Boundaries were then adjusted to encompass associated PPH and PGH. Small populations within southwestern Montana were combined into a single analysis area and, in portions of Idaho, some subpopulations were delineated separately or grouped due to similarities in threats or geography. The resulting population areas, used in the analysis below, reflect discrete geographic portions of the sub-region.

Based on GIS analysis, there are approximately 18,114,000 acres of PPH and PGH, inclusive of all landownerships, in the sub-regional analysis area (**Table 3-2, [Acres of GRSG Habitat by Population Area within the Idaho and Southwestern Montana Planning Area](#)**~~Acres of GRSG Habitat by Population Area within the Idaho and Southwestern Montana Planning Area~~). This is inclusive of habitats in Idaho, southwestern Montana, and a small portion of

northern

Utah

### **Predation**

The GRSG is potential prey to a variety of predator species, such as the golden eagle (*Aquila chrysaetos*), ferruginous hawk (*Buteo regalis*), common raven (*Corvus corax*), American badger (*Taxidea taxus*), coyote (*Canis latrans*), red fox (*Vulpes vulpes*), weasels (*Mustela* spp.), and others (Schroeder et al. 1999; Coates 2007), but none of these species prey especially upon GRSG (Hagen 2011). Adults are susceptible to predation while on leks or nests, and eggs are vulnerable as well (Schroeder et al. 1999; Coates 2007; Hagen 2011). Predation is the most commonly identified cause of direct mortality for GRSG during all life stages (Connelly et al. 2011; USFWS 2010a citing others), but studies suggest that predation is not limiting populations (Hagen 2011). As a result, there is little scientific support for predator management over broad geographic or temporal scales (Hagen 2011).

Information on the numbers of GRSG taken by specific predators is not readily available; however, some studies report overall predation rates on age-classes, sex, and nests. Connelly et al. (2000), in a review of long-term data, reported 83 percent of male GRSG deaths and 52 percent of female deaths were attributed to predation. Gregg et al. (2007), cited in USFWS (2010a), reported mortality of GRSG chicks from predation during the first few weeks after hatching was 82 percent. Coates and Delehanty (2010) monitored 87 GRSG nests, and 42.5 percent were preyed upon. Of these nests, an increase of 1 raven per 10 km (3.86 mi) of survey transect monitored was associated with a 7.5 percent increase in the odds of nest failure. Coates (2007) documented predation at 17 GRSG nests; ravens accounted for 10 nests (59 percent) and badgers 7 nests (41 percent).

In areas where habitat is not limited and of good quality, predation is not a threat to the persistence of the species (USFWS 2010a). However, predation may limit population growth in fragmented habitats or areas where predator populations have supplemental food sources,

such as where landfills or other human factors attract and concentrate scavengers (Coates 2007), or where electrical transmission or other human-made structures facilitate nesting and perching by avian predators such as ravens (Howe 2012; Hagen 2011).

As land-management agencies, the primary role of the BLM and Forest Service is the management of habitats, land uses, and associated authorizations. Therefore, the reduction of predator effects on GRSG in this conservation strategy is best accomplished through the appropriate management, improvement, or restoration of sagebrush habitats and the siting and design of human-made structures in a way that eliminates or reduces risk from predators that may utilize them to their advantage. Direct predator control would occur under the purview of the states of Idaho and Montana and the USDA APHIS Wildlife Services, in cooperation with the USFWS.

### 3.2.2 Habitat Conditions and Trends

The general condition and trend of habitats on BLM- and Forest Service-administered lands varies by geographic area within the sub-region and is a result of various threats that are currently occurring or that have occurred historically.

In Idaho, threats to GRSG were ranked by an independent science panel and addressed in the *Conservation Plan for the Greater Sage-grouse in Idaho* (Idaho Sage-grouse Advisory Committee 2006). Highest ranking threats, in order of relative score, included wildfire, infrastructure, annual grasslands, livestock impacts, human disturbance, and West Nile virus. Additional habitat-associated threats of concern in portions of southern Idaho included conifer encroachment, seeded perennial grasslands, sagebrush control, urban and exurban development, and mines, landfills and gravel pits. In 2012, the Idaho Governor's Sage-Grouse Task force reiterated concerns about wildfire, invasive species and infrastructure, as well as recreation, improper livestock grazing and West Nile virus (Idaho Governor's Sage-grouse Task Force 2012). Landscape conditions and trend of BLM-administered and Forest Service-administered lands in the sub-region are summarized in **Table 3-4, [Habitat Conditions, Trends and Primary Threats to GRSG Habitat in the Idaho and Southwestern Montana Planning Area](#)**~~Habitat Conditions, Trends and Primary Threats to GRSG Habitat in the Idaho and Southwestern Montana Planning Area.~~

### 3.2.3 Regional Context

As stated above, the majority of the Idaho and Southwestern Montana planning area is within Management Zone IV; a small portion in the southeast is within MZ II.

#### ***Management Zone IV (Snake River Plain Management Zone)***

Management Zone IV covers nearly all of Idaho's GRSG habitat, with the majority of occupied habitat within the Northern Great Basin (South Side Snake) and Snake River Plain population areas (Mountain Valleys, North Side Snake, and Southwest Idaho), as well as southwestern Montana, on both BLM-administered and Forest Service-administered lands. MZ IV also includes eastern Oregon and northern Nevada, and the Box Elder population in Utah, outside the planning area. This area supports the largest population of GRSG outside

Population Area	Existing Condition Based on Modeled Vegetation <sup>a</sup>	Landscape Conditions and Trends on BLM-Administered Lands	Landscape Conditions and Trends on Forest Service-Administered Lands	Primary Threats <sup>a</sup>
		Conifer encroachment (primarily Utah juniper) into sagebrush communities is of concern in the southern portion.		National Forest.  Cheatgrass expansion in lower elevations (i.e., Wyoming big sagebrush).
<b>Sawtooth</b>	98% of habitat overall is 10 to 30% sagebrush cover of mixed species or subspecies.	N/A	Habitat is primarily higher elevation mountain big sagebrush, generally relatively good condition in the Sawtooth Valley/ headwaters of the Salmon River. Includes smaller areas of noxious weeds and/or low diversity of native forbs diversity. Long term trend in areas is downward due to encroachment by Douglas-fir and lodgepole pine.  Sawtooth National Forest personnel occasionally observe GRSG. Last documented observation in fall 2010.	Little recent information available on the population, which is apparently isolated from other populations. Last documentation of lek attendance was of 2 male GRSG in 1993 at 1 of the 3 known leks.  Conifer encroachment (Douglas-fir, lodgepole pine).  Potential concerns with domestic sheep grazing and native forb diversity.  Noxious and invasive weeds.

**Table 3-4  
Habitat Conditions, Trends and Primary Threats to GRSG Habitat in the Idaho and Southwestern Montana Planning Area**

Population Area	Existing Condition Based on Modeled Vegetation <sup>a</sup>	Landscape Conditions and Trends on BLM-Administered Lands	Landscape Conditions and Trends on Forest Service-Administered Lands	Primary Threats <sup>a</sup>
<b>Bear Lake (Idaho portion)</b>	99% of habitat overall is 10 to 30% sagebrush cover, of mixed species or subspecies.	Relatively small area of southeastern Idaho; Sagebrush is largely intact in many areas. Patchy landownership.	The Forest Service administers a limited amount of sagebrush habitat in the Idaho portion of the Bear Lake population area, totaling about 1,391 acres. The majority (1,037 acres) is over 30% canopy cover; the remainder is 10 to 30%.  Wyoming sagebrush transitions to mountain big sagebrush at higher elevations. Sagebrush communities are largely intact with little to moderate amounts of cheatgrass in understory.	Some potential for oil/gas development; urban expansion, infrastructure
<b>Weiser</b>	72% of habitat overall is 10 to 30% sagebrush cover.  Habitat proportion in the 10 to 30% cover range by species or subspecies is as follows:  Low Sagebrush 78%	Sagebrush is largely intact in portions. There are some annual and perennial grasslands in the periphery due to wildfires. Landownership is patchy.	N/A	Exurban development, infrastructure, wildfire; invasive annual grasses

**Table 3-4  
Habitat Conditions, Trends and Primary Threats to GRSB Habitat in the Idaho and Southwestern Montana Planning Area**

Population Area	Existing Condition Based on Modeled Vegetation <sup>a</sup>	Landscape Conditions and Trends on BLM-Administered Lands	Landscape Conditions and Trends on Forest Service-Administered Lands	Primary Threats <sup>a</sup>
	Mountain Big Sagebrush 71%			
	Wyoming Big Sagebrush 71%			
<b>Butte Field Office</b> This area of BLM-administered land is within the sub-regional boundary but Land Use Plans are not being amended.	Not modeled	Historically, the species was present but breeding has not been documented since 1992. Habitat (sagebrush stands) is widely dispersed and separated, lacking the expansiveness or landscape extent needed for GRSB.  The Big Belts are an isolated mountain range on the east side of the Missouri River adjacent to Canyon Ferry reservoir. Foothills are drier with scattered Rocky Mountain juniper and limber pine and a variety of shrubs on some sites. At the lowest elevations the habitat is dominated by grasslands and scattered big sagebrush.	Timber harvest has occurred throughout this area, particularly on the north end. There are high road densities in some locations.  Fire suppression has led to an increase in forest density and high insect populations as well as colonization of shrublands by juniper and Douglas-fir.  The area is dominated by livestock grazing.  Many private ranches have sold and subdivided their land.	Habitat fragmentation from urban development and roads.  Wildfire  Douglas-fir and juniper colonization of sagebrush stands.  Invasive species (mainly Dalmatian toadflax, spotted knapweed, and leafy spurge)  Livestock grazing  Fences  Potential oil and gas development from Birch Creek to Deep Creek, in the Mount Baldy area and the

		Many of these habitats have been converted to dry land grain production and irrigated cropland		Horseshoe Hills.

Source: Idaho Sage-grouse Advisory Committee 2006; Idaho Governor's Sage-grouse Task Force 2012; Montana Sage-Grouse Work Group 2005; BLM 2006

of the Wyoming Basin and has high connectivity between populations, though small populations such as Weiser and East-Central Idaho are at risk of fragmentation (USFWS 2013). This MZ population is moderately vulnerable, with a 10.5 percent chance of falling below 200 males by 2037 (Garton et al. 2011). The area has a long history of agricultural land use, which has left the residual sagebrush ecosystem drier than the historical condition (Manier et al. 2013). Across this MZ, 63 percent of land is federally managed. Primary threats include wildfire, infrastructure development, and invasive weeds (USFWS 2013). Fire risk is high across 81 percent of the region, and cheatgrass high risk areas are widespread (Manier et al. 2013). Though oil and gas development potential is low, geothermal energy potential is high along with development of utility infrastructure in designated corridors, such as Gateway West (Manier et al. 2013).

#### ***Management Zone II (Wyoming Basin Management Zone)***

Management Zone II in Idaho is located in the southeastern part of the state. It covers the portion of the Wyoming Basin (Bear Lake) population area within Idaho. The Wyoming Basin population area stretches into Colorado and Utah and has the highest abundance of GRSG relative to other management zones across GRSG range (more than 20,000 males), one of the largest areas of habitat, and the most highly connected GRSG lek network (USFWS 2013). Although long-term trends are slightly downward, populations in the Wyoming Basin are considered stable, with a 0.3 percent chance of declining below 200 males by 2037 (Garton et al. 2011). The northern portion of this MZ, including the Idaho portion, has high connectivity between habitats across the Wyoming Basin (Knick and Hanser 2011). Federal land comprises 54 percent of sagebrush habitat. The major threat to GRSG in this MZ is energy development, primarily oil and gas, in Wyoming (USFWS 2013). Impacts from infrastructure development, fire, cheatgrass spread, and improper grazing also pose threats in this region (Manier et al. 2013).

#### ***Population Metrics***

Several metrics are available that provide a relative index to GRSG populations (**Table 3-5, Occupied<sup>a</sup> Lek Metrics for GRSG Population Areas within the Idaho and Southwestern Montana Sub-Region**~~Occupied<sup>a</sup> Lek Metrics for GRSG Population Areas within the Idaho and Southwestern Montana Sub-Region~~). While population estimates for the sub-region or population areas are not currently available, the Idaho Department of Fish and Game, the Montana Department of Fish, Wildlife, and Parks, and the Utah Division of Wildlife Resources do compile monitoring data annually for hundreds of leks. Not all population areas are monitored or surveyed with the same intensity due to logistical, financial, meteorological, physical, or staffing constraints. Even so, the leks that are surveyed do provide useful information that can help provide additional context to the description of the environment. While **Table 3-5** provides a means of comparing the population areas, in some areas, lek data are very limited, and the information shown may be more a function of lower survey effort than of actual low numbers of males. Therefore, available habitat information and population indices must be considered in conservation planning for GRSG.

Two metrics that can be used to compare geographic areas are the number of occupied leks and the total maximum annual counts of males. Quantitative data are not available for

females across the analysis area as monitoring is confounded by their coloration and cryptic

**Table 3-5  
Occupied<sup>a</sup> Lek Metrics for GRSG Population Areas within the Idaho and Southwestern  
Montana Sub-Region**

Population Area	Number of Occupied Leaks	Proportion of Occupied Leaks Within the Sub-region	Average Number of Males Per Occupied Lek	Maximum Annual Total Count of Males and Proportion Relative to the Sub-Region
East-Central Idaho	12	1.3 %	6.7	92 (0.5%)
Mountain Valleys	169	18.7 %	18.6	5,125 (27.5%)
SW Montana (BLM Dillon Field Office and Beaverhead National Forest)	21	2.3 %	1.4	57 (0.3%)
North Side Snake	260	28.7 %	13.5	5,493 (29.4%)
Southwest Idaho	177	19.6 %	14.1	3,930 (21.1%)
South Side Snake (Includes the Sawtooth National Forest in Utah)	234	25.8 %	8.8	3,424 (18.3%)
Sawtooth	0	0 %	0	0 (0%)
Bear Lake	17	1.9 %	15.9	343 (1.8%)
Weiser	15	1.7 %	8.7	205 (1.1%)
<b>TOTAL</b>	<b>905</b>	<b>100%</b>	<b>12.9</b>	<b>18,884 (100%)</b>

<sup>a</sup>Occupied lek is defined as exhibiting at least 2 displaying males during at least one year during the 2007-2011 baseline period. Inclusive of all landownerships.

behavior. Occupied leks in this analysis are defined as those at which at least two male GRSG have been documented displaying in at least one breeding season from 2007 to 2011. A five-year timeframe was used since not all leks are surveyed each year due to logistical constraints; therefore, using a range of several years ensures a greater proportion of leks are considered in the analysis. IDFG also uses a five-year window in defining lek occupancy (IDFG 2012). However, population areas vary greatly in size, with some, such as the Southwest Idaho, South Snake, and North Snake, being quite large, while others, such as the Weiser, Sawtooth, and Bear Lake areas, are considerably smaller. Large areas may inherently harbor a larger number of leks and males by virtue of their scale, and smaller areas may have fewer leks or males.

Within the sub-region's population area, there were 905 occupied GRSG leks in 2011, inclusive of all landownerships, based on IDFG, MFWP, Utah Department of Wildlife

Resources (UDWR) and Wyoming Game and Fish Department data. Of the nine population areas in the sub-region, the Southwest Idaho, South Side Snake, and North Side Snake population areas encompassed the largest number of occupied leks, about 74 percent, in the sub-region. The total maximum annual count of males across all occupied leks within the nine population areas was 18,669. Population areas with the highest proportion of males at occupied leks, relative to the sub-region's total male count as a whole, included the North Side Snake (29.4 percent), Mountain Valleys (27.5 percent), and Southwest Idaho (21.1 percent). The Sawtooth (0.0 percent), Southwest Montana (0.3 percent), East-Central Idaho (0.5 percent), Weiser (1.1 percent), and Bear Lake (1.8 percent) harbored small proportions of the sub-region's total male count.

Another metric for comparing population areas is to calculate the average number of males per occupied lek. Average annual maximum number of males per occupied lek in the sub-region between 2007 and 2011 was 12.9. Population areas with the highest average maximum male attendance per lek were the Mountain Valleys (18.6), Bear Lake (15.9), and Southwest Idaho (14.1) population areas. The lowest average number of males per lek occurred in the Sawtooth (0.0), Southwest Montana (1.4), and East-Central Idaho (6.7) population areas. In the relatively isolated Sawtooth population area, GRSG have been observed by Forest Service personnel as recently as fall 2010 (Garwood 2013), but the last documented lek activity (2 males) at any of the three known leks was in 1993 (Idaho Department of Fish and Game 2012).

From both a regional and rangewide perspective, the South Side Snake and Southwest Idaho population areas are especially important to long-term conservation of GRSG in Management Zone IV. This is because they comprise a substantial portion of the Great Basin core population (Connelly et al. 2004), shared with Nevada, Utah, and Oregon, this is one of the two remaining major population strongholds in the range of the species. The North Side Snake and Mountain Valleys provide additional and substantial population contributions within Idaho. The latter also provides known connectivity with the Southwest Montana population area.

Several other population areas, albeit relatively less substantial in terms of certain population metrics, are nonetheless important to conservation. The Bear Lake, Southwest Montana, and Weiser population areas provide known or potential connectivity with GRSG in the adjacent states of Wyoming, Utah, Idaho, and Oregon. GRSG in these three population areas, as well as in East-Central Idaho and the Sawtooth, may also be somewhat more vulnerable to human disturbances or habitat loss due to comparatively smaller population indices or smaller geographic extent. The Sawtooth and East-Central Idaho population areas are also limited in terms of available lek data; therefore, the associated population metrics shown in **Table 3-5** may be conservative.

### 3.3 Vegetation

The composition and distribution of plant communities in the planning area are influenced by many factors, including climate, elevation, topography, soils, drought, insects, fire, cultivation, invasive plants, and livestock grazing. As a result, a wide variety of plant

communities occur, many of which play a role in providing seasonal or year-round habitat for GRSG. The major plant communities providing GRSG habitat are further detailed below. These plant communities vary greatly in their relative ecological health as a result of stressors that influence the distribution and abundance of the plant components within the general community. GRSG are a sagebrush obligate species and rely on a variety of sagebrush dominated communities to meet various needs throughout their lifecycle (Miller et al. 2011). In winter, GRSG feed almost exclusively on sagebrush leaves (Patterson 1952; Wallestad et al. 1975). A healthy vegetative understory complete with perennial grasses and a variety of forbs provide important components of nesting and brood rearing habitat (Barnett and Crawford 1994; Gregg et al. 1994). These vegetative communities also support a wide variety of insects which provide additional food sources for rearing habitat. Some plant communities play a role in seasonal habitat such as riparian areas, or in the case of annual grasses, or conifer stands, may influence the quality and abundance of habitat over time.

### 3.3.1 Conditions within the Planning Area

#### *Northern Sagebrush-Steppe*

Two major sagebrush communities that provide GRSG habitat occur within the planning area: the Snake River Plain and Wyoming Basin. The Snake River Plain sagebrush community makes up the vast majority of the habitat with a small portion of the Wyoming Basin community on the eastern side of the planning area. These communities are considered part of the northern sagebrush-steppe where sagebrush typically co-dominates with perennial bunchgrasses (Miller et al. 2011). Human alterations, uses, and impacts coupled with natural stressors (e.g., drought and fire) have changed the extent, condition, and distribution of sagebrush-steppe and the ecosystem services these communities provide (Meinke et al. 2009); current GRSG range is estimated to be 56 percent of distribution prior to Euro-American contact (Schroeder et al. 2004). Three of the fundamental characteristics of the sagebrush community that have been altered from prior to European contact conditions include: (1) the total area of sagebrush shrublands has been reduced; (2) the composition and structure of sagebrush communities has been changed, with increased abundance and vigor of invasive species and decreased abundance and vigor of native species; and (3) fragmentation created by roads, power-lines, fences, energy developments, urbanization, and other anthropogenic features (Connelly et al. 2004). Much of the sagebrush-steppe occurring on private lands with deeper soils has been converted to agricultural croplands (Connelly et al. 2004). Intense, historic land use in the late 19th and early 20th centuries reduced the dominance of native grasses, trampled microbiotic crusts, and encouraged expansion of Eurasian grasses (Anderson and Inouye 2001; Ponzetti et al. 2007; Root and McCune 2012). These changes are most intense at low elevations near valley floors and may have disproportionate effects on GRSG populations reliant on these habitats during critical portions of the year (Leu and Hanser 2011).

Some portions of the planning area contain relatively intact sagebrush-steppe communities. Plant communities such as these are in good to excellent ecological condition and maintain adequate forb and perennial grass in the understory to supply habitat requirements for GRSG.

Data available for analysis in this effort are limited to general overstory vegetation classes of tall shrub (e.g., basin big sagebrush, Wyoming big sagebrush, and mountain big sagebrush) and low shrub (e.g., black sagebrush and low sagebrush). This information can be further stratified based upon landscape characteristics to approximate the relative proportion of the various types of sagebrush plant communities. Data are not widely available concerning the relative ecological health of the plant communities within the project area.

#### ***Riparian and Wetlands***

Riparian vegetation includes plants that require higher amounts of available water supply than those found in adjacent upland areas and are generally associated with water courses and wet meadow areas. Riparian areas, wetlands, and wet meadows provide valuable GRSG late summer brood rearing habitat because these areas provide succulent forbs and insects later in the summer when most forbs in upland habitats have dried out and are senescent. These communities make up a small percentage of the vegetation in relation to other types but are quite important in providing the seasonal habitat mentioned.

#### ***Forest and Woodland***

The conversion of sagebrush-steppe communities into conifer woodlands is a factor contributing to GRSG habitat decline in portions of the planning area. Trees increase raptor perch and nest sites, potentially making GRSG more vulnerable to predation. Conifer expansion is generally attributed to fire suppression reducing fire frequency and allowing conifers to expand into riparian areas, shrublands, and grasslands. This conversion is mostly an issue in the mountain big sagebrush types where reduced fire frequency has allowed the invasion of juniper (Utah, Rocky Mountain, or Western) and in some areas Douglas-fir and pine may be expanding into shrub habitats.

#### ***Noxious Weeds and Invasive Species***

Noxious weeds and invasive species include plants listed as “noxious” by state laws and also those plants known to be altering the dynamics of native plant communities by replacing native plants through competition or altering some ecological process to the detriment of the native plant community such as in the case of annual bromes increasing fire frequency.

Specific noxious weeds causing localized impacts within the planning area include rush skeletonweed, leafy spurge, diffuse knapweed, and spotted knapweed. Although not yet well established in the planning area, yellow starthistle is known to have a similar range as cheatgrass, and many of the areas currently supporting annual grass communities could support this noxious weed. Other weeds listed as noxious occur within the planning area but are not as widespread or detrimental as those listed.

Invasion by exotic annual grass species has resulted in dramatic increases in number and frequency of fires with widespread, detrimental effects on habitat conditions (Young and Evans 1978; West and Young 2000; West and Yorks 2002; Connelly et al. 2004). Increased fire frequency typically results in removal of the sagebrush canopy in affected areas with replacement by annual species that provide little to no habitat value (Knapp 1996; Epanchin-Niell et al. 2009; Rowland et al. 2010; Baker 2011; Condon et al. 2011). Invasive annuals include numerous species of annual bromes, most notably cheatgrass (*Bromus tectorum*) as well

as medusahead rye (*Taeniatherum caput-medusae*). An annual species that may be a threat in higher elevation communities providing GRSG habitat is ventenata (*Ventenata dubia*). Wyoming sagebrush plant communities are particularly susceptible to conversion to annual grasslands after fire when the understory contains higher densities of annual grass.

Once converted to exotic annual grasses, these plant communities have crossed a threshold that precludes their returning to traditional plant community composition through normal plant succession processes. These areas are essentially lost in their ability to provide GRSG habitat unless significant investment in restoration inputs are undertaken. Even then, these projects may fail if conditions do not exist for successful establishment of desired species. The potential for cheatgrass occurrence has been modeled, which can help discern locations and habitats that have the greatest risk of cheatgrass dominance after disturbance events such as fire.

#### ***Modified Grasslands***

Some portions of the planning area formerly composed of sagebrush plant communities currently support introduced perennial bunchgrasses or in some cases a mixture of introduced and native bunch grasses. These communities can include common native forbs and over time may develop a sagebrush overstory. Introduced bunchgrasses that may inhabit these areas include a numerous crested wheatgrass varieties (e.g., Fairway, Ephraim, Douglas, Nordan, and Hycrest) as well as Siberian wheatgrass and, in the case of higher precipitation zones, pubescent or intermediate wheatgrass. In some cases, nonnative grasses were seeded to increase livestock forage, but were also be better adapted in competing with and suppressing invasive annual grasses. These plant communities also provide habitat for GRSG once the overstory of sagebrush is re-established.

#### ***Permanent Conversion***

Within the planning area, portions have been permanently converted to uses that preclude them from providing GRSG habitat. This includes conversion to agricultural lands as well as development or urbanization. In much of the Snake River Plain, these lands were at one time supporting sagebrush plant communities.

#### **3.3.2 Conditions on BLM-Administered Lands**

The habitat most important to BLM-administered lands in this planning effort is the overstory vegetation component. As described above, GRSG are a sagebrush obligate species, so an overstory component of sagebrush is a good indicator of potential habitat. Perennial grasslands are also an important component to track as they are still capable of providing habitat if the overstory of sagebrush is returned. Tracking the relative expansion or reduction in annual grass dominated lands is also a potential indicator of our success in protecting GRSG habitat. These broad-scale vegetation types are currently being tracked through various efforts.

### 3.3.3 Conditions on Forest Service-Administered Lands

In general the plant communities and disturbance factors that influence them are the same on Forest Service-administered lands as on BLM-administered lands. As a general rule, the Forest Service-administered lands with GRSG habitat in the planning area tend to be on the higher end of the precipitation and elevational gradient. Therefore, the relative proportion of sagebrush plant communities on Forest Service-administered lands would be higher for the mountain big sagebrush plant communities, at the higher elevation and precipitation gradient, and lower for Wyoming big sagebrush plant communities which occur at the lower end of the precipitation range for big sagebrush. Due to the more resilient nature of mountain big sagebrush communities after disturbance, it is less likely they will be impacted by invasive annual grass and convert to annual grass plant communities.

### 3.3.4 Trends

The main disturbance factors with the potential to alter vegetation providing GRSG habitat over a majority of the planning area include conversion to annual grassland following fire disturbance, modification of plant communities due to livestock grazing, and the potential impacts of climate change. To a lesser extent, some permanent conversion to agriculture or urbanization may occur, but typically these areas are already highly disturbed and not likely to be providing high-quality GRSG habitat.

### 3.4 Fish and Wildlife

#### 3.4.1 Terrestrial Wildlife

##### *Conditions within the Planning Area*

The BLM and Forest Service manage wildlife habitat, and the state wildlife management agencies manage wildlife populations. These habitats reflect the influence of a variety of past and ongoing human activities and disturbances, resulting in increases in some species populations, declines in others, and the modification of large blocks of habitat. These habitats and the wildlife species that rely on them rarely exist solely on BLM-administered or Forest Service-administered lands, and often extend across administrative boundaries to other federal, state, and private lands. Further information regarding wildlife on Forest Service-administered lands is provided in **Appendix M** and **Appendix N**.

The BLM-administered and Forest Service-administered lands in the Idaho and Southwestern Montana planning area provide a variety of habitats. Landownership ranges from mostly sagebrush habitats in Owyhee County, Idaho, to scattered BLM-administered and Forest Service-administered lands with intermingled private and state lands composed of sagebrush habitats in southwestern Montana. On BLM-administered and Forest Service-administered lands, these habitats can be segregated into four major habitats groups: sagebrush steppe, riparian/wetlands, nonnative grasslands, and conifer woodlands/forests. These habitats serve as a basis, to the extent practical, for describing existing conditions, and for developing and comparing management alternatives throughout the planning effort.

*Sagebrush Steppe Habitats*

Sagebrush steppe habitats in the planning area are found in the Snake River Plain and minor portions in the Wyoming Basins floristic provinces identified by West (1983). These sagebrush habitats are the dominant habitat within the planning area. Riparian and wetland habitats, nonnative grasslands, and conifer/woodland forest habitats are interspersed within and adjacent to sagebrush habitats.

Sagebrush habitats occur from lower elevation (2,500 feet) drier salt desert shrub communities to mountain shrub communities at 10,100 feet in elevation. Sagebrush habitats support a wide diversity of generalist wildlife species, as well as sagebrush-dependent wildlife species.

At mid- to lower elevations, Wyoming big and basin sagebrush are the dominant habitat types that provide important winter habitat for wildlife species such as mule deer, pronghorn, and GRSG, and localized yearlong habitat by sagebrush-obligate species such as pygmy rabbit. Much of the basin big sagebrush habitats are limited to deeper soils near ephemeral drainages. Intermingled occurrences of basin big sagebrush, mountain big sagebrush, tall three-tip sagebrush, and several low sagebrush's such as low (little) and black sagebrush add to the diversity of vegetation and habitat structure. At higher elevations, moist mountain big sagebrush communities provide elk calving and GRSG brood-rearing habitat along with dispersed spring, summer, and fall habitat for numerous other species, often in association with conifer woodland/forested habitat. Mixed sagebrush communities and localized dominance by other sagebrush species on specific sites within the broader sagebrush types often support uniquely dependent wildlife uses, such as pygmy rabbits.

Many sagebrush steppe habitats have been modified or disturbed throughout the planning area during the past 150 years; therefore the species dependent upon them have usually been negatively affected. Primary factors causing change in sagebrush steppe habitats are wildfire and changes in fire regimes, invasive species, anthropogenic development, and livestock grazing (Miller et al. 2011, Knick et al. 2011). Wildfire and changes in fire regimes effects xeric sagebrush steppe and is highly influenced by the spread of invasive species, especially exotic annual grasses such as cheatgrass or medusahead. In these lower elevation habitats, fire return intervals are greatly shortened and prevent the reestablishment of sagebrush. Large areas of the Snake River Plain in southern Idaho have undergone these habitat changes, thus making habitats less suitable for wildlife.

Past management activities that reduce sagebrush habitats include herbicide application, plowing, or other techniques followed by seeding of nonnative perennial grasses. These land treatments or burned areas following wildfire have historically been seeded to highly competitive introduced species such as crested wheatgrass, desert wheatgrass, and Siberian wheatgrass. The characteristics that made these introduced species effective for seeding establishment also created communities dominated by near monocultures, which resulted in poor quality habitats for wildlife lacking sagebrush or forbs (Pyke 2011). Recent policies have encouraged native seed mixes, but many times native seed supplies are limited or not affordable within current budgets. Seed in some seed mixes used in these treatments may have been selected for other wildlife species and not specifically for GRSG (Knick et al. 2011).

In higher elevations of sagebrush steppe, conifer woodlands/forests have encroached into sagebrush habitats. Miller and Rose (1999) identified that the encroachment of conifer woodlands/forests was the result of longer fire return intervals that permitted woodland expansion to occur into sagebrush steppe. Conifers greater than 50 years old on productive sites and greater than 90 years on nonproductive sites results in reduced fire frequency,

permitting the establishment of conifers on the site (Burkhardt and Tisdale 1976; Bunting 1984; Miller and Rose 1999). A number of studies identified a widespread decline in fires at the sagebrush/conifer interface with the coincidence of large numbers of livestock in the late 1800s (Miller and Rose 1999; Heyerdahl et al. 2006; Swetnam et al. 2001). These large numbers of cattle may have reduced the current year's fuel loads and changed the structure and abundance of fuels, thus reducing the frequency of wildfires (Miller et al. 2011). Increased tree dominance by conifers results in a decline of cover by sagebrush and other shrubs.

Anthropogenic development has reduced the amount and quality of sagebrush steppe habitat across much of the planning area. The activities have occurred on private lands but infrastructure to support urbanization and agriculture along the Snake River Plain and other waterways has occurred on BLM-administered and Forest Service-administered lands. Many of these types of facilities or uses include railroads, roads, power lines, pipelines, irrigation canals, communication towers, military training, and off-highway vehicle use (Knick et al. 2011).

Livestock grazing is the most widespread land use across sagebrush steppe habitats from the 1880s to present. Livestock numbers and use of these habitats was greatest from the late 1880s through the 1930s. During this period the greatest change occurred to these habitats as a result of heavy livestock use and drought that resulted in loss of soil and depleted native vegetation communities that greatly impacted these habitats (Knick et al. 2011). From the 1940s until the 1980s, plowing, herbicides, and burning followed by seeding nonnative perennial grasses to increase forage for livestock production occurred, thus impacting many sagebrush habitats in southern Idaho.

In recent decades, management emphasis has shifted towards maintaining healthy, functioning native ecosystems and reducing the spread of nonnative species. Grazing regulations enacted in 1995 mandated that public land grazing allotments conform to the Fundamentals of Rangeland Health, as well as subsequent Standards and Guidelines (S&Gs), and that changes to grazing management be made if livestock management is determined to be a significant causal factor in failing to meet Fundamentals of Rangeland Health or S&Gs. Since that time, the BLM has been reviewing rangeland health conditions and modifying livestock grazing management as necessary to conform with the Fundamentals of Rangeland Health and S&Gs. In addition, vegetation treatments have occurred on many allotments in an effort to restore functionality of impacted sagebrush steppe habitats. For more information about livestock grazing, see **Section 3.8**, Livestock Grazing.

#### *Riparian/Wetland Habitats*

Riparian habitats are regarded as one of the most important habitats for wildlife due to the availability of water and the structural diversity of the vegetation communities. Approximately 75 percent of all wildlife species utilize riparian habitats for at least some portion of their annual life cycle (USEPA 1990). Riparian habitats are estimated to make up approximately 1 percent of all habitats in the planning area. The riparian habitats in the planning area are composed of lotic systems that are associated with running water or lentic/wetland habitats associated with standing water.

Riparian habitats in the planning area have been subject to many activities that have affected their functionality and their ability to support wildlife. These activities include dewatering for irrigation, domestic cattle grazing, road construction, dam construction, and land treatments. The impacts from these activities include changes in plant species composition and structure, vegetative cover, sedimentation, changes in water quality and temperature, streambank alteration, and duration of available water.

Wildlife habitat values are degraded on riparian habitats with functional-at-risk or nonfunctional conditions. Information on proper functioning condition is not available at the sub-regional planning scale.

#### *Big Game*

The planning area hosts a wide variety of big game species including mule deer, pronghorn, and elk that use habitats associated with sagebrush steppe and riparian habitats. Other big game species that are found in these habitats but in lesser amounts include bighorn sheep, moose, and white-tailed deer. The planning area provides habitat for all seasonal use periods for mule deer, pronghorn, elk, bighorn sheep, and other species. These species are generally widespread across the entire planning area.

Mule deer are the most abundant and widely distributed big game animal. Mule deer populations and mule deer habitat have changed greatly during the past 100 years. Loss of shrub-steppe habitats, conversion of native landscapes to agriculture or residential development, and past and current grazing management are key management issues for mule deer populations throughout the planning area (Cox et al. 2009).

Within the planning area mule deer populations vary greatly from current population objectives. In southeast Idaho populations have undergone declines following the winters of 1992-1993 and have been slow to respond to changes in management activities (IDFG 2011a). This has resulted in IDFG developing an initiative to target this area of the state to modify management strategies and improve habitat conditions for mule deer. In other portions of the planning area, including south-central Idaho and southwestern Montana, populations appear to be stable or increasing but are below levels observed in the late 1980s and early 1990s (IDFG 2011a; MFWP 2012).

Mule deer are primarily browsers and their diet is composed mostly of leaves and twigs of shrubs, especially during the winter. Grasses and forbs are also crucial components of their diet in the spring and summer. The quality and quantity of nutritious forage in spring (April through July) has major implications on the production and survival of fawns. Summer and fall ranges are important because this is where deer produce fat reserves that will allow survival through winter. The quality of summer-fall forage also directly influences pregnancy and ovulation rates and, therefore, fawn production (Cook et al. 2001; Tollefson et al. 2010; Vavra 1992). Much of Idaho's historic mule deer winter range has been developed for other uses and is now occupied by man. Residential, commercial, and industrial developments located in the foothills and at lower elevations have eliminated winter range (IDFG 2011a).

Pronghorn distribution has changed relatively little since the early 1980s but numbers have trended downward since the winters of 1993-1994 (IDFG 2011b). Pronghorn are typically associated with sagebrush habitats but readily use grasslands if there are adequate amounts of forbs (Yoakum 2004a). In sagebrush habitats, pronghorn diets consist of sagebrush and other shrubs during all seasons, but particularly in the fall and winter (Yoakum 2004a). Forbs are preferred by pronghorn when available (Yoakum 2004b). The availability of forbs in sagebrush habitats may have important implications for pronghorn because they are rich in nutritional values required for reproduction (Pyrah 1987; Yoakum 2004b). Large landscape level fires have reduced the availability of sagebrush in parts of their range. In portions of the planning area, extensive fencing has contributed to the inability of some populations to access otherwise suitable habitats. Noxious weeds, livestock grazing, and drought has also impacted current pronghorn populations and their habitat.

Elk are found throughout the planning area in sagebrush steppe and associated conifer/forested woodlands. Elk are considered generalists and are not totally dependent upon sagebrush steppe, but they do require food, water, and where hunted, hiding cover and security areas. The combination of the resources determines the distribution and number of elk within sagebrush steppe. Elk populations in the planning area are generally at or above state wildlife management agencies objectives (IDFG 2011c; MFWP 2004).

Other big game species, such as moose, bighorn sheep, and white-tailed deer are also found in the planning area. Moose and white-tailed deer are generally associated with riparian/wetland habitats. Bighorn sheep usually are found near escape terrain composed of steep rugged slopes and make use of sagebrush steppe year round in southwest Idaho. In east-central Idaho and southwestern Montana, bighorn sheep generally make use of sagebrush steppe near escape terrain during the winter and spring.

#### *Migratory Birds*

There are numerous species of migratory birds that use the planning area during part of the year, including over 40 species of greatest conservation need in Idaho and in Montana (IDFG 2005; BLM 2006). These birds are as diverse as the Calliope hummingbird, green-tailed towhee, Brewer's sparrow, ferruginous hawk, mallard, and sandhill crane. Most of these birds are summer residents that use habitats ranging from low elevation wetlands to high elevation forests for breeding and raising young. Some species such as American robin and mallard are migratory, but small populations may be present yearlong depending on seasonal conditions. Winter residents such as the rough-legged hawk, snow buntings, and rosy-crowned gray finches arrive from arctic breeding grounds, or high elevation alpine areas to utilize winter habitats in sagebrush steppe, seasonally replacing summer residents.

The 1988 amendment to the Fish and Wildlife Conservation Act mandates the USFWS to "identify species, sub species, and populations of all migratory nongame birds that, without additional conservation actions, are likely to become candidates for listing under the Endangered Species Act of 1973." Birds of Conservation Concern 2008 (USFWS 2008) is the most recent effort to carry out that mandate and identifies those species in greatest need of conservation action in specific geographic bird conservation regions. The planning area overlaps three bird conservation regions. These regions include the Great Basin, Northern

Rockies, and a very small portion of the Southern Rockies/Colorado Plateau. The list of species likely to inhabit sagebrush steppe and riparian/wetlands of this planning area for these three conservation regions can be found in **Appendix O**. This mandate was emphasized with the issuance of Executive Order 13186, which directs federal land management agencies to develop cooperative plans to protect and manage habitat for all migratory birds. Expansion of funding opportunities under the North American Wetlands Conservation Act and other partnership opportunities through the North American Bird Conservation Initiative will support increased management consideration for these species.

#### *Furbearers/Upland Game/Non-Game*

A large variety of other wildlife species use both sagebrush steppe, riparian/wetland habitats, and nonnative grasslands and conifer woodland/forests habitats within and adjacent to sagebrush steppe in the planning area. Furbearers commonly found in these habitats include red fox, bobcat, muskrat, beaver, and mink. River otter may be present, but the species is generally associated with larger river riparian systems. Cottontail and pygmy rabbits are found throughout the planning area and their numbers are variable as populations are cyclic (USFWS 2010b). Pygmy rabbits, a species of greatest conservation need in Idaho and southwestern Montana, are found in sagebrush habitats with relatively deep, loose soils that provide food and shelter. Upland game birds common or locally abundant in the planning area include Columbian sharp-tailed grouse, pheasant, mourning dove, chukar, gray partridge, California quail, dusky (blue) grouse, and ruffed grouse.

Many other species of nongame wildlife have limited information on their distribution or life history requirements. Information on these species is maintained by the Idaho, Montana, Utah, and Nevada Natural History Programs within each state. Site-specific inventories have not been conducted for many of the species but information about species distribution and relative abundance continues to be modified as funding becomes available. **Appendix O** identifies wildlife species likely to occur in sagebrush steppe and riparian/wetland habitats in the planning area.

#### *Amphibians/Reptiles*

Amphibians, specifically frogs and toads, have been recognized as important indicators of ecosystem health, as many populations are declining in the western US. Amphibians are generally found near some form of water. There are eight species of salamanders, frogs, and toads found in the planning area, including three species of greatest conservation need in Idaho; there are three amphibian species on the BLM special status species list in Montana (IDFG 2005; Montana Natural Heritage Program 2013). **Appendix O** identifies the species that are likely to occur in or adjacent to sagebrush habitats and riparian/wetland habitats.

There are 16 species of reptiles occurring in sagebrush habitats and riparian/wetland habitat in the planning area. These include seven lizard species, one turtle species, and eight snake species. The sagebrush lizard and short-horned lizard are two of the most common species associated with sagebrush habitats. Two snake and two reptile species found in the planning area are species of greatest conservation need in Idaho (IDFG 2005). There are no BLM special status reptile species in the southwestern Montana portion of the sub-region

(Montana Natural Heritage Program 2013). **Appendix O** identifies the species that are likely to occur in or adjacent to sagebrush habitats.

#### *Insects*

Insect occurrence and distribution are not generally specifically considered in land management activities. Three species of insects that are identified as sensitive species due to their limited distribution occur in or immediately adjacent to sagebrush habitats. These species include Idaho pointheaded grasshopper, St. Anthony Sand Dunes tiger beetle, and Bruneau Dunes tiger beetle (See **Section 3.5**, Other Special Status Species).

Insects provide important food sources for many species of wildlife including adult and juvenile GRSG. Although there are thousands of species of insects occurring in sagebrush and riparian and wetland habitats, species in the *Scarabaeidae* and *Tenebrionidae* (beetle) families, *Formicidae* (thatch ants) family, and *Orthoptera* (grasshopper) family play a crucial role in the diet of many wildlife species (including GRSG) as a high protein food source (Klebenow and Gray 1968; Peterson 1970; Johnson and Boyce 1990; Pyle 1993; Fischer 1994; Drut et al. 1994).

### **3.4.3 Aquatic Wildlife**

#### ***Conditions within the Planning Area***

Fish of interest within the planning area consist primarily of cold-water species. The condition of aquatic habitat is influenced by upland and riparian processes. Uplands influence aquatic habitat primarily through hydrologic processes. For example, the arid nature of the planning area makes the influence of groundwater on surface water particularly important. Therefore, impacts on uplands, such as compaction, that reduce water infiltration have the potential to reduce the amount of groundwater being released into streams. Water in compacted areas can pond on the surface and be lost into the atmosphere through evaporation or be delivered rapidly to channels during high flows. The amount of water and whether it enters stream channels via surface flow or subsurface flow have a significant effect on sediment delivery and deposition, streamside vegetation, and water quality. Riparian areas influence aquatic habitat more directly due to their proximity to water. For example, riparian vegetation shades streams from solar radiation which reduces increases in water temperature, and provides organic material to streams which act as a food source for aquatic macroinvertebrates. Well-vegetated floodplains dissipate energy of flood flows, provide velocity refugia for juvenile and adult fish during flood events, filter sediment during floods, and store water for release during lower flows. Fine sediment deposition within the substrate; and water quality, including, temperature, turbidity, and dissolved oxygen affect fish and fish habitat.

Aquatic habitat within the planning area includes perennial and intermittent streams, springs, lakes, and reservoirs that support fish during at least a portion of the year.

The majority of the planning area within Idaho is within the Snake River basin, while the portion of the planning area within Montana is within the Missouri River basin. The portion

of the southeast corner of Idaho is located within the Bear River basin which flows into the Great Salt Lake.

The climate throughout the planning area is generally arid, with runoff being dominated by spring snowmelt. Summer flows are provided by snowmelt, subsurface storage, and thunderstorm events. Native fish species consist primarily of salmonids, sculpin, and minnows, and suckers.

**Conditions on BLM-Administered and Forest Service-Administered Lands**

Fish-bearing streams, and lakes, ponds, and reservoirs within the planning area provide habitat for a variety of native and nonnative game and nongame fish species. **Table 3-17**, Native and Nonnative Fish Species Found within the Planning Area and their Status, displays the various fish species that occur within the planning area.

**Table 3-17  
Native and Nonnative Fish Species Found within the Planning Area and their Status**

Common Name	Scientific Name	Status

**Status of Aquatic Species in the Planning Area**

The following discussion on status of aquatic species focuses on native species and particularly special status species. Twelve of the seventeen special status species are salmonids, three are sculpin, one is the white sturgeon, and one is the northern leatherside chub. None of the special status species are ubiquitous across the planning area. Each

species is found in a particular portion of the planning area with some of the species being endemic to a particular water body or portion of a water body.

Three of the 12 salmonids are anadromous fish found in the BLM Challis and Salmon field offices and the Payette, Salmon-Challis, and Sawtooth national forests, and each is listed under the ESA. Snake River Basin steelhead and Snake River spring/summer-run Chinook salmon are listed as threatened under the ESA and Snake River sockeye salmon are listed as endangered under the ESA. Adults passing Lower Granite dam on the Snake River are counted for all three of these species (Columbia Basin Research 2013). The 10-year average number of adults passing Lower Granite dam from 2003 through 2012 for steelhead is 190,535, for spring/summer-run Chinook salmon is 67,241, and for sockeye salmon is 610.

Bull trout within the planning area are found in the BLM Salmon, Challis, Jarbidge, and Upper Snake field offices and the Boise, Payette, Salmon-Challis, and Sawtooth national forests, and are listed as threatened under the ESA. Bull trout in the planning area largely occupy higher elevation areas with cold water temperatures.

The native range of redband trout within the planning area is the Snake River and its tributaries up to Shoshone Falls and the upper Salmon River basin. The current distribution of redband trout has been significantly reduced relative to the historical distribution, and it is likely that across its range slightly more than 44 percent of the occupied stream miles contain redband that have been genetically altered due to extensive stocking of hatchery fish (Wild Trout Enterprises 2012). Conditions for occupied redband trout habitat across its range was rated as part of the 2012 redband trout status assessment (Wild Trout Enterprises 2012). Approximately 5 percent of habitats were judged to be in excellent condition, 27 percent were judged to be in good condition, 34 percent in fair condition, 18 percent in poor condition, and 16 percent of the occupied habitats were not rated.

Three cutthroat trout species occur within the planning area: Westslope cutthroat, Yellowstone cutthroat, and Bonneville cutthroat. In Idaho, Westslope cutthroat only occur in the Salmon River portion of the planning area, while they occur in the entire portion of the planning area within Montana. Wild Trout Enterprises (2009) estimated that Westslope cutthroat currently occupy 58 percent of the stream miles they historically occupied across their range. Conditions for occupied Westslope cutthroat habitat across its range were rated as part of the 2009 Westslope cutthroat status assessment (Wild Trout Enterprises 2009). Approximately 18 percent of habitats were judged to be in excellent condition, 41 percent were judged to be in good condition, 24 percent in fair condition, 4 percent in poor condition, and 13 percent of the occupied habitats had an unknown condition. Within the planning area, Yellowstone cutthroat occur in the Snake River system above Shoshone Falls and within the Yellowstone River system. May et al. (2007) determined that Yellowstone cutthroat currently occupy 43 percent of the stream miles they historically occupied. Conditions for occupied Yellowstone cutthroat habitat across its range were rated as part of the 2006 Westslope cutthroat status assessment (May et al. 2007). Approximately 14 percent of habitats were judged to be in excellent condition, 52 percent were judged to be in good condition, 20 percent in fair condition, 5 percent in poor condition, and 9 percent of the occupied habitats had an unknown condition. In the planning area, Bonneville cutthroat

trout only occur within the Bear River drainage in southeast Idaho. An adfluvial population occurs in Bear Lake. The range-wide status of Bonneville cutthroat improved considerably from 1980 to 2000 (Lentsch et al. 2000).

Seven of the remaining nine special status fish species are endemics. Four species, Bear Lake whitefish, Bonneville whitefish, Bonneville cisco, and Bear Lake sculpin are endemic to Bear Lake. While the Big Lost River whitefish is endemic to the Big Lost River system, the Shoshone sculpin is endemic to springs and spring creeks in the Hagerman Valley, and the Wood River sculpin is endemic to the Wood River system.

The white sturgeon occurs in the Snake River below Shoshone Falls. Their numbers have been greatly reduced largely due to the lack of passage at dams and reduced spawning habitat due to the reservoirs behind the dams. The sturgeon fishery in the Snake River is popular, but no harvest of white sturgeon is allowed.

The northern leatherside chub has a patchy distribution within the planning area. The species occupies habitat within the Goose Creek and Salt River systems. They are generally found sporadically, in low numbers, and in the presence of other minnow species, such as redbelly shiners and speckled dace. The USFWS completed a status review for the species in 2011, and found that they were not warranted for listing under the ESA.

In general, the remaining fish in **Table 3-17** are more broadly distributed within the planning area. Special status aquatic mollusks are discussed in the Special Status Species section of the EIS.

### 3.5 Other Special Status Species

#### 3.5.1 Conditions within the Planning Area

The list of special status species for BLM-administered lands in Idaho and the Western Montana District; the Beaverhead-Deerlodge, Boise, Caribou, Challis, Payette, Salmon, Sawtooth, and Targhee National Forests; and the Curlew National Grassland includes mammals, birds, reptiles, amphibians, fish, invertebrates, and plants (**Appendix P**). There are 383 special status species. Of these, 28 species are mammals, 51 are birds, 4 are reptiles, 8 are amphibians, 25 are fish, 21 are invertebrates, and 246 are plants.

The BLM's objectives for special status species are to conserve and recover ESA-listed species and the ecosystems on which they depend so that ESA protections are no longer needed for these species, and to initiate proactive conservation measures that reduce or eliminate threats to BLM sensitive species to minimize the likelihood of and need for listing of these species under the ESA. The BLM 6840 Manual, Special Status Species Management, sets policy for the management of candidate species and their habitat. The 6840 manual directs the BLM to undertake conservation actions for such species before listing is warranted and also to "work cooperatively with other agencies, organizations, governments, and interested parties for the conservation of sensitive species and their habitats to meet agreed on species and habitat management goals."

The BLM 6840 Manual requires the BLM to identify strategies, restrictions, management actions, and provisions necessary to conserve or recover ESA-listed species and conserve BLM sensitive species. The 6840 Manual also requires managers to determine to the extent practicable, the distribution, abundance, population condition, current threats, and habitat needs for sensitive species, and evaluate the significance of actions in conserving those species.

Similarly, Forest Service direction for threatened and endangered species is to manage habitats and activities to achieve recovery of these species so that special protection measures provided under ESA are no longer necessary. Direction for sensitive species is to develop and implement management practices to ensure that these species do not become threatened or endangered because of management actions. Additionally, the Forest Service Manual 2670 directs the Forest Service to maintain viable populations of all native and desired nonnative wildlife, fish, and plant species.

Activities within the planning area are likely to primarily affect sagebrush habitat. Areas of conifer encroachment (primarily western or Utah juniper; Douglas-fir in some limited areas) targeted for sagebrush restoration to benefit GRSG will also be affected to varying degrees depending on time and scale. Therefore, only those species that depend on sagebrush habitat or that are strongly associated with juniper will be analyzed. **Table 3-18**, Special Status Species, identifies these species, their status, and where the designations apply. There are a total of 215 special status species that depend on sagebrush habitat. Of these, 16 species are mammals, 20 are birds, 4 are reptiles, 3 are amphibians, 3 are invertebrates, and 169 are plants.

### 3.6 Wild Horse and Burro Management

The Wild Free-Roaming Horses and Burros Act of 1971, as amended by FLPMA and the Public Rangeland Improvement Act of 1978, directs the protection and management of wild horses and burros on BLM-administered and Forest Service-administered lands. Both the

BLM and Forest Service have responsibility for managing Wild and Free Roaming Horses and Burros. Under the Act, the BLM identified herd areas as places used as habitat by a herd of wild horses at the time the Act was passed. To carry out its duties under the 1971 law, the BLM periodically evaluates each herd area to determine if it has adequate food, water, cover, and space to sustain healthy and diverse wild horse and burro populations over the long-term. The areas that meet these criteria are then designated as HMAs, where horses or burros can be viably managed as a component of the BLM-administered lands. The BLM designates an appropriate management level (AML) and specifies an allowable range in horse numbers for each HMA based upon available forage and other resources necessary to sustain the horse or burro populations, as well as resource objectives and other designated uses of the BLM-administered lands.

Wild horse and burro management areas on Forest Service-administered lands are called territories. However, no active territories exist within the planning area. There are two inactive territories in Idaho on the Challis National Forest which no longer have any wild horses.

### 3.6.1 Conditions on BLM-Administered Lands

Within the planning area, the BLM manages six HMAs, all in the state of Idaho: four in the Boise District, one in the Twin Falls District, and one in the Idaho Falls District. Additionally, there are nine herd areas within the planning area, five of which are in southwestern Montana, and four of which are in Idaho (see **Figure 3-2**, Wild Horse and Burro Herd Management Areas and Herd Areas). The HMAs encompass approximately 361,900 acres of BLM-administered lands, and support between 424 and 617 head of horses when populations are within AML. Approximately 551 horses are on BLM-administered lands within these HMAs based upon current population estimates (**Table 3-19**, [HMAs within the Planning Area](#)).

### 3.6.2 Conditions on Forest Service-Administered Lands

The Forest Service does not manage any wild horses or burros within the planning area.

### 3.6.3 Regional Context

**Table 3-20**, [Acres of Wild Horse and Burro Areas within GRSG Habitat in the Planning Area](#), displays acres of wild horse and burro territories in GRSG habitat (Manier et al. 2013). In the table, data are presented by surface management agency and their occurrence within occupied habitat in the planning area.

### 3.7 Wildland Fire Management

The Federal Wildland Fire Management Policy was developed by the Secretaries of the Departments of the Interior and Agriculture in 1995 in response to dramatic increases in the frequency, size, and catastrophic nature of wildland fires in the US. The 2001 review and update of the 1995 Federal Wildland Fire Management Policy consists of findings, guiding principles, policy statements, and implementation actions, and replaces the 1995 Federal Wildland Fire Management Policy. Known as the 2001 Federal Wildland Fire Management Policy (DOI et al. 2001), this update recommends that federal fire management activities and programs include the following:

- Provide for firefighter and public safety
- Protect and enhance land management objectives and human welfare
- Integrate programs and disciplines
- Require interagency collaboration
- Emphasize the natural ecological role of fire
- Contribute to ecosystem sustainability

The Federal Wildland Fire Management Policy provides nine guiding principles fundamental to the success of the federal wildland fire management program and the implementation of review recommendations. These umbrella principles compel each agency to review its policies to ensure compatibility.

The wildland fire management program encompasses the full range of hazardous fuels, management of wildfire, and the rehabilitation of lands affected by wildfire.

The wildfire suppression program utilizes a coordinated effort to respond to all unplanned ignitions (wildfire) with a preplanned, appropriate response. Each response is guided by LUP and fire management plan direction. As the severity and number of wildfires escalates, the further response and prioritization of fire suppression resources becomes a collaborative effort with all management levels within BLM and Forest Service working closely with interagency partners.

Trend analysis of fire starts and acres burned in the sage steppe ecosystem is very general and dependent predominately upon weather and fuels conditions. The relative fuel conditions of live fuel moistures and fine fuel loadings coupled with weather conditions such as relative humidity, wind speed, and days since last rainfall drive large fire growth in the grass fuel type.

Fire occurrence is weighed towards human causes, especially around urban centers and along major highway corridors. However, lightning is the major contributor to multiple large fire days and high numbers of acres burned. Lightning storms generally track from southwestern towards eastern Idaho, leaving successive lightning starts across all three southern districts, often times in remote or difficult to reach areas. These lightning events are commonly associated with strong winds, which contribute to rapid large fire growth. Summer storms commonly lack significant rainfall. It should be reasonably expected that the majority of large fire days correspond to high percentile Burning Index days. Burning Index is a number related to the contribution of fire behavior to the effort of containing a fire. The Burning Index rates fire danger related to potential flame length over a fire danger rating area.

Since 2006, emphasis upon the protection of GRSG habitat during suppression actions has taken center stage in planning and operational discussions. High numbers of PPH and PGH acres were burned in 2007 and 2012. The majority of these acres were burned during

corresponding high Burning Index days or periods. Fire season generally extends from early June thru October, and large fires can be expected during that time.

*Fire Regime Condition Class*

Natural Fire Regime: A natural fire regime is a general classification of the role fire would play across a landscape without modern human mechanical intervention (Agee 1993; Brown 1995). The five natural fire regimes are classified based on average number of years between fires (fire frequency) combined with the severity of the fire on the dominant overstory vegetation (amount of vegetation replacement). These five regimes include:

- I – 0 to 35 year frequency and low (surface fires most common) to mixed (less than 75 percent of the dominant overstory vegetation replaced) severity
- II – 0 to 35 year frequency and high severity (greater than 75 percent of the dominant overstory vegetation replaced)
- III – 35 to 100+ year frequency and mixed severity (less than 75 percent of the dominant overstory vegetation replaced)
- IV – 35 to 100+ year frequency and high severity (greater than 75 percent of the dominant overstory vegetation replaced)
- V – 200+ year frequency and high severity (greater than 75 percent of the dominant overstory vegetation replaced)

Fire regime condition class (FRCC) is a classification of the amount of change in fire frequency and severity from the natural fire regime (Hann and Bunnell 2001). The three classes are based on low (FRCC 1), moderate (FRCC 2), and high (FRCC 3) change from the natural fire regime (Hardy et al. 2001; Schmidt et al. 2002). The change in natural fire regime results from changes to one or more of the following fire regime attributes: vegetation characteristics (e.g., species composition, structural stages, stand age, canopy closure, and mosaic pattern); fuel composition; fire frequency, severity, and pattern; and other associated disturbances (e.g., insect and disease mortality, grazing, and drought).

Characteristic vegetation and fuel conditions are considered to be those that occurred within the natural fire regime. Uncharacteristic conditions are considered to be those that did not occur within the natural fire regime. Examples of uncharacteristic conditions include invasive species (e.g., weeds, insects, and diseases) or excessive vegetation removal. The amount of change is based on comparison of the fire regime attributes as identified above to the natural fire regime. The amount of change is then classified to determine the FRCC.

**3.7.1 Conditions within the Planning Area**

The Hazardous Fuels Reduction Program (HFR) involves a variety of treatments to accomplish the following:

- Modify vegetation to provide for firefighter safety
- Reduce the potential of wildfire spread
- Reduce the detrimental effects of wildfire on a landscape
- Restore ecosystem resiliency
- Allow the natural role of fire on the landscape
- Protect private holdings and infrastructure
- Decrease the costs of rehabilitation efforts after a wildfire has occurred

Depending on the specifics of the overall project, multiple treatment types may be involved over several years to obtain the specifications for the project. One example of this would be: For an annual grass dominated area, prescribed fire will be used to remove existing layers of the annual grass and reduce the seed source. Chemical applications would be utilized to further reduce the seed source and the resulting new annual grass plants. Mechanical seedings of perennial (native or nonnative, grass/shrub/forb) mixtures would occur, pending the most successful time of year for applications.

Examples of treatment types include:

- **Prescribed Fire (Treatment)** – An HFR Treatment Category for any fire ignited by management actions to meet specific objectives and to achieve Fire Management objectives.
- **Mechanical (Treatment)** – An HFR Treatment Category that describes work that manually or mechanically removes or modifies fuel load structures to achieve Fire Management objectives.
- **Other (Treatment)** – An HFR Treatment Category that describes work involving the use of chemicals and biological methods to achieve Fire Management objectives.

In Idaho, the HFR Program has been in place since the start of the 2000 National Fire Plan identified the need and funding source to develop and maintain the program. Within the last 5 years, which would represent the most current treatments on the existing landscape, the following acreage and types of treatments are shown below. The prescribed fire acreages have decreased from historical levels due to multiple large scale wildfires accomplishing the removal of undesirable vegetation in areas planned for future projects. Mechanical treatments have increased in, both, seeding and mechanical reductions of conifer encroachment throughout PPH and PGH areas. The use of chemical or “Other” types of treatments has grown to increase the probability of success of seeding(s) of perennial (native or nonnative, grass/shrub/forb) mixtures by removing the dominance and competitiveness of the undesirable annual grass and weed species. Biological or “Other” treatments (insects, goat, and specific pathogens) have recently been of interest in very specific areas due to the

“high risk” in areas that may have significant values should accidents occur during implementation of mechanical treatments (e.g., rocks and windows).

### 3.7.2 Trends

**Table 3-21, BLM Treatment Types and Acreages Over the Past Five Years**, presents fuel treatment types and acreages over the past 5 years.

**Table 3-21  
BLM Treatment Types and Acreages Over the Past Five Years**

Treatment Type	2008	2009	2010	2011	2012
Prescribed Fire	11,199 acres	8,647 acres	7,189 acres	6,398 acres	3,021 acres
Mechanical	46,073 acres	38,992 acres	33,975 acres	30,987 acres	30,725 acres
Other	59,003 acres	47,991 acres	36,500 acres	39,895 acres	71,666 acres

Source: BLM 2013a

Over the past few years, the focus of the HFR program was to treat acreages within the WUI. This was specific to protecting private in-holdings in the attempt to decrease the detrimental effects of wildfire to human structures and the associated infra-structure for the communities.

#### ***Emergency Stabilization and Rehabilitation (ESR)***

Alteration to the historic fire regime has substantially reduced the sagebrush steppe communities of the Sub Unit and the larger Great Basin. The exclusion of wildfire within the upper elevations shrub steppe communities (primarily mountain big sagebrush) has converted GRSG habitat into juniper woodland.

The greatest loss of GRSG habitat however has been from cheatgrass proliferation and wildfire within the lower elevation sagebrush communities (primarily Wyoming big sagebrush). Historically, wildfire was not a common occurrence within the Wyoming big sagebrush sites. Current literature estimates the fire interval at approximately 100 years. When these sites did burn, the discontinuous fuels of the scattered native bunch grasses likely resulted in small, discontinuous fires. Conversely, cheatgrass is highly flammable due to its uniform fine fuels which dry out early in the growing season. Each recurring fire set the stage for further cheatgrass expansion, resulting in an ever increasing cheatgrass/fire cycle and loss of GRSG habitat. On many of these sites, fire-return intervals have been shortened to between 2 and 4 years (Whisenant 1990).

Lower elevation shrub steppe communities within the subunit (even those containing minimal cheatgrass understories) will cross a threshold into fire maintained cheatgrass dominated communities unless they are successfully rehabilitated within the first couple years following wildfire. Such areas are also highly susceptible to noxious weed invasions. Therefore, successfully reestablishing perennial vegetation within this narrow time frame is essential for reducing the loss of low elevation GRSG habitat.

Fire rehabilitation consists of mitigating damaging effects from wildfire and in restoring vegetative structure and function to recently burned fire damaged areas which cannot recover on their own. These efforts consist of seeding perennial grasses, shrubs, and forbs. The seeding technique is based largely on seed size. Most grasses (which have relatively large seeds) are drill seeded to effectively cover the seed, whereas sagebrush and many forbs (which consist of small seeds) are most successful broadcast seeded.

Drought and invasive annual grass competition are the two biggest challenges to reestablishing perennial vegetation following wildfire on the low elevation sites. Seedings are most successful during years of adequate precipitation and on sites where cheatgrass competition is minimal such as recently burned sagebrush stands in good condition, or sagebrush stands with cheatgrass in the understory which burned hot enough consume cheatgrass seed lying on the soil surface underneath the sagebrush canopy. Accordingly, the higher the density of sagebrush cover prior to the burn, the greater the likelihood for seedings success. Because sagebrush fires burn hotter and slower than grassland fires, the cheatgrass seed lying on the soil surface underneath the sagebrush canopy is usually consumed, whereas the seed laying outside of the sagebrush canopy or other shrub free areas (such as previously burned cheatgrass-dominated sites) is not consumed and remains viable. Accordingly, the areas underneath the burned sagebrush canopy create a cheatgrass free “clean” seedbed which allows seeded species to establish relatively free of cheatgrass competition. Although the areas outside of the canopies will remain dominated by cheatgrass, the established plants underneath the former sagebrush canopy will usually outcompete the adjacent cheatgrass over time. However, strong wind-driven fires often prevent consumption of cheatgrass seed, thereby require cheatgrass control. Seeding previously burned cheatgrass-dominated sites devoid of a brush overstory, is not usually successful because these rapid cheatgrass driven fires do not provide enough heat to consume cheatgrass seed lying on the soil surface.

Herbicides have proven to be the most effective and noninvasive method for controlling annual grasses prior to seeding. Before 1991, the use of herbicides to control invasive annual grasses was prohibited on public land. Therefore, various tilling methods such as plowing and disking were the only available options. Unfortunately, these treatments damaged remaining native vegetation and biologic soil crusts, increased site susceptibility to wind erosion and often resulted in seed being drilled too deeply, thereby opening the site for total cheatgrass domination when seedings were unsuccessful. Prescribed fire was used in attempts to kill cheatgrass seed while still on the plant. Although such fires kill some seed still on the plant, they do not burn hot enough to kill cheatgrass seed on the soil surface.

Intensive livestock grazing is often suggested for controlling cheatgrass competition. Although targeted grazing may have some applications for fuels management, it is not effective in reducing cheatgrass competition (Hempy-Mayer and Pyke 2008). During the short time when cheatgrass is highly palatable in the spring, a sufficient number of livestock cannot be concentrated on a small enough area to reduce the cheatgrass seed significantly or reduce cheatgrass seed lying on the soil surface. In addition, this type of grazing can be

detrimental to remaining perennial grasses, opening the site up for further cheatgrass expansion in the future.

The BLM and Forest Service are authorized to use various approved contact and pre-emergent herbicides for controlling invasive annual grasses. Both types of herbicides have their advantages and shortcomings.

Contact herbicides such as Glyphosate have been widely and successfully used within the Boise, Twin Falls, and Idaho Falls Districts in Idaho. These herbicides must be applied during the short period that cheatgrass is actively growing, and before seed development occurs. When numerous cheatgrass crops occur on a given year, repeated applications are required. Additionally, application rates must be tuned to minimize damage to existing perennial plants while effectively controlling the invasive annuals. Glyphosate binds quickly to soil particles and is inactivated. Unbound glyphosate is degraded by soil bacteria.

Pre-emergent herbicides such as imazapic and sulfometuron methyl are highly effective in controlling invasive annual grasses while having minimal impacts on most established perennial species. They are also classified as nontoxic to fish and wildlife. These herbicides do not require the specific application timing needed with glyphosate, and their residual action in the soil controls annual grasses whenever they happen to germinate. The residual action lasts from 1 to 3 years, depending on soil moisture, pH, and temperature. In addition to controlling invasive annual grasses prior to seeding, these herbicides could be used to help maintain and protect existing native plant communities which have been invaded with annual grasses. Such treatments would allow the natives to gain a competitive advantage over the exotic annuals, and the associated reduction in annual grass fuels would reduce the site's risk to wildfire. A limitation of these herbicides is their potential to damage crops at extremely low concentrations. Accordingly, these herbicides must be used in accordance to the label and/or other appropriate restrictions in such situations.

Recent research on naturally occurring fungi and bacteria for controlling cheatgrass is encouraging and may prove to be an effective future control method. Examples include Dooley and Beckstead's (2010) *Characterizing the interaction between a fungal seed pathogen and a deleterious rhizobacterium for biological control of cheatgrass*; Stewart's (2009) *The grass seed pathogen *Pyrenophora semeniperda* as a biological agent for annual Bromo grasses*; and Meyer et al.'s (2008). *Cheatgrass (*Bromus tectorum*) biocontrol using indigenous fungal pathogens*.

Selecting plant materials which can establish and persist in these arid cheatgrass competitive environments is essential for restoring GRSG habitat lost through wildfire. Prior to the mid-1980s, fire rehabilitation funds could not be used for sagebrush seeding. Since that time, sagebrush is included in most fire rehabilitation seedings on its respective ecological sites. Occasionally, during busy fire years, sagebrush seed shortages restrict its use to priority burned GRSG habitat.

Native grasses and forbs are preferred over introduced species when they can meet the above requirements. Historically, few adapted native grass seed was available which could persist in these desert environments, thereby requiring the use of durable introduced species

such as crested wheatgrass. Over time, selections of native blue bunch wheatgrass, basin wildrye, Snake River wheatgrass, squirreltail, Indian ricegrass, and Sandberg bluegrass have become increasingly available and are now used extensively in fire rehabilitation seedings for areas that receive at least 10 inches of annual precipitation in recently burned sagebrush communities. For the past ten years, the BLM has been funding the interagency Great Basin Native Plant Selection and Increase Project for increasing native seed availability, especially native forbs important to GRSG, and to improve the success of land managers in establishing native plants (Forest Service 2013b).

However, some important native grasses (such as Thurber's needlegrass) are still not widely available and or effective in competing with cheatgrass in the harshest environments. In these areas, durable introduced species as Siberian wheatgrass and Russian wild rye are still the only viable option. Even those species are often unsuccessful on those sites. Additionally, restoring native plant communities in repeatedly burned annual dominated grasslands has proven largely unsuccessful. Considerable speculation and research has attempted to understand why. A lack of mycorrhiza, soil nutrients, and other changes to the soil environment from years of invasive annual grass domination is believed to be at least partially responsible.

The theory of "assisted succession" is suggested as a method for ultimately restoring these areas by first vegetating with resilient introduced species to break the fire cycle, removing annual grass dominance and deplete annuals' seed source, and restore soil characteristics which may in time make the site more hospitable to restoring the native community, followed by eventual seeding with natives. Accordingly, this is a long term costly process which cannot begin to be implemented until the fire cycle has been broken. Until the majority of annual grass dominated landscapes can be rehabilitated to less fire prone species in the long-term, these short fire cycles will result in a continual loss of these investments, and in the remaining native sagebrush steppe communities.

Seeded areas require rest from livestock use to become fully established, followed by livestock management which will maintain plant health and vigor. BLM policy traditionally prescribes a minimum of two growing seasons rest from livestock grazing, and until plant establishment objectives are met. Depending on moisture and other site conditions, longer rest is often needed before grazing can be resumed. However, a true native restoration could require years of rest from grazing to become successfully established (depending on plant materials used and site characteristics). Such large-scale treatments could have significant repercussions to grazing permittees, and may also necessitate more restrictive management to maintain the native seeded species over the long term.

The ability to protect these areas from recurring wildfire is crucial to maintaining the reestablished sagebrush component. Successful fire rehabilitation seeding can contribute to this goal by changing the fuels from highly flammable annual grasses with high fuel continuity, into less-fire-prone perennial bunch grasses, which stay greener longer and which provide much less fuel continuity (Pellant 1992). Accordingly, when fire does return to these rehabilitated areas, the fires are often spotty and leave substantial unburned sagebrush

islands and a seed source for naturally reestablishing sagebrush. Additionally, the burned perennial grasses quickly re-sprout and compete effectively with annual weeds.

Also warranted is a system of effectively managed fuel breaks consisting of durable, fire-resistant vegetation, such as forage kochia, placed primarily along roads or other appropriate, strategic features. In general, vegetative fuel breaks have characteristics that disrupt fuel continuity, harbor lower fuel loads, and have lower volatile compounds and increased moisture content (Pellant 1992). Fuel breaks help provide defensible anchor points for facilitating fire suppression activities and can allow fires to be compartmentalized, ultimately reducing potential fire size.

#### ***Burned Area Emergency Response***

The Forest Service's Burned Area Emergency Response (BAER) program is designed to address emergency situations through its key goals of protecting life, property, and critical natural and cultural resources. The objective of the program is to determine the need for and to prescribe and implement emergency treatments on federal lands to minimize threats to life or property resulting from the effects of a fire or to stabilize and prevent unacceptable degradation to natural and cultural resources. Loss of vegetation exposes soil to erosion; runoff may increase and cause flooding, sediments may move downstream and damage houses or fill reservoirs, and put endangered species and community water supplies at risk.

BAER teams are staffed by specially trained professionals, and BAER assessments usually begin before a wildfire has been fully contained. There are a variety of emergency stabilization techniques that the BAER team might recommend. Reseeding of ground cover with quick-growing or native species, mulching with straw or chipped wood, construction of straw, rock or log dams in small tributaries, and placement of logs to catch sediment on hill slopes are the primary stabilization techniques used. The team also assesses the need to modify road and trail drainage mechanisms by installing debris traps, modifying or removing culverts to allow drainage to flow freely, adding additional drainage dips and constructing emergency spillways to keep roads and bridges from washing out during floods.

### **3.7.3 Regional Context**

**Table 3-22**, Acres of Wildland Fire within GRSG Habitat, and **Table 3-23**, Acres with High Probability for Wildland Fire within GRSG Habitat, display wildland fire data for GRSG habitat in the planning area (Manier et al. 2013). **Table 3-23** also uses data from the Forest Service's fire simulator, FSim. FSim generates burn probabilities by simulating fires using historical weather data and current landcover data. **Figure 3-3**, Fire History in the Planning Area, and **Figure 3-4**, Fire Frequency in the Planning Area, illustrate fire issues in the sub-region.

### 3.8 Livestock Grazing

The foremost authority that provides for grazing of BLM-administered lands is the Taylor Grazing Act which was passed on June 28, 1934, to protect public rangelands and their resources from degradation, to provide for orderly use to improve and develop public rangelands, and to stabilize the livestock industry. Following various homestead acts, the Taylor Grazing Act established a system for allotting grazing privileges. The FLPMA and the Public Rangeland Improvement Act (1978) also provide authority for managing grazing on public rangelands managed by the BLM. BLM grazing administration, excluding of Alaska, is governed by 43 CFR Part 4100.

The primary laws that govern grazing on Forest Service-administered lands are the Organic Administration Act of 1897, Granger-Thye Act of 1950, Multiple Sustained Yield Act of 1960, FLPMA, Forest Rangeland Renewable Resources and Planning Act of 1974, National Forest Management Act of 1976, and Public Rangelands Improvement Act of 1978. The Forest Service manages livestock grazing under direction in 36 CFR Part 222, Forest Service Manual 2200, and Forest Service Handbook 2209.13. In addition, LUPs identify the suitability of land on Forest Service-administered units to produce forage for grazing animals and establish programmatic direction for grazing activities, including goals, objectives, desired conditions, standards, guidelines, and monitoring requirements. Although an area may be deemed suitable for use by livestock in a LUP, a project-level analysis evaluating the site-specific impacts of the grazing activity, in conformance with NEPA, is required in order to authorize livestock grazing on specific allotments.

The BLM grazing administration regulations were revised in 1995 to include Fundamentals of Rangeland Health and Standards and Guidelines for Grazing Administration (43 CFR 4180). In accordance with 43 CFR 4180.2, both the Idaho Standards for Rangeland Health and Guidelines for Livestock Grazing Management, and the Standards for Rangeland Health and Guidelines for Livestock Grazing Management for Public Lands Administered by the BLM for Montana and the Dakotas were placed in effect on August 12, 1997, and subsequently apply to grazed BLM-administered lands in the planning area. Standards are integrated into the BLM's land management through incorporation into grazing permits and LUPs, as a basis for environmental assessments and through NEPA analysis, and as a basis for monitoring. Guidelines are integrated into land management by incorporating them into livestock grazing authorizations and management practices. The standards and guidelines provide a clear statement of agency policy and direction for those who use BLM-administered lands for livestock grazing and for those who are responsible for their management and accountable for their conditions. In accordance with 43 CFR Part 4180, if it is determined that grazing management practices or levels of grazing are significant factors in failing to achieve the standards and conform with the guidelines, appropriate action shall be taken prior to the next grazing season to make progress towards Standards and conform to the Guidelines.

### **3.8.1 Conditions within the Planning Area**

Grazing permits and leases are the documents that authorize livestock grazing on BLM-administered lands (43 CFR 4100.0-5). The kind and number of livestock, the period of use (seasonal), the allotment to be used, and the amount of use in animal unit months (AUMs) are mandatory terms and conditions of every grazing permit or lease (43 CFR 4130.3). An AUM is the amount of forage necessary for the sustenance of one cow or its equivalent for one month and an allotment is an area of land designated and managed for grazing of livestock (43 CFR 4100.0-5). Livestock graze on approximately 12,129,800 acres of BLM-administered land within 2,654 allotments in the planning area.

Grazing on Forest Service-administered lands is permitted through term grazing permits that authorize grazing on Forest Service-administered lands. The term grazing permit authorizes the number, kind, and class of livestock as well as the period of use and grazing allotment on

which livestock are permitted to graze. Permit holders may not assign or transfer grazing privileges in whole or part (36 CFR 222.1-4). There are 319 allotments on 9,646,900 acres on Forest Service-administered land in the planning area.

**Table 3-24, Idaho and Southwestern Montana Sub-Region Planning Area – Allotments** provides information on the allotments managed in the planning area.

**Table 3-24

Source: BLM 2013a; Forest Service 2013a; Forest Service 2013c

Facilities for livestock management on BLM-administered and Forest Service-administered lands in the planning area occur at varying densities based upon management needs, landownership patterns and other factors. These facilities include, but are not limited to fences, cattle guards, corrals, pipelines, water troughs, wells and reservoirs. Fences are used to delineate allotment boundaries, pastures within allotments, landownerships, and to exclude the impact of ungulate grazing from certain resources. Corrals are smaller fenced areas that are occasionally located on BLM-administered and Forest Service-administered lands for the purposes of gathering, sorting and handling livestock. Watering facilities are

used to improve livestock distribution in areas where naturally occurring surface water is not available, and to reduce livestock use of naturally occurring springs and streams. In addition, supplemental salt, mineral, and protein may be provided for livestock grazing on BLM-administered and Forest Service-administered lands, to aid with distribution of authorized livestock.

Since 1999, an assessment of rangeland health standards and guidelines has been made on 2,219 of the 2,736 BLM allotments comprising 9,978,899 acres within the planning area. Of the allotments which have been assessed, 1,403 allotments comprising 3,509,733 acres are meeting all applicable standards and guidelines. An additional 451 allotments comprising 4,581,851 acres are not achieving one or more of the applicable standards and guidelines due to livestock grazing management, but management actions have been implemented to correct the identified issues. On 61 allotments comprising 660,901 acres, standards are not being achieved due to livestock grazing management, but management actions have not yet been taken to make progress towards meeting standards. On 293 allotments comprising 1,226,179 acres, one or more applicable standards was not met due to factors other than livestock grazing management. Standards and guidelines assessments have not been completed on 528 allotments comprising 2,406,238 acres within the planning area. The Forest Service does not have an equivalent assessment to the BLM's rangeland health standards and guidelines, nor are similar assessment data available for Forest Service-administered lands.

Commented [BER1]: IDMTSG-14-0105-23

### 3.8.2 Regional Context

**Table 3-25**, Acres of Grazing Allotments within GRSG Habitat, through **Table 3-27**, Miles of Fences within GRSG Habitat, display grazing data for GRSG habitat in the planning area (Manier et al. 2013). In each table, data are presented by surface management agency and their occurrence within occupied habitat in the planning area. It should be noted that for **Table 3-26**, Acres of BLM Allotments Not Meeting Land Health Standards within GRSG Habitat, data were assembled in 2008 from available records, and progress has been made towards meeting standards and guidelines since this time. In addition, this table reflects only those allotments not meeting Idaho Standards for Rangeland Health and Guidelines, Standard 8 (Threatened and Endangered Plants and Animals).

### 3.9 Recreation

The diverse planning area offers multiple settings for a wide range of opportunities for recreation requiring no permits and no or minimal fees on BLM- and Forest Service-administered land.

#### 3.9.1 Conditions within the Planning Area

##### ***BLM Recreation***

Objectives of the BLM recreation program are to: (1) provide broad spectrum of resource dependent recreation opportunities to meet the needs and demands of public land visitors, (2) foster agency-wide efforts to improve service to the visiting public, (3) maintain high quality recreation facilities to meet public needs and enhance the image of the agency, and (4) improve public understanding and support of the BLM by effectively communicating the

agency's multiple use management programs to the recreation visitor. The BLM accomplishes these objectives by focusing on visitor services, information and interpretation, resource enhancement and protection, facility maintenance and development, tourism programs, improved accessibility, and essential administrative functions. In meeting these objectives, the BLM also considers the presence of other federal, state and local, and private recreation opportunities; the need to assist states and local communities served by the agency to broaden and improve their economic base; and the need to continually monitor recreation trends, customer preferences, and technological advances to improve short, medium and long range strategic planning efforts.

BLM recreation planning and management is based on the establishment of Recreation Management Areas. Recreation management areas fall into two categories: 1) Special Recreation Management Areas (SRMA) and 2) Extensive Recreation Management Areas (ERMA). The BLM Recreation Planning Manual 8320 was released in 2011. Manual 8320 made policy changes to how BLM addresses planning for recreation management areas. Because the policy changes are recent, there are currently no LUPs that have recreation decisions based on the new policy. Consequently, the management decisions described here are done so in the context of the previous recreation policy.

Recreation management areas are administrative sub-units that serve as the basic land unit for recreation management. Each area is identified and managed as a unit based on similar or interdependent recreation values, homogenous or interrelated recreation use, land tenure and use patterns, or administrative efficiency.

SRMAs are established to direct recreation program priorities, including the allocation of funding and personnel, to those BLM-administered lands where a commitment has been made to provide specific recreation activity and experience opportunities on a sustainable basis. This includes a long term commitment to manage the physical, social, and administrative settings to sustain these activities and experience opportunities. Delineation is based on administrative/management criteria, including the existence of congressional designations, similar or interdependent recreation values, homogenous or interrelated recreation uses, land tenure and use patterns, transportation systems, administrative efficiency, intensity of use, high resource values, public concerns, or interagency considerations. These areas usually require a high level of recreation investment and/or management. They include recreation sites, but recreation sites alone do not constitute a SRMA. SRMAs established to reflect a congressional designation may be larger than the designation boundary when significant recreation issues or management concerns occur outside the designated area.

ERMAs are where recreation management is only one of several management objectives and where limited commitment of resources is required to provide extensive and unstructured type of recreation activities. They may contain recreation sites. The areas consist of the remainder of land areas not included in SRMAs within a field office.

The number of SRMAs and ERMAs are listed in **Table 3-28**, Recreation Management Areas, and are mapped in **Figure 3-5**, Special Recreation Management Areas.

**Table 3-28**  
**Recreation Management Areas**

SRMAs	48
ERMAs	18

Source: BLM 2013a

Figure 3-5 Special Recreation Management Areas

*Idaho and Southwestern Montana Sub-Region Greater Sage-Grouse LUPA/EIS*  
October 2013

Within the recreation management area, there are approximately 400 recreation sites. These sites range in size and intensity of use from intensely used OHV areas (e.g., St Anthony Sand Dunes), boat ramps, and campgrounds to lightly used overlooks, trailheads and interpretive wayside exhibits.

BLM-administered lands received over 6 million visits in 2012. The BLM estimates that 20 to 25 percent of recreation visits were related to OHV use (e.g., motorcycles, all-terrain vehicles, and trucks). OHV use on BLM-administered lands has seasonal variations. In early spring when the forests often still have snow, BLM-administered lands will get recreational OHV use. As the temperatures rise and the lower elevation areas get hotter, OHV users will migrate to higher elevations where temperatures are cooler (often making more use of national forests). Use on BLM-administered lands in the fall will increase as temperatures cool and hunting season starts. There are BLM-administered lands that see little recreation use except during hunting season. OHV use is low during the cold winter months.

Depending on the OHV designation, use will be on routes in limited areas or possibly off routes where the area is designated as open (see **Section 3.10**, Travel Management, for OHV designations).

Other types of recreation activity that occur include bicycling, camping, hiking, horseback riding, skiing, snowmobiling, rafting/floating, power boating, fishing, swimming, photography, wildlife viewing, and hunting.

#### ***Forest Service Recreation***

The Forest Service provides and manages a myriad of recreation opportunities for the visiting public. The National Forests and Grasslands provide the greatest diversity of outdoor recreation opportunities in the world, connecting visitors with nature in an unmatched variety of settings and activities. Visitors can hike, bike, ride horses, and drive OHVs; picnic, camp, hunt, fish, and navigate waterways; view wildlife and scenery; and explore historic places. Visitors glide through powder at world class alpine resorts and challenge themselves on primitive cross-country ski or snowmobile routes. With many partners, the recreation program strives to promote healthy lifestyles, support local economies, and connect citizens to their public lands. The Intermountain Region of the Forest Service manages over 34 million acres of forests and grasslands (5.8 million in Wilderness), with almost all of it open for public use and enjoyment. In 2012, over 11.5 million visitors came to enjoy the resources provided within the region.

#### ***BLM Special Recreation Permits***

The BLM manages organized, commercial, and competitive recreation activities on BLM-administered lands and related waters with special recreation permits (SRPs). As a management tool, SRPs reduce user and resource conflicts, mitigate adverse impacts on resources, provide opportunities for monitoring activities, enhance visitor experience opportunities, and, with user fee requirements, allow for a fair return for these types of land uses. Issuance of an SRP is discretionary, with proposed activities subject to NEPA compliance and mitigation requirements specific to the proposed activity. The BLM may deny a permit request if assessment indicates unacceptable impacts; if an approved

moratorium or restricted allocation system exists for the proposed activity, location, or time-frame; if there are serious health and safety concerns; or if past performance by an applicant has been deemed unacceptable and problematic. The BLM may require an applicant to possess appropriate insurance, bonding, certifications of training, and state permits/licenses to protect resource values, the served public, and the federal government.

In 2012, the BLM had 341 active SRPs. Of those SRPs, 241 were commercial river permits and 24 are commercial big game hunting permits. The remaining SRPs are for organized groups, competitive events, or other types of commercial recreation outfitters (e.g., bike tours).

#### ***Forest Service Special Use Permits***

The Forest Service manages trail, river, and similar recreation opportunities and their access and supports facilities under the principles enumerated in FSM 2303. Special Use Permits are issued for specific types of recreation activities on Forest Service managed land and may be required when extra measures are needed to protect natural or cultural resources. The following are recreation special uses that involve facilities:

- Recreation special use permits involving privately owned facilities include resorts, marinas, ski areas, target ranges, organization camps, recreation residences, and other facilities. These permits are typically authorized under term permits and users pay a land use fee based on a percent of revenue or appraised value of the land.
- Recreation special uses involving government-owned facilities are concession campgrounds, resorts, organization camps, and some other facilities.
- Recreation special uses involving commercial public services are outfitting and guiding for a broad range of activities, groomed cross-country ski trails, and recreation events (including competitive races, eco-challenges, dog trails, adventure games, and endurance races). These uses are usually authorized under the Recreation Enhancement Act, which allows fees to be retained by the administrative unit that collected them.

Additionally, noncommercial group use permits are required for groups of 75 or more people. These users do not pay fees.

The Forest Service has 910 active recreation special use permits within the planning area (197 at Boise National Forest, 258 at Sawtooth National Forest, 114 at Salmon-Challis National Forest, 29 at Payette National Forest, and 312 at Caribou-Targhee National Forest).

No permits are required for private, non-commercial use of public lands for camping, fishing, hiking, hunting, horseback riding, or similar activities.

In 2012, the Intermountain Region of the Forest Service had 2335 recreation special use permits and 267 recreation special use permits for group activities and recreation events. Of the total recreation special use permits about 1400 were for recreation residences, 796 were

for outfitter and guiding services, 53 were for organizational camps, 42 were for resort and marina permits, 28 were for concessionaires, and 16 were for ski areas.

### 3.9.1 Trends

Recreation use is expected to continue to grow throughout the planning area. The proximity of many recreation opportunities to the area surrounding Boise has dramatically increased recreational visitation within portions of the planning area and is expected to continue to do so.

Five key drivers are causing changes to recreation in the planning area:

1. Increased urbanization as a result of population growth and changing demographics
2. Changing public expectations and demand for outdoor recreation opportunities, especially for dispersed recreation
3. Increased energy development in portions of the planning area
4. Close proximity of BLM-administered lands to private property, and the growing use of BLM-administered lands as a community-based recreation asset
5. Technological advances, such as all-terrain or utility vehicles and mountain bikes, affordable global positioning system (GPS) units, as well as better outdoor equipment and clothing

These drivers will impact the activity opportunities that can be offered and the recreation experience and benefit opportunities that can be produced by land managers and partners.

#### *Hunting*

Although hunting licenses issued have dropped over the last decade, hunting remains a popular recreation activity within the region. While deer and elk are the most popular game in the planning area, of more relevance to this analysis are falconry and upland bird hunting.

#### *Falconry*

Falconry permit holders were surveyed after the Fall 2010-Spring 2011 hunting season (Table 3-29, Falconry Permits).

**Table 3-29  
Falconry Permits (Fall 2010-Spring 2011)**

159 hunters purchased Idaho falconry permits which would allow hunting in Fall 2010-Spring 2011.

### *Upland Birds*

Idaho offers a multitude of upland game bird hunting opportunities on millions of acres of BLM- and Forest Service-administered land.

Hunters can pursue three species of forest grouse – dusky, ruffed, and spruce – and two species of prairie grouse – Columbian sharp-tailed grouse and GRSG – all native to Idaho. Forest grouse hunting opportunities exist across the state, while Columbian sharp-tailed grouse and GRSG hunting is limited to certain areas only.

While GRSG are widely distributed in areas with large blocks of sagebrush, the hunting season is generally short (1 week during 2012) and opportunities are limited to areas of southern Idaho.

Idaho also offers chukar and gray partridge hunting, and has robust populations of California quail. Chukar and gray partridge (huns) thrive on large tracts of public ground and are available to everyone willing to make the effort to hunt them.

Chukar are typically found in rocky, arid areas covered with cheatgrass and sagebrush. Gray partridge (huns) are often found in close proximity to chukar and adjacent to cultivated land across the state. Expect to find the best populations of chukar and gray partridge in the Clearwater, Magic Valley, and Southwest regions.

California quail occur from south-central Idaho, west to the Oregon border and north to the Palouse Prairie. Good populations live along rivers and streams with brushy cover below 3,500 feet in elevation.

Historically, Idaho was a destination pheasant hunting location, but populations have declined because of changes in farming practices and the resultant loss of habitat.

Upland game population trends are monitored through harvest surveys, August roadside counts, August helicopter flush counts, mourning dove coo counts, hunter check stations,

and wing barrel harvest data. Each region collects data using various methods based on regional bird densities and sampling constraints. Statewide, telephone surveys assess overall hunter activity and harvest of upland game species. From 1996-2000, telephone surveys estimated statewide rather than regional trends (except turkey) due to budget constraints. A separate telephone survey has been conducted since 2000 for GRSG and sharp-tailed grouse to improve sample size for these two species that have been considered for listing under the ESA.

In 2009, approximately 40,100 resident hunting license buyers hunted upland game and approximately 5,300 nonresident hunting license buyers hunted upland game. This represents 18 percent of all resident hunting license buyers and 16 percent of all nonresident hunting license buyers.

For GRSG, the season framework was altered in 1996 to provide three different types of seasons: liberal, conservative, and closed. In 2002, the season framework was modified. The Birch Creek Valley and the Big Desert areas, closed to GRSG hunting from 1995 to 2001, were reopened. Research suggested that the closed season did not have any measurable effect on GRSG populations, as measured by number of GRSG counted on lek routes. In 2009, there was a 7-day season with a 1-bird daily bag limit in Zone 2, and a 23-day season with a 2-bird daily bag limit in Zone 3.

Starting in 2000, GRSG hunters were required to purchase a GRSG hunting validation. This requirement provided a means to collect better harvest estimates from a sample of GRSG hunters through a telephone survey. Approximately 4,400 hunters harvested 7,200 GRSG in 2009.

Numerous check stations are run in the state to gather information on reproductive success in different areas. In general, the sample size has decreased at these check stations in recent years due to shortened seasons and reduced hunter participation.

### **3.10 Travel Management**

#### **3.10.1 Conditions on BLM-Administered Lands**

Travel and transportation are integral parts of virtually every activity that occurs on BLM-administered lands. The BLM has taken a comprehensive approach to travel and transportation management (TTM). It is an interdisciplinary approach to travel and transportation planning and management that addresses resource uses and associated access to BLM-administered lands and waters, including motorized, nonmotorized, mechanical, and animal-powered modes of travel.

Travel and transportation management planning means providing clear and specific direction that addresses public and administrative access needs on the proper levels of land and water for all modes of travel. The TTM process addresses variability among landscapes, users' interests, equipment options, and cultural and biological resource constraints. The primary goal of TTM is to develop a systematic network of routes with appropriately designated uses that provides opportunities for a diverse set of activities to occur on BLM-administered

lands, such as recreation, energy development, grazing, and wildlife management. Travel management objectives serve as the foundation for appropriate travel and access prescriptions.

There is considerable overlap between travel management and all other uses on BLM-administered lands. For example, many people visit BLM-administered lands for recreation purposes. For these visitors, a route system may serve as either a means to reach a destination where the activity occurs (e.g., a road to a trailhead or parking area) or as the focus of the recreation activity itself (e.g., four-wheel driving, hiking, or horseback riding trails).

To reduce the duplication of narrative between travel management and the other sections of this document, this section addresses only public travel and access (i.e., OHV management area designations, route designations, types of travel, and seasonal area limitations). The interrelated recreation components, such as OHV use, are addressed under **Section 3.9, Recreation**.

#### ***Modes of Travel***

Visitors to BLM-administered lands use roads and trails for a variety of activities involving various modes of travel. Motorized travel in the planning area ranges from standard passenger vehicles driving on maintained roads to OHVs operating on primitive roads and trails. OHV is synonymous with off-road vehicle, as defined in 43 CFR 8340.0-5(a):

*Off-road vehicle means any motorized vehicle capable of, or designed for, travel on or immediately over land, water, or other natural terrain, excluding: 1) Any nonamphibious registered motorboat; 2) Any military, fire, emergency, or law enforcement vehicle while being used for emergency purposes; 3) Any vehicle whose use is expressly authorized by the authorized officer or otherwise officially approved; 4) Vehicles in official use; and 5) Any combat or combat-support vehicle when used in times of national defense emergencies.*

OHVs commonly used in the planning area include off-road motorcycles, all-terrain vehicles, utility terrain vehicles, jeeps, specialized 4-by-4 trucks, and snowmobiles. Other modes of travel include mountain biking, cross-country skiing, snowshoeing, horseback riding, pack animal driving, hiking, boating, hang-gliding, paragliding, ballooning, and wheelchairs. The type and amount of use and the location of roads and trails influence physical, social, and administrative recreation setting and the overall quality of the recreation experience.

#### ***Travel Designations***

Executive Order 11644 and 43 CFR 8340 both require the BLM to designate all BLM-administered lands nationally as open, closed, or limited for OHV use.

#### ***Open***

Areas designated as Open are areas where all types of vehicle use are permitted at all times anywhere in the area. Use is subject to any operating regulations and vehicle standards established in other parts of the CFR.

*Limited*

Areas designated as Limited are areas restricted at certain times, in certain areas, or to certain vehicular use. These restrictions may be of any type but can generally be accommodated within the following categories: numbers of vehicles; types of vehicles; time or season of vehicle use; permitted or licensed use only; use on existing roads and trails; use on designated roads and trails; and other restrictions.

*Closed*

Areas designated as Closed are areas restricted at certain times, in certain areas, and to certain vehicular use. These restrictions may be of any type but can generally be accommodated within the following type of categories: numbers of vehicles; types of vehicles; time or season of vehicle use; permitted or licensed use only; use on existing roads and trails; use on designated roads and trails; and other restrictions.

***Federal Regulations***

Route designation criteria are described in 43 CFR 8342.1 and state:

The authorized officer shall designate all public lands as open, limited, or closed to off-road vehicles. All designations shall be based on the protection of the resources of the public lands, the promotion of the safety of all the users of the public lands, and the minimization of conflicts among various uses of the public lands; and in accordance with the following criteria:

- (a) Areas and trails shall be located to minimize damage to soil, watershed, vegetation, air, or other resources of the public lands, and to prevent impairment of wilderness suitability.
- (b) Areas and trails shall be located to minimize harassment of wildlife or significant disruption of wildlife habitats. Special attention will be given to protect endangered or threatened species and their habitats.
- (c) Areas and trails shall be located to minimize conflicts between off-road vehicle use and other existing or proposed recreational uses of the same or neighboring public lands, and to ensure the compatibility of such uses with existing conditions in populated areas, taking into account noise and other factors.
- (d) Areas and trails shall not be located in officially designated wilderness areas or primitive areas. Areas and trails shall be located in natural areas only if the authorized officer determines that off-road vehicle use in such locations will not adversely affect their natural, esthetic, scenic, or other values for which such areas are established.

***National Guidance***

On a national level and in response to increasing demand for motorized and mechanized recreation trails on BLM-administered lands, the BLM first developed an OHV strategy and then a mountain bike strategy. These strategies emphasize that the BLM should be proactive

in seeking travel management solutions that conserve natural resources while providing for ample recreation opportunities.

The BLM released the current version of the Land Use Planning Handbook (H-1601-1) in March 2005. Guidance on determining Open, Limited, and Closed OHV Area designations during the planning process was incorporated into the Comprehensive Trails and Travel Management Section (Appendix C, Section II D).

Additional TTM guidance continued to be developed and culminated with the release of the Travel and Transportation Management Manual (1626) in July 2011. Current policy states that Open areas will be limited to a size that is geographically identifiable and can be effectively managed and that expansive open areas allowing cross-country travel will not be designated in LUP revisions or new travel management plans.

The Travel and Transportation Handbook (H-8342) was released in March of 2012. It provides detailed guidance using the designation criteria in 43 CFR 8342.1 for area and route selection. It includes guidance for developing other implementation plans including but not limited to sign plans, education and outreach plans, law enforcement plans, and maintenance plans.

### **3.10.2 Conditions on Forest Service-Administered Lands**

The Forest Service published its Travel Management Rule in 2005. It required each national forest to designate roads, trails, and areas open or closed to motor vehicles. Designations were made in accordance with criteria described in Executive Order 11644 and included the type of vehicle and, if appropriate, time of year for motor vehicle use. A given route, for example, could be designated for use by motorcycles, ATVs, or street-legal vehicles. Once designation was complete, the rule prohibited motor vehicle use off the designated system.

In addition to its formal regulations, the Forest Service developed TTM planning guidance, including the Travel Management Manual, FSM 7700 (2008), and the Travel Planning Handbook, FSH 7709.55 (2008).

#### ***Federal Regulations***

The criteria for Forest Service route designation are found in 36 CFR 212.55 (a), General criteria for designation of Forest Service-administered roads, Forest Service-administered trails, and areas on Forest Service-administered lands and state:

In designating National Forest System roads, National Forest System trails, and areas on National Forest System lands for motor vehicle use, the responsible official shall consider effects on National Forest System natural and cultural resources, public safety, provision of recreational opportunities, access needs, conflicts among uses of National Forest System lands, the need for maintenance and administration of roads, trails, and areas that would arise if the uses under consideration are designated; and the availability of resources for that maintenance and administration.

(b) Specific criteria for designation of trails and areas. In addition to the criteria in paragraph (a) of this section, in designating National Forest System trails and areas on National Forest System lands, the responsible official shall consider effects on the following, with the objective of minimizing:

- (1) Damage to soil, watershed, vegetation, and other forest resources;
- (2) Harassment of wildlife and significant disruption of wildlife habitats;
- (3) Conflicts between motor vehicle use and existing or proposed recreational uses of National Forest System lands or neighboring Federal lands;
- (4) Conflicts among different classes of motor vehicle uses of National Forest System lands or neighboring Federal lands. In addition, the responsible official shall consider:
- (5) Compatibility of motor vehicle use with existing conditions in populated areas, taking into account sound, emissions, and other factors.

### 3.10.3 Current Conditions

Travel planning is complete for all lands administered by the Forest Service in the planning area. Forest Service-administered lands with a designated route system are considered the same as the Limited designation on lands administered by BLM.

The BLM has not conducted travel management planning throughout the sub-region. In areas with a designation of Limited, motorized use will be limited to existing roads until individual route selection and designation occurs during subsequent implementation-level planning.

### 3.10.4 Regional Context

**Table 3-30**, Miles of Roads within GRSG Habitat, and **Table 3-31**, Acres of Roads within GRSG Habitat, display data for roads within GRSG habitat in the planning area. In each table, data are presented by surface management agency and their occurrence within occupied GRSG habitat in the planning area and MZs that overlap the planning area.

### 3.11 Lands and Realty

The primary goal of the BLM Lands and Realty program is to enhance the administration of public landownership to provide the most effective configuration of lands and interests in land, consistent with land use plans developed through a full and open public involvement process, and to further the purposes of FLPMA. The objectives of the Forest Service landownership adjustment program are to achieve the optimum landownership pattern for the protection and management of resource uses, settle land title claims, and provide resource administrators with title information about the use of and resources on the land they administer.

Lands and realty actions can generally be divided between land tenure adjustments and land use authorizations. Land tenure adjustments focus on land exchange, acquisition (including purchase and easement acquisition), and disposal. Withdrawals, while managed as part of land and realty, are administrative actions that do not affect land tenure. Land use authorizations consist of ROWs and other leases or permits for the use and occupancy of public land.

Forest Service land use plan prescriptions are similar to BLM exclusion and avoidance areas. Prescriptions can restrict or prohibit certain uses in a planning area. It should also be noted that the Forest Service grants special use authorizations (granting ROWs, permits, easements, and leases), while the BLM grants ROWs on their respective agency lands. Lastly, the Forest Service completes landownership adjustments (purchase, exchange, donation, and ROW acquisition), while the BLM conducts land tenure adjustments (exchanges, disposals, and acquisitions).

### 3.11.1 Conditions within the Planning Area

The lands within the planning area are owned and may be managed by multiple federal, state, and local agencies, as well as private landowners. The configuration of landownerships and their proximity to each other is an important factor when considering land tenure adjustments and evaluating land use authorization applications. The planning area contains lands managed by several federal and state agencies, the Bureau of Indian Affairs (in trust for Native American tribes), and private lands. **Table 3-32**, Acres of GRSG Habitat by Surface Management, shows the acreage and overall percent ownership for each land manager in the planning area.

**Table 3-32**

Source: BLM 2013a

Within the planning area, BLM-administered lands have been classified for retention or disposal pursuant to Section 7 of the Taylor Grazing Act (43 USC 315f), FLPMA, and 43

CFR Parts 2400 and 2500; BLM-administered lands have also been identified as ROW exclusion or avoidance areas, and ROW corridors, pursuant to FLPMA and 43 CFR Part 2800. Section 205 of the FLPMA authorizes the Secretary of Agriculture to acquire access (lands or interest therein) over non-federal lands to units of the National Forest System by purchase, exchange, donation, or eminent domain. Several acts of Congress authorize occupancy and use of Forest Service-administered lands and interests in lands administered by the Forest Service. The applicable statutory authority determines the appropriate special use authorization. For example, some permits and temporary permits are issued under the provisions of the Organic Administration Act of June 4, 1897 (16 USC 477-482, 551), while some easements and leases and other types of permits are issued under the provisions of Title V, Federal Lands Policy and Management Act of October 21, 1976 (43 USC 1761-1771), and the Forest Roads and Trails Act of 1964.

**Table 3-33**, Land Classifications/Designations in Planning Area (Acres), lists the number of acres identified with land tenure classifications and ROW designations in the planning area. **Figure 3-6**, Authorized Rights-of-Way in the Planning Area, and **Figure 3-7**, Pending and Expired Rights-of-Way in the Planning Area, provide an overview of the extent of lands currently occupied by ROWs.

**Table 3-33**  
**Land Classifications/Designations in Planning Area (Acres)**

Land Status	Acres within Planning Area
Disposal by sale	869,400
Disposal by exchange	942,900
Withdrawals (Total)	4,610,000
Withdrawals (BLM)	4,025,900
Withdrawals (Forest Service)	584,100
ROW Avoidance (Total)	8,280,200
ROW Avoidance (BLM)	1,087,000
ROW Avoidance (Forest Service)	7,193,200
ROW Exclusion (Total)	3,494,600
ROW Exclusion (BLM)	1,036,000
ROW Exclusion (Forest Service)	2,458,600

#### ***Land Tenure Adjustments***

Landownership (or land tenure) adjustment refers to those actions that result in the disposal, acquisition, purchase, exchange, or donation of land or acquisition or grant of ROW by the BLM; or purchase, exchange, or donation of land, or ROW acquisition by the Forest Service. Section 102(a) of FLPMA requires that land be retained in federal ownership unless, as a result of land use planning, it is determined that disposal of certain parcels will service in

Figure 3-6 Authorized Rights-of-Way in the Planning Area

October 2013

the national interest. In all land tenure adjustments, keeping the surface and mineral estate intact on both the lands disposed of and acquired would benefit the future owners and their use of the land.

#### *Disposals*

Disposal areas include tracts of land that are economically difficult to manage, and/or parcels that could serve important public objectives, including, but not limited to, expansion of communities and economic development. These lands are usually disposed of through exchanges or land sales.

The Forest Service has very limited authority to sell or otherwise dispose of Forest Service-administered lands. Most authorities allowing the sale of lands have specific criteria or identify only a small number of properties for sale or disposal in a limited geographical area. The tool used most often for conveyance of lands within National Forest boundaries is land exchange.

LUPs relevant to the planning area identify 1,812,300 acres of BLM-administered land for disposal. Of these, 559,300 acres lie within PPH, while 257,400 acres lie within PGH. No Forest Service-administered land has been identified for disposal in the planning area.

Exchanges. Exchange is the process of trading lands or interests in lands and serves as a viable tool for the BLM to accomplish its goals and mission. Exchanges must be in the public interest and conform to applicable BLM LUPs. The lands to be exchanged must be of approximately equal monetary value and located within the same state. BLM-administered lands may be exchanged for lands or interests in lands owned by corporations, individuals, or government entities. Except for those exchanges that are congressionally mandated or judicially required, exchanges are voluntary and discretionary transactions with willing landowners.

Land exchanges are used to bring lands and interests in land with high public resource values into public ownership, consolidate land and mineral ownership patterns to achieve more efficient management of resources and BLM programs, and dispose of BLM-administered land parcels identified for disposal through the planning process.

Forest Service-administered lands are exchanged to achieve a desired national forest landownership pattern that supports forest land and resource goals and objectives, addresses fragmentation, reduces future management costs, and responds to urban and community needs. The objective of the Forest Service land exchange program is to use land exchanges as a tool, in concert with the purchase program, to implement Forest land and resource management planning and direction; to optimize National Forest System landownership patterns; to further resource protection and use; and to meet the present and future needs of the American people.

There are land exchanges pending on 76,982 acres (37,141 federal acres and 39,841 nonfederal acres) within the planning area. One land exchange totaling 52 acres has been identified on Forest Service-administered land in the planning area.

Land Sales. Section 203 (a) of FLPMA provides for sale of public lands if one of the following criteria is met: (1) the tract is difficult and uneconomic to manage as part of the public lands and is not suitable for management by another federal agency; (2) such tract was acquired for a specific purpose and the tract is no longer required for that or any other federal purpose; or (3) disposal of such tract will serve important public objectives, including but not limited to, expansion of communities and economic development that cannot be achieved prudently or feasibly on land other than public land. Public lands that have been identified for consideration for disposal by sale in the approved LUPs meet one or more of these criteria. Public lands must be sold at fair market value.

Section 209 of FLPMA authorizes the conveyance of federal minerals through sale and specifies the conditions under which the mineral rights would be conveyed. The mineral rights could be sold with the land surface, sold as a separate transaction, or retained. Conveyance of mineral rights has occurred only in conjunction with the sale of land.

The Forest Service has very limited authority to sell or otherwise dispose of Forest Service-administered lands. Most authorities allowing the sale of lands have specific criteria or identify only a small number of properties for sale or disposal in a limited geographical area. The tool used most often for conveyance of lands within National Forest boundaries is land exchange. Thus, no Forest Service-administered land has been identified for sale in the planning area.

Withdrawal. Withdrawal are formal actions that accomplish one or more of the following actions:

- Transfers total or partial jurisdiction of federal land between federal agencies
- Segregates (closes) public lands to appropriation under public land laws including mineral laws
- Dedicates public land for a specific public purpose

There are three major categories of formal withdrawals: (1) congressional withdrawals, (2) administrative withdrawals, and (3) Federal Power Act or Federal Energy Regulatory Commission (FERC) withdrawals. Congressional withdrawals are legislative withdrawals made by Congress in the form of public laws (acts of Congress). Administrative withdrawals are made by the President, Secretary of the Interior, or other authorized officers of the executive branch of the federal government. Federal Power Act or FERC withdrawals are power project withdrawals established under the authority of the “Federal Power Act” of 1920. Such withdrawals are automatically created upon filing an application for a hydroelectric power development project with FERC.

Federal policy now restricts all withdrawals to the minimum time and acreage required to serve the public interest, maximize the use of withdrawn lands consistent with their primary purpose, and eliminate all withdrawals that are no longer needed. Management and adjustment of withdrawals focuses on the establishment, management, modification, and revocation of withdrawals.

The purpose of a withdrawal is to withhold Forest Service-administered land from operation of various federal laws, to either reserve the area for some future use or to maintain other public values of the area. A withdrawal may prevent the land from leaving federal ownership, may prevent mineral leasing or may prevent entry under the mining laws. In recent years most withdrawals prevent entry under the mining laws since it is a nondiscretionary action.

The main object of a Forest Service withdrawal is to protect administrative sites and other capital improvements, and to protect designated management areas not compatible with mining activity. Other agencies such as FERC and the Bureau of Reclamation often request withdrawal of Forest Service-administered land for their purposes. The Department of Defense use of Forest Service-administered lands is by special use authorization, agreement, or the Interchange Act of 1956.

There are currently 28 withdrawals in the planning area, encompassing 4,025,900 acres of BLM-administered lands. Of these withdrawals, 1,437,200 acres reside on PPH, and 782,000 acres reside on PGH. There are approximately 584,100 acres of Forest Service withdrawals in the planning area.

#### *Acquisition*

Acquisition of and interests in lands are important components of the BLM's land tenure adjustment strategy. Acquisition of lands can be pursued to facilitate various resource management objectives. Acquisitions, including easements, can be completed through exchanges (see above), land purchases, or donations.

The Forest Service purchases lands through the Land and Water Conservation Fund to protect critical resource areas and provide increased public recreation opportunities. Land donations are accepted to consolidate Forest Service-administered lands and protect critical resource areas. The legal public use of Forest Service-administered lands is improved by acquiring ROWs for roads and trails.

Lands and interests in lands are acquired for the following actions:

- Improve management of natural resources through consolidation of federal, state, and private lands
- Secure key property necessary to protect endangered species, promote biological diversity, increase recreational opportunities, and preserve archeological and historical resources
- Implement specific acquisitions authorized or directed by acts of Congress

Forest Service objectives in lands or interests in lands through purchase, donation, and rights-of-way are to:

- Enhance the multiple use and sustained yield of the goods and services from Forest Service-administered lands

- Protect and improve the quality of renewable resources
- Protect and preserve important historic, cultural, and natural aspects of the national heritage
- Provide for access, use, and enjoyment of the forest resources by the public
- Improve administrative efficiency and effectiveness of Forest Service-administered lands

One Forest Service land exchange is proposed in Idaho that would affect 52 acres of land within PGH.

Purchases. The BLM has the authority, under Section 205 of FLPMA, to purchase lands or interests in lands. Similar to other acquisitions, purchase is used to acquire key natural resources or to acquire legal ownership of lands that enhance the management of existing public lands and resources. Acquiring lands and interests in lands through purchase helps consolidate management areas to strengthen resource protection. Acquisitions are used primarily to enhance recreational opportunities and acquire crucial wildlife habitats.

#### ***Land Use Authorizations***

The most common form of authorization to permit uses of BLM-administered lands by commercial, private, or governmental entities is the ROW grant. A ROW grant is an authorization to use a specific piece of BLM-administered land for certain projects such as roads, pipelines, transmission lines, or communication sites.

Some uses of BLM-administered lands are short-term uses and authorized through land use permits such as filming activities or apiary sites (bee hives).

Authorizations grant rights and privileges for a specific use of the land for a specific period of time. The BLM's objective is to grant land use authorizations to any qualified individual, business, or government entity, and to direct and control the use of authorizations on BLM-administered lands in a manner that:

- protects the natural resources associated with BLM-administered lands and adjacent lands, whether private or administered by a government entity
- prevents unnecessary or undue degradation to BLM-administered lands
- promotes the use of authorizations in common, considering engineering and technological compatibility, national security, and area LUPs
- coordinates, to the fullest extent possible, all BLM actions with local, state, Native American, and other federal agencies; interested individuals; and appropriate quasi-public entities (43 CFR 2801.2)

Forest Service special use permits authorize and administer use of Forest Service-administered lands by individuals, companies, organized groups, other federal agencies and state or local levels of government in a manner that protects natural resource values and

public health and safety. For example, special use permits authorize uses that contribute to the nation's infrastructure for generating and transmitting energy resources, such as: electric transmission facilities, oil and gas pipelines, hydropower facilities, and wind and solar facilities. They authorize uses for communications, commerce, public health and safety, and homeland security, such as fiber-optic and wireless telecommunications, water development systems, federal, state, and local highways.

The Forest Service objectives of granting ROWs for roads and trails are to:

- Provide ROWs for the public road system, including the federal-aid system, when such roads cross Forest Service-administered lands or interests in lands
- Accommodate the access needs for the protection, development, and utilization of lands and resources owned by private interests or administered by public agencies when the planned forest development road system and public road system do not meet those needs adequately
- Protect and enhance the quality of air, water, soil, and natural beauty of Forest Service-administered lands in the granting of any ROW
- Cooperate with intermingled and adjacent landowners in developing roads that serve the needs of both parties through the exchange of ROWs
- Provide access across Forest Service-administered lands to private land that is adequate to secure the owners thereof of reasonable use and enjoyment of their land without unnecessarily reducing the management options of the Forest Service or damaging Forest Service-administered lands or resources

#### *ROW Avoidance and Exclusion Areas*

Areas closed to mineral leasing, having a no surface occupancy restriction, or otherwise identified as unsuitable for surface disturbance or occupancy are generally identified as avoidance or exclusion areas for ROW authorizations. Restrictions and mitigation measures could be modified on a case-by-case basis for avoidance areas, depending on impacts on resources, while exclusion areas are strictly prohibited from ROW development. See **Table 3-33** for the number of acres currently identified as ROW avoidance and exclusion areas.

#### *ROW Corridors*

Designated utility corridors are developed to concentrate the effects of utility lines in manageable locations on BLM- and Forest Service-administered lands, which often provide suitable locations for utility transmission lines. The corridors may contain power line, transcontinental fiber optic communications cables, and trans-state gas pipelines. Designated utility corridors are designated in BLM and Forest Service LUPs. Such corridor designations are relatively uncommon in the sub-region. The mere presence of a transmission line or pipeline does not imply that it is within a formally designated corridor. Under this planning effort there are no undesignations or changes to the character of previously existing designated corridors; for example, all West-Wide Energy Corridors in Idaho allow for both

overhead and buried utilities; those designations will not change. Also, this plan does not attempt to establish any new formally designated ROW corridors.

For PPMA, new utility pipelines or transmission lines exceeding 50kV are excluded, unless they can be sited within a utility corridor previously designated in a BLM or Forest Service LUP (and subject to appropriate BMPs and siting considerations for GRSG). See **Table 3-33** for the number of acres currently identified as ROW avoidance and exclusion areas.

### ***Renewable Energy***

Solar, wind, biomass, and geothermal (which is managed as a fluid leasable mineral) are considered renewable energy resources. Renewable energy resources all have different requirements related to economic development; however, some issues are common to all renewable energy resources, including connection to the existing power transmission facilities and compatibility with existing federal land use.

Wind and solar resource facilities are permitted with ROW authorizations, through the Lands and Realty Program. Geothermal resources, as mentioned above, are considered fluid leasable minerals (See **Section 3.12**, Mineral Resources). As a result, management actions related to the Lands and Realty Program and leasable minerals could affect renewable energy resources. Special management designation areas, such as ACECs and WSAs, could also affect the use of renewable energy resources by limiting the location of these facilities.

Forest Service renewable energy generation and transmission includes wind, solar, and geothermal energy facilities. Section 501(a)(4) of the FLPMA authorizes the Forest Service to issue ROWs for the use and occupancy of Forest Service-administered lands for generation, transmission, and distribution of electric energy. The Energy Policy Act of 2005 recognizes the Forest Service's role in meeting the renewable energy goals of the US.

Consistent with Forest Service policies and procedures, the use and occupancy of Forest Service-administered lands for alternative energy production, such as wind energy development, are appropriate and will help meet the energy needs of the US. Permits for solar energy power facilities are issued only if non-Forest Service-administered lands are not available and if adverse impacts can be minimized. Permits for geothermal energy power facilities are issued only if feasibility studies have determined that it is not feasible to transmit geothermal water to a power-generating facility on non-Forest Service-administered lands and if adverse impacts can be minimized.

### **3.11.2 Trends**

#### ***Land Use Authorizations***

Land use authorization requests are customer driven. Within the planning area most authorizations processed are primarily for roads, electric distribution lines, and communications sites. Major ROWs are those large-scale utility projects, such as for 500kV electric transmission, wind, and solar development. Land use authorization requests are customer driven.

Over the last 6 years in the planning area, the BLM has received a number of applications for major transmission line projects to traverse the state. Prior to that time, it had been over 20 years since major transmission line applications were received by the BLM. The BLM has not received any applications for utility-scale solar production in the planning area, nor are there solar resources comparable to the areas where utility-scale solar production projects are being proposed or built.

Over the last six years, the BLM has authorized and then relinquished a ROW for wind development and has two pending applications. Wind testing sites have been authorized on BLM lands in the planning area, though no wind developments have been authorized and constructed.

### 3.11.3 Regional Context

**Table 3-34, Acres of GRSG Habitat within City Limits**, through **Table 3-42, Acres of Wind Energy Authorizations within GRSG Habitat**, displays data for GRSG habitat in the planning area (Manier et al. 2013). In each table, data are presented by surface management agency and their occurrence within occupied GRSG habitat in the planning area and across the entire MZs.

The conversion of sagebrush habitat to agricultural land or urban areas can result in GRSG habitat becoming fragmented and increases in domestic predators such as cats and dogs (Knick and Rotenberry 1995). **Table 3-34, Acres of GRSG Habitat within City Limits**, illustrates the locations where agricultural or urban development could occur given the location within a city boundary.

Communication towers, transmission lines, electrical distribution lines and other vertical structures provide additional perching opportunities for ravens and other birds of prey can result in habitat fragmentation, habitat avoidance, and can increase vehicle traffic during maintenance operations (USFWS 2010a). **Table 3-35, Number of Communication Towers within GRSG Habitat**, presents the number of communication towers in each MZ.

### 3.12 Mineral Resources

#### *Fluid Leasable Minerals*

The right to drill for and develop fluid minerals, namely oil and gas and geothermal resources, on federal land may only be acquired through a mineral lease, offered and administered by the BLM in accordance with the Mineral Leasing Act of 1920, as amended and supplemented (30 USC 181 et seq.). The limit for a competitive oil and gas lease is 2,560 acres in size, while a geothermal lease can be up to 5,280 acres in size. If an oil and gas lease is not sold during the competitive sale, it may be sold noncompetitively and may be combined with other parcels for a total of 10,240 acres, but the maximum size for a geothermal lease remains 5,280 acres.

The leases have a 10-year term. If there is no discovery in 10 years, the leases expire. There is no renewal for diligence. If there is a discovery, the lease may be held as long as there is production. The BLM can modify the right conveyed by a lease by attaching a stipulation, which is an enforceable condition of the lease. During the leasing process, the BLM may apply stipulations (for example No Surface Occupancy, Controlled Surface Use, and Timing Limitations) to all or parts of a lease in order to protect a wide range of resources including soils, watersheds, cultural resources, and wildlife (e.g., GRSG). Stipulations may impact the availability of fluid mineral resources on a lease by restricting the timing and/or location of exploration and development activities. On Forest Service-administered lands, the BLM cannot issue a lease without Forest Service consent. Forest Service consent includes stipulations that must be added to the lease to protect the resources on the Forest.

The issuance of a lease does not, in and of itself, authorize any surface-disturbing activities. If a lessee wishes to conduct exploratory drilling, an application for permit to drill must be submitted to the BLM for approval. An environmental analysis is conducted and as a result, the BLM may attach additional, site-specific and activity-specific conditions, called Conditions of Approval or Best Management Practices, to the drilling permit. The Forest

Service approves the Surface Use Plan of Operations portion of the application for permit to drill, and may also add COAs. The BLM cannot deny operations on a lease unless the operation would violate other nondiscretionary statutes, such as the ESA or the Clean Water Act. In cases where surface operations would have unacceptable environmental impacts, the BLM's authority to deny operations on the lease, if not specified in a particular statute, must be established in the lease through the use of lease stipulations.

All leases, regardless of whether they have additional stipulations, are offered with standard terms and conditions. In accordance with a 2002 Instruction Memorandum from the BLM Washington Office, all fluid mineral leases must include the following stipulation:

*Endangered Species Act Section 7 Consultation Stipulation*

The lease area may now or hereafter contain plants, animals or their habitats determined to be threatened, endangered, or other special status species. BLM may recommend modifications to exploration and development proposals to further its conservation and management objective to avoid BLM-approved activity that will contribute to a need to list such a species or their habitat. BLM may require modifications to or disapprove proposed activity that is likely to result in jeopardy to the continued existence of a proposed or listed threatened or endangered species or result in the destruction or adverse modification of a designated or proposed critical habitat. BLM will not approve any ground-disturbing activity that may affect any such species or critical habitat until it completes its obligations under applicable requirements of the Endangered Species Act as amended, 16 USC 1531 *et seq.*, including completion of any required procedure for conference or consultation.

All geothermal and oil and gas leases in Idaho contain the ESA consultation stipulation. There is also a mandatory cultural resource protection stipulation applied to all leases.

Stipulations to protect other resources, such as GRSG, are developed during the land use planning process. Stipulations must be necessary and justifiable: If a lessee is to be prevented from extracting oil and gas on a lease and the prohibition is not mandated by a specific, nondiscretionary statute such as the ESA, the stipulation is necessary and is to be used. A stipulation is justifiable if there are resource values, uses, and/or users present that cannot coexist with fluid mineral operations, cannot be adequately managed and/or accommodated on other lands for the duration of operations, and provide a greater benefit to the public than that of the fluid mineral operations. If a ground disturbing activity is proposed on the lease during any given year, the authorized officer may modify or waive restrictions if actual conditions do not warrant them.

### **3.12.1 Conditions within the Planning Area**

#### ***Oil and Gas***

There has never been a single producing oil and gas well in the entire state of Idaho, despite the drilling of over 150 wildcat wells in the state since the early 1900s. As of January 18, 2013, Idaho BLM has four federal oil and gas leases – two are located on split-estate and BLM-administered lands on the Bear Lake Plateau, and two are located on split-estate lands near Gray's Lake in Bonneville County. The leases were issued in 2006 for an initial term of 10 years. No drilling or exploration has occurred on any of the leases nor has any activity

been proposed; however, a wildcat well was drilled on private land near the Gray's Lake leases in 2007. The well was drilled to approximately 11,000 feet without encountering an economically viable hydrocarbon source. Additionally, a company has drilled numerous wells on private lands in the New Plymouth area of southwest Idaho, and is planning to develop a natural gas field. BLM-administered lands are located near this field and have been nominated for leasing, however leasing is being deferred until completion of the Four Rivers RMP. There is no GRSG habitat in this area.

The two leases on the Bear Lake Plateau are located in GRSG habitat and each have the following stipulation (as well as several others not directly related to GRSG):

In order to protect important seasonal wildlife habitat (sage grouse leks, sage grouse brood rearing, sage grouse winter range, and deer winter range), exploration drilling and other development activity will be allowed only during the period from 7/1 to 11/30. This limitation does not apply to maintenance and operation of producing wells. Exceptions to this limitation in any year may be specifically authorized in writing by the Authorized Officer of the BLM.

The Dillon Field Office has 47 active oil and gas leases, none of which are producing, according to LR2000. None of the leases appear to be located in GRSG habitat, however many leases likely contain timing limitations for other wildlife species, as the Dillon RMP shows that much of the field office is covered by stipulations restricting activities during critical seasons for other wildlife species or prohibiting all surface occupancy.

**Figure 3-**, Oil and Gas Potential of Federal Oil and Gas Mineral Estate depicts the oil and gas potential within the planning area.

#### ***Geothermal***

Idaho's prospects for development of geothermal resources are better than those for oil and gas. There are currently 25 federal leases in Idaho, covering approximately 60,000 acres. Leases are scattered across southern Idaho, but are primarily located near Raft River, Crane Creek, and Parma, Idaho. There are no active leases currently in the Dillon Field Office. Seventeen of Idaho's 25 geothermal leases are located in GRSG habitat, and all have existing stipulations protecting GRSG habitat during critical seasons (as well as having stipulations to protect crucial habitat for other species):

- Each of the nine leases at Raft River have a stipulation restricting exploration and development work in GRSG strutting/brood-rearing habitat from April 1 through June 15.
- Each of the four leases at Crane Creek contain a stipulation requiring that a survey be conducted for the presence of active GRSG leks in key habitat, prior to authorization of surface disturbing activities. If active leks are present (defined as being used at least once in a five-year period), two stipulations will apply. One is a timing limitation precluding exploration or drilling activities between March

Idaho and Southwestern Montana  
Draft LUPA/EIS

15 and May 1 from 6 pm to 9 am within two miles of an active lek. The other

*Idaho and Southwestern Montana Sub-Region Greater Sage-Grouse LUPA/EIS*  
October 2013

*Chapter 3 – Affected Environment 3-107*

Figure 3-8 Oil and Gas Potential of Federal Oil and Gas Mineral Estate

*Idaho and Southwestern Montana Sub-Region Greater Sage-Grouse LUPA/EIS*  
October 2013

stipulation precludes construction of wells, geothermal plants, power lines, pipelines, or other such permanent structures that would fragment or degrade nesting habitat within two miles of an active lek.

- Both of the geothermal leases located west of Weiser have the following stipulations:
  - Controlled surface and timing limitation use near GRSG leks and/or nesting/early brood rearing habitat: Potentially disruptive major construction and maintenance activities (e.g., infrastructure/energy development and similar projects), shall be avoided within 4 miles (6.4 kilometers) of occupied or undetermined status GRSG leks from February 15 to June 30 to reduce disturbance to lekking birds, or April 15 to June 30 for nesting GRSG (and/or hens with early broods). Major construction and maintenance activity will be avoided in GRSG winter range from December 1 to February 15. Specific dates may be earlier or later, depending on local breeding chronology. The spatial buffer may be increased or decreased based on site-specific factors analyzed and documented in an environmental assessment or EIS and authorized via the appropriate decision document. Exceptions may be granted for activities involving only infrequent, short term disturbance (less than 1 hour within a 24-hour period in a specific area); or if there are intervening topographic features or line-of-site screening that buffer the lek or nesting habitat from disturbance; or if recent (within the past 5 years) site-specific studies or local expertise suggest that leks or nesting hens are unlikely to be present within the 4-mile zone surrounding the project activity.
  - For smaller-scale human disturbances, (e.g., water pipeline construction, routine fence maintenance, and facility maintenance), a 0.62 mile (1 kilometer) lek disturbance buffer will apply between approximately March 15 and May 1 in lower elevations and March 25 through May 15 in higher elevations, from 6 p.m. to 9 a.m. in a specific area to minimize disturbance to lekking GRSG.
- The two geothermal leases located on the north side of Magic Reservoir have the same stipulations (concerning GRSG) as the leases west of Weiser.

Geothermal exploration and development activity on federal lands in Idaho has been sporadic, due largely to economic factors. Idaho now has one 10 megawatt geothermal power plant currently operating, as of 2007. It is located on private land at Raft River, south of Burley, Idaho. Nine federal leases surround the plant and extend up the southeast flank of Jim Sage Mountain. The BLM approved five geothermal drilling permits on a lease at Raft River in 2010, however no drilling has occurred to date. The drilling permits have several Conditions of Approval attached to protect wildlife. These include fencing reserve pits and safeguarding migratory birds from hazards associated with pits and treatment facilities, including but not limited to pit screening or netting, and placing protective cones over vent

stacks. In addition, drilling is prohibited during the GRSG strutting and brood-rearing season (lease stipulation).

**Figure 3-9, Geothermal Potential of Federal Geothermal Mineral Estate**, depicts the geothermal potential of the federal mineral estate in the planning area.

***Mineral Materials***

Mineral materials include sand, gravel, most building and landscaping stone, pumice, and other common variety materials that are not subject to mineral leasing or location under the mining laws. The Materials Act of 1947, as amended (61 Stat. 681) authorizes disposal of mineral materials on BLM-administered lands through a sales system, and provides for free use of material by government agencies, municipalities or nonprofit organizations, if the material is not to be used for commercial purposes. Permitting the removal or extraction (i.e., disposal) of mineral materials on BLM-administered lands is a discretionary activity. The BLM will not authorize the disposal of mineral materials if it is determined that the aggregate damage to BLM-administered lands and resources would exceed the public benefits that the BLM expects from the proposed disposal; nor will the BLM dispose of mineral materials from areas identified in land use plans as not appropriate for mineral materials disposal (43 CFR 3601.11 and 3601.12). Disposal of mineral materials on Forest Service-administered lands is covered by 36 CFR 228D.

Most BLM-administered land in Idaho is available for consideration of mineral material disposal; however, existing guidance in many of the LUPs in the planning area encourages the use of existing disposal sites until the material is depleted. **Table 3-43, Existing Mineral Materials Cases**<sup>1</sup>, shows the numbers of mineral material disposal cases within the planning area. **Figure 3-10, Mineral Material Commodity Types in the Planning Area**, shows the geographic distribution of mineral materials in the planning area.

October 2013

Community pits are sites established by the BLM and Forest Service for the public to acquire mineral materials by purchasing a short-term permit over-the-counter at the field office. Free Use Permits are usually sand and gravel pits, and are requested by county highway districts and nonprofit organizations for road construction and maintenance of county roads. A negotiated sale is an exclusive site proposed by a single party, often commercial, as the party must now pay for the BLM to process the permit.

The number of sales out of a community pit varies by site, from less than one to more than 50 per year. Many of the most popular community pits are for landscaping rock and building stone that is simply picked up by hand from the ground surface or from a talus slope. Most of these sales are for less than one ton. Most Free Use Permit sites are used sporadically and may be scattered throughout a field office or ranger district office, so that when the county needs material it has a nearby source, thereby reducing haul costs. A pit may be inactive for several years before it is needed for a road project in the area.

A gravel pit is initially developed by scraping off the vegetation and topsoil, which is then stockpiled for future reclamation. Most gravel pits are 5 to 15 acres in size. No infrastructure other than an access road is needed for mineral materials disposals. Most mineral material removal activity occurs during the summer months and during daylight hours.

Very few mineral material sites have mitigation measures protecting GRSG habitat. One exception is the St. Anthony Sand Dune Community Pit, which has a provision stating “Proposals to remove sand between March 1st and June 15th will be evaluated to determine if breeding birds are utilizing the area.”

#### ***Locatable Minerals***

Under the General Mining Act of 1872 (17 Stat. 91), any US citizen, or person with the intent to become a citizen, may stake a mining claim for locatable minerals on federal lands (unless administratively withdrawn from mineral entry). This gives the claimant a possessory right to develop the locatable mineral resource. Lands withdrawn from mineral entry are Wilderness, ACECs, and other specially designated areas. The staking of a mining claim is a nondiscretionary activity: As long as the lands are open to locatable mineral entry, and as long as the claimant maintains the mining claim on an annual basis in accordance with regulations at 43 CFR 3830 through 3838, the mining claim is considered active. If the claimant fails to properly locate or maintain the claim on an annual basis, the claim is forfeited. The BLM’s role is limited to recording and adjudicating the location notices and maintenance filings, and preventing undue or unnecessary degradation of the lands under FLPMA. **Figure 3-11**, Locatable Mineral Potential in the Planning Area, shows areas where locatable minerals are considered to be more likely to be found and **Figure 3-12** shows existing Surface Management Plans or Notices in the planning area.

If a claimant wants to perform mining operations other than casual use on BLM-administered lands, a Notice or Plan, filed under 43 CFR 3809, must be filed with the BLM (or 43 CFR 3802, if the claim is located on lands under wilderness review). The Forest Service has similar locatable minerals management regulations at 36 CFR 228A. For

Figure 3-11 Locatable Mineral Potential in the Planning Area

October 2013

Figure 3-12 Existing Surface Management Plans or Notices in the Planning Area

operations on Forest Service-administered lands, a Notice of Intent must be filed. In addition, a Plan of Operations is required if the proposed activities will cause “significant disturbance of surface resources” (36 CFR 228.4[a][4]). Where there is a reference to notices or plans, it means both notices or plans on BLM-administered lands and Notices of Intent or Plans of Operation on Forest Service-administered lands. Later in this document, the terms Notice/Notice of Intent or Plan/Plan of Operation are roughly equivalent for the purpose of this analysis. The purpose of these regulations is to prevent unnecessary or undue degradation of surface resources by operations authorized by the mining laws. The subparts establish procedures and standards to ensure that operators and mining claimants meet their obligation to prevent undue or unnecessary degradation and to reclaim disturbed areas.

The existing land use plans identify areas that are closed to mineral entry but are silent on mitigation measures to be taken in GRSG habitat. **Table 3-44, [Authorized or Pending 3809 Plans and Notices](#)<sup>1</sup>**, shows the numbers of 3809 Plans and Notices that are authorized or pending in the planning area.

**Table 3-44**

Source: BLM 2013a

<sup>1</sup> Data current as of December 14, 2012

The Boise District currently has eight 3809 Plans in GRSG habitat for mostly small operations for zeolite and bentonite along the Owyhee Front. Three of the plans are located in the Castle Creek drainage south of Oreana (zeolite, bentonite); two plans are located close to the Oregon border near US Highway 95 (both for zeolite); and two plans on the Owyhee Plateau near the Upper Deep Creek area.

The Twin Falls District currently has seven 3809 Plans in GRSG habitat. Six are building stone operations south of Oakley, and one is the Eskridge pumice pit north of Magic Reservoir. At least three companies operate quarries on Middle Mountain south of Oakley, extracting a variety of micaceous quartzite called Oakley Stone. Oakley Stone is highly prized as a building and flooring material, as it has very high tensile strength and can be split into large, thin sheets. Building stone quarry operations have been active on Middle Mountain for over sixty years in the vicinity of active GRSG leks.

The operations are confined to discrete quarries located at mid-elevation on the west slope of Middle Mountain. The quarries expand very slowly over the years, and no infrastructure such as power lines or pipelines are required. Very little mechanical equipment is used, as the stone is split to the desired thickness using only small hand tools such as pry bars, hammers and chisels, and is then placed on pallets by hand. However, operators also use excavators, dump trucks, front end loaders, and other equipment in their daily operations, and blasting is used occasionally. Most of the quarry workers are employed seasonally and are housed on-site, thereby reducing traffic and dust. The quarries are strung out north-south along Middle Mountain such that each quarry has a separate road to access the Goose Creek road, an improved gravel road that leads to Oakley.

During the field season (roughly May to November), semi-truck traffic, hauling pallets of Oakley Stone, can be fairly intense on the Goose Creek road, making 10 to 20 round trips per day. One of the operations has a mill site adjacent to the Goose Creek Road where stone is split and palletized for shipping. All of the operations shut down in the winter, so in the fall pallets of stone are brought off the mountain and stockpiled in Oakley. Several of the quarries have been patented and are therefore privately owned. No stipulations pertaining to GRSG are currently applied to the Plans of Operations for any of these quarries. Altogether, the quarries employ approximately 100 people year-round and approximately 600 seasonal workers (Southern Idaho Living 2012).

The Eskridge pumice pit is located north of Magic Reservoir, on both sides of US Highway 20. The mining claimants have mined pumice for landscaping material since the 1940s. Current operations are located on the south side of the highway, where disturbance consists of 15 acres of quarry and staging area. A few years ago, the claimant moved the operation from the north side of the highway, and reclaimed (sloped and seeded) 34 acres of previous disturbance. The operation is active throughout the year, but activities rotate approximately every 3 years, depending on demand for the material. In the first year of the cycle, bulldozers are used to rip the material from the quarry face. In the second year, the material is classified based on size and color, and stockpiled. In the third year, the stockpiles are loaded into belly dump trucks and transported to Gooding, where it is loaded onto train cars and shipped to Rexburg, where it is sold.

The Idaho Falls District currently has four 3809 Plans located in GRSG habitat, all in the Challis Field Office. Two plans are for building stone (including Three Rivers Stone) and 2 are for zeolite. The Three Rivers Stone quarry is a large building stone quarry operation situated along the south side of US Highway 93, east of the confluence of the East Fork and the Main Salmon rivers. The quarry is operated in a similar manner as those on Middle Mountain: The stone (a variegated argillaceous quartzite) is split into thin sheets using hand tools and is palletized at the quarry. The pallets are hauled to the mill site adjacent to the highway, from which they are shipped. At peak production in 2007, there were 99 people employed by the quarry's operator, L&W Stone. In January, 2013, however, the company announced that it would be shutting down production at the quarry while it undergoes bankruptcy proceedings.

In the Dillon Field Office, there are currently no 3809 Plans located in GRSG habitat. Eight out of twenty-four 3809 Notices are in GRSG habitat.

On the Raft River division of the Sawtooth National Forest in Utah, there are several quarries of building stone. They are located on the southern slopes of the Raft River Range, in GRSG habitat.

#### ***Nonenergy Solid Leasable Minerals***

The Pocatello Field Office has a large nonenergy solid leasable mineral program, as the phosphate resource in southeast Idaho is significant. The goal in the Pocatello RMP is to manage the federal mineral estate while minimizing adverse impacts on resource values. The 2012 Pocatello RMP does not have any stipulations or minerals guidance for nonenergy leasable minerals which specifically address GRSG.

Phosphate has been mined in southeast Idaho for over one hundred years. Of the 86 federal phosphate leases that BLM administers in Idaho, only ten are located in GRSG habitat. These are located primarily north and west of Blackfoot Reservoir. None of these leases have had active mining operations on them, nor is any mining planned on the leases in the next 5 to 10 years. Most of the leased acreage around Blackfoot Reservoir is split-estate (privately owned or state-owned surface with federal minerals). The Trail Creek and Caldwell Canyon leases, located in GRSG habitat east of Conda Mountain, are currently undergoing drilling. One additional lease is located in priority GRSG habitat northwest of Bear Lake near Paris, Idaho. Exploration drilling was conducted in 2012 on lease, and on the private lands and unleased split-estate lands surrounding the small lease. Timing restrictions for GRSG were applied to the approval for the drilling. If developed, this property would likely be developed as an underground mine, due to geologic factors. The Dillon Field Office has one nonenergy solid leasable lease, for phosphate. It is not located in GRSG habitat.

**Figure 3-13**, Unleased Known Phosphate Leasing Areas, shows gas potential within the planning area.

#### ***Coal***

No economically viable coal resources have ever been discovered in Idaho, and most plans are silent on the subject. The Dillon RMP states its goal is to make coal resources available on a site-by-site basis. A plan amendment would be required to lease coal, along with the appropriate level of NEPA analysis. No specific mitigation measures for GRSG are identified in any of the land use plans. Coal mining is regulated in accordance with the Surface Mining Control and Reclamation Act of 1977 (30 USC 1201 et seq.). BLM's coal mining regulations are found at 43 CFR 3400. According to 43 CFR 3420.1-4 (e)(1), only those areas that have development potential may be identified as acceptable for further consideration for leasing. As there is no development potential in the planning area, the lands are determined to be unsuitable for leasing. For this reason, the impacts on GRSG from the development of a coal resource will not be discussed further in this document.

October 2013

### 3.12.2 Trends

#### *Oil and Gas*

Interest in oil and gas leasing in Idaho has been sporadic over time, and it is expected to remain so. Many leases were held in the 1970s and 1980s throughout much of Idaho, when leasing was done under a noncompetitive system. After passage of the Federal Oil and Gas Royalty Management Act in the early 1980s, leasing became a competitive process, and BLM's standards for leasing became more rigorous. Lease nominations dropped dramatically in Idaho and for many years, BLM's oil and gas program in Idaho was nonexistent. With passage of the Energy Policy Act in 2005, Idaho BLM experienced an uptick in leasing interest, with over 400,000 acres of federal land nominated since that time<sup>2</sup>.

Interest in leasing is currently high in the Payette area, due to the recent wildcat discovery of natural gas and planned development in that area (181,000 acres nominated for leasing, overlapping). Much of the land nominated for leasing is split estate, and only the northernmost nominated parcels are located in GRSG habitat. The Bear Lake area has been nominated for leasing by several parties, most recently in 2012 (59,700 acres, overlapping acreage). Interest in leasing the Bear Lake Plateau was at its highest in the early 1980s, when a discovery of gas was made 10 miles south of the Idaho/Utah state line, and in adjoining areas in Wyoming. Several wells were drilled in Idaho at that time, but were reported to be dry. Other areas that have been nominated for leasing recently include approximately 90,000 acres in Twin Falls County, south of Rogerson, and approximately 60,000 acres in Clark County, on the Idaho-Montana border in the Targhee National Forest. All of these nominated lands have GRSG habitat.

Several geophysical surveys have been conducted recently in the Payette area (two-dimensional and three-dimensional seismic surveys). It is likely that additional geophysical surveys will be conducted in the planning area. Seismic reflection surveys are the most commonly used geophysical tool. Very little surface disturbance is associated with a seismic survey, as no excavating or drilling is involved. All that is required is a seismic energy source and an array of receptors. The most common type of survey seen in Idaho involves mechanically vibrating or "thumping" the ground using truck-mounted equipment. This creates seismic waves that are recorded by a series of receptors placed on the ground surface along a three- to five-mile line. This process requires a crew of about 10 to 15 people and 5 to 7 vehicles. No reclamation is usually required.

Despite the occasional interest in leasing in Idaho, no drilling permits have ever been filed on BLM-administered lands in Idaho. This trend is expected to continue, however, for the sake of this analysis, a description of the drilling process is included in this report, since the issuance of a lease commits those lands to the possibility of exploration and development of the oil and gas resource. Exploration drill holes for oil and gas range in depth from a few thousand feet to many thousands of feet, but in much of Idaho would probably be 7,000 to 11,000 feet deep. These wells are 30 inches in diameter or larger at the surface, then narrow

---

<sup>2</sup> Some of this acreage overlaps, due to multiple nominations for the same land

(telescope) to 12 inches at the bottom of the well. In order to drill these deep, large-diameter holes, a large drilling rig would be utilized. The top of the drill rig derrick could be as much as 155 feet above the ground surface, and the rig floor could be at least 25 feet above the ground surface. These rigs are typically equipped with diesel engines, fuel and drilling mud storage tanks, mud pumps, and other ancillary equipment. Blow-out prevention equipment would be utilized while drilling to prevent uncontrolled flow at the surface if a pressurized hydrocarbon deposit is encountered.

Temporary roads would likely be needed to transport and maintain the drill rig and other heavy equipment. Either existing roads would be improved or new roads would be constructed to accommodate the traffic. Typically, roads are constructed with a 20-foot wide graveled running surface with adjacent ditches and berms, for a total disturbance width of about 40 feet. It may be necessary to haul in gravel to obtain a good road base, as well as a base for the well pad. Based on the road density in the planning area, it is assumed that access to the drill pads may require up to one mile of road construction or improvement. Surface disturbance from construction of one mile of road equals about five acres.

Getting the rig and ancillary equipment to the site may require 15 to 20 trips by full-sized tractor-trailers, with a similar amount for de-mobilizing the rig. There would be 10 to 40 daily trips for commuting and hauling in equipment. Drilling operations would likely occur 24 hours a day and 7 days a week. It takes approximately one month to drill one well. A drilling operation generally has from 10 to 15 people on-site at all times, with more people coming and going periodically with equipment and supplies.

During this exploratory or wildcat phase of drilling, it is likely that a drill pad, to accommodate the rig and equipment, would be required at each well location. A drill pad is usually 2.5 acres in size (300 feet by 350 feet), but it can vary considerably due to the depth of the target zone, surface topography, and equipment needs for various drilling methods. In order to obtain a level pad, cut and fill of the site may be required. Topsoil would first be removed from the well pad site and stored on site for reclamation. In addition to the drill rig, the well pad may house a reserve pit for storage or disposal of water, drill mud, and cuttings; several mud pits and pumps, a tool shed, drill pipe rack, a fuel tank, a water tank, a generator and several compressors, equipment storage, and several trailers for temporary lab and office quarters. Depending on the contents of the reserve pit and environmental sensitivity of the site, it may be lined or unlined.

Well drilling also requires water. As much water as possible is recycled on site, yet about 5,000 to 15,000 gallons of water may be needed each day depending on well conditions. Initially, water would need to be provided, either by wells or trucked in, to meet demands. Many oil or gas wells encounter water at depth when drilling for oil and/or gas and can be utilized when production is ongoing. Any water rights required would likely need to be filed in the name of the BLM.

Various tests are then run down the hole and data is collected to determine whether the well is capable of production. At the conclusion of well testing, if paying quantities of oil and gas are not discovered, the operator is required to plug the well according to federal and state

standards. Cement plugs are placed above and below water-bearing units with drilling mud placed in the space between plugs. When abandonment is complete, the site is reclaimed, which includes pad and road recontouring, topsoil replacement, and seeding with approved mixtures. Erosion control measures would be incorporated into the reclamation design as needed.

The drilling site could be active for approximately 1 year, from the start of drill pad and access road construction; through drilling and well testing; to completion of production facilities or plugging the hole and reclamation of the surface, which usually involves removing all infrastructure, disposal of any waste generated, reshaping pads and roads, and re-seeding. The total surface disturbance expected from the drilling of a single exploratory well and the construction of one mile of access road is approximately eight acres.

If a producible quantity of oil or gas is discovered, additional development wells would be drilled to confirm the discovery, establish the limits of the field, and drain the field. Depending on the field characteristics, well spacing may be from 40 to several hundred acres per well.

The speed at which a field is developed is dependent on the anticipated productivity. It may take from 1 to 3 years to fully develop an oil or gas field. Large fields with several operators may be unitized to reduce surface impacts. In addition, directional drilling may allow for drilling more than one well per pad.

During field development, the road system may be greatly expanded. Temporary roads are usually improved to accommodate more traffic and increased duration of use. Improvements may include crowning, capping, and implementing additional erosion controls. New roads would also be constructed. Depending on well location and topography, a main access road is built with smaller secondary roads running to each pad. In addition to roads, other facilities may also be installed including power lines, tank farms, pipelines, oil/water separators, and injection wells.

Where oil and gas flow to the surface naturally, control valves and collection pipes are attached to the well head. Otherwise pumps are installed. Oil is typically produced along with water and gas. Separation facilities are constructed on site to remove water, carbon dioxide, and hydrogen sulfide. The oil and natural gas are then separated. Water, usually saline, is disposed of either through surface discharge, evaporation ponds or re-injection into the producing formation.

If gas is present in economic quantities and a pipeline is located within close proximity, a network of pipelines would likely be constructed to collect and transport the gas. If not, gas would likely be re-injected into the reservoir. Oil would be collected in a similar manner and stored in tanks in a central location. Well operators would likely have service operations (e.g., cementing, logging, bits, and testing) provided by established oil field service companies in Wyoming or Utah.

The producing life span of an oil or gas field varies depending on field characteristics. A field may produce for a few years to many decades. Commodity price, recovery technique, and the political environment also affect the life of a field. Well abandonment may begin as soon as it is depleted, or it may be rested for a period of time and put back into production.

#### ***Geothermal***

Interest in geothermal is sporadic in Idaho, depending on factors such as the economy, political climate, government incentive programs, such as the renewable energy tax credit, and technological advances. It is anticipated that drilling will occur on federal leases at Raft River over the next 10 to 15 years, and that an additional power plant would be constructed, likely on private lands, but with wells on federal land.

#### ***Mineral Materials***

Demand for mineral materials is expected to remain fairly steady, although the collapse of the housing industry in 2008 definitely resulted in fewer sales throughout the planning area. The implementation of full cost recovery for individual sales has caused a decline in that case type.

#### ***Locatables***

While Idaho's mining claim numbers fluctuate with the price of gold, the number of plans and notices remains fairly steady. Production of building stone in the Middle Mountain area remains steady, however it was recently reported that L&W Stone's Three River Stone quarry near Clayton has been shut down due to bankruptcy. Several Plans of Operations are in the approval process on Middle Mountain.

#### ***Nonenergy Solid Leasable Minerals***

Demand for phosphate remains high, and the companies that mine in southeast Idaho continue to develop new mines as old ones are reclaimed and remediated. There is no indication that the leases west of Soda Springs in GRSG habitat will be developed in the foreseeable future. It is anticipated that, over the next 10 years, new mines will be developed on phosphate leases at Dairy Syncline, Husky/Dry Ridge, Caldwell Canyon, and Trail Creek, as current mines are depleted of ore and are reclaimed. Only the Caldwell Canyon and Trail Creek leases are located in GRSG habitat. Both of these leases are located primarily on split estate lands: at Caldwell Canyon, the majority of the surface estate is privately owned (1,200 acres), with only 160 acres on BLM-administered lands; the Trail Creek lease is composed of a mix of state and private surface estate. In the spring of 2013 it was announced that a company plans to open an underground operation near Paris, Idaho, on patented lands in GRSG habitat. The announcement stated that initial development would not involve federal minerals; however, exploration drilling occurred on federal minerals in 2012.

#### ***Coal***

It is highly unlikely that any coal exploration or development will occur in the planning area.

### **3.13 Special Designations**

Within the planning area are a variety of lands set aside through congressional or administrative action to protect certain values, such as Wilderness, Wilderness Study Areas,

National Landscapes, National Scenic and Historic Trails, and Wild and Scenic Rivers (**Figure 3-14**, Special Designations in the Planning Area).

### 3.13.1 Areas of Critical Environmental Concern (ACEC)

An ACEC is defined in FLPMA, Section 103(a), as an area on BLM-administered lands where special management attention is required to protect and prevent irreparable damage to important historic, cultural, or scenic values, fish and wildlife resources, or other natural systems or processes, or to protect life and ensure safety from natural hazards. BLM regulations for implementing the ACEC provisions of FLPMA are found in 43 CFR 1610.7-2(b).

ACECs differ from some other special management designations in that designation by itself does not automatically prohibit or restrict other uses in the area. The special management attention is designed specifically for the relevant and important values and, therefore, varies from area to area. Restrictions that arise from an ACEC designation are determined at the time the designation is made and are designed to protect the values or serve the purposes for which the designation was made. The BLM identifies goals, standards, and objectives for each proposed ACEC as well as general management practices and uses, including necessary constraints and mitigation measures. In addition, ACECs are protected by the provisions of 43 CFR 3809.1-4(b)(3), which requires an approved plan of operations for activities resulting in more than 5 acres of disturbance under the mining laws.

Research natural areas are areas where natural processes are allowed to predominate, and that are preserved for the primary purposes of research and education. Under current BLM policy, research natural areas must meet the relevance and importance criteria of ACECs and are, therefore, designated as ACECs. Under current guidelines, ACEC procedures also are used to designate outstanding natural areas.

There are portions of fifty two Idaho and 7 Montana ACECs in the planning area that overlap occupied GRSG habitat (see **Figure 3-15**, Existing Areas of Critical Environmental Concern with Preliminary Priority and General Habitat). Refer to **Table 3-45**, BLM Areas of Critical Environmental Concern, which summarizes the acres of ACECs within GRSG habitat and the identified relevant and important values for each. None of the existing ACECs were designated solely for the purpose of protecting GRSG habitat.

As part of this effort, the BLM called for and received nominations for ACECs to protect GRSG. A BLM interdisciplinary team reviewed nominations to determine which areas meet the relevance and importance criteria, as defined by 43 CFR 1610.7-2(a)(1), and 43 CFR 1610.7-2(a)(2), and guidance in BLM Manual 1613, Areas of Critical Environmental Concern. Details of the process and information on those areas found to meet the relevance and importance criteria can be found in **Appendix H**, BLM ACEC Evaluation and Forest Service Zoological Areas.

### 3.13.1 Wilderness

#### ***BLM***

In 1964, the Wilderness Act (the Act) established the National Wilderness Preservation System to be managed by the Forest Service, National Park Service, and USFWS. In 1976, with the passage of the FLPMA, Congress made the BLM the fourth agency with wilderness management authority under the Wilderness Act.

Section 4(b) of the Act further sets forth the agencies' responsibilities in administering wilderness areas and states that the preservation of wilderness character is the primary management mandate. In the relevant part, the Act states: "Except as otherwise provided in

this Act, each agency administering any area designated as wilderness shall be responsible for preserving the wilderness character of the area.”

As set forth in Section 2(c) (“Definition of Wilderness”) of the Wilderness Act, wilderness character is composed of four mandatory qualities and a fifth, optional, quality. These are:

- i. **Untrammelled.** The Wilderness Act states that wilderness is “an area where the earth and its community of life are untrammelled by man.” A “trammel” is literally a net, snare, hobble, or other device that impedes the free movement of an animal. Here, used metaphorically, “untrammelled” refers to wilderness as essentially unhindered and free from modern human control or manipulation. This quality is impaired by human activities or actions that control or manipulate the components or processes of ecological systems inside wilderness.
- ii. **Natural.** The Wilderness Act states that wilderness is “protected and managed so as to preserve its natural conditions.” In short, wilderness ecological systems should be as free as possible from the effects of modern civilization. Management must foster a natural distribution of native wildlife, fish, and plants by ensuring that ecosystems and ecological processes continue to function naturally. Watersheds, water bodies, water quality, and soils are maintained in a natural condition; associated ecological processes previously altered by human influences will be allowed to return to their natural condition. Fire, insects, and diseases are allowed to play their natural role in the wilderness ecosystem except where these activities threaten human life, property, or high value resources on adjacent nonwilderness lands. Additional guidance on this is provided in section 1.6.C of this manual, which addresses the management of specific activities in wilderness. This quality may be affected by intended or unintended effects of human activities on the ecological systems inside the wilderness.
- iii. **Undeveloped.** The Wilderness Act states that wilderness is an area “of undeveloped Federal land retaining its primeval character and influence, without permanent improvements or human habitation,” “where man himself is a visitor who does not remain,” and “with the imprint of man’s work substantially unnoticeable.” Wilderness has minimal evidence of modern human occupation or modification. This quality is impaired by the presence of structures or installations, and by the use of motor vehicles, motorized equipment, or mechanical transport that increases people’s ability to occupy or modify the environment. More detail on the activities that impair this quality is found in Section 1.6.B of this policy.
- iv. **Solitude or Primitive and Unconfined Recreation.** The Wilderness Act states that wilderness has “outstanding opportunities for solitude or a primitive and unconfined type of recreation.” Wilderness provides opportunities for people to experience: natural sights and sounds; remote, isolated, unfrequented, or secluded places; and freedom, risk, and the physical and emotional challenges of self-discovery and self-reliance. Any one wilderness does not have to provide all

these opportunities, nor is it necessary that they be present on every acre of a given wilderness. Where present, however, the preservation of these opportunities is important to the preservation of wilderness character as a whole. This quality is impaired by settings that reduce these opportunities, such as visitor encounters, signs of modern civilization, recreation facilities, and management restrictions on visitor behavior.

- v. Unique, Supplemental, or Other Features. The Wilderness Act states that wilderness areas “may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.” Though these values are not required of any wilderness, where they are present they are part of that area’s wilderness character, and must be protected as rigorously as any of the four required qualities. They may include historical, cultural, paleontological, or other resources not necessarily considered a part of any of the other qualities. These values are identified in a number of ways: in the area’s designating legislation, through its legislative history, by the original wilderness inventory, in a wilderness management plan, or at some other time after designation.

Section 4(b) of the Wilderness Act states that: “Except as otherwise provided in this Act, wilderness areas shall be devoted to the public purposes of recreational, scenic, scientific, educational, conservation, and historical use.” In most cases the public purposes reflect one or more qualities of wilderness character and are administered so as to preserve the wilderness character of the area.

Section 4(c) of the Wilderness Act lists uses and activities that are specifically prohibited in wilderness: “Except as specifically provided for in this Act, and subject to existing private rights, there shall be no commercial enterprise and no permanent road within any wilderness area designated by this Act and, except as necessary to meet minimum requirements for the administration of the area for the purpose of this Act (including measures required in emergencies involving the health and safety of persons within the area), there shall be no temporary road, no use of motor vehicles, motorized equipment or motorboats, no landing of aircraft, no other form of mechanical transport, and no structure or installation within any such area.”

The BLM Wilderness Manual 6340 states: Wildlife management within wilderness is guided by all relevant laws, including the Wilderness Act, acts designating specific wilderness areas, the Endangered Species Act, the Migratory Bird Treaty Act, Native American treaty rights, 43 CFR 6300 (Management of Designated Wilderness Areas), 43 CFR 24 (Department of the Interior Fish and Wildlife Policy: State-Federal Relationships), and applicable State laws and policies regarding wildlife.

Many wilderness areas provide important habitat for federally listed threatened or endangered wildlife species. The BLM will manage wilderness areas to protect and recover known populations of federally listed threatened or endangered species and to aid in their recovery in previously occupied habitat. The wilderness restrictions can directly or indirectly influence GRSG and their habitat.

The BLM has seven wilderness areas within the planning boundary (**Table 3-46**, BLM-Administered Wilderness Areas). These seven areas are all within Owyhee County and were designated by Congress in 2009 through the Omnibus Public Lands Management Act.

A wilderness management plan for the seven BLM wilderness areas will be released in draft in February 2013. A final plan should be completed by mid to late 2013.

**Table 3-46**  
**BLM-Administered Wilderness Areas**

BLM Wilderness Name	Wilderness Acres
Bear Trap Wilderness	6,350
Big Jacks Creek Wilderness	52,800
Bruneau-Jarbidge Rivers Wilderness	90,000
Little Jacks Creek Wilderness	50,900
North Fork Owyhee Wilderness	43,400
Owyhee River Wilderness	267,300
Pole Creek Wilderness	12,500
<b>Total BLM Wilderness</b>	<b>523,250</b>

#### ***Forest Service***

The Forest Service, National Park Service, and BLM manage wilderness areas under the same legislation; the 1964 Wilderness Act. The agencies have similar objectives and policies related to wilderness. Below is text from the Forest Service wilderness manual.

Wilderness is a unique and vital resource. In addition to offering primitive recreation opportunities, it is valuable for its scientific and educational uses, as a benchmark for ecological studies, and for the preservation of historical and natural features.

Manage the wilderness resource to ensure its character and values are dominant and enduring. Its management must be consistent over time and between areas to ensure its present and future availability and enjoyment as wilderness. Manage wilderness to ensure that human influence does not impede the free play of natural forces or interfere with natural successions in the ecosystems and to ensure that each wilderness offers outstanding opportunities for solitude or a primitive and unconfined type of recreation. Manage wilderness as one resource rather than a series of separate resources (FSM 2300 Sec. 2320.6).

#### *Objectives*

- Maintain and perpetuate the enduring resource of wilderness as one of the multiple uses of Forest Service-administered land.
- Maintain wilderness in such a manner that ecosystems are unaffected by human manipulation and influences so that plants and animals develop and respond to natural forces.

- Minimize the impact of those kinds of uses and activities generally prohibited by the Wilderness Act, but specifically excepted by the Act or subsequent legislation.
- Protect and perpetuate wilderness character and public values including, but not limited to, opportunities for scientific study, education, solitude, physical and mental challenge and stimulation, inspiration, and primitive recreation experiences.
- Gather information and carry out research in a manner compatible with preserving the wilderness environment to increase understanding of wilderness ecology, wilderness uses, management opportunities, and visitor behavior.

*Policy*

- Where there are alternatives among management decisions, wilderness values shall dominate over all other considerations except where limited by the Wilderness Act, subsequent legislation, or regulations.
- Manage the use of other resources in wilderness in a manner compatible with wilderness resource management objectives.
- In wildernesses where the establishing legislation permits resource uses and activities that are nonconforming exceptions to the definition of wilderness as described in the Wilderness Act, manage these nonconforming uses and activities in such a manner as to minimize their effect on the wilderness resource.
- Cease uses and activities and remove existing structures not essential to the administration, protection, or management of wilderness for wilderness purposes or not provided for in the establishing legislation.
- Because wilderness does not exist in a vacuum, consider activities on both sides of wilderness boundaries during planning and articulate management goals and the blending of diverse resources in forest plans. Do not maintain buffer strips of undeveloped wildland to provide an informal extension of wilderness. Do not maintain internal buffer zones that degrade wilderness values. Use the Recreation Opportunity Spectrum (FSM 2310) as a tool to plan adjacent land management.
- Manage each wilderness as a total unit and coordinate management direction when they cross other administrative boundaries.
- Use interdisciplinary skills in planning for wilderness use and administration.
- Gather necessary information and carry out research programs in a manner that is compatible with the preservation of the wilderness environment.
- Whenever and wherever possible, acquire non-federal lands located within wildernesses, as well as non-federal lands within those areas recommended for inclusion in the system.

The Forest Service manages eight wilderness areas that are either all or portions of within the planning area (**Table 3-47, ~~Forest Service-Administered Wilderness Areas~~ Forest Service-Administered Wilderness Areas**).

**Table 3-47  
Forest Service-Administered Wilderness Areas**

Forest Service Wilderness Name	Wilderness Acres
Sawtooth	217,100
Frank Church River of No Return	2,366,900
Anaconda Pintler	158,600
Gates of the Mountains	28,600
Lee Metcalf	264,600
Red Rock Lakes	32,400
Absaroka Beartooth	943,600
<b>Total Forest Service Wilderness</b>	<b>2,709,100</b>

Source: BLM 2013a

***National Park Service***

The following is from the National Park Service Wilderness Management Policy 2006: The National Park Service will manage wilderness areas for the use and enjoyment of the American people in such a manner as will leave them unimpaired for future use and enjoyment as wilderness. Management will include the protection of these areas, the preservation of their wilderness character, and the gathering and dissemination of information regarding their use and enjoyment as wilderness. The purpose of wilderness in the national parks includes the preservation of wilderness character and wilderness resources in an unimpaired condition and, in accordance with the Wilderness Act, wilderness areas shall be devoted to the public purposes of recreational, scenic, scientific, educational, conservation, and historical use.

Craters of the Moon National Monument manages one wilderness area within the planning boundary (**Table 3-48, National Park Service Wilderness Areas**).

**Table 3-48  
National Park Service Wilderness Areas**

Craters of the Moon National Wilderness	43,200
<b>Total National Park Service Wilderness</b>	<b>43,200</b>

Source: BLM 2013a

**3.13.2 Wilderness Study Areas**

Section 603 of FLPMA directed the BLM to carry out a wilderness review of the BLM-administered lands. The wilderness inventory was conducted from 1978 to 1980. The original inventory focused on roadless areas of BLM-administered lands of 5,000 acres or

more and on roadless islands, but also included areas of less than 5,000 acres that had wilderness characteristics in association with contiguous roadless lands managed by another agency, and areas of less than 5,000 acres that had wilderness characteristics and could practicably be managed to keep those characteristics in an unimpaired condition. Additional WSAs were designated through the BLM land use planning process under the authority of Sections 201, 202, and 302 of FLPMA after the reports to Congress were completed in 1993.

The inventory phase identified areas that were found to have the characteristics of wilderness enumerated by Congress in Section 2 (c) of the Wilderness Act of 1964:

“A wilderness... (1) generally appears to have been affected primarily by the forces of nature, with the imprint of man’s work substantially unnoticeable; (2) has outstanding opportunities for solitude or a primitive and unconfined type of recreation; (3) has at least five thousand acres of land or is of sufficient size as to make practicable its preservation and use in an unimpaired condition; and (4) may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.” When these characteristics were found within a defined boundary, the presence of the wilderness resource was documented and the area was classified as a WSA.

During the study phase, all values, resources, and uses occurring within each WSA were analyzed, pursuant to the NEPA, through legislative environmental impact statements. When the study was completed, recommendations as to the suitability or unsuitability of each WSA for designation as wilderness were submitted to the President through the Secretary of the Interior, and then from the President to Congress.

Consistent with BLM Manual 6330 and FLPMA Section 603(c), the BLM currently manages approximately 770,000 acres of WSAs within the planning boundary. This includes 10 WSAs in the Dillon Field Office and 34 WSAs in the Idaho Field Offices. **Table 2-2** identifies acres of WSAs that contain GRSG habitat in the decision area for this LUPA/EIS.

### **3.13.3 National Landscapes, Monuments, and Conservation Areas**

#### ***National Landscape Conservation System***

The National Landscape Conservation System (NLCS) was created in 2000 through an order signed by Interior Secretary Babbitt. The concept of the NLCS was for the BLM to manage a system of lands with a dominant conservation mission. In the order, Secretary Babbitt included lands, rivers, and trails designated by acts of Congress or presidential proclamations under the 1906 Antiquities Act as units in the NLCS. In 2009, Congress passed the Omnibus Public Lands Management Act, which permanently established the NLCS “... to conserve, protect and restore nationally significant landscapes that have outstanding cultural, ecological, and scientific values for the benefit of current and future generations.”

Since the creation of the NLCS, the BLM has promoted understanding of the system. As a way to help the public recognize the NLCS, the BLM has developed a brand and logo: National Conservation Lands.

Within the planning area, there are multiple units representing the National Conservation Lands. These include a National Monument, a National Conservation Area, Wilderness Areas, Wilderness Study Areas, Wild and Scenic Rivers, and National Scenic and Historic Trails.

***National Monuments and National Conservation Areas***

National Monuments are areas either designated by Congress or by presidential proclamation (under the authority of the Antiquities Act of 1906) to protect unique historic landmarks, historic and prehistoric structures, or other objects of historic or scientific interest. Within the planning area, the BLM and the National Park Service jointly administer the Craters of the Moon National Monument and Preserve (737,700 acres). The BLM portion of the monument was designated in 2000 to protect *kipukas* (small areas surrounded by lava). These are some of the last undisturbed vegetation communities on the Snake River Plain and the surrounding sagebrush (*Artemisia* spp.) steppe ecosystem. They consist of diverse communities of grasses, sagebrush, and shrubs that provide habitat for a variety of wildlife. This area also includes lava tube caves, older volcanic formations, and volcanic buttes. Craters of the Moon is managed to protect and preserve the objects and values for which it was designated.

National Conservation Areas (NCAs) are designated by Congress to conserve, protect, enhance, and manage public land areas for the benefit and enjoyment of present and future generations. NCAs feature exceptional natural, recreational, cultural, wildlife, aquatic, archaeological, paleontological, historical, educational, and scientific resources. Within the planning area, the BLM manages the Morley Nelson Snake River Birds of Prey National Conservation Area (485,000 acres). Congress established the NCA in 1993 to protect a unique environment that supports one of the world's most dense concentrations of nesting birds of prey. Falcons, eagles, hawks, and owls are found here in exceptional profusion and variety. The NCA is managed to conserve, protect, and enhance raptor populations and their associated habitats.

The BLM manages National Monuments and National Conservation Areas in accordance with the direction provided in BLM Manual 6220. This policy will be adhered to during any site-specific NEPA analyses that are conducted within either of these areas.

***National Scenic and Historic Trails***

A National Historic Trail (NHT) is congressionally designated as an extended long-distance trail, not necessarily managed as continuous. It follows as closely as possible and practicable the original trails or routes of travel of national historic significance. The purpose of an NHT is to identify and protect the historic route and the historic remnants and artifacts for public use and enjoyment. An NHT is managed to protect the nationally significant resources, qualities, values, and associated settings of the areas through which such trails may pass, including the primary use or uses of the trail.

While National Scenic and Historic Trails cross lands managed by different agencies, trails and trail segments that cross BLM-administered lands are managed in accordance with BLM

Manual 6280, Management of National Scenic and Historic Trails and Trails Under Study or Recommended as Suitable for Congressional Designation. This manual mandates that the BLM establish NHT's Management Corridors to assist in the management of the resources, qualities, values, and associated settings and the primary use or uses for which the NHT was designated. The designation of NHT's Management Corridors in the future may encompass lands that include GRSG habitat and may include management decisions and actions that likely will have positive effects on GRSG populations.

**Table 3-49**, National Historic Trails, lists the NHTs in the planning area, by planning district.

### 3.13.4 Wild and Scenic Rivers

The National Wild and Scenic Rivers System was created by Congress in 1968 (Public Law 90-542; 16 USC 1271 et seq.) to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The Act is notable for safeguarding the special character of these rivers, while also recognizing the potential for their appropriate use and development. It encourages river management that crosses political boundaries and promotes public participation in developing goals for river protection.

*It is hereby declared to be the policy of the United States that certain selected rivers of the Nation which, with their immediate environments, possess outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historic, cultural or other similar values, shall be preserved in free-flowing condition, and that they and their immediate environments shall be protected for the benefit and*

*Idaho and Southwestern Montana Sub-Region Greater Sage-Grouse LUPA/EIS  
October 2013*

*enjoyment of present and future generations. The Congress declares that the established national policy of dams and other construction at appropriate sections of the rivers of the United States needs to be complemented by a policy that would preserve other selected rivers or sections thereof in their free-flowing condition to protect the water quality of such rivers and to fulfill other vital national conservation purposes. (Wild & Scenic Rivers Act, October 2, 1968)*

Rivers may be designated by Congress or, if certain requirements are met, the Secretary of the Interior. Each river is administered by either a federal or state agency. Designated segments need not include the entire river and may include tributaries. For federally administered rivers, the designated boundaries generally average one-quarter mile on either bank in the lower 48 states and one-half mile on rivers outside national parks in Alaska in order to protect river-related values.

#### ***River Classification***

Rivers are classified as wild, scenic, or recreational.

- Wild River Areas – Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.
- Scenic River Areas – Those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.
- Recreational River Areas – Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Regardless of classification, each river in the National System is administered with the goal of protecting and enhancing the values that caused it to be designated. Designation neither prohibits development nor gives the federal government control over private property. Recreation, agricultural practices, residential development, and other uses may continue. Protection of the river is provided through voluntary stewardship by landowners and river users and through regulation and programs of federal, state, local, or tribal governments. In most cases not all land within boundaries is, or will be, publicly owned, and the Act limits how much land the federal government is allowed to acquire from willing sellers. Visitors to these rivers are cautioned to be aware of and respect private property rights.

The Act purposefully strives to balance dam and other construction at appropriate sections of rivers with permanent protection for some of the country's most outstanding free-flowing rivers. To accomplish this, it prohibits federal support for actions such as the construction of dams or other instream activities that would harm the river's free-flowing condition, water quality, or outstanding resource values. However, designation does not affect existing water

rights or the existing jurisdiction of states and the federal government over waters as determined by established principles of law.

The Forest Service manages two designated rivers within the planning boundary (**Table 3-50, ~~Forest Service-Administered Wild and Scenic Rivers~~ Forest Service Administered Wild and Scenic Rivers**). The Middle Fork of the Salmon is wholly within the planning boundary whereas only a portion of the Salmon River is within the planning boundary.

**Table 3-50  
Forest Service-Administered Wild and Scenic Rivers**

Name	Classification	River Miles
Salmon River	Wild	79
	Recreational	46
Middle Fork of the Salmon River	Wild	103
	Scenic	1

The BLM manages 16 designated rivers that are wholly within the planning boundary (**Table 3-51, ~~BLM-Administered Wild and Scenic Rivers~~ BLM Administered Wild and Scenic Rivers**). All of the 16 rivers are within wilderness areas. Where the wilderness policy is more restrictive than the Wild and Scenic Rivers policy regarding actions within wilderness, the wilderness policy takes precedence; however, Wild and Scenic Rivers must be administered so as to protect and enhance the values that caused it to be designated.

**Table 3-51  
BLM-Administered Wild and Scenic Rivers**

Name	Classification	River Miles
Battle Creek	Wild	23.4
Big Jacks Creek	Wild	35
Bruneau River	Recreational	0.6
	Wild	39.3

<sup>2</sup> Note: BER combined acres for MZs II and VII

### 3.14 Soil Resources

Many resources and resource uses, including livestock grazing, wildlife habitat, riparian habitat, special status species, fisheries, recreation, water quality and forestry, depend on suitable soils. Consequently, soil attributes and conditions are important to BLM and Forest Service management [decisions/reaction](#).

Soils are defined by the processes that form them. Through time, these processes form unique soil types and influence what plants may grow upon them. Soil surveys indicate that climate and topography are the primary influences on soil formation. Soil development processes, such as rock weathering, decomposition of plant materials, accumulation of organic matter, and nutrient cycling, are controlled largely by climate. Soil moisture and temperature strongly affect the rates of addition, removal, translocation, and transformation of material within the soil. Topography influences site conditions such as precipitation amounts and effectiveness, drainage, runoff, erosion potential, and temperature.

Soils play an integral part in vegetation community development. Plants use soil as an anchor, a means to provide water for growth, and a storehouse for the nutrients needed for growth. Plant communities are most noticeably influenced where soil texture and thickness of soil horizons change, depth to restrictive layers including abrupt soil horizon boundaries

exist, and by soil drainage, moisture holding capacity, or depth to water table. Native plant communities require management considerations that include the ability of the soil to produce a healthy ecosystem over the long term. Reducing the risk of erosion from water and air processes, limiting compaction from traffic source or grazing, and allowing the water to infiltrate at a normal rate for the given soil texture will allow vegetative communities to thrive and further protects the soil resources.

The NRCS provides soil mapping across the United States. Soil information and mapping from the NRCS are provided below under existing conditions to describe soil resources.

Land uses strive to conform to Standards for Public Land Health on BLM-administered lands, which describe conditions needed to sustain public land health and relate to all uses of the BLM-administered lands.

### **3.15 Conditions within the Planning Area**

#### ***Soil Productivity***

Soil productivity within the planning area varies widely due to the diversity of soils and site characteristics, specifically differences in elevation and slope gradient. The planning area landscape varies greatly from broad valleys to mountains.

The average annual precipitation and temperature in the project area vary greatly by elevation and aspect. Some of the most productive soils are found in well drained valley bottoms, toe-slopes, benches, and broad ridge topes. On uplands where rainfall is moderate to low, medium-textured soils may produce favorable conditions, depending on land uses such as livestock grazing. Soils that feature shallow clay pans, hardpans, or salts pose substantial constraints to land use and land use management.

Management practices affect the ability of soils to maintain productivity by influencing disturbances such as displacement, compaction, erosion, and alteration of organic matter and soil organism levels. When soil degradation occurs in semiarid, high desert regions, natural processes are slow to return site productivity. Prevention of soil degradation is far more cost-effective and time effective than remediation or waiting for natural processes. Management practices, such as proper stocking rates for livestock, rotation of grazing, periodic rest from grazing, improved design, construction and maintenance of roads, selective logging, rehabilitation of unneeded surface disturbance, restricting vehicles to roads and trails, rehabilitating mined areas, and control of concentrated recreational activities, have reduced erosion effects and improved soil conditions.

#### ***Soil Erosion***

Erosion is a continuing natural process that can be accelerated by human disturbances. Factors that influence soil erosion include soil texture, structure, length and percent of slope, vegetative cover, and rainfall or wind intensity. Soils most susceptible to erosion by wind or water are typified by bare or sparse vegetative cover, noncohesive soil particles with slow infiltration rates, and moderate to steep slopes. Wind erosion processes are less affected by slope angle but are highly influenced by wind intensity.

The semi-arid planning area has a low percentage of natural plant community ground cover, allowing the soils to erode naturally in wind and during infrequent rain events. In addition, management actions affect the rate at which soil erodes. Activities that remove vegetative cover increase the erosion rate. Some soils are particularly vulnerable to soil erosion.

NRCS soil map unit descriptions rate soils in the planning area according to their susceptibility to water and wind erosion. Wind erosion is particularly a hazard when surface litter and vegetation are removed by fire or other disturbances. Soils in the planning area were screened based on several relevant characteristics that indicate potentially fragile soils or high erosion hazards. These characteristics include:

- soils rated as highly or severely erodible by wind or water, as described in NRCS soil survey reports
- landslide areas as identified in NRCS soil survey reports
- soils on slopes greater than 35 percent

#### ***Soil Types***

When making land management decisions based on soil related hazards or limitations, the BLM evaluates soil surveys available from the NRCS. Soils mapped according to the boundaries of major land resource areas, which are geographically associated land resource units that share common characteristics related to physiography, geology, climate, water resources, soils, biological resources, and land uses. Each soil survey describes the specific properties of soils in the area surveyed and shows the location of each kind of soil on detailed maps. The BLM evaluates soil map units to make management decisions that would likely affect soils. Each soil survey applicable to the planning area describes soil map units by the individual soil or soils that make up the unit. These descriptions indicate the limitations and hazards inherent in each unit. Descriptions include soil depth, range of elevation, origin, climate, physical properties, runoff capabilities, erosion hazard, associated native vegetation, wildlife habitat use, and capability for community development and other uses.

Soil can be classified in many ways according to a whole host of parameters. For the generalization of soils in the planning area, the taxonomy of soil order is a convenient starting place. Most of the soils in the planning area are part of the largest soil order, Mollisols. The remaining areas are composed of similar young developmental soils in the Inceptisol, Entisol, and Andisol orders, with a very small amount of Histisols and Vertisols that have particular properties that may be of importance.

Soil properties can provide information as to why certain plants may grow in one area and not another, or why erosion occurs by wind and not water. The NRCS provides a suite of risk ratings, interpretations, and basic soil data that describes soils resources. The soil texture for most soils across the planning area is a loam as composed of the representative percent of sand, silt and clay. Some greater or lesser amounts of these percentages produce clayey loams and silty loams for the most part. The soils have very low amounts of organic matter (2 percent), low available moisture content in the top 10 inches (25.4 cm) and are considered

well drained. The risk of erosion by water is slight, except in those very steep canyons and exposed bedrock ridges that have a severe to very severe rating. The overall majority of the planning area is considered to be of slight risk for erosion. The soils are prone to degradation when soil is removed in excess of the ability to rebuild it. In this area of the state, the amount of loss can be significant with wind exposure or increased erosion from water. Only 1 to 2 tons of soil per acre per year needs to be removed in approximately half of the planning area to have a loss of long term productivity.

The amount of sand, silt and clay in the soil alters the water infiltration. Soils with higher amounts of silt and clay infiltrate water more slowly than soils with higher amounts of sand. For most of the planning area water infiltrates rapidly into the soil resulting in little standing water.

Hydric (wet) soils and unique biological soil crusts are key soil resources in the planning area.

Hydric Soils. Hydric soils constitute only a small portion of the planning area. Hydric soils are associated with riparian areas and wetlands. Riparian-wetland soils are found throughout the planning area along water courses, near springs, seeps, playas, and adjacent to reservoirs. Because of the presence of water, riparian-wetland soils have properties that differ from upland areas.

Biologic Soil Crusts. Biologic soil crusts are made up of tiny living plants and bacteria that grow together on the soil surface. They help keep the soil from washing or blowing away, fix nitrogen from the atmosphere into the soil, help keep out weeds, and promote the health of plant communities. Loss of biological soil crusts is a contributing factor in the replacement of native vascular plants by invasive species such as cheatgrass or medusa head.

Based on research throughout the west, parameters for the ecology and management of biological soil crusts have been developed by the Department of the Interior. Factors found affecting presence, density, cover, and species diversity of macrobiotic crusts include elevation, soils, and topography, disturbances, timing of precipitation, vascular plant community, ecological gradients and microhabitats.

### 3.15.1 Trends

Soil resources change slowly unless catastrophic or larger scale disturbance events such as landslides, floods, volcanoes, or wildfires occur. Then, erosion or deposition would change the ground cover at one point or many. Thus, the degree of change in the planning area would be considered low or insignificant, with the direction of change being the most likely to occur naturally over time. There have been larger wildfire events and to some degree restoration activities that have altered the vegetation communities where juniper has been invading sagebrush communities.

The overall guidance for soil resources is to maintain or improve the ability of the soil to support vegetation and allow water and nutrients to be cycled by either macro or microorganisms, all of which promote and improve the health of the land. Degradation by excessive grazing, erosion, or land developments will cause a reduction in soil function as

one or perhaps many of the soil properties are changed thereby affecting the functions necessary for healthy soils. In the planning area, impacts on soil resources have resulted from energy development, grazing, recreation, natural processes, and other activities. The potential for maintaining or restoring these communities and conserving the soil resource depends on the specific soil types and how resource programs are managed.

### **3.16 Water Resources**

Water on BLM- and Forest Service-administered lands is regulated by the Clean Water Act, Safe Drinking Water Act, Public Land Health Standards, and other laws, regulations, and policy guidance at the federal, state, and local levels. Water resources in Idaho are regulated by the EPA, US Army Corps of Engineers, and the Idaho Department of Environmental Quality.

The Idaho Department of Environmental Quality has granted designated management agency status to the BLM. As a designated management agency, the BLM must: (1) implement and enforce natural resource management programs for the protection of water quality on federal lands under its jurisdiction; (2) protect and maintain water quality where it meets or exceeds applicable state and Tribal water quality standards; (3) monitor activities to assure that they meet standards and report the results to the State of Idaho; and (4) meet periodically to recertify water quality BMPs. BMPs include methods, measure, or practices to prevent or reduce water pollution, including but not limited to structural and nonstructural controls, operations, and maintenance procedures. BMPs are applied as needed to projects.

#### **3.16.1 Existing Conditions**

The discussion of existing conditions includes a description of water resources for the planning area, regardless of landownership. Where appropriate, it also includes a more detailed description of water resources for just BLM-administered lands within the planning area. For this, the description is limited to describing water resources associated with GRSG and their habitat. Wetlands and livestock water developments are important sources of water that can influence GRSG and their habitat.

#### **3.16.2 Conditions within the Planning Area**

The BLM is the overwhelming land manager in the planning area. The Forest Service, USFWS, Bureau of Indian Affairs, and State of Idaho all have lands within the planning area that also contain a suite of water resources.

Within the planning area, the major water features are streams, lakes, wetlands, playas, and dry lakes. Streams can be ephemeral, intermittent, or perennial. Ephemeral streams do not flow during an average water year, but do flow in response to large precipitation events. Intermittent streams flow during spring runoff for an average water year, but generally dry up later in the summer. Perennial streams contain some water all year for an average water year. Lakes can be permanent or temporary. Wetlands and floodplains vary in extent and depth throughout the year. Permanent waters can also be in the form of ponds and reservoirs developed for human or livestock consumption.

Stream channels and floodplains are important because their shape and condition affect how rapidly water flows through a river system, how much water is stored within the basins, the quality of the water, and how much erosion occurs. These functions, in turn, affect fish and wildlife habitat, agriculture, recreation, and the susceptibility of local communities and landowners to floods.

As early land management reduced vegetation in the watershed, overland flow of water increased, and stream channels deepened to match the increased supply of water and sediment. Major flood events in the late 1800s were the likely immediate cause of the deepening channels. Channel incisions eventually lead to bank failures and subsequent channel widening. As channel widening and bank failures continued, new low flow channels began to form in the debris from bank failure. Many of the stream channels in the planning area were in the process of this initial buildup in the 1980s. The result of this process is that new channels are usually lower than pre-disturbance channels, and the old floodplain now functions primarily as a terrace. Some terraces may be the result of climatic variations and associated changes in flow and sediment supply. The final stage of channel evolution results in a new bankfull channel and active floodplain at a new, lower elevation. Many stream channels in the planning area have new, lower elevation channels and floodplains.

#### ***Surface Water***

The US is divided and sub-divided into successively smaller hydrologic units called regions, sub-regions, accounting units (basins), and cataloging units (sub-basins). Each hydrologic unit is identified by a unique hydrologic unit code consisting of two to eight digits. The fourth level of classification (sub-basin) is represented by an eight-digit hydrologic unit code.

The historic scarcity of stream flow in the planning area has led to increased flow regulation by the State of Idaho. Projects for irrigation, livestock, human use, and flood control have significantly altered natural flow regimes. This has changed habitat conditions, channel stability and timing of sediment and organic material transport. Stream flow has been altered by management activities such as water impoundments, water withdrawals, road construction, vegetation manipulation, grazing, fire suppression, and timber harvesting.

Most surface runoff in the planning area is from snowmelt or rainfall producing peak discharges in the spring and early summer. Many of the streams in the lower elevation semi-arid areas are either intermittent, with segments of perennial flow near springs, or ephemeral, with flow only during spring runoff and intense summer storms.

#### ***Riparian Areas and Wetlands***

Riparian areas are ecosystems that occur along rivers, streams or water bodies. These areas exhibit vegetation or physical characteristics reflective of a permanent surface or subsurface water influence. Typical riparian areas include lands along, adjacent to, or contiguous with perennially and intermittently flowing rivers, streams, and shores of lakes and reservoirs with stable water levels. Excluded are sites such as ephemeral streams or washes that do not exhibit vegetation dependent on free water in the soil. Wetlands are areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support and which under normal circumstances do support a prevalence of vegetation typically adapted

for life in saturated soil conditions. Wetlands include marshes, swamps, lake shores, lakeshores, sloughs, bogs, wet meadows, and riparian areas. Even through riparian and wetlands areas occupy only a small percentage of the planning area, these areas provide a wide range of functions critical to many different wildlife species, improve water quality, provide scenery, and recreational opportunities.

The BLM uses proper functioning condition (PFC) assessments for evaluating riparian-wetland areas and uses it to supplement existing stream channel and riparian area evaluations and assessments. Each riparian-wetland has to be judged against its capability and potential. The capability and potential of natural riparian-wetland areas are characterized by the interaction of hydrology, vegetation, and erosion/deposition. PFC is defined separately for lotic (moving water systems, such as rivers, streams, and spring and lentic (standing water systems, such as lakes, ponds, seeps, and wet meadows). If a riparian or wetland area is not in PFC, it is placed into one of three other categories; functional at risk, nonfunctional, or unknown.

The majority of BLM stream channels and floodplains within the planning area are not meeting the BLM standard of PFC. However relatively few stream channels are nonfunctioning. More intermittent stream channels are in nonfunctioning condition than perennial streams but they also have more miles of stream at potential and PFC.

#### *Water Quality*

Water quality as defined by the Clean Water Act, includes all the physical, biological, and chemical characteristics which affect existing and designated beneficial uses. The state of Idaho is required to identify which beneficial uses a water body currently supports or could support in the future. Water quality standards are established to protect the beneficial uses of the State's waters. Beneficial uses in planning area are public and private domestic water supplies, industrial water supply, irrigation, livestock watering, fish and aquatic life, and recreation.

The State of Idaho is required by section 303(d) of the Clean Water Act to identify waters which are water quality impaired because of failing to meet their designated beneficial uses. Section 303(d) requires that each state develop a list of water bodies that fail to meet water quality standards and delineate stream segments and listing criteria for all streams. The Section 303(d) list of impaired waters is updated biannually, and the state is required to develop a total maximum daily load allocation for each pollutant of concern.

Water quality is evaluated based on the ability of a water body to support beneficial uses of the water. Generally, key water qualities are those that support native fish and wildlife and support human uses such as agriculture, recreation, and domestic water supply.

The major water quality concern for streams in the planning area has been water temperature. These water temperature concerns correlate to the beneficial use of fish spawning and rearing habitat. Conditions that affect stream temperature can be summaries as amount of near stream vegetation, channel shape, and hydrology. Many of these conditions are interrelated, and many conditions vary considerably across the landscape. For

example, channel width measurements can change greatly over even small distances along a stream. Some conditions vary daily and or seasonally. Stream orientation from a north-south to an east-west can change solar heating considerably when stream width and vegetation type remain the same.

Removal of riparian vegetation and the shade it provides contributes to elevated stream temperatures. Channel widening can similarly increase solar loading. The principal source of heat energy delivered to the water column is solar energy striking the stream surface directly. Exposure to solar radiation can cause an increase in stream temperature. The ability of riparian vegetation to shade the stream throughout the day depends on aspect and vegetation height, width, density, and position relative to the stream, as well as aspect the stream flows.

Causes of stream degradation are removal of riparian vegetation and destabilization of streambanks. The land use most commonly associated with these problems in the planning area is livestock grazing. Other land uses associated with degraded streams include roads, trails, water withdraw, reservoir storage and release, altered physical characteristics of the stream and wetlands alteration.

#### ***Groundwater***

Groundwater is used for irrigation, domestic use, and livestock use. The quality of the groundwater is a function of the chemical makeup of the underground formation containing the water. Most of the planning area contains good quality water but the water is usually hard and contains moderate amounts of dissolved minerals.

Springs and seeps occur in areas where water from aquifers reaches the surface. Many springs begin in stream channels and others flow into small ponds or marshy areas that drain into channels. Some springs and seeps form their own channels that reach flowing streams, but other springs lose their surface expression and recharge alluvial fill material or permeable stratum.

Springs and seeps are important to aquatic habitats because of the perennial base flow they provide to a stream. The outflow from springs in summer usually helps to maintain lower water temperatures. In winter, especially in small streams, base flow helps to maintain an aquatic habitat in an otherwise frozen environment.

#### ***Water Quantity***

Water balance across the US is approximately 30 percent runoff and 70 percent evaporation. This may be different across the planning area due to higher temperatures and lower relative humidity in some areas.

Peak flows are connected with the spring runoff and snow melt with a decrease to near base flow during the month of July. Seasons and years of low water yield are particularly crucial periods for most of the planning area's beneficial uses.

The annual flow patterns may have changed since the 19<sup>th</sup> century. Historical descriptions indicate that streams were relatively stable with good summer streamflow and good water

quality and heavy riparian cover. Streambanks were covered with dense growths of aspen, poplar, and willow; cottonwood galleries were thick and wide; and beaver were abundant. Now peak flows are greater and late season flows are diminished. This may be the normal condition of larger flowing streams in the planning area. It is suspected that these effects are due to reduced rates of soil infiltration, reduced capacity for groundwater/riparian storage, and loss of in channel storage in beaver ponds.

### 3.16.3 Trends

Demands on water resources have increased over the past few decades. Although most early water rights were established for irrigation and mining, today's demand includes municipal water supplies, commercial and industrial supplies, and maintenance of adequate streamflow for fish, recreation, and water quality.

The availability of water in much of the planning area is limited and may hamper additional developments that depend on water. Future water development for wildlife, recreation, and livestock would require a State of Idaho water right before project implementation could occur.

### 3.17 Cultural Resources

In this section the term "cultural resources" is used to encompass the broad scope of resources that must be considered by the BLM and Forest Service and as further defined below. A cultural resource is a definite location of human activity, occupation, or use identifiable through field survey, historical documentation, or oral evidence (BLM Manual 8100). The term cultural resources is inclusive and has been adopted and widely used to refer to the diverse human record found in sites, structures, objects and places created and/or used by people. These may comprise archaeological, historic, or architectural sites, structures, objects, or places, and may include locations of traditional cultural or religious importance to a particular social and/or cultural group, often referred to as Traditional Cultural Properties. The term includes "historic properties," as defined in the National Historic Preservation Act of 1966, as amended (NHPA), and the implementing regulations found at 36 CFR Part 800. Historic properties are cultural resources determined to be eligible for listing on the National Register of Historic Places (NRHP). The term also includes "archaeological resources" as defined in the Archaeological Resources Protection Act of 1979, and other sites, structures, objects, items and places as addressed in other statutes/regulations (e.g., American Indian Religious Freedom Act of 1978, the Antiquities Act of 1906, NEPA, and the Native America Graves Protection and Repatriation Act of 1990).

Cultural resources are represented by the full temporal range of human occupation of the continent, from the first peoples' arrival and settlement in the region over 13,000 years ago and subsequent tribal groups expansion and use throughout all of the sub-region and other parts of the West to more recent incursions of fur trappers, homesteaders and miners and ranchers of the last 200 years. Cultural resources can include surface and buried artifacts and cultural features made and left by human cultures in archaeological sites; items built by past

cultures (e.g., houses/house remains and activity areas); and places associated with traditional cultural uses.

### **3.17.1 Considering Effects on Cultural Resources Pursuant to Section 106 of the NHPA**

Cultural resources are most frequently identified and recorded through federal compliance with Section 106 of the NHPA and subsequent consultation with Native American tribes and State Historic Preservation Offices (SHPO). Section 106 requires that federal agencies that fund, approve, authorize, license, or permit actions or undertakings to consider effects on “historic properties” that could occur due to the proposed undertakings. It is important to emphasize again that the term “historic property” has a specific meaning under the NHPA, referring only to those properties determined to be eligible for or listed in the NRHP regardless of property type or period of use (e.g., traditional cultural property or archaeological site, and historic or prehistoric).

Federal regulations define specific criterion for NRHP eligibility and provide the measures for evaluating cultural resources for their eligibility. These criteria are found at 36 CFR 60.4. Once a cultural resource has been determined to be eligible for the NRHP the agency must consider the potential effects of the proposed action on the historic property and provide measures to either reduce or mitigate any adverse effects. Consequently, compliance with Section 106 provides a primary mechanism for federal agencies to assess and take into account the effects of proposed federal actions or undertakings on cultural resources during NEPA reviews.

The BLM follows alternative procedures, defined in state specific protocols, for meeting its Section 106 obligations allowed for and pursuant to the implementing regulations of the NHPA (36 CFR 800.14). In collaboration with the Advisory Council on Historic Preservation and the National Conference of State Historic Preservation Officers, the BLM developed alternative procedures that define the manner in which the agency will comply with Section 106 of the NHPA. These procedures are defined in a national Programmatic Agreement, revised in 2012, between the three parties. The national Programmatic Agreement procedures are implemented by the state specific protocol agreements with each state’s SHPO. The protocols further define how the BLM will coordinate with the SHPO in each state to fulfill Section 106 responsibilities.

Prior to initiating proposed actions for protection and enhancement of GRSG and GRSG habitat, the responsible manager shall determine the area of potential effect; review existing information on known and anticipated historic properties that could be affected; seek information (in coordination with environmental review and land use planning processes) from Native American tribes and other parties likely to have knowledge of or concern with historic properties (including places of traditional cultural and religious significance); determine the need for field surveys or other actions to identify historic properties; make a good faith effort to identify and evaluate historic properties; assess and determine effects on historic properties; and identify measures to avoid, lessen or mitigate adverse effects on historic properties.

As the various types of GRSG/habitat improvement projects are identified, effects on cultural resources can be assessed on a case by case or programmatic level; however, given current information, it is assumed that all future actions will require separate NHPA analyses. Any programmatic procedures not covered by the BLM's national Programmatic Agreement or state protocols will require either (a) separate NHPA analysis, or (b) a separate Section 106 agreement.

### 3.17.2 Conditions of the Planning Area

The planning area includes federal lands administered by the BLM Boise, Twin Falls, and Idaho Falls Districts in Idaho and the Dillon Field Office of the Western Montana District in Montana. Forest Service-administered lands include lands administered by the Boise, Sawtooth, Salmon-Challis, and Caribou-Targhee National Forests in Idaho, and the Beaverhead-Deerlodge National Forest in Montana. A majority of the habitat is sagebrush steppe on BLM-administered land, with upland sagebrush steppe and sub-alpine habitat or ecotones located on Forest Service-administered lands. The Snake and Salmon Rivers, and the headwaters of the Missouri river, are three major watershed systems within the planning area.

In general, and as extrapolated from BLM survey and site location data, on average 15 percent of BLM-administered lands within the planning area have been inventoried, resulting in the recordation of 17,801 archaeological resources (**Table 3-53, Recorded Cultural Resource Surveys and Sites within GRSG Habitat in the Planning Area**~~Recorded Cultural Resource Surveys and Sites within GRSG Habitat in the Planning Area~~), including prehistoric and historic sites. These data indicate that, on average, six to eight sites occur per square mile on BLM-administered lands within the planning area. Formal determinations of eligibility have not been completed for most sites in the planning area; however, recorded resources are treated as eligible until determined otherwise. Based on logged eligibility determinations for known sites on BLM-administered lands, roughly 14 percent of recorded sites have been determined to be eligible for listing on the NRHP. These data indicate that over 2,492 of the recorded sites on BLM-administered lands are eligible for the NRHP (**Table 3-53, Recorded Cultural Resource Surveys and Sites within GRSG Habitat in the Planning Area**~~Recorded Cultural Resource Surveys and Sites within GRSG Habitat in the Planning Area~~).

**Table 3-53**  
**Recorded Cultural Resource Surveys and Sites within GRSG Habitat in the Planning Area**

Habitat	Idaho BLM Surveys	Idaho BLM Resources	Montana BLM Surveys	Montana BLM Resources	Planning Area Totals
PPH	2,057 surveys	12,517	596 surveys	723	718,292 acres
	692,778 acres		25,514 acres		13,240 Resources
PGH	1,226 surveys	4,561	538 surveys	564	763,170 acres
	739,277 acres		23,893 acres		5,125 Resources
<b>Totals</b>	<b>1,432,055 acres</b>	<b>17,078</b>	<b>49,407 acres</b>	<b>1,287</b>	<b>1,481,462 acres</b> <b>18,365 Resources</b>

Source: BLM 2013a

The total extent of the cultural resource base is unknown for the National Forests in PPH or PGH, as the entire land base has not been inventoried. Survey coverage of GRSG habitat on the National Forests in the sub-region varies between 5 and 15 percent on most of the National Forests, with most surveys conducted for range allotment plans, wildlife habitat improvement projects, and commercial activities. The exact number of cultural resource surveys and sites located on the National Forests changes as new surveys are conducted; therefore, providing exact numerical information would not be accurate.

Several well-known historic properties and districts occur in the planning area, as listed by field office in **Table 3-54**, Well Known Historic Properties within the Planning Area. These historic properties along with other eligible properties in the planning area would need evaluation for the effects of proposed undertakings for GRSG habitat improvement prior to implementation. Areas not previously inventoried would be subjected to full cultural resources analysis for ground-disturbing actions.

**Table 3-54**

Salmon – Challis NF	58	Leesburg Townsite and Cemetery Lemhi Pass National Historic Landmark Custer Townsite

***Cultural Use of the Planning Area***

Three cultural areas are located within the planning area. Cultural areas have often been correlated to physiographic regions, with the planning area falling within the northern Great

Basin, southeastern Plateau and western Plains regions. These cultural areas roughly correspond to distinctly different indigenous groups with different languages and moderately different resource-based economic systems and social structures. While these areas are associated to cultural groups and distinct tribes, cultural boundaries are fluid and overlapping. The main homelands and cultural traits of tribal groups that inhabit the region are generally defined by the cultural areas. Tribes that inhabit the region today and in the past include Great Basin groups such as the Shoshone-Paiute Tribes, Shoshone-Bannock Tribes, and the Eastern Shoshone; the Plateauan Nez Perce, Coeur d'Alene, Pend d'Oreille, Confederated Salish-Kootenai Tribes, Confederated Tribes of the Colville Reservation, Confederated Tribes of the Umatilla Reservation; and Plains groups including the Blackfoot Tribe, Chippewa Cree Tribes, and the Crow.

Tribal members actively use BLM- and Forest Service-administered lands for traditional resource procurement. The planning area contains populations of economically important plant and animal resources to tribal groups and individuals with certain species dominating depending on the region and the particular preferences of tribes or individuals. The sagebrush steppe and rocky upland flats are likely to support populations of plants such as bitterroot, biscuit root, Indian carrot, Indian rice grass and needle grass and other important root plants, such as camas in wetland areas. Modern traditional food plant gathering focuses almost entirely on root crops and wild fruits especially if they are found near the various reservations. Other types of cultural food plants such as seeds are not collected today to the degree they were collected in former times. Cultural plants for weaving appear to be collected wherever they are found. Medicinal cultural plants are undoubtedly collected today but practitioners of indigenous healing methods may not share the types of species used as readily as those collecting plants for subsistence and weaving. Rabbits, deer, elk, and fish are also important animal resources in the planning area.

The most common type of prehistoric site or cultural resource in Idaho and southwestern Montana is the lithic scatter. These types of sites contain mainly flaked stone (debitage) and/or stone tools left during the process of creating or repairing bifacial tools, such as arrow points, spear points, dart points, knives or scrapers. Lithic scatters often represent the remnants of prehistoric tool manufacturing/maintenance, locales created during subsistence pursuits, including hunting camps, animal butchering sites, or quarries. The lithic scatter comprises approximately 70 percent or more of recorded prehistoric sites in the planning area. Other site types may include habitation sites with remnants of house pits, house rings and hearths, as well as milling and storage equipment, such as pottery and basketry, and stone circles and wickiups in far eastern Idaho and Montana. Ceremonial sites may also exist in the planning area, but only a few may leave an archaeological signature, such as cairns, pits (e.g., eagle catching and fasting) or stacked rock of a vision quest site, or medicine wheels, and may require tribal consultation with practitioners and elders to identify. Other site types include trails, such as the Oregon National Historic Trail (NHT) and Nez Perce NHT, petroglyphs and pictographs, hunting drivelines and blinds, rock shelters, and caves.

While researchers in Idaho and Montana have developed varying cultural chronologies for prehistoric human use of the region, the general periods of use are similar and are discussed in very general terms here to outline prehistoric use of the planning area. The prehistoric

cultural chronology for both Idaho and Montana include five general periods, the Early Prehistoric (Paleo-Indian), circa 13,500 to 8,000 years before the present, three sub-periods of the Middle Prehistoric 8,000 to 300 years before the present and the Protohistoric/Early Historic 300 to 150 years before the present. General overviews of archeological research in the region are provided in studies by Butler (1978, 1986), Meatte (1990), and Plew (2008), for southern Idaho, and Deaver and Deaver (1990), and Foor (1996) in southwestern Montana.

The most common type of historic cultural resource in the planning area relates to the mining of gold, silver, lead, and copper during the latter part of the 19th century and the early part of the 20th century. Such properties include mining camp remnants, ghost towns, miner's cabins, mining shafts, adits, mills, smelters, and an assortment of other mining related buildings, structures, and landscape features. Several comprehensive overviews of historic metal mining in Idaho and Montana have been produced in recent years, and provide the important context with which to evaluate such properties (McKay 2011; Godfrey 2003; Warhank 1999; Herbort 1995a, 1995b). Other historic period sites include transportation networks, trails, including the Oregon and California NHTs and associated side trails (e.g., Goodale's and Hudspeth Cutoffs) and the Lewis and Clark NHT, notable Lewis and Clark campsites, lumber mills, fur trapping shelters and cabins, homesteads, historic cemeteries, irrigation ditches, cow/sheep camps, shepherd cairns, stage stops and trash dumps.

### 3.17.3 Trends

Federal lands will continue to be managed for the protection and preservation of cultural resources pursuant to regulation and policy. More concerted government-to-government consultation with tribes is occurring to address tribal resources and concerns. Prehistoric and historic resources are nonrenewable and overtime have been diminished by unauthorized collection, looting and cumulative project impacts. However, efforts have increased in public education and outreach creating awareness about our nation's cultural heritage and tribal interests. These efforts have improved public understanding and awareness, resulting in increased preservation of cultural resources.

### 3.18 Tribal Interests

The federal government has a unique and distinctive relationship with federally recognized Native American tribes as set forth in the Constitution of the US, treaties, statutes, Executive Orders, judicial decisions, and agreements. This relationship is different from the federal government's relationship with state and local governments or other entities. The US government has a trust responsibility to federally recognized Native American tribes that covers lands, resources, money, or other assets held by the federal government in trust and the ability of those tribes to exercise their tribal rights. The US recognizes Native American tribes as sovereign nations. The tribes maintain active interests in the planning area. Tribal members use BLM-administered lands to gather plants or other native materials (e.g., stone for flint-knapping), hunt animals, and fish.

Native American treaties are negotiated contracts made pursuant to the Constitution of the US and are considered the "supreme law of the land." They take precedence over any

conflicting state laws because of the supremacy clause of the Constitution (Article 6, Clause 2). Treaty rights are not gifts or grants from the US, but are bargained for concessions. These rights are grants-of-rights from the tribes rather than to the tribes. The reciprocal obligations assumed by the federal government and Native American tribes constitute the chief source of present-day federal Native American law.

The BLM, Forest Service, and other federal agencies have the responsibility to identify and consider potential impacts of project alternatives identified for GRSG planning on Native American trust resources, including fish, game, and plant resources, and on off-reservation, treaty-reserved fishing, hunting, gathering, and similar rights of access and resource use on BLM-administered lands. This also includes rights of access and use for ceremonial and other traditional cultural practices. The BLM, as lead federal agency, also has the responsibility to ensure that meaningful consultation and coordination concerning GRSG planning is conducted on a government-to-government basis with federally recognized tribes to consider tribal treaty rights and trust resources. BLM-administered lands retain social, economic, and traditional value for tribal people, as well as contemporary and ongoing spiritual and cultural uses. Through consultation with the tribes, the BLM is aware of their treaty and trust obligations and the tribes' desire to capitalize on opportunities that maintain or enhance resources critical to the exercise of treaty rights, traditional customs, subsistence, and cultural uses of the land.

BLM and Forest Service consultation with Native American tribes, as it pertains to tribal interests, treaty rights and trust responsibilities, is conducted in accordance with the following direction:

- Executive Order No. 13175 – Consultation and Coordination with Indian Tribal Governments, November 6, 2000
- Secretarial Order 3317 – Department of Interior Policy on Consultation with Indian Tribes, December 1, 2011
- Bureau Manual Handbook H-8120-1 – Guidelines for Conducting Tribal Consultation (Transmitted 12/03/04)
- The National Historic Preservation Act of 1966 as amended (PL 89-665; 80 Stat. 915; 16 USC 470)
- Archaeological Resources Protection Act of 1979 (PL 96-95; 93 Stat. 721; 16 USC 470aa et seq.) as amended (PL 100-555; PL 100-588)
- American Indian Religious Freedom Act of 1978 (PL 95-431; 92 Stat. 469; 42 USC 19960)

The planning area is within the traditional and historical use area of the Blackfeet Tribe, Chippewa Cree Tribe, Confederated Salish-Kootenai Tribes, Confederated Tribes of the Colville Reservation, Confederated Tribes of the Umatilla Reservation, Crow Tribe, Eastern Shoshone Tribe, Nez Perce Tribe, Shoshone-Bannock Tribes, and the Shoshone-Paiute Tribes. These tribes lived, hunted, fished, gathered plant foods, buried their dead, and conducted religious ceremonies on lands within the planning area.

During the 1850s and 1860s, the US negotiated treaties with some tribes in order to acquire lands for homesteading. The treaties that apply to the project area include the Crow Treaty, Fort Benton Treaty, Fort Bridger Treaty, Hell Gate Treaty, Nez Perce Treaty, and Walla Walla, Cayuse, and Umatilla Treaty. More information on these specific treaties is presented below. No tribal treaties were afforded to the Chippewa Cree and the Confederated Tribes of the Colville Indian Reservation. The Shoshone-Paiute Tribes of the Duck Valley Indian Reservation assert aboriginal rights to their traditional homelands; however, the Boise Valley Treaty of 1864 and the Bruneau Valley Treaty of 1866 were never ratified. The Shoshone-Paiute Tribes believe that title to these lands was not relinquished and they continue to claim title, rights, and interests associated with these lands.

On May 7, 1868, the Crow Tribe and the US signed the Treaty with the Crows, 1868, referred to as the Crow Treaty (15 Stat. 649). In the Crow Treaty, the tribes relinquished ownership of thousands of acres of land to the US. The treaty also guaranteed a permanent homeland for the Crow Tribe in southeastern Montana, which became known as the Crow Reservation. Article 4 of the treaty also states the tribe's right to "hunt on the unoccupied lands of the US so long as game may be found thereon."

On October 17, 1855, the Blackfeet and the US signed the Blackfeet Treaty of Fort Benton, 1855, referred to as the Fort Benton Treaty (11 Stat. 657). In the Fort Benton Treaty, a great majority of the land was designated as common hunting ground for the Blackfeet and neighboring tribes. In 1888, lands were set aside in north-central Montana for the Blackfeet Indian Reservation.

On July 3, 1868, the Eastern Band Shoshone and Bannock Tribes and the US signed the Treaty with the Eastern Band Shoshoni and Bannack, 1868, referred to as the Fort Bridger Treaty (15 Stat. 673). In the Fort Bridger Treaty, the tribes relinquished ownership of approximately 20 million acres to the US. The Eastern Band Shoshone were guaranteed a permanent homeland in western Wyoming, which has become known as the Wind River Indian Reservation. The Bannock and other bands of Shoshone were guaranteed a permanent homeland as well which ended up being in southeast Idaho, known as the Fort Hall Indian Reservation. Article 4 of the treaty also retains the tribes' rights to hunt, fish, and gather natural resources (including timber), and provides other associative rights necessary to effectuate these rights on the unoccupied lands of the US.

On July 16, 1855, the confederated tribes of the Flathead, Kootenay (sic), and the Upper Pend d'Oreille Indians and the US signed the Treaty with the Flatheads, etc., 1855, referred to as the Hell Gate Treaty (12 Stat. 975). The treaty guaranteed a permanent homeland for the confederated tribes in northwestern Montana, which has become known as the Flathead Reservation. Article 3 of the treaty also retains the tribes, "privilege of hunting, gathering roots, and berries, and pasturing their horses and cattle upon open and unclaimed lands."

On June 11, 1855, the Nez Perce Tribe and the US signed the Treaty with the Nez Percés, 1855, referred to as the Nez Perce Treaty (12 Stat. 957). In the Nez Perce Treaty, the tribes relinquished ownership of millions of acres of land to the US. The treaty also guaranteed a permanent homeland for the Nez Perce Tribe in northern Idaho, which became known as the Nez Perce Reservation. Article 3 of the treaty also asserts the tribe's right to "take fish at all usual and accustomed places in common with citizens of the [Washington] Territory; and of erecting temporary buildings for curing, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land."

On June 9, 1855, the Walla Walla, Cayuses, and Umatilla tribes and the US signed the Treaty with the Walla Walla, Cayuse, etc., 1855 (12 Stat. 945). In the treaty, the tribes relinquished 6.4 million acres of land to the US. The treaty also guaranteed a permanent homeland for the Walla Walla, Cayuse, Umatilla, and other tribes in northeastern Oregon, which became known as the Confederated Tribes of the Umatilla Indian Reservation. Article 1 of the treaty also retained the tribes' right to "hunt, gather roots and berries, and pasture stock on unclaimed lands of the US."

The BLM manages portions of these "unoccupied or unclaimed lands." Members of the tribes affected by this proposed action exercise their hunting, fishing, and gathering rights on federal lands outside of the boundaries of their reservations. Currently, there is little specific information available on the exact animal species hunted, plant species gathered, or locations used by Native Americans exercising their treaty rights within the boundaries of the project area.

### **3.19 Visual Resources**

Visual quality of western landscapes is an increasingly sensitive issue. Impacts on visual resources are identified as a significant issue to address in RMPs, Forest Plans, and major EISs such as the renewable energy and transmission programmatic environmental impact

statements. The general public's increasing awareness of the vertical scale, footprint, character and visible prominence associated with utility scale renewable energy and transmission line development has increasing the need for Visual Resource Management (VRM).

### 3.19.1 Conditions on BLM-Administered Lands

The BLM manages scenic values using the VRM program. VRM policy was initially launched in 1976 in response to both NEPA requirements placed on federal land management, and FLPMA requirements for scenery resource inventory and management. The BLM developed the current VRM policy manual (M-8400) and handbooks (H-8410-1, H-8431-1) in the mid-1980s to guide the field offices through an objective and systematic program for managing scenery resources.

VRM requires that the BLM field offices complete a visual resource inventory of the lands under their management control. The visual resource inventory is a systematic process for determining the visual values on the BLM-administered lands. The inventory process has three parts: scenic quality evaluation, sensitivity level analysis and delineation of distance zones. Based on the combinations of the three, BLM-administered lands can then be categorized as Class I (most valued and highest quality of scenery) down to Class IV (areas of low scenic quality and sensitivity at most or all distance zones). These inventory classes represent the existing visual resources.

VRM provides a way to inventory and classify visual resources, describe characteristic landscapes, determine contrasts from proposed actions, and potential mitigation from impacts on visual resources.

BLM Handbook 8410 describes the three basic landscape characteristics used to indicate visual resources in VRM: 1) scenic quality; 2) sensitivity levels; and 3) distance zones. Scenic quality is a measure of the visual appeal of a tract of land. Areas can be sub-divided into Scenic Quality Rating Units of similar visual character on the basis of like physiographic characteristics, similar visual patterns, texture, color, and variety; and areas which have similar impacts from man-made modifications. The size of the Scenic Quality Rating Units may vary from several thousand acres to 100 or less, depending on landscape feature similarities, and the desired inventory detail. Seven key factors determine the scenic quality of a unit: landform, vegetation, water, color, adjacent scenery, scarcity, and cultural modifications. Resource specialists consider these factors when ranking units for scenic quality (A = high, B = medium, C = low).

Visual sensitivity is a measure of public concern for scenic quality. BLM-administered lands are assigned high, medium, or low sensitivity levels by analyzing various indicators of public concern, such as: type of user, amount of use, public interest, adjacent land uses, and special areas.

Sensitivity level rankings are not available for the planning area.

Landscapes can be divided into three distance zones based on relative visibility from travel routes or observation points. They are foreground-midground, background, and seldom seen. The foreground-midground zone includes areas seen from highways, rivers, or other viewing locations that are less than five miles away. The background zone is generally between 5 and 15 miles away. The seldom-seen zone includes areas usually hidden from view.

During the resource management planning process, the BLM determines how the visual landscape will be managed in the future. The VRM decisions that are made in the planning process result in areas being assigned a VRM class. VRM classes determine how much change will be allowed in the landscape. VRM Class I areas are managed to preserve the existing character of the landscape and allow for limited management activity. Class II allows for low levels of landscape change that do not attract attention of the casual observer. Class III allows for moderate changes to the landscape that may attract attention but are not dominant and Class IV areas allow for high levels of landscape change.

The BLM uses a VRM contrast rating system that addresses form, line, color and texture of the landscape to determine if proposed projects are in compliance with the designated visual resource management class.

These management classes are separate from the visual resource inventory classes and guide management irrespective of the underlying visual resource (i.e., areas that have an inventory Class II could be designated and managed as a VRM Class IV to allow for major changes in the landscape).

In the past, especially in older management framework plans, BLM field offices would often adopt the VRM inventory classes as the management class (**Table 3-56**, BLM Visual Resource Management Class Acres). In some plans, the BLM did not make any decisions regarding the VRM classes. In such cases, the VRM inventory class has generally been used as the VRM class. A majority of the BLM-administered lands within the planning area do not have a current visual resource inventory.

**Table 3-56**  
**BLM Visual Resource Management Class Acres**  
**(approximate for offices with designated VRM classes)**

VRM Class	Class I	Class II	Class III	Class IV
Acres	510,924	2,058,432	3,983,572	2,052,936

### 3.19.2 Conditions on Forest Service-Administered Lands

Forest Service Manual 2380.3 requires the agency to “inventory, evaluate, manage, and, where necessary, restore scenery as a fully integrated part of the ecosystems of Forest Service-administered lands through the land and resource management and planning process.” Scenery must be treated equally with other resources. The Forest Service

developed a visual management system to provide a mechanism for inventory and analysis of landscape resources and the effects of land management activities on those resources.

The Forest Service established the Visual Management System in 1974 to inventory, evaluate, and manage scenic resources. The Visual Management System is described in Agriculture Handbook No. 462, National Forest Landscape Management. Using an established physiographic character type as a frame of reference, the Visual Management System determines the inherent scenic quality based on the different degrees of landscape variety within an area.

Inherent scenic quality is a measure of the natural landscape's scenic beauty based on attributes, such as landform, vegetation, water features, and rock formations. The basic assumption of the Visual Management System is that all landscapes have some inherent value, but those with the most variety and diversity have the greatest potential for "high scenic value." Three variety classes, designated A, B, and C, represent inherent scenic quality.

Sensitivity levels are identified in the Visual Management System and are defined as the measure of people's concern for the scenic quality of the landscape. Basically, all viewed landscape is rated for a level of sensitivity. Sensitivity levels are overlaid with distance zones to identify all the viewed and unseen landscape within a given area. The Visual Management System defines distance zones—that is, the distance from which a landscape is viewed—as foreground, middleground, and background. Distance zones are important in evaluating how change is perceived in the landscape because the closer the features in the landscape are to the viewer, the more pronounced they appear and the more detail is observed.

Visual quality objectives are determined in the Visual Management System by combining the sensitivity levels and scenic quality. Visual quality objectives are assigned to the landscape to describe the degree of acceptable alteration of the natural landscape. The Visual quality objectives classifications are Preservation, Retention, Partial Retention, Modification, and Maximum Modification. Preservation allows for ecological changes only, while Maximum Modification allows for landscape changes that may dominate the natural landscape character.

#### ***Scenery Management System***

The Visual Management System process has been updated as the Scenery Management System, which is being incorporated into respective Forest Management Plans. The Scenery Management System is described in Landscape Aesthetics: A Handbook for Scenery Management (Forest Service 1995). Adoption of the Scenery Management System is to occur as each National Forest revises its LUP. For National Forests not currently undergoing the forest-plan revision process, or for those requiring extensive time for revision, application of the Scenery Management System will occur at the subforest or project level.

In general, the Scenery Management System differs from the Visual Management System in that it is integrated with ecosystem management and addresses landscape character, constituent preferences, scenic integrity, and landscape visibility as key aesthetic

considerations. Landscape character describes the visual patterns of form, line, color, texture, dominance, scale, and diversity of elements in the landscape and the cultural attributes that make the landscape identifiable and give it a “sense of place.” Constituent preferences convey the aesthetic experience of forest visitors, communities, and tourists and the significance of scenic quality to these user groups.

The Scenery Management System entails identifying the landscape character, visual sensitivity, and scenic integrity. The Scenery Management System provides an overall framework for the orderly inventory, analysis, and management of scenery. It is a tool for integrating the benefits, values, desires, and preferences regarding aesthetics and scenery for all levels of land management planning. The Scenery Management System also considers Concern Levels, which are a categorization of the importance of scenic resources to forest visitors.

Three concepts of the Scenery Management System are of key importance: (1) Scenic Attractiveness, (2) Landscape Character, and (3) Scenic Integrity. These concepts and landscape character are defined below:

Scenic Attractiveness is the primary indicator of the scenic importance of a landscape based on human perceptions of the intrinsic beauty of landforms, rock outcrops and forms, waterforms, vegetation patterns, and cultural features. It reflects varying visual perception attributes of variety, unity, vividness, intactness, coherence, uniqueness, harmony, balance, and pattern. The frame of reference for scenic attractiveness (generally at the section scale) is landscape character.

Three levels of scenic attractiveness are identified during the scenery inventory process: (A) Distinctive, (B) Common or Typical, and (C) Undistinguished (FSM 2380, Landscape Management).

Landscape character is a combination of physical, biological, and cultural images that gives an area its visual and cultural identity and helps to define a sense of place. Landscape character provides a frame of reference from which to determine scenic attractiveness and to measure scenic integrity (FSM 2380, Landscape Management).

Scenic Integrity Objectives define the degrees of deviation from the landscape character that occur at any given time by using the process described in Agriculture Handbook 701, Landscape Aesthetics: A Handbook for Scenery Management (FSM 2380, Landscape Management). When discussing Scenic Integrity Objectives, the degree of alteration is measured in terms of visual contrast with the surrounding natural landscape. The objectives of each Scenic Integrity Objectives classification are included below:

- Very High – Management activities, except for very low visual-impact recreation facilities, are prohibited. Allows for ecological changes only. The existing landscape character and sense of place is expressed at the highest possible level.
- High – Management activities are not visually evident to the casual observer. The landscape character appears intact. Deviations may be present but must repeat

the form, line, color, texture, and pattern common to the landscape character so completely and at such scale that they are not evident. Changes in the qualities of size, amount, intensity, direction, pattern, etc., should not be evident.

- Moderate – Management activities remain visually subordinate to the characteristic landscape being viewed. Activities may repeat form, line, color, or texture common to the characteristic landscape but may not change in their qualities of size, amount, intensity, direction, pattern, etc.
- Low – Management activities begin to visually dominate the original characteristic landscape. However, activities of vegetative and landform alteration must borrow from naturally established form, line, color, or texture so completely and at such a scale that its visual characteristics are those of natural occurrences within the surrounding area or character type. Structures must remain visually subordinate to the proposed composition.
- Very Low – Management activities of vegetative and landform alterations may dominate the characteristic landscape. While alterations may not borrow from attributes such as size, shape, edge effect, and pattern of natural openings, vegetative type changes, or architectural styles within or outside the landscape being viewed, they must be shaped and blended with the natural terrain so that elements such as unnatural edges, roads, landings, and structures do not dominate the composition.

#### ***Visual Management Classes***

For both the BLM and Forest Service, where management decisions have been made to preserve and protect the visual characteristics of the landscape, these areas are likely to provide better habitat and protection for GRSG.

#### **3.20 Lands with Wilderness Characteristics**

The purpose and need of the National GRSG Planning Effort is limited to providing LUP guidance specific to the conservation of GRSG habitats. No decisions related to the management of lands with wilderness characteristics will be made as part of this planning effort; therefore, management of lands with wilderness characteristics is considered outside the scope of this plan amendment process. Impacts on lands with wilderness characteristics from the alternatives being analyzed for this planning effort are presented in **Section 4.14**.

Section 201 of FLPMA and BLM Manual Section 6310 require the BLM to maintain on a continuing basis an inventory of all BLM-administered lands and their resources and other values, which includes wilderness characteristics. It also provides that the preparation and maintenance of the inventory shall not, of itself, change or prevent change of the management or use of BLM-administered lands. Regardless of past inventory, the BLM must maintain and update as necessary, its inventory of wilderness resources on BLM-administered lands. In some circumstances conditions relating to wilderness characteristics may have changed over time, and an area that was once determined to lack wilderness

characteristics may now possess them. The BLM determines when it is necessary to update its wilderness characteristics inventory.

Under the following circumstances, the BLM considers whether to update a wilderness characteristics inventory or conduct a wilderness characteristics inventory for the first time:

1. The public or the BLM identifies wilderness characteristics as an issue during the NEPA process.
2. The BLM is undertaking a land use planning process.
3. The BLM has new information concerning resource conditions, including wilderness characteristics information submitted by the public that meets the BLM's minimum standard described in the Wilderness Characteristics Inventory Process section of this policy.
4. A project that may impact wilderness characteristics is undergoing NEPA analysis.
5. The BLM acquires additional lands.

There also may be other circumstances in which BLM will find it appropriate to update its wilderness characteristics inventory.

The original FLPMA Section 603 mandated inventories that were conducted during past RMP revisions and amendments and through other lands with wilderness characteristics inventory updates that have recently taken place. Inventories for wilderness characteristics were conducted between 2009 and 2013 and reflect the most up-to-date lands with wilderness characteristics baseline information for this planning area. For inventories that were conducted after 2011, findings were documented following guidance in BLM IM 2011-154, Requirement to Conduct and Maintain Inventory Information for Wilderness Characteristics and to Consider Lands with Wilderness Characteristics in Land Use Plans, which is now encompassed in BLM Manuals 6310 and 6320. Lands with wilderness characteristics inventories will be updated for any site-specific NEPA analyses that are conducted in the planning area. This will be to determine if a project will have impacts on lands with wilderness characteristics identified through previous or updated inventories.

The primary function of an inventory is to determine the presence or absence of wilderness characteristics. The BLM has completed lands with wilderness characteristics inventories in the Bruneau, Jarbidge, Salmon, Pocatello and Dillon Field Offices. Upper Snake has a draft inventory, and partial inventories have been completed in the Owyhee, Shoshone, and Burley Field Offices. The Pocatello Field Office found that it has no lands with wilderness characteristics. The Bruneau, Salmon, Owyhee, Burley, Shoshone, Dillon, and Jarbidge Field Offices found areas that do contain lands with wilderness characteristics.

Currently no Field Offices have taken their lands with wilderness characteristics through a complete planning process to determine how they will be managed. There are 252,296 acres

of lands with wilderness character within the planning area boundary (**Table 3-57**, Lands with Wilderness Characteristics within the Planning Area).

**Table 3-57  
Lands with Wilderness Characteristics within  
the Planning Area**

BLM Field Office	Acres
Bruneau	153,900
Burley	31,000
Dillon	68,400
Jarbidge	88,500
Owyhee	102,500
Salmon	7,300
Shoshone	760
<b>Total</b>	<b>452,360</b>

Source: BLM 2013a

**Figure 3-16**, Lands with Wilderness Characteristics and Roadless Areas in Planning Area, shows BLM Lands with Wilderness Characteristics and Forest Service Roadless Areas in the planning area.

### 3.21 Forest Service Roadless Areas

Under 36 CFR 294, the Forest Service designated Roadless Areas in Idaho (**Figure 3-16**). The purpose of designating Roadless Areas is to conserve areas with wilderness attributes.

The Forest Service organizes Roadless Areas into five management classifications. These management classifications are; 1. Wild Land Recreation, 2. Special Areas of Historic or Tribal Significance, 3. Primitive, 4. Backcountry/Restoration, and 5. General Forest, Rangeland, and Grassland. Management of Roadless Areas is impacted by the management classification into which a Roadless Area falls. The Forest Service restricts activities such as road construction and reconstruction, timber cutting, and mineral activities to various degrees under each management classification in order to protect Roadless Areas (36 CFR 294).

There are approximately 1,695,900 acres of Roadless Areas on Forest Service-administered lands.

### 3.22 Air Quality and Climate Change

Air resources include air quality, air quality related values, and climate change. As part of the decision-making process, the BLM and Forest Service consider and analyze the potential effects of agency and agency-authorized activities on air resources.

Figure 3-16 Lands with Wilderness Characteristics and Roadless Areas in Planning Area

The US Environmental Protection Agency (USEPA) has the primary responsibility for regulating air quality, including seven criteria air pollutants subject to National Ambient Air Quality standards (NAAQS). Pollutants regulated under NAAQS include carbon monoxide (CO), lead, nitrogen dioxide (NO<sub>2</sub>), ozone, particulate matter with a diameter less than or equal to 10 microns (PM<sub>10</sub>), particulate matter with a diameter less than or equal to 2.5 microns (PM<sub>2.5</sub>), and sulfur dioxide (SO<sub>2</sub>). Two additional pollutants, nitrogen oxides (NO<sub>x</sub>) and volatile organic compounds (VOCs), are regulated because they form ozone in the atmosphere. Air quality is determined by pollutant emissions and emission characteristics, atmospheric chemistry, dispersion meteorology, and terrain. Air quality related values include effects on soil and water, such as sulfur and nitrogen deposition and lake acidification, and aesthetic effects, such as visibility.

In addition to USEPA regulations, air quality is also regulated by the Idaho Department of Environmental Quality, Air Quality Division. This agency develops state-specific regulations and issues air quality permits to emission sources.

Climate is the composite of generally prevailing weather conditions of a particular region through the year, averaged over a series of years. Climate change includes both historic and predicted climate shifts that are beyond normal weather variations.

### 3.22.1 Conditions within the Planning Area

#### *Air Quality*

Human Health. The USEPA classifies areas of the US according to whether they meet the NAAQS. Areas that violate air quality standards are designated as nonattainment areas for the relevant criteria air pollutants. Areas that comply with air quality standards are designated as attainment areas for the relevant criteria air pollutants. Areas that have been reclassified from nonattainment to attainment are considered maintenance areas. The majority of the planning area is in attainment for all of the NAAQS.

The Air Quality Index is an USEPA health index that normalizes the various air pollutants in order to report one health level. The Air Quality Index is reported on a scale of 0 to 300, with 0 to 50 indicating good air quality; 51 to 100 indicating moderate air quality; 101 to 150 indicating air quality unhealthy for sensitive groups; 151 to 200 indicating unhealthy air quality; and 201 to 300 indicating very unhealthy air quality. Idaho Department of Environmental Quality publishes annual data summaries of Idaho's air quality that describe the Air Quality Index for all areas where air quality is monitored. The Air Quality Index is computed using the 24-hour average for PM<sub>2.5</sub> and the eight hour average for ozone.

Visibility and Regional Haze. There are no mandatory Class I areas on BLM-administered lands in the planning area; all designated wilderness areas on BLM-administered lands are Class II.

#### *Climate Change*

Climate change is defined by the Intergovernmental Panel on Climate Change (IPCC) as "a change in the state of the climate that can be identified (e.g., using statistical tests) by changes

in the mean and/or the variability of its properties, and persist for an extended period, typically decades or longer. It refers to any change in climate over time whether due to natural variability to as a result of human activity (IPCC 2007).” Climate change is generally described on a global, national, or regional scale (state or multi-state), while greenhouse gas emissions in the US are generally reported on a national or statewide scale.

Climate change is manifested in several ways, of which the most commonly analyzed are precipitation, temperature, and snowpack. Temperature and precipitation data for the planning area were retrieved from WestMap, a climate analysis and tracking tool that uses hydrologic basins as the mapping unit.

#### *Greenhouse Gas Emissions*

There are six greenhouse gases tracked by the IPCC, carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>), nitrous oxide (N<sub>2</sub>O), hydrofluorocarbons (HFCs), perfluorocarbons, and sulfur hexafluoride (SF<sub>6</sub>); US Department of State 2010). Hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride are also known as high global warming potential due to their warming effectiveness (140 to 23,900 times the warming potential compared to carbon dioxide, depending on the compound) and their essential permanence in the atmosphere (remaining over 3,000 years; US Department of State 2010; USEPA 2012). Carbon dioxide, methane, and nitrous oxide have both natural and human generated sources, while high global warming potential gases are strictly human generated from various industrial processes. Greenhouse gas emissions are tracked as carbon dioxide equivalents (CO<sub>2</sub>e) with one gram of carbon dioxide molecule counting as one and other molecules some multiple. Emissions are usually reported in teragrams or million metric tonnes, which are equivalent measures (USEPA 2010).

In the US, USEPA tracks and reports greenhouse gas emissions; the Department of State also reports emissions.

Greenhouse gas emissions in the US and in Idaho are similar in terms of percentages and in the main sources of the different gases. Idaho’s greenhouse gases have remained about 1 percent of the US emissions from 1990 to 2010. Carbon dioxide is the primary greenhouse gas, comprising 83 to 85 percent of total emissions in the US and in Idaho, with fossil fuel combustion for energy the primary sources of carbon dioxide. Methane production accounts for 7 to 10 percent of greenhouse gas emissions. In the US, the primary source is natural gas systems, while in Idaho the primary source is enteric fermentation from domestic livestock. Nitrous oxide production accounts for 4 to 6 percent of the total emissions, slightly more in Idaho than in the US with agricultural soil management the primary sources.

The high global warming potential gas comprises 1 to 3 percent of total emissions, more in Oregon than in the US. The primary sources of hydrofluorocarbons are the production of substitutes for ozone-depleting compounds, while aluminum production and semiconductor manufacturing are the primary sources of perfluorocarbons and electricity transmission and distribution are the primary sources of sulfur hexafluoride.

The USEPA also estimates greenhouse gas sinks arising from land use, land use changes, and forestry. These sinks effectively reduce total greenhouse gas emissions by 15 to 16 percent nationally (USEPA 2010). The proportion in Idaho may be somewhat higher due to the productivity of Idaho forests.

### 3.22.2 Conditions on BLM-Administered and Forest Service-Administered Lands

#### *Air Quality*

Air quality conditions on BLM-administered and Forest Service-administered lands are generally as described for the planning area.

### 3.22.3 Trends

#### *Air Quality*

Human Health. There are no clear long term trends in particulate emissions or the number of unhealthy days in the planning area; the lack of trends maybe due to a number of factors. There are no trends in the number of wildfires of acres burned or in the prescribed burning programs of BLM districts or National Forests; there are also no documented trends in the other particulate emitting sectors. The recent downturn in the economy may have resulted in temporary or permanent changes in the number or types of particulate emitters. The 2010 Clean Air status and trends network report indicates that 2009 was the lowest year on the 15 year recorded for several criteria pollutants, with increases in 2010 (USEPA 2012). That trend would be consistent with the recent downturn and slow recovery. In the western states as a whole, mean annual sulfur dioxide and particulate sulfur concentrations, total nitrate levels, total nitrogen deposition, and ozone concentrations have declined between 1996 and 2010 (Hand et al. 2011; USEPA 2012).

#### *Climate Change*

Certain precipitation, temperature, and snowfall trends within the planning area are similar, while others differ. The reasons for the observed differences are not clear. In the Oregon closed basins, precipitation has increased annually and in all four season, with the greatest seasonal increase in spring. Temperatures are also increasing, with greater increases in minimum temperature in winter and summer, consistent with observed national and global trends. Even temperatures are warming, above a threshold elevation that varies by mountain range; temperatures are still cold enough for winter precipitation to fall as snow. The combination of warmer temperatures and increased water vapor means that either more snow, snow with a higher moisture content, or some combination of these two factors will occur.

#### *Projections*

Karl et al. (2009) summarize the observed trends and projections in climate for the US, with an updated report due in 2013. In the US, average temperature has risen 2 degrees Fahrenheit (°F) in the last 50 years, compared to the 1961 to 1979 baseline, and is projected to increase by 2 to 3°F by the 2020s. Precipitation has increased by 5 percent in the last 50 years. Summers are expected to become drier over most of the US, and winters are expected to become wetter. Spring is expected to become drier in the southern tier of the US. The amount of rain falling in the heaviest storms has increased by 20 percent. This trend is

expected to continue, with the greatest increase in the wettest places. In contrast, the amount of rain falling in the lightest storms has decreased, with the trend expected to continue. Extreme weather events such as heat waves and drought have become more frequent and more intense. Heat event frequency is expected to increase from 1 every 20 years to 1 every 2 to 3 years, with the number of days above 90°F increasing as well. Snowpack is expected to decrease, especially in the western US. Cold season storm tracts should continue to shift northward, and the strongest winter storms are expected to become stronger and more frequent.

For the Pacific Northwest (Oregon, Washington, Idaho, and western Montana) the projections are somewhat different than for the US as a whole (Mote and Salathe 2010). Most climate models tend to over predict precipitation as compared to observed means in the Pacific Northwest, so must be corrected in any projections. In the Pacific Northwest, temperatures are expected to increase by about 1 to 3 degrees by the 2020s, 1.5 to 5 by mid-century, and 3 to 10 by the end of the century. The greatest warming is expected in summer, and least is expected in spring. Annual precipitation is expected to change little, but summers should become drier and all other seasons possibly wetter. As with the US as a whole and globally, the frequency of extreme precipitation events, heat waves, and droughts are expected to increase, and snowpack is expected to decrease.

#### *Greenhouse Gas Emissions*

Between 1990 and 2010, total us greenhouse gas emissions increased by 10.5 percent, averaging 0.5 percent per year (USEPA 2012). Carbon dioxide emissions, particularly those associated with energy production and use, are the dominant factor in US trends. Emissions from fossil fuel combustion increased by 13.7 percent between 1990 and 2010, and increased by 3.5 percent between 2009 and 2010. Emissions tend to decline during economic slowdowns and increase during economic recoveries. Emissions in Idaho followed similar trends as the US as a whole. The State Department (2010) projected greenhouse gas emissions for 2015 and 2020 based on data through 2007. Carbon dioxide emissions are expected to increase only slightly from 2007 levels, although the projected increase is considerably lower than the observed trend. All other emissions are expected to increase as well, with the least increase in methane and the most increase in the high global warming potential gases.

### **3.23 Social and Economic Conditions (Including Environmental Justice)**

Due to the nature of social, economic, and environmental justice conditions, the social and economic analysis is based on a somewhat different area for analysis than is used for other resources. Specifically, the Socioeconomic Study Area is made up of counties within the Idaho-Southwestern Montana sub-region that contain GRSG habitat and within which social and economic conditions might reasonably be expected to change based on alternative management actions. In addition, the BLM reviewed the need to include additional counties within a secondary study area that may not contain GRSG habitat but are closely linked from an economic and/or social perspective to counties that do contain habitat. This latter category includes what are sometimes called “service area” counties, or counties from which businesses operate that regularly provide critical economic services, such as recreational

outfitting or support services for the livestock grazing sector, within the counties that contain habitat (METI Corp/Economic Insights of Colorado 2012). Including service area counties is important because a change in economic activity in a county containing habitat may result in changes in economic activity within service area counties as well.

The Socioeconomic Study Area contains 27 counties in Idaho: Adams, Bear Lake, Bingham, Blaine, Bonneville, Butte, Camas, Caribou, Cassia, Clark, Custer, Elmore, Fremont, Gem, Gooding, Jefferson, Jerome, Lemhi, Lincoln, Madison, Minidoka, Oneida, Owyhee, Payette, Power, Twin Falls, and Washington; and two counties in Montana: Beaverhead and Madison. Each of these counties contains GRSG habitat. A secondary study area is included that contains an additional four counties in Idaho: Ada, Bannock, Boise, and Canyon; and two counties in Montana: Gallatin and Silver Bow. All of these counties are included in the secondary study area because of identified links to the primary area based on commuter patterns (OMB 2009; US Census Bureau 2012a).<sup>3</sup>

**Table 3-58**, Commuter Patterns in the Socioeconomic Study Area, 2010, shows the share of workers employed in a given county of the Primary and Secondary Socioeconomic Study Areas and that reside in the same county. It also shows other counties that provide labor to the selected primary or secondary study area.

**Table 3-58**  
**Commuter Patterns in the Socioeconomic Study Area, 2010**

Geographic Area of Employment	Live in Same Area of Employment	Other Counties Where Considerable Share of Workers Live
<b>Primary Socioeconomic Study Area</b>		
Adams County, Idaho	69.4%	Valley (7.3%), Idaho (6.7%), Washington (3.5%)
Bear Lake County, Idaho	77.2%	Ada (2.7%), Bannock (2.4%)
Bingham County, Idaho	64.3%	Bannock (10.2%), Bonneville (9.5%), Ada (2.0%)
Blaine County, Idaho	70.9%	Ada (6.7%), Lincoln (3.6%), Canyon (2.6%), Twin Falls (2.6%)
Bonneville County, Idaho	61.0%	Bingham (8.7%), Jefferson (8.3%), Bannock (6.3%), Madison (3.3%), Ada (2.5%)

<sup>3</sup> Other counties considered but excluded from the secondary area were: (a) Valley County, Idaho, which has its main commuter tie to Ada County, Idaho, a secondary area county; (b) Franklin County, Idaho, which has its main commuter tie to Cache County, Utah, a county outside of the Socioeconomic Study Area; (c) Teton County, Idaho, which has its main commuter tie to Teton County, Montana, a county outside of the Socioeconomic Study Area; (d) Jefferson and Broadwater Counties, Montana, both of which have their main commuter ties to Lewis and Clark County, Montana, a county outside of the Socioeconomic Study Area; (e) Ravalli County, Montana, which has its main commuter tie outside the primary study area, is linked to the Salmon Challis National Forest or the Beaverhead Deerlodge National Forest, but is less likely to be affected by GRSG habitat management alternatives because GRSG habitat is concentrated in the southeast of Lemhi County, Idaho, at a distance from Ravalli County; (f) Deer Lodge and Park counties in MT, whose main ties are to Silver Bow and Gallatin, counties of the secondary area; and (g) the counties of Missoula, Granite, and Powell (all in Montana) were not included in the secondary study area because the Beaverhead Deerlodge National Forest areas potentially affected by GRSG habitat management alternatives are located considerably to the south of those counties.

**Table 3-58**  
**Commuter Patterns in the Socioeconomic Study Area, 2010**

<b>Geographic Area of Employment</b>	<b>Live in Same Area of Employment</b>	<b>Other Counties Where Considerable Share of Workers Live</b>
Butte County, Idaho	21.5%	Bonneville (40.9%), Bingham (14.2%), Bannock (7.6%), Jefferson (6.5%), Custer (2.1%), Madison (2.0%)
Camas County, Idaho	58.5%	Gooding (10.9%), Blaine (8.3%), Twin Falls (5.7%), Jerome (3.0%), Ada (2.6%), Elmore (2.6%)
Caribou County, Idaho	56.8%	Bannock (11.4%), Bear Lake (9.8%), Ada (2.8%), Bonneville (2.8%), Franklin (2.8%)
Cassia County, Idaho	49.9%	Minidoka (23.8%), Twin Falls (6.8%), Ada (3.0%), Jerome (2.5%), Bonneville (2.1%)
Clark County, Idaho	51.4%	Bonneville (18.3%), Jefferson (18.3%), Bannock (2.2%), Madison (2.2%)
Custer County, Idaho	65.7%	Lemhi (13.6%), Butte (2.8%), Bonneville (2.7%), Ada (2.6%)
Elmore County, Idaho	69.7%	Ada (11.3%), Canyon (4.2%), Twin Falls (2.3%)
Fremont County, Idaho	70.5%	Madison (10.3%), Bonneville (6.2%), Jefferson (2.9%)
Gem County, Idaho	60.0%	Ada (15.4%), Canyon (10.7%), Payette (2.7%)
Gooding County, Idaho	48.5%	Twin Falls (17.3%), Jerome (10.7%), Lincoln (2.5%), Ada (2.3%)
Jefferson County, Idaho	51.6%	Bonneville (23.7%), Madison (8.4%), Bingham (2.4%)
Jerome County, Idaho	42.8%	Twin Falls (26.1%), Gooding (8.8%), Ada (3.3%), Cassia (2.4%), Minidoka (2.2%)
Lemhi County, Idaho	88.1%	Bonneville (2.1%)
Lincoln County, Idaho	49.7%	Twin Falls (14.2%), Gooding (12.4%), Jerome (7.0%), Minidoka (3.3%), Blaine (2.0%)
Madison County, Idaho	49.6%	Bonneville (12.9%), Fremont (12.2%), Jefferson (9.5%), Bannock (3.2%), Bingham (2.3%)
Minidoka County, Idaho	54.9%	Cassia (19.7%), Twin Falls (7.2%), Ada (2.3%), Bannock (2.2%)
Oneida County, Idaho	78.3%	Bannock (7.0%), Bonneville (2.5%), Box Elder, UT (2.1%)
Owyhee County, Idaho	42.2%	Canyon (31.5%), Ada (8.2%), Elmore (4.3%), Malheur, OR (2.4%),
Payette County, Idaho	51.3%	Canyon (14.4%), Malheur, OR (10.4%), Ada (8.0%), Washington (4.6%), Gem (3.4%)
Power County, Idaho	45.5%	Bannock (24.2%), Bingham (6.5%), Twin Falls (5.0%), Ada (2.7%)
Twin Falls County, Idaho	64.8%	Jerome (7.0%), Ada (5.2%), Gooding (2.6%), Cassia (2.6%), Canyon (2.5%), Minidoka (2.5%)
Washington County, Idaho	63.4%	Payette (6.3%), Ada (4.7%), Malheur, OR (4.5%), Canyon (4.5%)
Beaverhead County, Montana	62.1%	Lewis and Clark (6.9%), Yellowstone (6.7%), Silver Bow (5.7%), Gallatin (3.6%), Missoula (3.2%), Cascade (2.8%)
Madison County, Montana	67.8%	Gallatin (17.3%), Jefferson (3.0%)

Because any effects on the secondary study area would be indirect and sometimes focused on specific sectors, this chapter focuses primarily on the social and economic conditions of the Socioeconomic Study Area and provides what is necessary to convey appropriate context for the impact analysis. The impact analysis in the next chapter will document potential effects on both the primary and the secondary study areas.

**Table 3-59** Table 3-59, BLM and Forest Service Plans, Management Units, and Counties within the Socioeconomic Study Area, shows the planning documents that may be altered by the Idaho-Southwestern Montana sub-region planning process and the counties containing GRSG habitat within the area encompassed by those plans.

Because of the nature of the Socioeconomic Study Area, the socioeconomic resources section has a slightly different format than the other resource analyses in the EIS. Rather than proceeding by field office and National Forest, the section provides information for the entire Socioeconomic Study Area except where the relevant information or data is tabulated for the specific geographic area of Field Office or National Forest. In addition, the analysis presents information about existing conditions and trends within the same section, because that is the common practice for analysis of social and economic conditions.

### 3.23.1 Indicators

Many of the indicators used to characterize social and economic conditions are quantitative, including population, demographics (e.g., age and gender breakouts), local industry (e.g., recreation and mineral development), employment, personal income, and presence of minority and low-income populations. Other indicators, especially for social conditions, are qualitative.

### 3.23.2 Existing Conditions and Trends

#### *Social Conditions*

Social conditions concern human communities, including towns, cities, and rural areas, and the custom, culture, and history of the area as it relates to human settlement, as well as current social values.

#### *Population and Demographics*

**Table 3-60**, Population Growth, 1990-2010, shows current and historic populations in the Socioeconomic Study Area.

**Table 3-60**  
**Population Growth, 1990-2010**

Geographic Area	1990	2000	2010	Percent Change (1990-2010)	Population as Percentage of Study Area Total (2010)
Adams County, Idaho	3,254	3,476	3,976	22.2%	0.6%
Bear Lake County, Idaho	6,084	6,411	5,986	-1.6%	0.9%
Bingham County, Idaho	37,583	41,735	45,607	21.4%	6.6%

**Table 3-60**  
**Population Growth, 1990-2010**

Geographic Area	1990	2000	2010	Percent Change (1990-2010)	Population as Percentage of Study Area Total (2010)
Blaine County, Idaho	13,552	18,991	21,376	57.7%	3.1%
Bonneville County, Idaho	72,207	82,522	104,234	44.4%	15.2%
Butte County, Idaho	2,918	2,899	2,891	-0.9%	0.4%
Camas County, Idaho	727	991	1,117	53.6%	0.2%
Caribou County, Idaho	6,963	7,304	6,963	0.0%	1.0%
Cassia County, Idaho	19,532	21,416	22,952	17.5%	3.3%
Clark County, Idaho	762	1,022	982	28.9%	0.1%
Custer County, Idaho	4,133	4,342	4,368	5.7%	0.6%
Elmore County, Idaho	21,205	29,130	27,038	27.5%	3.9%
Fremont County, Idaho	10,937	11,819	13,242	21.1%	1.9%
Gem County, Idaho	11,844	15,181	16,719	41.2%	2.4%
Gooding County, Idaho	11,633	14,155	15,464	32.9%	2.3%
Jefferson County, Idaho	16,543	19,155	26,140	58.0%	3.8%
Jerome County, Idaho	15,138	18,342	22,374	47.8%	3.3%

Minidoka County, Idaho	19,361	20,174	20,069	3.7%	2.9%
Oneida County, Idaho	3,492	4,125	4,286	22.7%	0.6%
Owyhee County, Idaho	8,392	10,644	11,526	37.3%	1.7%
Payette County, Idaho	16,434	20,578	22,623	37.7%	3.3%
Power County, Idaho	7,086	7,538	7,817	10.3%	1.1%
Twin Falls County, Idaho	53,580	64,284	77,230	44.1%	11.2%
Washington County, Idaho	8,550	9,977	10,198	19.3%	1.5%
Beaverhead County, Montana	8,424	9,202	9,246	9.8%	1.3%
Madison County, Montana	5,989	6,851	7,691	28.4%	1.1%
Socioeconomic Study Area	420,204	491,581	562,795	33.9%	100.0%
Idaho	1,006,734	1,293,953	1,567,582	55.7%	-
Montana	799,065	902,195	989,415	23.8%	-
United States	248,790,925	281,421,906	308,745,538	24.1%	-

Sources: US Census Bureau 1990, 2000, 2010a

Since 1990, the population in Idaho has increased by 55.7 percent, more than doubling the United States population growth rate (24.1 percent) during the same time period. In contrast, Montana's population has grown 23.8 percent, closer to the rate of the United States as a whole. Both states experienced a higher percentage of population growth from 1990 to 2000 than they did from 2000 to 2010. The Socioeconomic Study Area population growth also

The “Communities of Place” section below provides more information about the character and history of the counties in the Socioeconomic Study Area. ~~Table 3-61~~ **Table 3-61**, Demographic Characteristics, Share in Total Population (percent), 2010, shows age and gender characteristics of the population in each county of the Socioeconomic Study Area.

**Table 3-61**  
**Demographic Characteristics, Share in Total Population (percent), 2010**

Geographic Area	Women	20 to 64 Years of Age	Under 20 Years of Age	65 Years of Age or Older
Adams County, Idaho	48.7	58.2	21.0	20.8
Bear Lake County, Idaho	50.4	52.1	29.5	18.4
Bingham County, Idaho	49.8	52.8	35.8	11.4
Blaine County, Idaho	49.1	62.4	26.0	11.6

Source: US Census Bureau 2010b

The Socioeconomic Study Area, Idaho, Montana, and the United States all generally follow the same trend in gender, with approximately half of the population being female. Of the counties within the Socioeconomic Study Area, Clark County, Idaho (44.7 percent) and Custer County, Idaho (46.9 percent) have the lowest percentages of women. And only one county, Madison County, Idaho (51.6 percent) has a higher percentage of women than the nation.

Idaho and the Socioeconomic Study Area have a younger population than the nation: each having 57 percent of the population between 20 and 64 years of age compared to 60 percent of the national population, and more than 30 percent of the population less than 20 years of age compared to only 27 percent of the national population. In contrast, Montana has a slightly older population than the nation, having nearly 15 percent of the population being 65 years or older compared to only 13 percent of the national population. Of the counties within the Socioeconomic Study Area, Bingham County, Idaho; Cassia County, Idaho; Jefferson County, Idaho; Jerome County, Idaho; Lincoln County, Idaho; Madison County, Idaho; and Power County, Idaho, have the highest percentages of residents under the age of 20, all at least 7 percentage points higher than the national average (60.1 percent). In contrast, Adams County, Idaho; Lemhi County, Idaho; Washington County, Idaho; and Madison County, Montana, have the highest percentages of residents over the age of 65, all at least 7 percentage points higher than the national average (13 percent).

#### *Interest Groups and Communities of Place*

There is a range of interest groups in the Socioeconomic Study Area, including groups that focus advocacy on resource conservation and others that focus advocacy on resource uses such as livestock grazing. There are also groups that represent coalitions of interest groups. A list of interest groups that have requested to receive a copy of the LUPA/DEIS are provided in Chapter 5. The types of interest groups identified within the Socioeconomic Study Area include the following: federal agencies, state agencies, county agencies, local agencies, congressional representatives, local representatives, academic institutions, civic organizations, local chambers of commerce, environmental groups, land conservation groups, outdoors groups, local school boards, farm associations, Native American groups and Tribal Governments, and various business groups. Specific types of business interest groups identified include the following: real estate, tourism, mineral extraction, farms/ranches, textile manufacturers, livestock growers, and news media.

The Socioeconomic Study Area includes various communities of people who are bound together because of where they reside, work, visit, or otherwise spend a continuous portion of their time. Stakeholder groups currently benefitting from BLM-administered and Forest Service-administered lands within the Socioeconomic Study Area include those associated with agriculture and livestock production; forest products; mining; travel, tourism, and recreation; and local residents (see, for example, BLM 2006 and 2008; Forest Service 2003).

A common perception is that there is a dichotomy of values and attitudes between stakeholder groups in the Socioeconomic Study Area between individuals or groups who feel that resource conservation and nonconsumptive uses of BLM-administered lands are more important than benefits derived from consumptive type uses, such as livestock grazing,

timber harvesting, and mining. At a more nuanced scale, however, personal attitudes, interests, and values are quite complex, and these groupings are not mutually exclusive. The high value that residents and visitors place on small town character, private property rights, low population density, scenery and landscape, outdoors and open space, the rural lifestyle, fishing, and hunting are commonly held throughout the Socioeconomic Study Area (BLM 2006 and 2008; Forest Service 2003). These values are also commonly expressed within individual county land use plans, and were also expressed by attendees at both scoping meetings and the Economic Strategies Workshop that BLM and Forest Service held in Twin Falls, Idaho, in June 2012.

A unifying theme expressed by residents of the Socioeconomic Study Area – including in previous planning processes – is the concern for the preservation of rural characteristics and values. For example, a shift toward larger, more mechanized agricultural operations, as well as the increasing diversification of local economies, have challenged traditional ways of life in many communities. These changes are evident in the declining number of mid-sized farms and the number of workers employed in agriculture and agriculture-based industries (Blaine County 1994; Power County 2009; Headwaters Economics 2012; US Department of Commerce 2012a). Nevertheless, farming and ranching remain important parts of the economy, society, and culture across the Socioeconomic Study Area.

In some areas, particularly those with scenic and recreational amenities, farmlands and ranches are being sold and used for recreation purposes or subdivided for homesites. This phenomenon is part of a larger trend in which many rural communities in the western United States have witnessed "migration turnaround," a reversal of the rural-to-urban migration that characterized much of the United States prior to the 1970s. Many rural areas are now experiencing a significant increase in population after decades of stability or decline (BLM 2006). In response to recent commercial and industrial expansion and the associated demand for affordable, diversified housing, many counties are encouraging infill development and other strategies to prevent the loss of agricultural lands and maintain the rural character of their communities (Caribou County 2006).

Despite population increases across most of the study area, some rural areas continue to lose population (Idaho Department of Labor 2011). This is due, in part, to the out-migration of young people and aging of the population (Idaho Commerce & Labor 2005). In contrast to communities where in-migration is occurring, residents of these communities may be more concerned about the economic survival of their communities. Multiple use management of and access to BLM-administered lands, which comprise a large portion of lands in many counties, are cited as paramount concerns in these areas (BLM 2006). Residents expressed some similar themes during public scoping and the June 2012 Economic Strategies Workshop for this planning effort (BLM and Forest Service 2012; BLM 2012b). Comments received from these outreach efforts came from nonprofit or citizen groups; local, state and federal agencies; the commercial sector and members of the general public. These comments strongly supported maintaining or expanding access to BLM-administered lands for grazing and recreational purposes. Many expressed concern that placing additional constraints on these activities might create economic hardship within their communities and alter

traditional cultural values and lifestyles. Additionally, some argued that constraints on livestock grazing would exacerbate existing trends of conversion of ranch lands to agricultural and residential uses, perhaps with the unintended consequence of decreasing open space and wildlife habitat. Other issues of concerns cited by residents include the management of invasive species, fire and fuels, and whether BLM-administered lands should be opened to wind energy development.

Economic activity and land use patterns in the Socioeconomic Study Area have been strongly influenced by the region's dramatic geography. Agriculture, timber harvesting, and mining have historically defined the character and lifestyle of much of the Study Area. Within the past two decades, however, increasing urbanization and the growth of service sector industries, including retail trade, local government, and health care, have been powerful agents of change on the landscape and local cultures (Headwaters Economics 2012; US Department of Commerce 2012a).

The rolling hills and valleys of the Northern Basin and Range, which stretches across much of southern Idaho, provide ample opportunities for livestock grazing with occasional croplands, and contains all or substantial parts of Caribou, Cassia, Oneida, Owyhee, Power, and Twin Falls Counties (McGrath et al. 2002). The region is still heavily dependent on agriculture and agriculture-based industries, despite stagnant or declining employment in these sectors (Headwaters Economics 2012; US Department of Commerce 2012a). Twin Falls is the most populous city in the Socioeconomic Study Area and the seventh largest city in the State of Idaho, and serves as the major commercial and industrial hub of south-central Idaho's Magic Valley region, so named due to the transformation of the basin into productive farmland through the construction of extensive irrigation systems in the early 1900s. Twin Falls is also the principal city of the Twin Falls, Idaho Micropolitan Statistical Area, which includes Jerome and Twin Falls Counties.

The broad Snake River Plain that arcs just north of Idaho's Basin and Range region contains all or substantial parts of Ada, Adams, Bingham, Canyon, Elmore, Gem, Gooding, Jefferson, Jerome, Lincoln, Madison, Minidoka, Payette, and Washington Counties. Potatoes, sugar beets, alfalfa, grains, and vegetables are grown in areas where irrigation and soil depth are suitable for crop production (McGrath et al. 2002). Other prominent land uses include livestock grazing, cattle feedlots, and dairy operations. The barren, lava-field landscape of Craters of the Moon National Monument is a popular visitor attraction showcasing the region's unique geologic history. Upward trends in population growth, fueled by expansion in the retail trade and small manufacturing sectors over the past decade, have left some school districts and governmental service struggling to provide maintain adequate levels of service (Jefferson County 2005).

Butte, Camas, Clark, Custer, and Lemhi Counties are located in Idaho's Rocky Mountain region, which rises sharply from the northern edge of the Snake River Plain. Here, timber harvesting, grazing, and recreation are the predominant land uses (McGrath et al. 2002). The counties of Bonneville, Butte, Caribou, and Fremont in Idaho and Beaverhead, and Madison in southwestern Montana also offer abundant opportunities for outdoor recreation. Popular activities include fishing, hunting, hiking, horseback riding, off-highway vehicle use, skiing,

and sightseeing, which attract residents, as well as visitors from all areas of the United States (BLM, 2005b, 2008). In many communities, growth in tourism and recreation industries has largely outpaced historical land uses. The in-migration of residents who purchase smaller ranches or farms, but do not depend on the economic return from these activities as their primary source of income, has created conflict with long-time rural residents (BLM 2008).

Bear Lake County, which occupies the far southeastern corner of Idaho and the Wasatch and Uinta Range, has remained largely rural but serves also as an important destination for tourists and recreationists.

#### *County Land Use Plans*

BLM-administered, Forest Service-administered, and other federal lands in the Socioeconomic Study Area are intermingled with state and private lands. County governments have land use planning responsibility for the private lands located within their jurisdictions. County-level LUPs (also referred to as Comprehensive plans or Growth Policies) were identified for 26 of the 29 counties within the Socioeconomic Study Area (Adams County, 2006; Bingham County, 2005; Blaine County, 1994; Bonneville County, 2004; Camas County, 2006; Caribou County, 2006; Cassia County, 2006; Clark County, 2010; Custer County, 2006; Elmore County, 2004; Fremont County, 2008; Gem County, 2010; Gooding County, 2010; Jefferson County, 2005; Jerome County, 2006; Lemhi County, 2007; Lincoln County, 2008; Madison County, 2008; Minidoka County, 2001; Owyhee County, 2010; Payette County, 2006; Power County, 2009; Twin Falls County, 2008; Washington County, 2010; Beaverhead County, 2009; Madison County, 2006). Of the counties with identified LUPs, all had some form of economic development component, such as promotion of specific industrial sectors and natural resource use.

#### *Economic Conditions*

Economic analysis is concerned with the production, distribution, and consumption of goods and services. This section provides a summary of economic information, including trends and current conditions. It also identifies and describes major economic sectors in the Socioeconomic Study Area that can be affected by management actions. Most likely affected would be those economic activities that rely or could rely on BLM-administered lands, such as recreation and livestock grazing.

#### *Economic Sectors, Employment, and Personal Income*

The distribution of employment and income by industry sector within the Socioeconomic Study Area is summarized in **Table 3-62**, Employment by Sector within the Socioeconomic Study Area, and **Table 3-63**, Labor Income by Sector within the Socioeconomic Study Area (2010 dollars), below. See **Appendix Q** for equivalent data by county.

**Table 3-62**

<sup>1</sup>Professional and technical services activities require a high degree of expertise and training. Example activities include: legal advice and representation; accounting, bookkeeping, and payroll services; architectural, engineering, and specialized design services; computer services; consulting services; research services; advertising services; photographic services; translation and interpretation services; and veterinary services.

Sources: US Department of Commerce, 2012a. Values reported in 2001 dollars were converted to 2010 dollars using the Consumer Price Index (Bureau of Labor Statistics [BLS] 2012a).

<sup>1</sup>Industry earnings are reported as a share of total labor earnings. Dividends, interest, and rent; personal current transfer receipts; and contributions to government social insurance are reported as a share of personal income.

<sup>2</sup>Total labor earnings are reported by place of work.

<sup>3</sup>Non-labor income includes dividends, interest, and rent and personal current transfer receipts.

<sup>4</sup>"Personal current transfer receipts" are benefits received by persons for which no current services are performed. They are payments by government and business to individuals and institutions, such as retirement and disability insurance benefits.

<sup>5</sup>"Contributions for government social insurance" consists of payments by employers, employees, the self-employed, and other individuals who participate in the following government programs: Old-age, Survivors, and Disability Insurance; Medicare; unemployment insurance; railroad retirement; pension benefit guarantee; veterans' life insurance; publicly-administered workers' compensation; military medical insurance; and temporary disability insurance (US Department of Commerce 2012b).

<sup>6</sup>Total personal income is reported by place of residence.

With respect to employment by industry sector, the services-related sector accounted for the largest share (55.4 percent) of total employment in the Socioeconomic Study Area in 2010. This reflects a growth rate of 20.3 percent from 2001 (compared to an overall employment growth rate for all sectors of 10.1 percent from 2001). Compared to the services related sector, the non-services related sector and the government sector represented lower levels of employment, 21.9 percent and 14.2 percent, respectively. At the industry level, retail trade (10.6 percent) accounted for the largest share of employment of all industries in the Socioeconomic Study Area in 2010, followed by local government (9.6 percent), professional and technical services (6.3 percent), and health care and social assistance (6.2 percent). Although mining contributed a relatively small share of total employment within the study area in 2010, a notable proportion of total employment within Caribou County (21 percent) and Custerlark County (32 percent) came from the mining industry, according to estimates from Headwaters Economics (2013). The industries that demonstrated the largest growth between 2001 and 2010 were utilities, with an increase of 103.7 percent; real estate rental and leasing, with an increase of 64.3 percent; and transportation and warehousing, with an increase of 61.8 percent. The industries with greatest decrease in employment levels from 2001 to 2010 were management of companies and enterprises (decrease of 24.8 percent), manufacturing (decrease of 11.2 percent), and farming (decrease of 8.5 percent).

**Appendix Q** provides county-level employment figures. The greatest difference in industry sector proportion between counties in 2010 was in the professional and technical services industry. Professional and technical services contributed a low 1.5 percent of total employment in Power County, Idaho, but a much larger percentage in Butte County, Idaho (83.8 percent). Other industries also showed large variation in shares of employment across counties, including the farm industry (from 1.5 percent in Blaine County, Idaho, to 25.6 percent in Gooding County, Idaho) and the manufacturing industry (from 0.6 percent in Butte County, Idaho, to 24.8 percent in Power County, Idaho). Other counties identified as having relatively high employment shares in the farming industry include Lincoln County, Idaho (22.5 percent); Oneida County, Idaho (22.6 percent); and Owyhee County, Idaho (25.3 percent). The federal government industry also showed a high level of variation in shares across counties (from 1 percent in Blaine County, Idaho, to 35.5 percent in Elmore County, Idaho). However, in 24 of the 29 counties included in the Socioeconomic Study Area, the federal government contributed less than 5 percent of employment. Recreation-related economic activity, including the arts, entertainment, and recreation; retail trade; and accommodation and food services industries, varied across the counties (by 8.4 percentage points, 12.7 percentage points, and 16.7 percentage points, respectively). Note that these sectors are influenced not only by recreation but also by many other industries. See **Appendix Q** for individual county detail.

With respect to labor earnings, the services-related sector accounted for the largest share (48.4 percent) of labor earnings in the Socioeconomic Study Area in 2010, followed by the non-services related sector (25.0 percent) and the government sector (18.7 percent). In 2010, the individual industries that generated the largest shares of labor earnings included the professional and technical services industry (11.0 percent), farming (10.3 percent) and the local government industry (10.1 percent). Labor earnings associated with utilities almost

tripled during the 2001-2010 period. Other sectors showing strong trends of growth since 2001 include transportation and warehousing (58.1 percent) and health care and social assistance (48.5 percent). During the same time period, management of companies and enterprises, construction and recreation experienced the largest decline in earnings of all the industry sectors (declines of 50.0 percent, 18.6 percent and 18.3 percent, respectively).

**Appendix Q** provides county-level labor earnings figures. The county-by-county patterns are similar to those for employment, with relatively more variation in income from professional and technical services than from other industries; professional and technical services contribute the most to earnings in Butte County, Idaho at 93.5 percent. At the other end of the range, professional and technical services accounts for only 1.2 percent of earnings in Elmore County, Idaho and only 1.3 percent in Power County, Idaho. Of the counties for which data are provided (20 of 29), only two earn more than 10 percent of income from the professional and technical services industry. Farm income varied from a low share of -2.1 percent of total earnings in Adams County, Idaho to highs of 47.3 percent in Gooding County, Idaho, followed by 46.9 percent in Owyhee County, Idaho. Manufacturing income varied in proportion across the counties, from 0.2 percent of earnings in Butte County, Idaho to 32.9 percent in Power County, Idaho. Earnings from the mining sector are left undisclosed in 15 of the 29 counties included in the Socioeconomic Study Area due to confidentiality requirements. Furthermore, mining sector earnings figures are not provided for nine of the 29 counties because the earnings amounted to less than \$50,000 in those counties. For the counties for which data are available, earnings from mining range from 0.1 percent in Twin Falls County, Idaho to a share of 12.7 percent of total earnings in Caribou County, Idaho. Accommodation and food services contributes 0.1 percent of total earnings in Butte County, Idaho and up to 16.6 percent in Madison County, Montana. The other recreation and travel-related industries (i.e., retail trade and arts, entertainment, and recreation) contribute between 0.1 percent (arts, entertainment, and recreation in Elmore County, Idaho) and 16.2 percent (retail trade in Adams County, Idaho).

In addition to industry shares of labor earnings, another metric – residence adjustment – provides information about the economic conditions in the Socioeconomic Study Area. Residence adjustment represents the net inflow of the earnings of inter-area commuters. A positive number indicates that, on balance, area residents commute outside to find jobs; a negative number indicates that, on balance, people from outside the area commute in to find jobs. Jefferson County, Idaho's residence adjustment represented 27.8 percent of its total personal income, the highest share of all counties in the Socioeconomic Study Area. Gem County, Idaho had the second highest share (25.8 percent). Residence adjustment accounted for the most lowest share of total personal income in Butte County, Idaho (-701.3 percent), followed by Caribou County, Idaho (-22.1 percent). See **Appendix Q** for individual county detail.

**Appendix Q** provides employment and earnings data for Ada, Bannock, Boise, and Canyon Counties in Idaho, and Gallatin and Silver Bow Counties in Montana, which constitute a secondary study area as discussed in the introduction. In 2010, overall employment in the six-county secondary study area (472,046) was greater than overall employment levels in the 29-county primary socioeconomic study area (309,753). Earnings (by place of work) in the

six-county secondary study area were \$19,896, considerably larger than earnings in the primary socioeconomic study area (\$11,793). The impact analysis in the next chapter will document potential effects on the economy in the secondary study area, as well as for the 29 counties within the primary socioeconomic study area.

**Table 3-64**, Annual Unemployment, 2007 – 2011, presents the unemployment rates for each county in the Socioeconomic Study Area, as well as the rates for the counties aggregated and the States of Idaho and Montana. The data show that unemployment in the Socioeconomic Study Area matches or approximates that of the state for each of the years listed. At the county level, in 2011, the unemployment rates in the Socioeconomic Study Area ranged from a low of 5.0 percent in Owyhee County to a high of 17.3 percent in Adams County.

*Recreation*

An estimated 15.3 percent of the employment in the primary study area is related to travel and tourism (Headwaters Economics 2012). This estimate is based on data from the US Census Bureau County Business Patterns and includes industrial sectors that, at least in part, provide goods and services to visitors, the local economy, and the local population. This estimate includes both full- and part-time jobs. Most of these jobs are concentrated in the “accommodation and food services” and “retail trade” sectors. Jobs related to travel and tourism are more likely to be seasonal or part-time and are more likely to have lower average annual earnings than jobs in non-travel and tourism-related sectors. The average annual wage per travel or tourism related job is roughly half that of jobs not related to travel and tourism. In 2010 dollars, the average annual wage was \$14,820 in 2011 compared to \$31.315 for jobs not related to travel and tourism (Headwaters Economics 2013).

Although much of the recreation use on BLM-administered lands is dispersed and far from counting devices (e.g., trail registers, fee stations, and vehicle traffic counters), approximations of the number of visitors to BLM-administered lands can be obtained from the BLM Recreation Management Information Service database, in which BLM recreation specialists provide estimated total visits and visitor days to various sites within their field office boundaries. **Table 3-65**, Estimated Annual Visits by Planning Unit, summarizes BLM visitation data in each field office area for fiscal year (FY) 2011 (i.e., the year ending September 30, 2011), and Forest Service visitation data from Round 2 of the National Visitor Use Monitoring program.

Visitor expenditures can be approximated by using the BLM Recreation Management Information Service database and Forest Service National Visitor Use Monitoring program visitation data in conjunction with data from Forest Service, which has constructed recreation visitor spending profiles based on years of survey data gathered through the Forest Service National Visitor Use Monitoring program. Although the data are collected from National Forest visitors, the analysis that follows is based on the National Visitor Use Monitoring program profiles because the BLM has no analogous database. The profiles break down recreation spending by type of activity, day use versus overnight use, local versus non-local visitors, and “non-primary” visits (i.e., incidental visits where the primary purpose of the trip was other than visiting BLM-administered lands). **Table 3-66**, Visitor Spending from Recreation on BLM- and Forest Service-Administered Land in Socioeconomic Study Area, FY 2011, summarizes individual and party visits and expenditures by trip type and estimated direct expenditure.

As **Table 3-66** shows, the estimated total visitor spending on BLM- and Forest Service-administered lands in the Socioeconomic Study Area was about \$737.82 million in FY 2011. It is important to note that this includes expenditures from local residents and from visitors whose use of BLM-administered lands was incidental to some other primary purpose.

*Grazing*

Farming employed approximately 25,639 people in the Socioeconomic Study Area in 2010, accounting for 8.2 percent of total employment. The average annual wage for a farm job in the Study Area was \$27,565 in 2011 (in \$2010 dollars). This was lower than the average annual wage for a non-farm job (\$28,603) (Headwaters Economics 2013).<sup>4</sup>

~~Table 3-67~~ **Table 3-67, Farm Earnings Detail, 2010 (2010 dollars)**, presents the proportion of personal income originating from farm earnings and the farm cash receipts from livestock received throughout the Socioeconomic Study Area and Idaho and Montana as a whole. As shown in **Table 3-67**, agricultural services are an important contribution in several counties; however, in some counties the data are not released for confidentiality reasons.

**Table 3-67** shows the relative contribution of farm earnings across the counties in the Socioeconomic Study Area. Farm earnings constitute the largest share of total earnings in Camas, Cassia, Clark, Gooding, Jefferson, Jerome, Lincoln, Minidoka, Oneida, Owyhee and Twin Falls Counties. Both livestock and crops provide substantial cash receipts, with some variations across the counties. Though approximately 62.5 percent of farm cash receipts in the Socioeconomic Study Area come from livestock, many counties have significant percentages of farm cash receipts from crops, including Camas, Caribou, Clark, Gem, Madison, Minidoka, Oneida, and Power Counties.

<sup>4</sup> All dollar values were converted to 2010 dollars using the Consumer Price Index (BLS, 2012a).

**Table 3-68**, Active and Billed Animal Unit Months, provides information on active and billed AUMs on BLM-administered and Forest Service-administered land, for each of the BLM field offices and National Forest areas. The estimated gross receipts in the table are calculated from data from the USDA Economic Research Service (ERS), which publishes annual budgets for cow-calf operations for different production regions across the country (USDA ERS 2012). The BLM calculated a ten-year inflation-adjusted average gross receipt per cow-calf operation from the ERS budgets, then converted that information to a per-AUM figure based on average forage requirements for a cow including other livestock (e.g., bulls and replacement heifers) that are needed to support the production from the cow (Workman 1986). Southwest Montana falls into the Basin and Range region, whereas southern Idaho is in the ERS's Fruitful Rim region. The BLM's calculations resulted in a ten-year average gross receipt in the Basin and Range region of \$50.24 per AUM (2010 dollars), and in the Fruitful Rim region of \$30.29 per AUM (2010 dollars). However, the BLM used the higher value for both regions, both to err on the side of conservative analysis and because the characteristics of livestock grazing in southern Idaho seem more like those in southwestern Montana (and across southeast Oregon, Nevada, and Utah, which are also in ERS's Basin and Range region) than like those in the remainder of the Fruitful Rim (e.g., much of the California coast, western Oregon, and Washington State).

**Table 3-68**  
**Active and Billed Animal Unit Months**

Total	2,328,676								\$117.0

Sources: BLM 2012d; Forest Service 2012a, 2012c; Workman 1986; USDA ERS 2012

Thus, the table above reflects a gross receipt value of \$50.24 per AUM, and the last column of the table represents annual gross receipts in the region from livestock operations in 2010 dollars.

Gross receipts are calculated based on active AUMs and ten-year average gross receipts, as described in the text.

The data in the table help to demonstrate the importance of livestock grazing throughout the Socioeconomic Study Area. It is important to remember, as well, that the data are only for forage values on BLM-administered and Forest Service-administered lands; forage on other

public and private lands contribute additional values to the Socioeconomic Study Area. The economic analysis of the alternatives, presented in Chapter 4, addresses additional indirect contributions of livestock grazing (as well as other resource uses) to the regional economy, comparing the alternatives to one another.

#### *Forestry and Wood Products*

Approximately 1,570 jobs (1 percent of total employment in 2011) in the Socioeconomic Study Area came from timber-related industries, which is 0.3 percentage points higher than the national average of 0.7 percent (Headwaters Economics 2013). This estimate is based on data from the US Census Bureau County Business Patterns. The proportion of employment associated with timber-related industries varied by county, with a low of zero percent in Butte, Camas, Clark, Jerome, Lincoln, and Minidoka Counties and highs of 25.3 percent in Adams County, 8.8 percent in Washington County, 6.8 percent in Owyhee County, and 6.5 percent in Payette County. These estimates include both full- and part-time jobs and reflect three timber-related industries: growing and harvesting, sawmills and paper mills, and wood products manufacturing.

Average annual earnings for timber-related jobs tend to be higher than for non-timber jobs. The average annual wage per timber-related job in the Socioeconomic Study Area in 2011 was \$35,521 (2010 dollars), compared to \$29,971 for non-timber jobs.<sup>5</sup>

#### *Mining and Minerals*

The data in **Table 3-69**, Mining Sector Employment by County, show that within the 29 counties included in the Socioeconomic Study Area, mining industries employed 1,248 people in 2010, accounting for approximately 0.4 percent of total employment, which is 0.3 percentage points higher than the national average (Headwaters Economics 2012). Mining industries include those for phosphate, metals, building stone quarrying, sand and gravel quarrying, geothermal exploration and development, oil and gas exploration, and mining-related businesses. The proportion of employment associated with mining industries varied by county, from zero percent in 12 of the counties up to 30.4 percent of total employment in Custer County and 22.7 percent of total employment in Caribou County. The average annual earnings per mining-related job in the Socioeconomic Study Area are higher than non-mining jobs. The average annual wage per job in this sector was \$56,239 (2010 dollars) in the Socioeconomic Study Area in 2011, compared to an average of \$33,926 for private sector jobs (Headwaters Economics, 2013). States receive 50 percent of all rents and royalties collected from mineral extraction on public lands. In FY2012, \$10 million was collected in Idaho (the state received \$5 million).

Phosphate mining in Caribou County for BLM-administered phosphate raw ore produced 4.2 million units for a sales total of \$167.4 million in 2011 (ONRR 2012). There are currently three companies operating mines and processing plants who employ over 1,800 people, in mines or plants (BLM 2013). Although some of the richest silver-producing regions in the

Source: Headwaters Economics 2012.

All dollar values were converted to 2010 dollars using the Consumer Price Index (BLS 2012a).

US are in the northern Idaho panhandle (outside the Socioeconomic Study Area), the study area does produce some silver, along with industrial minerals such as molybdenum (Idaho Mining Association 2010). Idaho has several large stone quarries that support the rural communities of Oakley (Cassia County) and Challis (Custer County). It is estimated that

approximately 40,000 tons of Oakley Stone are mined annually from unpatented mining claims in southern Idaho/northern Utah (not including patented claims). Approximately 60 people are employed full-time from these operations, and an additional 100 to 200 skilled laborers are employed during the summer months (BLM 2013d).

#### *Other Values*

BLM-administered lands provide a range of goods and services that benefit society in a variety of ways. Some of these goods and services, such as timber and minerals, are bought and sold in markets, and hence have a readily observed economic value (as documented in the sections above); others have a less clear connection to market activity, even though society derives benefits from them. In some cases, goods and services have both a market and a non-market component value to society. This section provides an overview of several non-market values described through a qualitative and quantitative economic valuation analysis.

The non-market values associated with BLM-administered lands can be classified as values that derive from direct or indirect use (e.g., recreation) and those that do not derive from use, such as existence values held by the general public from self-sustaining populations of GRSG. This section and the related appendix describe the use and nonuse economic values associated with recreation, populations of GRSG, and land that is currently used for livestock grazing and ranch operations. The sections that follow discuss each of these values in turn. **Appendix R** provides more discussion of the concepts and measurement of use and nonuse nonmarket values. It is important to note that these nonmarket values are not directly comparable to previous sections that describe output (sales or expenditures) and jobs associated with various resource uses on BLM-administered and Forest Service-administered lands (see **Appendix R** for more information).

#### *Values Associated with Recreation*

Actions that promote the conservation of GRSG habitat may result in changes in recreation activity, by changing opportunities or access for different recreational activities. Opportunities for some activities such as wildlife viewing may increase as the amount of habitat may increase for species that depend on BLM-administered lands, including GRSG. The Environmental Consequences analysis (**Chapter 4**) addresses this issue for each of the management alternatives. This section documents baseline nonmarket values visitor receive associated with recreation activities. This is measured by what economists call consumer surplus, which refers to the additional value that visitors receive over and above the price they pay. **Appendix S** provides an explanation of consumer surplus. Fees to use BLM-administered lands for recreation are typically very low or nonexistent, so the value people place on BLM-administered land recreation opportunities is not fully measured simply by the entrance fees people pay.

Economists estimate the consumer surplus from recreation by measuring how the variation in visitors' travel costs corresponds to the number of visits taken. This "travel cost method" has been developed extensively in academic literature and is used by federal agencies in economic analyses; the method is explained more fully in **Appendix R**. Conducting original travel cost method studies can be time-consuming and expensive. For this project, the BLM

and Forest Service relied on estimates of consumer surplus from prior recreation studies in the same geographic region, using an established scientific method called “benefit transfer.” Based on the studies reviewed and cited in **Appendix R**, visitors to natural areas, such as BLM-administered and Forest Service-administered lands, gain values (in excess of their direct trip cost) ranging from approximately \$32 per day for camping, to about \$175 per day for mountain biking.

To calculate the aggregate “consumer surplus” value of recreation in the study area, BLM multiplied this per-day value of recreation by the estimated number of visitor days associated with each activity type. Visitation estimates by activity are derived based on the BLM Recreation Management Information Service database and the Forest Service National Visitor Use Monitoring program for the study area.

Accounting for the value per day and the number of days, the total nonmarket value of recreation on BLM- and Forest Service-administered lands in the study area was estimated to be about \$431.8 million per year (see **Appendix S** for details). Based on the quantity of recreational trips and the economic value of each type of activity, the largest annual nonmarket values are associated with hunting, camping, fishing, hiking, sightseeing, floatboating/rafting/canoeing, and pleasure driving. These categories omit downhill skiing, because there is little or no overlap between GRSG habitat and lands used for downhill skiing. The Environmental Consequences section (**Chapter 4**) discusses how recreational visits and total nonmarket value for recreation may change under the alternatives being considered.

#### *Values Associated with Populations of GRSG*

The existence and perseverance of the Endangered Species Act and similar acts reflects the values held by the American public associated with preventing species from going extinct. Economists have long recognized that rare, threatened and endangered species have economic values beyond those associated with active “use” through viewing. This is supported by legal decisions and technical analysis (see **Appendix R** for details), as well as a number of conceptual and empirical publications that refine concepts and develop methods to measure these nonuse or existence values.

The dominant method uses surveys to construct or simulate a market or referendum for protection of areas of habitat, or changes in populations of species. The survey asks the respondent to indicate whether they would pay for an increment of protection, and if so how much they would pay. Economists have developed increasingly sophisticated survey methods for nonuse value over the last two decades to improve the accuracy of this method. **Appendix R** offers an in-depth discussion of this method of value estimation.

Original surveys to estimate nonuse values are complex and time-consuming; rather than perform a new survey, the BLM and Forest Service reviewed existing literature to determine if there were existing nonuse value studies for GRSG. No existing studies on valuation specific to the GRSG were found. However, there are several studies published in peer-reviewed scientific journals for bird species that the BLM judged to have similar characteristics with GRSG, including being a candidate for listing as threatened or

endangered and being a hunted species. These studies find average stated willingness to pay of between \$15 and \$58 per household per year in order to restore a self-sustaining population or prevent regional extinction (see **Appendix S** for details). These values represent a mix of use and nonuse values, but the nonuse components of value are likely to be the majority share, since the studies primarily address species that are not hunted. Since GRSG protection is a public good available to all households throughout the intermountain west, if similar per-household values apply to the species the aggregate regional existence value could be substantial.

#### *Values Associated with Grazing Land*

BLM-administered land managed for livestock grazing provides both market values (e.g., forage for livestock) and nonmarket values, including open space and western ranch scenery, which provide value to some residents and outside visitors, and may also provide some value to the nonusing public (e.g., the cultural icon of the American cowboy). Many people who ranch for a living or who otherwise choose to live on ranches value the ranching lifestyle in excess of the income generated by the ranching operations. This could be seen as a nonmarket value associated with livestock grazing. On the other hand, some residents and visitors perceive nonmarket opportunity costs associated with livestock grazing. Although some scholars and policy makers have discussed nonmarket values associated with livestock grazing, the process for incorporating these values into analyses of net public benefits remains uncertain, and the BLM and Forest Service did not attempt to quantify these values for the present study.

Furthermore, some of the lifestyle value of ranching is likely to be captured in markets, such as through the property values of ranches adjacent to BLM-administered lands with historic leases or permits for grazing on BLM-administered land. Economists typically use a method called the hedonic price method to estimate values associated with particular amenities; this method may be used to explain the factors that influence the observed sale prices of ranch land. **Appendix R** provides more information about this method, as well as additional information to address potential nonmarket values associated with grazing.

#### *Fiscal*

Most of Idaho's tax revenue comes from three sources: income, sales and use, and property taxes (US Census Bureau 2010d). The Idaho State Tax Commission collects income tax and sales and use tax, while property taxes fund local governments and are imposed and collected by the county where the property is located. Idaho imposes a sales and use tax of 6 percent, a corporate net income tax of 7.6 percent, and an individual income tax rate that ranges from 1.6 percent to 7.8 percent. States receive 50 percent of rents and royalties collected from federal mineral leases. In 2012, \$4.6 million was disbursed to the State and individual counties, primarily from phosphate royalties, but also from geothermal rent (BLM 2013f). In addition, Idaho imposes a severance tax rate of 2 percent of the market value of oil and gas produced or sold in the state. It also imposes a mine license tax of 1 percent of the value of ores mined or extracted, which accounted for approximately \$2.5 million in tax revenue in 2011 (Idaho State Tax Commission 2011).

Idaho's counties receive most of their revenue from property taxes, charges for local services and redistribution of State and Federal sources. In 2009-2010, Idaho counties received approximately 25 percent of their revenues from property taxes, 25 percent from charges, and 40 percent from state government intergovernmental transfers (US Census Bureau 2010e). Major sources of state funds received by counties include state liquor revenues, highway user taxes and fees, sales taxes and education funds and endowments (Idaho Association of Counties 2011). Public elementary and secondary schools received, in 2008-2009, approximately 67 percent of their resources from state sources, 10 percent from federal funds, and 23 percent from local funds, mostly property taxes (National Center for Education Statistics 2012).

The largest source of revenue in Montana is the individual income tax. The second largest source is severance and other taxes (US Census Bureau 2010d), although most of the mineral production in Montana is outside the Socioeconomic Study Area for this sub-region. Two-thirds of the severance and other taxes category is made up of an oil and gas production tax, with the remainder of the category being composed of mining taxes and other miscellaneous taxes. While it is collected at the state level, about half of the oil and gas tax is distributed to local governments and school districts. Montana does not have a general sales tax, but selective sales taxes account for about 14 percent of state tax revenue (Montana Department of Revenue 2010).

In Montana, local government and school district tax collections come almost entirely from property taxes. Local jurisdictions also collect a coal gross proceeds tax, a local severance tax that imposes a flat tax on the value of production so that all mines pay the same rate (Montana Department of Revenue 2010).

The primary government revenues that are directly linked to BLM- and Forest Service-administered lands are Payments in Lieu of Taxes, which are federal government payments based on the presence of all federal lands (not just BLM-administered lands) within each county. **Table 3-70, [Payments in Lieu of Taxes \(PILT\) Received in the Socioeconomic Study Area by County in 2010](#)**~~Payments in Lieu of Taxes (PILT) Received in the Socioeconomic Study Area by County in 2010~~, shows the payments each county received in 2010. The nontaxable status of federal lands is of interest to local governments, which must provide public safety and other services to county residents. BLM revenue-sharing programs provide resources to local governments in lieu of property taxes because local governments cannot tax federally owned lands the way they would if the land were privately owned.

Other federal payments to states, counties, and public schools associated to the presence of federal lands include Forest Service revenue transfers and federal mineral royalties. Since 2008, the Forest Service pays 25 percent of its receipts to states for use on roads and schools in the counties where national forests are located. The decline in the sale of timber from Federal lands over time has led to the decline in these payments. However, Secure Rural Schools and Community Self-Determination Act of 2000 has attempted to limit this decline (Congressional Research Service 2012). Idaho and Montana also receive federal mineral royalties from mining activities on federal land. In Idaho, 90 percent of these receipts are

distributed to the Public School Income Fund and the other 10 percent are distributed to the

general fund of the counties where the revenue was generated. In Montana, 25 percent of federal mineral royalties are distributed to counties (Headwaters Economics 2011). Other revenues from federal lands include fees for grazing, recreation, and rents on ROWs.

*BLM Expenditures and Employment*

BLM offices provide a direct contribution to the economy of the local and surrounding area. BLM operations and management make direct contributions to area economic activity by employing people who reside within the area and by spending on project related goods and services. Contracts for facilities maintenance, shuttling vehicles, and projects contribute directly to the area economy and social stability as well. **Table 3-71**, BLM and Forest Service Employment and Related Expenditures in the Socioeconomic Study Area, provides available information on the BLM expenditures from each field office, including both labor and nonlabor expenditures.

**Table 3-71

*Environmental Justice*

Environmental justice pertains to the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment means that no group of people, including racial, ethnic, or socioeconomic groups, should bear a disproportionate share of the adverse environmental consequences resulting

from industrial, municipal, and commercial operations or the execution of federal, state, local, and Tribal programs and policies). The BLM and Forest Service incorporate environmental justice into its planning process, both as a consideration in the environmental effects analysis and by ensuring a meaningful role in the decision-making process for minority and low-income populations.

Executive Order 12898 requires federal agencies to “identify and address the disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations.” The BLM Land Use Planning Handbook reiterates the BLM’s commitment to environmental justice – both in providing meaningful opportunities for low-income, minority, and Tribal populations to participate in decision-making, and to identify and minimize any disproportionately high or adverse impacts on these populations. Similarly, the US Department of Agriculture’s Departmental Regulation on Environmental Justice provides direction to agencies for integrating environmental justice considerations into USDA programs and activities, including those of Forest Service. Specifically, the Departmental Regulation on Environmental Justice calls for the identification, prevention, and mitigation of disproportionately high and adverse human health or environmental effects of USDA programs and activities on minority and low-income populations and provision for the opportunity for minority and low-income populations to participate in planning, analysis, and decision-making that affects their health or environment.

According to the Council on Environmental Quality Environmental Justice Guidance Under the National Environmental Policy Act (CEQ 1997), “minority populations should be identified where either: (a) the minority population of the affected region exceeds 50 percent or (b) the minority population percentage of the affected region is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis.” The same document states that, “In identifying low-income populations, agencies may consider as a community either a group of individuals living in geographic proximity to one another, or a set of individuals (such as migrant workers or Native Americans), where either type of group experiences common conditions of environmental exposure or effect.”

Additionally, the same guidance (CEQ 1997) advises that, “In order to determine whether a proposed action is likely to have disproportionately high and adverse human health or environmental effects on low-income populations, minority populations, or Indian tribes, agencies should identify a geographic scale, obtain demographic information on the potential impact area, and determine if there is a disproportionately high and adverse effect on these populations. Agencies may use demographic data available from the Bureau of the Census to identify the composition of the potentially affected population. Geographic distribution by race, ethnicity, and income, as well as a delineation of tribal lands and resources, should be examined.”

*Minority Populations*

**Table 3-72**, Population Race and Ethnicity, 2010, summarizes the percentage of the population made up of ethnic minority groups in each county of the Socioeconomic Study Area and in the State of Idaho, the State of Montana, and the United States as a whole.

**Table 3-72**

<sup>1</sup> Individuals who identify themselves as Hispanic or Latino might be of any race; the sum of the other percentages under the “Percent of Total Population” columns plus the “Hispanic or Latino” column therefore does not equal 100 percent, and the sum of the percentages for each racial and ethnic category does not equal the percentage of “total minorities”.

<sup>2</sup> The total minority population, for the purposes of this analysis, is the total population for the geographic unit analyzed minus the non-Latino /Hispanic white population.

Of the 27 Idaho counties in the Socioeconomic Study Area, 14 have a higher minority population than Idaho as a whole, while neither of the 2 Montana counties in the Socioeconomic Study Area have a higher minority population than Montana as a whole. The percentage of minorities among counties ranges from a low of 4.6 percent in Madison County, Montana, to a high of 42.9 percent in Clark County, Idaho. Several Idaho counties have a Hispanic or Latino population greater than 25 percent, with the highest being Clark County (41 percent). Additionally, Montana as a whole has a high percentage of Alaska Native or American Indian residents (6.3 percent), though neither of the Montana counties included in the study area have a population of this minority group higher than 2 percent.

*Low-income Populations*

**Table 3-73**, Low-Income Populations, 2006-2010 Average, summarizes the percentage of the population below the poverty line in each county of the Socioeconomic Study Area and in Montana, Idaho, and the United States as a whole. Following the Office of Management and Budget’s Directive 14, the Census Bureau uses a set of money income thresholds that

vary by family size and composition to detect what part of the population is considered to be in poverty (US Census Bureau 2012b).

Of the 27 Idaho counties in the Socioeconomic Study Area, 14 have a higher percentage of residents below the poverty line than Idaho overall (13.6 percent), and 1 of the 2 Montana counties has a higher percentage of residents below the poverty line than Montana as a

**Table 3-73**

Source: US Census Bureau 2010c

whole (14.5 percent). Both Idaho and Montana have a higher percentage of residents above the poverty line than the United States as a whole (13.8 percent). The percentages of residents below the poverty line range from a low of 8.4 percent in Caribou County, Idaho, to a high of 32.2 percent in Madison County, Idaho.

#### *Tribal Populations*

Five Native American reservations in the State of Idaho are home to federally recognized tribes. These reservations comprise almost 2 million acres in trust. The Shoshone-Bannock Tribe of the Fort Hall Indian Reservation (Bannock, Bingham, Caribou, and Power Counties) and Shoshone-Paiute Tribe of the Duck Valley Indian Reservation (Owyhee County) are located within the Socioeconomic Study Area. Other tribes outside the Socioeconomic Study Area include Coeur d'Alene in Benewah and Kootenai Counties; Kootenai in Boundary County; and Nez Perce in Clearwater, Idaho, Latah, Lewis, and Nez Perce Counties (Rodríguez 2011).

Several major tribes live in Montana: the Blackfeet nation, the Confederated Salish, the Pend d'Oreille, the Kootenai, the Assiniboine, the Sioux, the Northern Cheyenne, the Crow Nation, the Gros Ventre, and the Little Shell Chippewa (Montana Office of Indian Affairs 2011). However, none of these tribes' reservations are located in or near the Socioeconomic Study Area.

#### **3.24 Forest and Woodland Products**

The NEPA, the FLPMA, the Water Quality Act of 1987, as amended from the Federal Water Pollution Control Act (Clean Water Act) of 1977, the Endangered Species Act of 1973, and the Archaeological Resources Protection Act of 1979 direct the protection and management of forest management and woodland products on BLM-administered lands. The FLPMA directs that BLM-administered lands be managed on the basis of multiple use and sustained yield without the permanent impairment of the productivity of the land and the quality of the environment. Guidance provided under FLPMA applies to those forested lands containing what is traditionally referred to as timber lands, capable of producing in excess of 20 cubic feet per acre per year; as well as woodlands, those forested lands producing less than 20 cubic feet per acre per year; and other vegetative material, or those lands containing cactus and other salable vegetation which were not previously covered by management policy. Other salable vegetation includes Christmas trees and plant seed. BLM forest management policy and requirements are identified in the BLM Forest Management regulations (43 CFR Part 5000).

In the analysis area there are approximately 368,000 acres of BLM-administered forest land; 250,000 acres of BLM-administered forest land (timberland) available for commercial management; 353,000 acres of BLM-administered woodland; and 197,000 acres of BLM-administered woodland available for commercial management.

In the analysis area, annual production of commercial product from timberlands has averaged approximately 2,877 thousand board feet (MBF) per year. Annual production of special forest products (wood) in the past ten years has averaged approximately: 4 MBF per year for sawtimber; 490 MBF for fuel wood; 8 MBF per year for fence posts; 11 MBF per

Idaho and Southwestern Montana  
Draft LUPA/EIS

year for fence poles; and 1 MBF per year for other wood products (such as mine timbers and teepee poles). Annual production of special forest products (nonwood, such as Christmas trees) in the past 10 years has averaged approximately 379 tickets per year.

**Subject:** RE: Webinar recap

Hi Brent,

I'm pretty much around and free to have the webinar anytime next week. If I don't hear anything this week, I'll coordinate with Nika directly and make it happen next week. I'll also incorporate your suggestion regarding anthropogenic disturbance, adaptive management, and coordination.

Also, if you have any of the appendices associated with the proposed plan, particularly the seasonal timing restrictions, buffers, and adaptive management components, please send those along. I think they will be useful for the effects analysis. And of course the acreages of allocations table when it's ready.

Meredith

Meredith,

Here are my thoughts. I think the coordination approach you have will work. As for the pieces of the GRSG assumptions that need revisited – that may need to be the first topic for the GRSG group, I don't think there is a need to involve the whole group again. The discussion on anthropogenic disturbance and the 3% that I instigated – after looking at the template I think it would be better dealt with as part of a section or heading – Anthropogenic Disturbance, Adaptive Management and Coordination. These three topics tie together in the management actions especially in the proposed plan and if we discussed these as a separate or additional section in each alternative that would get at the comment I was trying to forward in the assumptions. We could take that out of the assumptions or include an assumption that is more holistic such as – To the extent lands are subject to adaptive management and/or an anthropogenic disturbance cap effects of threats would be further restricted based on the applicable thresholds and caps. Coordination between State and Federal managers would further ensure the application and implementation of these thresholds and caps.

I'll be out of the office after the 4<sup>th</sup>, and we need to get some input on the other assumptions – livestock/range and wild horses primarily. I may have some time Wednesday the 8<sup>th</sup> but am unavailable for such a call on Monday, Tuesday or Thursday next week. Could you take the lead in setting something up with the team and especially Nika? I have a few comments on those assumptions that I'll pass along if I can't call-in.

Brent Ralston  
Greater Sage-Grouse Planning Lead

**To:** Brent Ralston  
**Subject:** Webinar recap

Hi Brent,  
Attached are the revised assumptions from our webinars this week. It looks like we may need to revisit some of the GRSG ones. I've also attached a draft Chapter 4 proposed plan template with some notes. Please provide feedback to let me know what you think.

In terms of the coordination calls with EMPSi and BLM/FS, I was going to advise my resource specialists to review the impacts from the proposed plan on their resource, going through the proposed plan resource by resource to identify the main impacts with BLM/FS. The Chapter 4 template could be used to document that all topics were addressed. Any additional literature to be incorporated will also be noted. In addition, we would identify any changes that need to be made based on the public comments. It may be useful to have the coordination calls as webinars or lync screen shares to ensure EMPSi captures the main impacts. I will have the EMPSi specialists send out doodle polls to see about having these calls the week of July 7<sup>th</sup>. Do you think this approach will work?

Thanks,  
Meredith

## 1.1 Special Status Species – Greater Sage-Grouse

### 1.1.1 Methods and Assumptions

This analysis is organized by threats to GRSG as categorized in the USFWS's *12-Month Findings for Petitions to List the Greater Sage-Grouse (Centrocercus urophasianus) as Threatened or Endangered* (USFWS 2010a).

#### ***Indicators***

Indicators of impacts on GRSG are as follows:

- Acres of sagebrush
- Direct habitat loss
- Habitat fragmentation
- Disruption to species life history requirements
- Population loss
- Habitat degradation
- Habitat restoration/improvement

Effects listed above may be characterized for each resource and alternative, as appropriate, and, where available, quantified by the indicators described below:

- Identified GRSG Habitat (PPH and PGH) – Identified habitat includes habitats considered vital to the persistence of GRSG populations at all scales. Acres impacted or improved by each resource is a general metric for acres of sagebrush, direct habitat loss, habitat degradation, and habitat restoration/improvement. The metrics provide a basis for a qualitative discussion of habitat loss and fragmentation and species life history requirements.
- Populations – Metric is strongly correlated to nesting habitat since radioed hens tend to nest within several miles of their lek of capture (Connelly et al. 2000). In Idaho lek to nest distances may vary spatially over large landscapes but roughly 80 percent of nests occur within 8 to 12 kilometers of the lek of capture (Connelly et al. 2013). The metric is derived by quantifying for each GRSG population area, the number of occupied leks in 2011, reflecting lek attendance by at least 2 males during at least one of the prior 5 years (2007-2011). This metric provides general insight into the population contribution of specific population areas relative to the sub-region overall, providing additional context for comparison. The metric also allows for inferences of risk to population persistence from certain threats or resource allocations (such as areas open to ROWs or mineral leasing), assuming that population areas with a smaller number

of occupied leks are more vulnerable to resource activities and that areas with a greater number of occupied leks imply larger populations and a greater opportunity for long term persistence, given effective conservation efforts (see **Section 3.2**). Where land or resource allocations overlap population areas and/or occupied leks, the allocation is considered to be affecting the grouse population, for purposes of analysis. **Table 4-1**, Resource Programs Impacting GRSG by Threat in the Sub-region, relates individual resource programs to threats to the species in order of priority within the sub-region. Impacts from each resource are assessed using the indicators described above.

- Areas of potential development – potential for habitat degradation/fragmentation/edge effect. Anthropogenic disturbance tables. % of anthropogenic disturbance and what is projected under each alternative (how to calculate this?). We have this number for Alt A. Use the RFD and management actions for each alternative to project the effects on disturbance. Clearly state your assumptions. (e.g., Alt A assume future development would occur in Core, but for Alt B, development would occur outside of Core). Table showing which alternatives would add to 3% disturbance cap and which would not (zero additive). **Revisit!**
- Habitat suitability – measured by VDDT, driven by sagebrush canopy cover and lack of conifer encroachment.

**Table 4-1**  
**Resource Programs Impacting GRSG by Threat in the Sub-region**

Threat/Issue	Resource Program
Wildfire	Fire, Fuels, Vegetation
Invasive Species	Fire, Fuels, Vegetation
Infrastructure	ROW Avoidance/Exclusion Areas, ACECs, Wilderness, Wilderness Study Areas
Energy Development	Areas Open/Closed to Fluid Mineral Exploration, Leasing and Development
Human Uses	ROW Avoidance/Exclusion Areas, ACECs, Wilderness, Wilderness Study Areas, areas Open, Limited or Closed to off road motorized travel
Conifer Encroachment	Fire, Fuels, Vegetation
Climate Change	Climate Change, Fire, Fuels, Vegetation
Livestock Grazing	Areas Open/Closed to Livestock Grazing
Mining	Areas Open/Closed to locatable and salable minerals

**Assumptions**

Three general categories of human disturbance (to habitats) or disruption (to animals) would be the most influential on GRSG and their habitat: 1) disturbance or disruption from casual use; 2) disturbance or disruption from permitted activity; and 3) changes in habitat condition, such as from fire or presence of noxious weeds and invasive species.

The assumptions listed below are intended for large-scale planning-level analysis; project-level assumptions for NEPA may differ.

The analysis includes the following assumptions:

- ~~GRSG Management Zone Designations are assumed to represent habitat adequate to maintain GRSG populations in the sub region. For Idaho, GRSG Habitat Designations were derived from modeling efforts completed in 2012, based on 75 percent Breeding Bird Density and 75 percent lek connectivity models as well as known winter habitat, connectivity considerations and other factors. In Montana, GRSG Habitat Designations were derived from habitat modeling of core areas by MTFWP with additional input by the BLM.~~
- ~~Insert bullet that describes Alternative G map.~~
- This analysis uses PPH and PGH categories for Alternative A only to facilitate comparison across the other alternatives. There are currently no BLM- or Forest Service-administered lands designated as GRSG PPH or PGH within the sub-regional planning area, and Alternative A would neither result in the designation of PPH or PGH nor assign additional management actions to PPH or PGH areas.
- Population and subpopulation boundaries (Connelly et al. 2004) were modified to include the entirety of mapped GRSG Management Zone Designations in the vicinity. (See **Section 3.2**).
- Habitat conditions and trends for each GRSG population area were determined by modeling vegetation dynamics such as wildfire, succession, insects and disease, habitat restoration projects (e.g., sagebrush seeding, grass seeding, and herbicide treatment of annual grass), prescribed fire, overgrazing, conifer encroachment and treatment, mechanical sagebrush treatment, and fuels reduction projects using the Vegetation Dynamics Development Tool (VDDT). Modeling was completed for population areas in Idaho, Utah (Sawtooth National Forest portion only), and southwestern Montana. Initial population areas from Connelly et al. (2004) were considered, but some were ultimately combined or delineated further, to accommodate similarities in vegetation models or disturbance regimes.
- Because GRSG are highly sensitive to habitat fragmentation, development, or changes in habitat conditions and require large, intact habitat patches to complete their annual life history, alternatives proposing to protect the most GRSG Habitat from disturbance are considered of greatest beneficial impact. These impacts can be described both qualitatively and quantitatively.
- Seasonal ranges of migratory and non-migratory GRSG are largely encompassed within GRSG Management Zone Designations but are not consistently mapped across the subregion to provide an assessment of direct impacts.

**Deleted:** Habitat

**Deleted:** Habitat

**Comment [MZ1]:** Revisit this bullet.

**Deleted:** Habitat

**Deleted:** sufficiently

- GRSG Management Zone Designations encompass adequate habitat for providing connectivity within populations and subpopulations. ~~Connectivity will be considered by incorporating population area scale information in the design and implementation of restoration projects.~~

**Deleted:** Habitat

Impacts on GRSG accrue over varying distances from origin depending on the type of development:

- Impacts from transmission lines constructed before 2002 are likely fully manifested. Therefore, co-locating new lines would have no additional long-term measurable impacts if the habitat disturbance were not to exceed the width of the existing right-of-way. BMPs, RDFs, COAs, and standard operating procedures are used for analysis and would be implemented to reduce impacts on GRSG. These are subject to modification based on subsequent guidance and new science.
- Ground-disturbing activities could positively or negatively modify habitat or cause loss or gain of individuals, depending on the size of the area disturbed, the nature of the disturbance, the species affected, and the location of the disturbance; for example, juniper reduction treatments disturb the ground but could positively modify habitat in the long term.
- A 4.25-mile (6.9-kilometer) foraging distance is assumed to adequately encompass possible direct and indirect effects for both nesting and roosting avian predators (Boarman and Heinrich 1999; Leu et al. 2008) in instances where increased predation from human infrastructure (e.g. power lines, wind turbines, communication towers, agricultural and urban development) is a threat.
- Energy extraction such as oil and gas, geothermal, and plan of operation mining can cause impacts up to 11.8 miles (19 kilometers) based on direct impacts of field development, including associated infrastructure, noise, lighting, and traffic (Johnson et al. 2011; Taylor et al. 2012).
- Interstate highways at 4.7 miles (7.5 kilometers) and paved roads and primary and secondary routes can cause impacts at 1.9 miles (3 kilometers) based on indirect effects measured through road density studies (Connelly et al. 2004; Holloran 2005; Lyon 2000).
- Site-specific disturbances such as small-scale mining and mineral material sites can cause impacts at 1.6 miles (2.5 kilometers) based on indirect influence distance from estimated spread of exotic plants (Bradley and Mustard 2006).

**Deleted:** C

**Comment [M22]:** driven by foraging outside of the nesting season – different impact than foraging nesting ravens (forage in a smaller area). May need to reword.

**Deleted:** avian predator

**Deleted:**

**Comment [M23]:** Move last 4 bullets to nature and type of effects section.

Short-term impacts would accrue over a timeframe of up to 10 years. Long-term impacts would accrue over timeframes exceeding 10 years.

## 1.2 Lands and Realty

### 1.2.1 Methods and Assumptions

#### Indicators

Indicators of impacts on lands and realty are as follows:

- Acres of surface ownership in the planning area
- ~~Acres of ROW allocations (e.g., exclusion, avoidance, open)~~
- ~~Acres of ROW restrictions (e.g., BMPs, RDFs, seasonal restrictions, buffers)~~
- ~~Acres/miles of designated ROW corridors open to ROW development~~
- Number and ~~acres~~ of surface-disturbing ROWs and leases
- ~~Acres~~ of land tenure adjustments (i.e., lands identified as suitable for disposal, acquisition, or exchange)

#### Assumptions

This analysis includes the following assumptions:

- Authorized ROWs, ~~permits and leases~~, would be managed ~~subject to~~ valid existing rights
- ~~Activities on dispersed private parcels within the planning area would continue to require new or upgraded services for small distribution facilities, including communication sites, roads, and utilities.~~
- ~~Power~~ lines and other vertical structures in areas naturally devoid of perching opportunities provide a perch for raptors and increase the potential for GRSG to abandon leks (Ellis 1984). Mitigation by burying lines or including design features that do not encourage perching on lines would reduce perching opportunities and subsequent impacts on GRSG (Connelly et al. 2000).
- The demand for both energy- and nonenergy-type ROWs is anticipated to remain steady or gradually increase over time.
- ~~No utility-scale (20 MW) solar energy ROWs are anticipated due to low solar energy potential.~~
- ~~Activities proposed or approved for mineral exploration or development have potential implications for lands and realty decisions for associated ROWs.~~
- ~~Maintaining and upgrading ROWs is preferred before the construction of new facilities in the decision area, but only if the upgrading can be accommodated within or next to the existing ROW.~~
- ~~Collocating new infrastructure in existing ROWs is preferred over creating new ROWs. Collocation does not eliminate the potential for new temporary or permanent surface disturbance.~~

**Deleted:** restrictions (i.e., avoidance or exclusion areas)

**Deleted:** types

**Deleted:** , including communication sites

**Deleted:** Number

**Deleted:** and type

**Deleted:** and landownership

**Comment [MZ4]:** Peter will check to see if we should include withdrawals.

**Deleted:** withdrawal,

**Deleted:** , purchase, donation, or ROW acquisition

**Deleted:** s

**Deleted:** and communication sites

**Deleted:** to protect

**Deleted:** , as long as those ROWs comply with the terms and conditions of their ROW grant

**Comment [MZ5]:** Move to RFDS

**Deleted:** <#>On renewal, assignment, or amendment of existing ROWs, permits, and leases, additional stipulations could be included in the land use authorization.¶

**Comment [MZ6]:** Duplicate this in the GRSG section.

**Deleted:** (including communication sites)

**Deleted:** Little to n

**Comment [MZ7]:** Incorporate into screening criteria in proposed plan

**Deleted:** <#>Geothermal energy development may occur during the life of the LUP but would be localized, and the number of ROW authorizations is anticipated to be less than those for wind. ¶

**Deleted:** utilities, communication sites, and other

**Deleted:** <#>Demand for small distribution facilities to extend and upgrade services, such as communication sites and utilities, is anticipated to increase as rural development occurs on dispersed private parcels within the planning area.¶ <#>The number of ROW applications for new communication and computer technology, such as fiber optic cable, is anticipated to continue to increase.¶

**Comment [MZ8]:** Move to proposed plan.

**Deleted:** The BLM and Forest Service

**Deleted:** c

**Deleted:** likelihood

- The BLM and Forest Service would continue to manage all previously withdrawn lands as withdrawn from entry, appropriation, or disposal under the public land laws. Withdrawals would be reviewed as needed and recommended for extensions, modifications, revocations, or terminations. All existing withdrawals initiated by other agencies ~~would be continued unless the initiating agency, BLM, or the Forest Service requests that the withdrawal be extended, modified, revoked, or terminated.~~
- Any lands that become unencumbered by withdrawals or classifications will be managed according to the decisions made in this LUPA. If the LUPA has not identified management prescriptions for these lands, they will be managed the same as adjacent or comparable public lands within the decision area.
- Designated utility corridors have a higher probability for development because of their designation in existing land use plans.

**Deleted:** ,

**Deleted:** such as the Bureau of Reclamation or the Department of Energy,

**Deleted:** If the unencumbered lands fall within two or more management scenarios where future planning criteria may not be clear, a plan amendment may be required.

**Deleted:** The existing designated ROW corridors within the decision area include the Western Utility Group updates to the Western Regional Corridor Study, Section 368 Energy Policy Act of 2005, and West-wide Energy Corridor Programmatic EIS, which are adopted and carried out under BLM IM-2013-118 (dated April 12, 2013). Designated transportation and utility corridors include linear ROWs, such as electric transmission facilities, pipelines, communication lines, and transportation systems.

### 1.3 Livestock Grazing

#### 1.3.1 Methods and Assumptions

##### *Indicators*

Indicators of impacts livestock grazing/range management are as follows:

- Changes in permitted AUMs in areas open to livestock grazing
- Changes in the type of livestock permitted on allotments
- Prohibitions or limitations on the construction or maintenance of structural and nonstructural range improvements
- Modifications to or removal of structural range improvements
- Closures of areas to livestock grazing for the life of the plan
- Changes to the timing, duration, or frequency of permitted use, including temporary closures

##### *Assumptions*

The analysis includes the following assumptions:

- All new and renewed leases and permits would be subject to terms and conditions determined to be necessary by the authorizing officer to achieve the management and resource condition objectives for BLM- and Forest Service-administered lands and to meet land health standards for BLM-administered lands and desired conditions on Forest Service-administered lands.

- Range improvements (e.g., fences, pipelines, water wells, troughs, and reservoirs) could create a localized loss of vegetation cover. Fencing would cause a temporary loss due to construction, whereas other types of improvements may cause vegetation loss for the improvements' useful life. Additionally, wells, troughs, and reservoirs might cause long-term vegetation loss due to repeated livestock disturbance where animals congregate, and would be revegetated only if abandoned. Vegetation would be reestablished through reclamation along water pipelines and naturally along fence lines within five years to the extent possible.
- The construction and maintenance of range improvements would continue in the decision area, and would vary according to the constraints imposed by each alternative. New range improvements would be subject to limitations, as defined in the plan. Range improvements are generally intended to improve livestock distribution and management, which would maintain or improve rangeland health and could benefit the forage base and wildlife and GRSG habitat.
- By definition in this plan, livestock grazing is not considered a surface-disturbing activity, but it could affect the surface in areas where livestock concentrate, such as around range improvements.

## 1.4 Locatable Minerals

### 1.4.1 Methods and Assumptions

The analysis of impacts on locatable minerals from this LUPA focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on locatable minerals would result from withdrawing an area from locatable mineral entry. An indirect impact would result by removing a road, which would change the economic feasibility of developing a site. Additional actions or conditions that might cause direct or indirect impacts on locatable minerals are described below.

#### *Indicators*

Indicators of impacts on locatable minerals are as follows:

- Acres withdrawn from locatable mineral entry
- Acres petitioned for withdrawal from locatable mineral entry
- The amount of land under claim subject to buyout or validity exam
- Acres over which restrictions, such as RDFs and conservation measures, are placed on locatable mineral development activities to prevent unnecessary or undue degradation of GRSG habitat as the law allows

**Deleted:** The amount of land

**Deleted:** The amount of land

**Comment [M29]:** Is this relevant? Did we analyze this?

**Deleted:** Application of

**Deleted:** that can be

Where information is available, consideration is given to the potential for locatable minerals on lands withdrawn from locatable mineral entry. For example, an indicator of an impact on

locatable minerals is if there were substantial withdrawals from locatable mineral entry in high potential areas.

### Assumptions

The analysis includes the following assumptions:

- ~~New information may lead to changes in delineated GRSG habitat. New habitats, or areas that are no longer habitat, may be identified. This adjustment would typically result in small changes to areas requiring the stipulations or management actions stated in this plan. Modifications to GRSG habitat would be updated in the existing data inventory through plan maintenance. In areas that are no longer habitat, the waiver/exception/modification process would be used to remove stipulations or management actions that were no longer needed.~~
- ~~(rephrase): Will apply management actions to split estate. Management actions to withdraw areas from locatable mineral entry or prevent unnecessary or undue degradation also apply to locatable mineral activity on lands overlying federal locatable mineral estate, which includes federal locatable mineral estate underlying BLM- and Forest Service-administered lands, and lands managed by other entities. There are 32,023,500 acres of federal locatable mineral estate within the decision area (29,772,700 acres of BLM- and Forest Service-administered surface with federal locatable minerals and 2,250,800 acres of surface with federal minerals on land not administered by the BLM). Federal locatable minerals refers to mineral estate where the federal government controls the locatable minerals.~~
- Information on locatable mineral withdrawals is not available for 33,000 acres of federal locatable mineral estate in the Butte Field Office in Montana (less than one percent of the federal locatable mineral decision area). These acres were not included in the analysis.
- Areas recommended for withdrawal would be withdrawn.
- Trends described in Section 3.12, Mineral Resources, are assumed to continue for the life of the analysis.
- Historical patterns of locatable mineral development in the planning area are used to assess the level of locatable mineral potential throughout the planning area. Areas with a high level of historical development are considered to have high potential for locatable minerals.

**Comment [MZ10]:** Move some of this text to the step-down implementation

**Comment [MZ11]:** Move acreages to Chapter 3.

**Deleted:** oil and gas

**Comment [MZ12]:** Katie will check on what the analysis assumption is.

**Deleted:** As discussed in

**Deleted:** there are 60 authorized plans of operations or notices in the planning area, and 20 more are pending. Demand for and development of locatable minerals in the planning area is expected to remain steady. However, new electronic products requiring materials that have not been historically used, such as rare earth elements, could change demand and development patterns in the future.

## 1.5 Mineral Materials (Salables)

### 1.5.1 Methods and Assumptions

Analysis of impacts on mineral materials from this LUPA focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on mineral materials would result from closing an area to mineral material disposal. An indirect impact would result from removing a road, which would change the economic feasibility of developing a site. Additional actions or conditions that might cause direct or indirect impacts on mineral materials are described under *Indicators*, below.

#### *Indicators*

Indicators of impacts on mineral materials are as follows:

- Acres closed to mineral material disposal
- Acres subject to timing limitations
- Acres managed as ROW avoidance areas
- Acres managed as ROW exclusion areas
- Acres over which RDFs are applied to solid minerals
- Application of restoration requirements

Where information is available, consideration is given to the potential for mineral materials on lands closed to mineral material disposal. For example, an indicator of an impact on mineral materials is if there were substantial closures to mineral material disposal in areas with high occurrence of mineral materials.

#### *Assumptions*

The analysis includes the following assumptions:

- Management actions also apply to mineral materials activity on lands overlying federal mineral material estate, which includes federal mineral material estate underlying BLM- and Forest Service-administered lands, and lands not administered by the BLM or Forest Service. There are 31,566,400 acres of federal mineral material estate within the decision area (29,636,500 acres of BLM- and Forest Service-administered surface with federal mineral material estate and 1,929,900 acres of surface with federal minerals not administered by the BLM or Forest Service). Federal mineral material estate refers to mineral estate where the federal government controls the mineral materials.
- Information on mineral material allocations is not available for 1,444,100 acres of federal mineral material estate in the Butte and Dillon Field Offices in Montana (five percent of the federal mineral material decision area).

**Deleted:** The amount of land

**Deleted:** The amount of land

**Deleted:** The amount of land

**Deleted:** The amount of land

**Deleted:** Application of

**Deleted:** that can be placed on

**Deleted:** s

**Comment [M213]:** Double check with Karen re: mineral material estate/split estate. Incorporate info into Chapter 3.

**Deleted:** <#>New information may lead to changes in delineated GRSG habitat. New habitats or areas that are no longer habitat may be identified. This adjustment would typically result in small changes to areas, requiring the stipulations or management actions stated in this plan. Modifications to GRSG habitat would be updated in the existing data inventory through plan maintenance. In areas that are no longer habitat, the waiver/exception/modification process would be used to remove stipulations or management actions that were no longer needed.¶

**Deleted:** ,

**Deleted:** oil and gas

- As discussed in Section 3.12, demand for mineral materials in the planning area is expected to remain fairly steady. However, this demand is influenced by market factors that influence construction.
- Historical patterns of mineral material development in the planning area are used to assess the level of mineral material potential throughout the planning area. Areas with a high level of historical development are considered to have high potential for mineral materials.

**Comment [MZ14]:** Rephrase as per locatable minerals

## 1.6 Nonenergy Leasable Minerals

### 1.6.1 Methods and Assumptions

Analysis of impacts on nonenergy solid leasable minerals from this LUPA focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on nonenergy solid leasable minerals would result from closing an area to leasing. An indirect impact would result from removing a road, which would change the economic feasibility of developing a site. Additional actions or conditions that might cause direct or indirect impacts on nonenergy solid leasable minerals are described under *Indicators*, below.

#### *Indicators*

Indicators of impacts on nonenergy solid leasable minerals are as follows:

- Acres closed to nonenergy solid mineral leasing
- Acres over which restrictions on timing are placed on nonenergy solid mineral leasing
- Acres over which RDFs are applied to solid minerals

**Deleted:** The amount of land

**Deleted:** The

**Deleted:** Application of

**Deleted:** that can be placed on

Where information is available, consideration is given to the potential for nonenergy solid leasable minerals on lands closed to leasing. For example, an indicator of an impact on nonenergy solid leasable minerals is if there were substantial closures to nonenergy solid mineral leasing in areas with high occurrence of nonenergy solid minerals.

#### *Assumptions*

The analysis includes the following assumptions:

- Management actions and conservation measures also apply to nonenergy solid leasable mineral activity on lands overlying federal nonenergy solid leasable mineral estate. This includes federal nonenergy solid leasable mineral estate underlying BLM-administered, National Forest System, and lands not administered by the BLM or Forest Service. There are 31,566,400 acres of federal nonenergy solid leasable mineral estate within the decision area (29,636,500 acres

**Deleted:** <#>New information may lead to changes in delineated GRSG habitat. New habitats or areas that are no longer habitat may be identified. This adjustment would typically result in small changes to areas, requiring the stipulations or management actions stated in this plan. Modifications to GRSG habitat would be updated in the data inventory through plan maintenance. In areas that are no longer habitat, the waiver/exception/modification process would be used to remove stipulations or management actions that were no longer needed.¶

of BLM- and Forest Service-administered surface with federal nonenergy solid leasable minerals and 1,929,900 acres of surface with federal minerals not administered by the BLM or Forest Service). Federal nonenergy solid leasable mineral material estate refers to mineral estate where the federal government controls the nonenergy solid leasable minerals.

**Comment [MZ15]:** Move to Chapter 3. Make paragraph consistent with locatable minerals text.

- Information on nonenergy solid leasable mineral allocations is not available for 1,444,100 acres of federal nonenergy solid leasable mineral estate in the Butte and Dillon Field Offices in Montana (five percent of the federal nonenergy solid leasable mineral decision area).

**Comment [MZ16]:** Follow up with MT to see about getting minerals data.

**Deleted:** mineral material

As discussed in Section 3.12, significant phosphate resources exist in the Pocatello Field Office within the planning area. There are ten active phosphate leases within GRSG habitat in this area; however, no development on these leases is planned for the next 5 to 10 years.

## 1.7 Leasable Minerals

### 1.7.1 Methods and Assumptions

The analysis of impacts on fluid minerals from this LUPA focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on fluid minerals would result from closing an area to fluid mineral leasing. An indirect impact would result from managing an area as ROW exclusion, which would change the economic feasibility of developing a site. Additional actions or conditions that might cause direct or indirect impacts on fluid minerals are described under *Indicators*, below.

#### *Indicators*

Indicators of impacts on fluid minerals are as follows:

- Acres of unleased land identified as closed to fluid mineral exploration and development
- Acres subject to NSO stipulations
- Acres subject to CSU stipulations
- Acres subject to TLs
- Number of leases and acres over which COAs are applied on fluid mineral development activities on leased parcels for the protection of GRSG
- Acres of restrictions on geophysical exploration in GRSG habitat
- Acres managed as ROW avoidance areas
- Acres managed as ROW exclusion areas

**Deleted:** The amount

**Deleted:** The amount of land

**Deleted:** The amount of land

**Deleted:** The amount of land

**Deleted:** Application of

**Comment [MZ17]:** Karen to revisit management actions

**Deleted:** R

**Deleted:** The amount of land

**Deleted:** The amount of land

Where information is available, consideration is given to the potential for fluid mineral resources on lands closed to leasing. For example, an indicator of an impact on fluid minerals is if there were substantial reductions in federal leasing and development of fluid mineral resources in high potential areas.

*Assumptions*

The analysis includes the following assumptions:

- Existing fluid mineral leases would not be affected by the closures proposed under this LUPA.
- Fluid mineral operations on existing federal leases, regardless of surface ownership, would be subject to COAs by the authorizing officer. The BLM can deny surface occupancy on portions of leases with COAs to avoid or minimize resource conflicts if this action does not eliminate reasonable opportunities to develop the lease or affect lease rights.
- Existing leases would be managed under the stipulations in effect when the leases were issued; new stipulations proposed under this LUPA would apply only on new leases. See the glossary for definitions of stipulations versus COAs.
- Under all alternatives, reclamation bonds would be required, pursuant to 43 CFR 3104 and 36 CFR 228.109(a), in an amount sufficient to ensure full restoration of lands to the condition in which they were found. In addition, Applications for Permit to Drill would be required under all alternatives in accordance with 43 CFR 3162.
- The lands in the Curlew Grassland area, as described in the Pocatello RMP, that are administratively unavailable for leasing will be included in the total number of acres/hectares closed to leasing under Alternative A.
- If an area is leased, it could be developed; development is expected as described in the RFDS (Appendix XX). [Combine with trends bullet below]
- As the demand for energy increases, so will the demand for extracting energy resources in areas with potential.
- Technological advancements, such as directional drilling, could lead to changes in levels of fluid mineral development potential throughout the planning area as additional resources become more easily accessible.
- Stipulations also apply to fluid mineral leasing on lands overlying federal oil and gas estate, which includes federal oil and gas estate underlying BLM-administered and Forest Service-administered lands and non-BLM-administered and Forest Service-administered lands. There are 32,028,100 acres of federal oil and gas estate within the decision area (29,638,300 acres of BLM-administered and Forest Service-administered surface with federal minerals and 2,389,800 acres of non-BLM-administered and non-Forest Service-administered surface with federal

**Deleted:** remain so for the life of the Pocatello RMP. Therefore, these acres/hectares are

**Deleted:** <#>New information may lead to changes in delineated GRSG habitat. New habitats, or areas that are no longer habitat, may be identified. This adjustment would typically result in small changes to areas requiring the stipulations or management actions stated in this plan. Modifications to GRSG habitat would be updated in the existing data inventory through plan maintenance. In areas that are no longer habitat, the waiver/exception/modification process would be used to remove stipulations or management actions that were no longer needed.¶

**Deleted:** however, not all leases would be developed within the life of this LUPA.

**Comment [MZ18]:** Incorporate this and the next bullet in RFDS.

**Comment [MZ19]:** Make changes per similar locatable mineral text.

minerals). Federal oil and gas estate refers to mineral estate where the federal government controls the oil and gas resources.

- As discussed in Section 3.12, Mineral Resources, interest in oil and gas and geothermal leasing in Idaho is expected to remain sporadic.

**Comment [MZZ0]:** Combine with above bullet. Refer to trends in Chapter 3.

**Deleted:** There is some interest in leasing oil and gas resources within occupied habitat in the Bear Lake area. However, no drilling permits have been applied for or issued in Idaho, and this trend is expected to continue.

## 1.8 Special Designations

### 1.8.1 Methods and Assumptions

Direct impacts on ACECs are considered to be those that either impair or enhance the relevant and important values for which the ACEC was proposed for designation. As such, this analysis focuses on relevance and importance criteria for each potential ACEC. There are no relevance and importance criteria for Forest Service ZAs. It also focuses on impacts on these values from either the special management derived from ACEC or ZA designation or, under alternatives where an ACEC or ZA is not proposed for designation, the management actions for other resources. All impacts discussed are direct, though some may not occur immediately after implementation of management actions.

#### *Indicators*

Impacts on ACECs would occur from management actions that protect or impair relevant and important ACEC values, including “important historic, cultural, or scenic values, fish and wildlife resources or other natural systems or processes” (BLM Manual 1613 – Areas of Critical Environmental Concern). As such, indicators of impacts are allocations for surface-disturbing activities within existing or potential ACECs that could affect the relevant and important values for which the ACEC was designated.

#### *Assumptions*

The analysis includes the following assumptions:

- Management of existing ACECs was determined in the applicable LUPs to be adequate to support the relevant and important values at the time of their designation. Impacts on these ACECs are not further discussed because the BLM would continue to manage these ACECs to protect their relevant and important values. Management to protect GRSG under the various alternatives could provide additional protections for existing ACECs and, at a minimum, would provide complementary management.
- Although management actions for most resources and resource uses have application throughout the decision area, ACEC and ZA management prescriptions apply only to those lands within each specific ACEC or ZA.
- Permitted activities would not be allowed to impair the relevant and important values for which the ACECs are designated. The exception is locatable minerals; until withdrawn from mineral entry, a mining claim can be filed, and subsequent

mining activities could have an impact. However, measures would have to be identified in a mine plan to mitigate unnecessary and undue degradation.

- ACEC designation provides protection and focused management of relevant values beyond that provided through general management of the relevant and important values elsewhere in the decision area.
- Any designated ACEC that falls within a WSA would be managed according to BLM Manual 6330, Management of Wilderness Study Areas, unless the ACEC management is more restrictive. Because activities within WSAs must meet the nonimpairment criterion, which generally restricts new surface disturbance, a WSA would generally protect relevant and important values. Also, it would have a beneficial effect on overlapping designated and undesignated ACECs. If Congress were to release a WSA from further consideration, the special management in designated ACECs would be designed to protect and enhance the relevant and important values.

## 1.9 Travel Management

### 1.9.1 Methods and Assumptions

#### *Indicators*

Indicators of impacts on travel and transportation management from BLM and Forest Service management to protect GRSG are changes in the following:

- The acreages designated as open, limited, or closed to motorized travel
- The types of transportation activities occurring on routes that could impact GRSG or habitat
- The number of acres where new road development would be allowed

#### *Assumptions*

In addition to the assumptions in **Section 4.1.1**, this analysis includes the following assumptions:

- The demand for general access to travel routes on BLM-administered and Forest Service-administered lands would continue to increase over the life of the LUPs.
- Administration of updated agency travel management policy, rules, and planning and design guidelines will change public land travel systems through design, making them more sustainable while decreasing potential impacts on resources.
- OHV use will continue to increase.

- The designation of individual routes is an implementation-level process and not considered as part of a planning-level process.
- The potential for resource and user conflict increases as OHV use increases and becomes more concentrated.
- Travel systems are dynamic and will be changed through subsequent implementation-level planning.
- Implementation of a travel management plan would include increased public education, signing, enforcement, and resource monitoring in regard to travel management.

## 1.10 Vegetation

### 1.10.1 Methods and Assumptions

#### *Indicators*

Indicators of impacts on vegetation are as follows:

#### *Upland Vegetation*

- Acres and condition of vegetation communities
- Extent of fragmentation

#### *Riparian and Wetland*

- Acres and condition of riparian and wetland vegetation

#### *Noxious Weeds and Invasive Species*

- Change in the likelihood for noxious weed or invasive species introduction or spread
- Change in the estimated acres of conifer encroachment

#### *Assumptions*

The analysis includes the following assumptions:

- All plant communities would be managed to achieve a mix of species composition, cover, and age classes across the landscape, except in site-specific situations where nonnative plantings are used to defer livestock grazing of native vegetation.
- The degree of impact attributed to any one disturbance or series of disturbances would be influenced by several factors. These are location in the watershed; the type, time, and degree of disturbance; existing vegetation; precipitation; and mitigating actions applied to the disturbance.

- Noxious and invasive weeds would continue to be introduced and spread as a result of ongoing vehicle traffic in and out of the planning area, recreation, wildfire, wildlife and livestock grazing and movements, and surface-disturbing activities.
- Activities that would disturb soils could cause erosion, topsoil loss, and soil compaction, which could affect the ability of vegetation to regenerate. Further, surface-disturbing activities could increase dust, which could cover vegetation and impair plant photosynthesis and respiration. Resulting impacts could include lowered plant vigor and growth rate, altered or disrupted pollination, and increased susceptibility to disease.
- Ecological health and ecosystem functioning depend on vegetative cover, species diversity, nutrient cycling and availability, water infiltration and availability, and percent cover of weeds.
- Climate fluctuation would continue to influence the health and productivity of plant communities annually.

Short-term effects would occur over two years or less, and long-term effects would occur over longer than two years.

## 1.11 Wild Horse and Burro Management

### 1.11.1 Methods and Assumptions

#### *Indicators*

Indicators of impacts on wild horses and burros are as follows:

- Changes in Acres available
- Changes in permitted AMLs
- Changes in allotted forage (AUMs)
- Changes in funding or resources available for management

#### *Assumptions*

The analysis includes the following assumptions:

- Horses and burros depend on the herbaceous component of a shrub/grass plant community. Encroachment of shrubs or pinyon-juniper onto established rangelands is adverse, and increases in grasses and forbs are beneficial. Vegetation treatments, such as prescribed burns or weed control, can enhance the plant community composition and forage availability.

- Although the BLM cannot control when wild horses and burros use certain areas, heavy or poorly timed wild horse and burro grazing may adversely affect plant composition, plant succession, and ground cover.
- Water is the primary resource associated with wild horse distribution, and water developments can improve wild horse distribution. Furthermore, human-made water developments that employ some type of mechanical device, such as a windmill or electric pump, can fail and cause horses to go without or to go elsewhere for water.
- Fences and other disturbances can restrict wild horse movement and access. Fences are sometimes necessary to restrict horse distribution to areas inside HMAs or to protect sensitive resources within HMAs.
- While wild horses and burros may be found on lands outside HMAs that have no forage allocated to them. The BLM has no authority to manage wild horses and burros outside of HMAs, except to remove them.
- The scheduling for wild horse and burro gathers is influenced by a national priority process. Factors affecting gather priorities are determinations of excess horses and overpopulations, wild horse and range condition, annual appropriations, litigation and court orders, emergency situations, such as disease, weather, and fire, availability of contractors, the market for adoption, and long-term holding availability for unadoptable excess horses. The principal factor affecting gather priorities is that short- and long-term holding facilities are at or near capacity, significantly reducing the number of excess wild horses and burros that can be removed from HMAs.
- Population growth suppression (fertility control agents, sterilization, and sex ratio adjustments) can aid in population control, but periodic gathers are still necessary to remove excess wild horses.
- Wild horse and burro distribution varies by season, climatic conditions, water and forage availability, and population size.
- Intensive livestock grazing management strategies (scheduled pasture rotations) that involve fences are generally not appropriate for long-term wild horse management.

## 1.12 Lands with Wilderness Characteristics

### 1.12.1 Methods and Assumptions

#### *Indicators*

Indicators of impacts on lands with wilderness characteristics are the management actions and allowable uses that would either protect or degrade the inventoried characteristics to a level at which the value of one or more wilderness characteristic would no longer be present

within the specific area. The inventoried wilderness characteristics are roadless areas of sufficient size, naturalness, outstanding opportunities for solitude or a primitive and unconfined type of recreation, and supplemental values, as described in **Section 3.20**, Wilderness Characteristics. Roadless Areas already experience some protections from Forest Service management, however, management actions that restrict uses in order to protect the GRSG would provide additional protections to Roadless Areas.

### ***Assumptions***

The analysis includes the following assumption:

- Some inventoried lands with wilderness characteristics have not yet been assessed in a LUP revision; therefore, no decisions have been made about whether to protect their wilderness characteristics. In this analysis, these lands with wilderness characteristics are treated like their wilderness characteristics are not protected to the same degree that congressionally designated wilderness areas would be protected and are discussed in this analysis. Lands with wilderness characteristics that are not managed only to exclusively protect those characteristics will simply be referred to as lands with wilderness characteristics throughout the remainder of the analysis in this section.

## **1.13 Wildland Fire Management**

### **1.13.1 Methods and Assumptions**

#### ***Indicators***

Indicators of impacts on wildfire management are as follows:

- Alteration of vegetative cover that is likely to result in a substantial shift in fire regime condition class (FRCC) across the planning area
- A substantial change in the likelihood or severity of wildfire, based on level of restrictions on uses that may introduce sources of ignition
- Management actions that substantially inhibit a response to wildfire or appropriate treatments to prevent wildfire

#### ***Assumptions***

The analysis includes the following assumptions:

- The spread of invasive annuals (e.g., cheatgrass) has lengthened the fire season in many parts of the planning area. These species often cure sooner than native perennial species and are more prone to ignition. Therefore, actions that reduce the spread or footprint of invasive annuals or restore perennial vegetation

communities would reduce the frequency and intensity of wildfires, while reducing wildfire management costs.

- Fuels treatments using chemical methods are likely to be the most effective in reducing fine fuels and fire intensity and severity.
- Fire is an important functional natural disturbance in many of the ecological systems found in the planning area.
- A direct relationship exists between fuel loading and potential fire intensity and severity.
- Demand for fuels treatments would likely increase over the life of this plan.

# CHAPTER 4

## ENVIRONMENTAL CONSEQUENCES

---

### 4.1 [INSERT NAME OF RESOURCE]

#### 4.1.1 **Methods and Assumptions**

##### **Indicators**

Indicators of impacts on Greater Sage-Grouse are as follows:

- <EMPSi specialist: Add bullets regarding indicators of impacts on your resource. The subsequent discussion of impacts should focus around these indicators. This helps to frame the discussion.>

##### **Assumptions**

The analysis includes the following assumptions:

- <EMPSi specialist: Add any assumptions used for your analysis. You do not need to repeat the assumptions below.>

#### 4.1.2 **Nature and Type of Effects**

<EMPSi specialist: Add text regarding the types of impacts that would occur from each resource to your resource. Nature and type of effects are general; the magnitude of these effects will be discussed under each alternative.>

<EMPSi specialist: Delete from the following paragraph any resources that will be discussed further. This paragraph remains at the end of the **Nature and Type of Effects** section.>

Implementing management for the following resources would have negligible or no impact on Greater Sage-Grouse and are therefore not discussed in detail: travel and transportation management, recreation, lands and realty, range management, fluid minerals, solid minerals, mineral split-estate, fire and fuels management, habitat restoration and vegetation management, and ACECs.

**Comment [MZ1]:** Do we want to include methods, assumptions, and the nature and type of effects section with the proposed plan? If so, do we want to repeat it in the main Chapter 4 section or refer to the proposed plan analysis?

### 4.1.3 Proposed Plan

<EMPSi specialist: Add introductory text regarding impacts common to all alternatives, if applicable. Impacts are only common to all alternatives if the magnitude of the impact would be the same across *all* alternatives, including the No Action alternative. If this isn't the case, evaluate whether you are really describing nature and type of effects or if the text should go under the alternatives discussion below. Delete resource headings if they are included in the list of no or negligible impacts under **Nature and Type of Effects.**>

#### **Impacts from Lands and Realty Management**

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from lands and realty management decisions to your resource.>

#### **Impacts from Habitat Restoration and Vegetation Management**

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from habitat restoration and vegetation management decisions to your resource.>

#### **Impacts from Invasive Species Management**

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from invasive species management decisions to your resource.>

#### **Impacts from Wildland Fire Management**

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from wildland fire management decisions to your resource.>

#### **Impacts from Non-Energy Leasable Minerals Management**

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from non-energy leasable minerals management decisions to your resource.>

#### **Impacts from Coal Management**

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from coal management decisions to your resource.>

#### **Impacts from Locatable Minerals Management**

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from locatable minerals management decisions to your resource.>

#### **Impacts from Salable Minerals Management**

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from salable minerals management decisions to your resource.>

#### **Impacts from Unleased Fluid Minerals Management**

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from unleased fluid minerals management decisions to your resource.>

**Comment [MZ2]:** Do we want to keep the headers from the DEIS or make the headers match the proposed plan? For instance, do we want to add a header for coordination, adaptive management, anthropogenic disturbance, etc?

***Impacts from Leased Fluid Minerals Management***

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from leased fluid minerals management decisions to your resource.>

***Impacts from Recreation and Visitor Services Management***

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from recreation and visitor services management decisions to your resource.>

***Impacts from Livestock Grazing Management***

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from livestock grazing management decisions to your resource.>

***Impacts from ACEC Management***

<EMPSi specialist: Add text regarding *impacts under the proposed plan* from ACEC management decisions to your resource.>

**Acronyms**

<EMPSi specialist: list and define acronyms used.>

**References**

<EMPSi specialist: list complete references used and include the specific PAGE NUMBERS referenced.>

**Subject:** Re: Percent of Disturbance

Brent

I know Don had files stored on a portable drive and there are various folders under sage-grouse with his fingerprints. However, we have not identified anything that appears to be a consolidated location for this work. I do have his personal number though and will give him a call.

A few more questions that came up during a recent call we had to discuss what we had learned so far from our assigned reading.

There is still some question on which scale we (SO/DO/FO) are focusing on. It appears the NOC has Broad scale and Mid-scale covered, with input from the SO/FO. We suspect the fine scale and site scale is what we need to focus on?

Can you tell us what you envision us providing you? Would it be similar to what is in the GRSG Monitoring Framework, identify data-sets to use, reasoning for these data sets, recommended methods, etc. or more of a narrative of what we are trying to do?

We assume there will we need to be an established baseline of existing disturbance. When would that need to be completed by?

Should we be coordinating our efforts with the surrounding states to be consistent?

Do you have time on the 22, 23, or 24th to meet with us?

That's about it for now, thanks Brent.

Rod,

This is a component that needs attention in the next 3-4 weeks so we can pull that information into to EIS. We do have the ability for overtime and comp time as necessary to complete our work. I'm not sure how far Don Major got on this work but I do believe he laid the groundwork or foundation that we can build upon. Rod – do you have access to his files?

Brent

The three of us have discussed the scope of this task from a very broad perspective, basically how difficult this will be to do....but we will begin doing our research and have already started sharing documents and a short list of people to begin talking too.

A couple of questions...for now, more to come I'm sure. What is our timeline and what resources do we have at our disposal?

Regards,

Brent R. mentioned that you have been asked to work on aspects of the local disturbance analysis for the GRSG effort. Frank Quamen at NOC recently polled those of us on the disturbance team as to additional data fields to consider locally. See attached. There was a conf. call on this today that I was unable to attend due to other meeting priorities so I do not know the outcome. Anyway, it might be helpful for you to talk with Frank directly as to this, and how it fits with what you are doing.

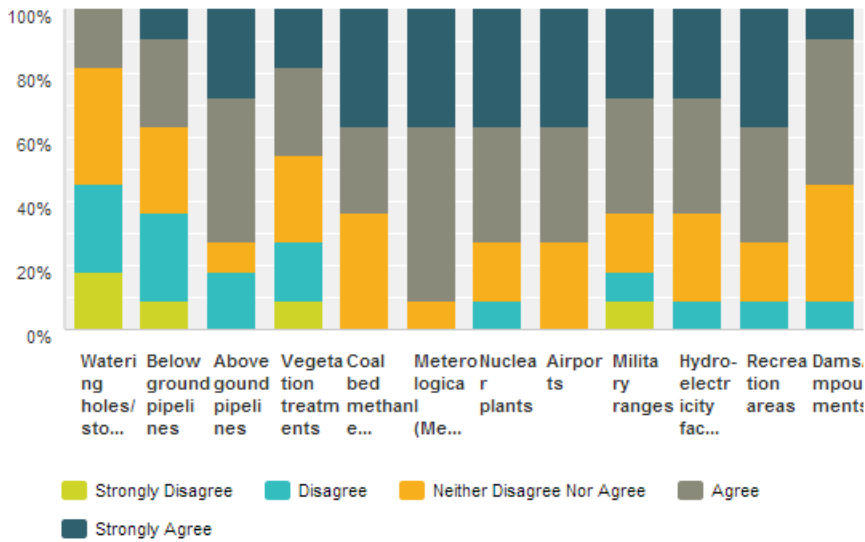

Paul

not sure	Yes?	yes - verified on 1:5,000 NAIP imagery	Yes - Would use actual disturbance footprint.

UT	ID	OR	NVCA
not sure if this is something that we include and if so, is it labelled as habitat loss or habitat degradation?	?Watering holes? Is the science there to actually count this as anthropogenic disturbance?	no	No
WY approach sounds reasonable			Yes - Would use actual disturbance footprint.
Some treatments, depends on the nature of the treatment and the anticipated impacts it will have on sage-grouse, we may be adding or subtracting habitat, or not doing either.	Need to define this. Should probably limit to "sagebrush reduction projects"?		N0 - treatments would be tracked but not counted as disturbance as they are to be beneficial. Would add back to sagebrush availability as the area meets habitat objectives.

UT	ID	OR	NVCA
this is a good one. .. But we have not consider yet, may depend on size and proximity to well...maybe group all together into one polygon.	Suggest adding		
don't know	Suggest adding		
n/a	Suggest adding		N/A
don't know	Suggest adding footprint of airstrips		N/A

UT	ID	OR	NVCA
don't know	Suggest adding. Some of these are extensive, and probably not germane but some e.g., ("Restricted Special Use Airspace) are used pretty intensively for low level aerial training exercises. Discuss?		No - Mostly airspace use.
Can you add "hydro-electricity facilities"			
		SageCon only (not BLM) - digitize on NAIP	N/A - Few developed sites on BLM Lands.\
		SageCon only (not BLM) - digitize on NAIP	N/A

**Questions Regarding Disturbance Thresholds and Adaptive Management Triggers**

1. In the current version of your ADPP, do you have a management action which articulates what will take place when a disturbance threshold objective is reached (as opposed to your adaptive management hard trigger response, as depicted in the flow chart)? For example, as described in the NTT Report (NTT alternative), "in priority habitats where the 3% disturbance threshold is already exceeded from any source, no further anthropogenic disturbances will be permitted by BLM until enough habitat has been restored to maintain the area under this threshold (subject to valid existing rights)."

Yes - Anthropogenic Disturbance (AD)-1: Limit anthropogenic disturbance to 3 percent as calculated within the biologically significant unit (BSU) (Map 3). The BSU is defined as the nesting and wintering habitat within Core and Important Management Zones within a Conservation Area, inclusive of all ownerships. Anthropogenic disturbance excludes habitat disturbance from wildfire and includes activities described in Appendix H. For Idaho this disturbance is measured by direct footprint or by ROW width for linear features. For Montana this disturbance is measured utilizing the Disturbance Density Calculation Tool process described in Appendix I.

AD-2: New anthropogenic disturbances within winter and nesting habitat within Core or Important management zones within a CA where the disturbance threshold is already exceeded from any source or where the proposed development would result in the threshold being exceeded would not be allowed until enough habitat has been restored to maintain the area under this threshold (subject to valid existing rights).

2. Do you think it is necessary to include additional information in your FEISs that describes how the disturbance threshold objective links to the adaptive management process and what happens when one of these is reached/tripped? This would be produced by the WO and would include something similar to the flow chart we went over on Friday and a list of Q/As. I am envisioning something that will be very easy to place into the FEISs as an appendix.

No!! Not the way adaptive management is being currently portrayed.

3. Will your ADPP include objectives/thresholds for sagebrush availability?

Yes – we have a Vegetation Management Objectives Table that includes objectives for sagebrush at both the broad and local scales.

4. Will your ADPP include an objective related to the density of anthropogenic disturbance (found on page 23 of the NTT)?

Yes, see above, that is how it is stated.

5. Will your soft and hard trigger responses be initiated when a population and habitat trigger is tripped or only when one of these two triggers is tripped?

## WO-210 Internal Document – Not for Distribution

Our triggers are initiated when either habitat or population meets the identified thresholds. We discussed this a lot but in the end it was understood that the biology of the bird drove this determination, in that the birds are very site loyal even if the habitat is not available, so the habitat could be lost in an area and population/birds numbers not show a change for 3-5 possibly 7 years later when the birds ended up dying out because of the lack of habitat. So if you waited until both conditions were met before initiating a change there is very little chance of actually retaining birds in that area.

6. Is it clear in your ADPP that your hard and soft triggers only apply to BLM managed lands?

Yes, the calculation is based on all lands regardless of ownership but the management changes are only applied to BLM and FS lands, just like any of the decisions we step forward in the RODs.

7. When developing your ADPP soft trigger, did you craft the trigger so that it is sufficient to not reach the disturbance threshold objective?

Our AM triggers were developed independently from the anthropogenic disturbance threshold and include different, but appropriate considerations in the calculation so that they are applied appropriately to the concerns they were developed to address. Taken together they are distinct and complimentary.

### Suggestions I noted from our call on Friday

- In our disturbance threshold objective, we should include a biologically significant scale in which we are measuring the threshold.
- We should take out “all land ownership types” from the land use plan objective and replace it with “BLM managed lands” (this would be a deviation from the NTT Report).
- Eliminate “field office” from the reporting unit.
- Stay away from using the term “cap.”
- Number each box for easy reading.

Implementation Monitoring Plan  
for the  
<INSERT LAND USE PLAN>

IDMT\_PUB\_12043  
6.3d  
12/7/2015

**I. Introduction**

The Implementation Monitoring Plan (IMP) provides information as to how the Land Use Plan will be monitored at the fine and site scale. The emphasis for the IMP is the project implementation of the Land Use Plan Amendment. The direction contained in this document is a programmatic approach and may vary as additional information is obtained during the implementation. The IMP contains four elements, 1) Habitat Condition Assessment, 2) Population Assessment, 3) Implementation Project Achievement and 4) Habitat Disturbance Monitoring.

**II. Habitat Condition Assessment (Availability)**

Local data and/or more current satellite imagery will be used to determine a more accurate measure of sage brush land cover, annual grasses, and conifer encroachment. In the short term (<5 years), locally derived vegetation data may not be available or easily rolled up and regional data layers may be used. The long-term goal is to have locally developed data layers that can be summarized at the WAWFA management zone level.

Disturbance associated fire, disease and other non-anthropogenic actions will be accounted for in the habitat assessment monitoring

**(Add Subregional information)**

**III. Population Assessment**

The <NAME OF STATE WILDLIFE AGENCY> will be lead agency in population data collection and analysis. The BLM and Forest Service resource specialist will participate in inventories and may conduct additional population surveys in accordance with agreed to protocols. For <INSERT PLANNING UNIT>

**(Describe the protocol).**

**IV. Project Achievement  
(To be completed)**

**V. Habitat Disturbance**

The disturbance activities identified for the broad and mid-scale (see Table 2 in *The Greater Sage-grouse Monitoring Framework*) will be used at the fine/site scale. Local data will be used to identify the amount of habitat degradation (loss). If local information is not available, the data layers identified at the broad and mid-scale will be used

Table (??\_1) identifies the disturbance activities that will be monitored, the attributed disturbance for each activity, and the data layer to be used for the existing disturbance

calculations. All future disturbances will use the information developed during the project design and approval. Any secondary development associated with a disturbance ( e.g. roads and powerlines), will be accounted for within the respective disturbance activity rather than accounted for within the primary project disturbance area.

**Table (??-1) Fine and Site Scale Disturbance Calculations**

## VI. Reporting

<sup>1</sup> **Roads** are linear routes managed for use by low clearance vehicles having four or more wheels, and are maintained for regular and continuous use.

<sup>2</sup> **Maintenance Levels** are described in???

<sup>3</sup> **Primitive Roads** are linear routes managed for use by four-wheel drive or high-clearance vehicles. They do not normally meet any design standards. Seasonal restrictions may be implemented to reduce resource damage, or to protect or mitigate other resource concerns

<sup>4</sup> **Temporary routes** are defined as short-term overland roads, primitive roads or trail authorized or acquired for the development, construction or staging of a project or event that has a finite lifespan. Temporary routes are not intended to be part of the permanent or designated transportation network and must be reclaimed when their intended purpose(s) has been fulfilled

<sup>5</sup> **Administrative routes** are routes that are limited to authorized users (typically motorized access). These are existing routes that lead to developments that have an administrative purpose, where the agency or a permitted user must have access for regular maintenance or operation

The results of the fine/site scale will be annually compiled and reported by the respective <INSERT BLM DISTRICT OR FOREST>. The information will be used to prioritize subsequent monitoring efforts, adjust project implementation designs, and/or project implementation schedule.

**Subject:** RE: Draft GRSG Preliminary Propsoed Plan  
**Attachments:** BSU Definition 073114.docx; ID swMT ADPP Appendix H 062014 Idaho Anthropogenic Disturbance Process.docx; IDswMT ADPP Appendix E GRSG-FINAL-Monitoring Framework 20140530.pdf

Lance,

Here is a bit more information on the disturbance cap (which still needs some refinement and description) and appendix H. Appendix E has a more thorough description of the data sets that may help answer your questions.

Hi Brent, I read the administrative draft- looks great I need to call you and run a couple of things by you just for clarification- also how do I get a hold of the appendixes? specifically appx. H  
I'm worried about the definition of Anthropogenic Disturbance- when we talked last- you said fuel breaks and road maintenance (of existing roads) would not be Anthropogenic Disturbance which would be good - I'm just worried about the 3% cap on disturbance in regards to fuels breaks and juniper treatments across the west owyhee. thanks for adjusting the burning in sage brush language - that will work.

On Mon, Jun 30, 2014 at 2:06 PM, Brent Ralston <[bralston@blm.gov](mailto:bralston@blm.gov)> wrote:

Lance,

I believe I promised this to you a while ago, and then we had some other issues come up that diverted me. I now have they Draft Proposed Plan and have attached that for your review. Please take a look to see if there are any components that cause some concern with regard to the site specific projects you are working on. Those projects embody the intent to reduce fire occurrence and spread, and subsequent habitat loss for GRSG while maintain consideration for the habitat both affected and at risk of loss due wildfire. The Draft Proposed Plan contains the broad scale direction to retain and protect habitat across the landscape. Both efforts are aimed at similar goals and we want to ensure that we don't have any inadvertent direction in the planning effort that would preclude our ability to implement beneficial projects on the ground to protect GRSG habitat.

- The likely direct and indirect impacts on the human and natural environment that could occur from implementing the Proposed Plan Amendment presented in **Chapter 2** were incorporated into **Chapter 4**. Analysis shown under the draft alternatives may be referenced in the Proposed Plan Amendment analysis with such statements as “impacts would be the same as, or similar to, Alternative D” or “impacts would be the same as Alternative D, except for...,” as applicable.
  - For alternatives with an adaptive management component, revised analysis was presented for Alternative D and analysis was added for the Proposed Plan. In the DEIS, Alternative E analyzed the effects of hard trigger responses imposing CHZ management decisions in HHZ.
  - General corrections (e.g., typographical errors), clarifications, and acreage recalculations were included.

Administrative Draft  
Cooperating Agency Review

1       **Environmental Consequences**

2       **Chapter 4**, Environmental Consequences, presents the direct and indirect impacts on the  
3 human and natural environment anticipated to occur from implementing the alternatives  
4 presented in **Chapter 2**. Cumulative impacts are presented in **Chapter 5**. The purpose of  
5 this chapter is to describe to the decision maker and the public how the environment could  
6 change if any of the alternatives in Chapter 2 were to be implemented. It is meant to aid in  
7 deciding which land use plan amendment, if any, to adopt.

8       This chapter is organized by topic, similar to Chapter 3. Each topic area includes the  
9 following:

- 10           • A method of analysis section that identifies indicators and assumptions
- 11           • An analysis of impacts for each of the six alternatives

12       Management actions proposed in Chapter 2 are planning-level direction that do not result in  
13 direct on-the-ground changes. The analysis focuses on impacts that could eventually result in  
14 on-the-ground changes. It does this by planning for land use on surface estate and federal  
15 mineral estate administered by the BLM and Forest Service over the life of the plan.

16       Some management actions may affect only certain resources and alternatives. This impact  
17 analysis focuses on those impacts that could impair a resource. If an activity or action is not  
18 addressed in a given section, either there are no impacts or the impacts are negligible, based  
19 on professional judgment.

20       The projected impacts on land use activities and the associated environmental impacts of  
21 land uses are characterized and evaluated for each of the alternatives. Impacts for the  
22 following resources are expected to be negligible, therefore they are not discussed in detail:  
23 air resources, soil resources, water resources, special status species (other than GRSG), fish  
24 and wildlife, cultural resources, tribal interests, paleontological resources, visual resources,  
25 cave and karst resources, forestry, recreation, and special designations (e.g., National Historic  
26 Trails, Wild and Scenic Rivers, Wilderness Areas, Wilderness Study Areas, National  
27 Monuments, and National Conservation Areas).

28       Impact analysis is a cause-and-effect process. The detailed impact analyses and conclusions  
29 are based on the following:

- 30           • The BLM and Forest Service planning team's knowledge of resources and the  
31 project area
- 32           • Reviews of existing literature
- 33           • Information provided by experts in the BLM and Forest Service, other agencies,  
34 cooperating agencies, interest groups, and concerned citizens

1 The baseline used for the impact analysis is the current condition or situation, as described in  
2 Chapter 3. Impacts on resources and resource uses are analyzed and discussed in detail,  
3 commensurate with resource issues and concerns identified through the process. At times,  
4 impacts are described using ranges of potential impacts or in qualitative terms.

#### 5 **4.1 Analytical Assumptions**

6 Several overarching assumptions have been made in order to facilitate the analysis of the  
7 project impacts. These assumptions set guidelines and provide reasonably foreseeable  
8 projected levels of development that would occur in the planning area during the planning  
9 period. These assumptions should not be interpreted as constraining or redefining the  
10 management objectives and actions proposed for each alternative, as described in Chapter 2.

11 The following general assumptions apply to all resource categories; any specific resource  
12 assumptions are provided in the methods and assumptions section for that resource:

- 13 • Sufficient funding and personnel would be available for implementing the final  
14 decision.
- 15 • Implementing actions from any of the LUPA alternatives would comply with all  
16 valid existing rights, federal regulations, BLM and Forest Service policies, and  
17 other requirements.
- 18 • Implementation-level actions necessary to execute the land use plan-level  
19 direction in this LUPA would be subject to further environmental review,  
20 including that under NEPA, as appropriate.
- 21 • Direct and indirect impacts of implementing the LUPA would primarily occur on  
22 BLM-administered and National Forest System lands in the planning area.
- 23 • Local climate patterns of historic record and related conditions for plant growth  
24 may change with warmer, drier conditions likely to occur over the life of this  
25 plan.
- 26 • In the future, as tools for predicting climate changes in a management area  
27 improve and climate change affects resources and necessitates changes in how  
28 resources are managed, the BLM and Forest Service may be required to  
29 reevaluate direction provided as part of this planning process and adjust  
30 management accordingly. It is speculative at this time to attempt to predict the  
31 specific nature or magnitude of such changes.
- 32 • The BLM and Forest Service would carry out appropriate maintenance for the  
33 functional capability of all developments.
- 34 • The discussion of impacts is based on best available data. Knowledge of the  
35 planning area and decision area and professional judgment, based on observation  
36 and analysis of conditions and responses in similar areas, are used for  
37 environmental impacts where data are limited.

- Restrictions (such as siting, design, and mitigation measures) apply, where appropriate, to surface-disturbing activities associated with land use authorizations and permits issued on BLM-administered and National Forest System lands.
- New information may lead to changes in delineated GRSG habitat. New habitats, or areas that are no longer habitat, may be identified. This adjustment would typically result in small changes to areas requiring the stipulations or management actions stated in this LUPA. Modifications to GRSG habitat would be updated in the existing data inventory through LUP maintenance.
- Acreage figures and other numbers used in the analyses are approximate projections for comparison and analysis only. Readers should not infer that they reflect exact measurements or precise calculations.
- For alternatives with an adaptive management component, hard trigger responses would impose PHMA/CHZ management decisions in IHMA/IHZ.

#### 4.1.1 General Methodology for Analyzing Impacts

Potential impacts are described in terms of type, context, duration and intensity, which are generally defined below.

Type of impact—Because types of impacts can be interpreted differently by different people, this chapter does not differentiate between beneficial and adverse impacts (except in cases where such characterization is required by law, regulation, or policy). The presentation of impacts for key planning issues is intended to provide the BLM and Forest Service decision makers and readers with an understanding of how multiple uses are balanced for each alternative.

Context—This describes the area or location (site-specific, local, planning area-wide, or regional) in which the impact would occur. Site-specific impacts would occur at the location of the action, local impacts would occur within the general vicinity of the action area, planning area-wide impacts would affect a greater portion of decision area lands in the sub-region, and regional impacts would extend beyond the planning area boundaries.

Duration—This describes the duration of an effect, either short term or long term. Unless otherwise noted, short term is defined as anticipated to begin and end within the first 10 years after the action is implemented; long term is defined as lasting beyond 10 years to the end of or beyond the life of this LUPA.

Intensity—Rather than categorize impacts by intensity (e.g., major, moderate, or minor), this analysis discusses impacts using quantitative data wherever possible.

Direct, indirect, and cumulative impacts—Direct impacts are caused by an action or implementation of an alternative and occur at the same time and place; indirect impacts result from implementing an action or alternative but usually occur later in time or are

1 removed in distance and are reasonably certain to occur. Cumulative impacts are effects on  
2 the environment that result from the impact of implementing any one of the Idaho and  
3 Southwestern Montana GRSB LUPA/EIS alternatives in combination with other actions  
4 outside the scope of this plan, either within the planning area or next to it. The cumulative  
5 effects analysis is provided in **Chapter 5**.

6 Required Design Features have been incorporated into the Forest Service Proposed Plan  
7 Amendment as planning-level Guidelines, which will be implemented during site-specific  
8 project analysis.

#### 9 **4.1.2 Incomplete or Unavailable Information**

10 The CEQ established implementing regulations for NEPA, requiring that a federal agency  
11 identify relevant information that may be incomplete or unavailable for evaluating reasonably  
12 foreseeable significant adverse impacts in an EIS (40 CFR 1502.22). If the information is  
13 essential to a reasoned choice among alternatives, it must be included or addressed in an  
14 EIS. Knowledge and information is, and would always be, incomplete, particularly with  
15 infinitely complex ecosystems considered at various scales.

16 The best available information pertinent to the decisions to be made was used in developing  
17 the LUPA. The BLM has made a considerable effort to acquire and convert resource data  
18 into digital format for use in the LUPA, both from the BLM itself and from outside sources.

19 Under the FLPMA, the inventory of BLM-administered and National Forest System land  
20 resources is ongoing and continuously updated. However, certain information was  
21 unavailable for use in developing the LUPA because inventories either have not been  
22 conducted or are not complete. Some of the major types of data that are incomplete or  
23 unavailable are the following:

- 24 • Comprehensive state-wide inventory of wildlife and special status species  
25 occurrence and condition
- 26 • Geographical information system data used for disturbance calculations on  
27 private lands

28 For these resources, estimates were made concerning the number, type, and significance of  
29 these resources based on previous surveys and existing knowledge. In addition, some  
30 impacts cannot be quantified, given the proposed management actions. Where this gap  
31 occurs, impacts are projected in qualitative terms or, in some instances, are described as  
32 unknown. Subsequent site-specific project-level analysis would provide the opportunity to  
33 collect and examine site-specific inventory data to determine appropriate application of  
34 LUP-level guidance. In addition, the BLM and other agencies in the planning area continue  
35 to update and refine information used to implement this LUPA.

### 4.1.3 Mitigation

This chapter describes the environmental consequences associated with the impacts to GRSG and its habitat from activities carried out in conformance with this plan, in addition to BLM and Forest Service management actions. In undertaking BLM and Forest Service management actions, and consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM and Forest Service will require mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. In addition, to help implement this Idaho and southwestern Montana sub-region GRSG LUPA/EIS, a WAFWA Management Zone Regional Mitigation Strategy (per **Appendix J**) will be developed within one year of the issuance of the Record of Decision. The Strategy will elaborate on the components identified in Chapter 2 (avoidance, minimization, compensation, additionality, timeliness, and durability), and will be considered by the BLM and Forest Service for BLM and Forest Service management actions and third party actions that result in habitat loss and degradation. The implementation of a Regional Mitigation Strategy will benefit GRSG, the public, and land-users by providing a reduction in threats, increased public transparency and confidence, and a predictable permit process for land-use authorization applicants.

## 4.2 Sage-Grouse and Sage-Grouse Habitat

This section discusses impacts on GRSG from proposed management actions under each alternative. Existing conditions concerning GRSG are described in **Section 3.2**.

### 4.2.1 Methods and Assumptions

Indicators of impacts on GRSG are as follows:

- Acres of sagebrush
- Direct habitat loss or gain
- Habitat fragmentation
- Impacts on life history requirements
- Population loss or gain
- Habitat degradation
- Habitat restoration/improvement

Effects listed above may be characterized for each resource and alternative, as appropriate, and, where available, quantified by the indicators described below:

- 1 • Identified GRSG Habitat (PHMA, IHMA, and GHMA) – Identified habitat  
2 includes habitats considered vital to the persistence of GRSG populations at all  
3 scales. Acres impacted or improved by each resource is a general metric for acres  
4 of sagebrush, direct habitat loss, habitat degradation, and habitat  
5 restoration/improvement. The metrics provide a basis for a qualitative  
6 discussion of habitat loss and fragmentation and species life history  
7 requirements.
  
- 8 • Populations – A surrogate metric for population information used in this analysis  
9 is number of occupied leks. Leks are strongly correlated with nesting habitat  
10 since radioed hens tend to nest within several miles of their lek of capture  
11 (Connelly et al. 2000). In Idaho, lek to nest distances may vary spatially over large  
12 landscapes, depending on the status of local GRSG populations, but roughly 80  
13 percent of nests statewide occur within 8 to 12 kilometers of the lek of capture  
14 (Connelly et al. 2013). In some parts of the state, a small proportion of hens  
15 (e.g., 5 to 7 percent) nested in excess of 15 km from lek of capture (Connelly et  
16 al. 2013). The metric was derived by quantifying for each GRSG population area,  
17 the number of occupied leks using the most recent lek data available (2014 for  
18 IDFG and MFWP; 2013 for Utah Division of Wildlife Resources), and lek  
19 occupancy or activity definitions consistent with those respective states.  
20 Numbers of occupied leks shown reflect leks with at least two or more displaying  
21 males in at least one of the past 5 years (2010 to 2014) for Idaho; for the last 10  
22 years (2005 to 2014) for Montana and Utah (2004 to 2013) respectively. This  
23 metric provides general insight into the population contribution of specific  
24 population areas relative to the sub-region overall, providing additional context  
25 for comparison. The metric also allows for inferences of risk to population  
26 persistence from certain threats or resource allocations (such as areas open to  
27 ROWs or mineral leasing), assuming that population areas with a smaller number  
28 of occupied leks are more vulnerable to resource activities and that areas with a  
29 greater number of occupied leks imply larger populations and a greater  
30 opportunity for long term persistence, given effective conservation efforts (see  
31 Section 3.2). Where land or resource allocations overlap population areas and/or  
32 occupied leks, the allocation is considered to be affecting the grouse population,  
33 for purposes of analysis.
  
- 34 • To the extent lands are subject to adaptive management and/or an  
35 anthropogenic disturbance cap, effects of threats would be further restricted  
36 based on the applicable thresholds and caps. Coordination between State and  
37 Federal managers would further ensure the application and implementation of  
38 these thresholds and caps.
  
- 39 • Habitat suitability – measured by Vegetation Dynamics Development Tool  
40 (VDDT) modeling, driven by sagebrush canopy cover and lack of conifer  
41 encroachment.

- 1           • Climate change - under projected climate change, cooler and moister sagebrush  
2 communities (i.e., nesting and brood rearing habitat) would decrease. In addition,  
3 Wyoming big sagebrush is expected to decline (Still and Richardson 2014).  
4 GRSG may have the ability to redistribute to areas that are currently cooler and  
5 wetter, as long as the new regions are suitable and available for sagebrush  
6 expansion (BLM 2013a, Knick et al. 2013). Climate change impacts are discussed  
7 for each threat where relevant.

8           ***Assumptions***

9           Three general categories of human disturbance (to habitats) or disruption (to animals) would  
10 be the most influential on GRSG and their habitat: 1) disturbance or disruption from casual  
11 use; 2) disturbance or disruption from permitted activities; and 3) changes in habitat  
12 condition, such as from fire or presence of noxious weeds and invasive species. The  
13 assumptions listed below are intended for large-scale planning-level analysis; project-level  
14 assumptions for NEPA may differ.

15          The analysis includes the following assumptions:

- 16           • GRSG Habitat Management Area designations are assumed to represent habitat  
17 adequate to maintain GRSG populations in the sub-region. For Idaho, GRSG  
18 habitat designations were derived from modeling efforts completed in 2012,  
19 based on 75 percent Breeding Bird Density and 75 percent lek connectivity  
20 models as well as known winter habitat, connectivity considerations and other  
21 factors. In Montana, GRSG habitat designations were derived from habitat  
22 modeling of core areas by MTFWP with additional input by the BLM. MZs were  
23 delineated by WAFWA in order to divide range-wide GRSG habitat into discrete  
24 areas for broad-scale planning. Population monitoring for GRSG is still done at  
25 finer scales including State, local working group, and Conservation Area.
- 26           • This analysis uses PPH and PGH categories for Alternative A only to facilitate  
27 comparison across the other alternatives. There are currently no BLM-  
28 administered or National Forest System lands formally designated as GRSG PPH  
29 or PGH within the sub-regional planning area, and Alternative A would neither  
30 result in the designation of PPH or PGH nor assign additional management  
31 actions to PPH or PGH areas.
- 32           • Population and subpopulation boundaries (Connelly et al. 2004) were modified  
33 to include the entirety of mapped GRSG Habitat Management Area designations  
34 in the vicinity. (See **Section 3.2**).
- 35           • Habitat conditions and trends for each GRSG population area were determined  
36 by modeling vegetation dynamics such as wildfire, succession, insects and  
37 disease, habitat restoration projects (e.g., sagebrush seeding, grass seeding, and  
38 herbicide treatment of annual grass), prescribed fire, overgrazing, conifer

1 encroachment and treatment, mechanical sagebrush treatment, and fuels  
2 reduction projects using the VDDT (**Appendix X**). Modeling was completed for  
3 population areas in Idaho, Utah (Sawtooth National Forest portion only), and  
4 southwestern Montana. Initial population areas from Connelly et al. (2004) were  
5 considered, but some were ultimately combined or delineated further, to  
6 accommodate similarities in vegetation models or disturbance regimes.

- 7 • Because GRSG are highly sensitive to habitat fragmentation, development, or  
8 changes in habitat conditions and require large, intact habitat patches for life  
9 history requirements, alternatives proposing to protect the most GRSG Habitat  
10 from disturbance are considered of greatest beneficial impact. These impacts can  
11 be described both qualitatively and quantitatively.
  
- 12 • Seasonal ranges of migratory and non-migratory GRSG are largely encompassed  
13 within GRSG Habitat Management Area designations but mapping is incomplete  
14 across much of the sub-region so an accurate assessment of direct impacts is not  
15 possible.
  
- 16 • GRSG Habitat Management Area designations encompass adequate habitat for  
17 providing connectivity within populations and subpopulations. Connectivity will  
18 be considered by incorporating population area scale information in the design  
19 and implementation of restoration projects.
  
- 20 • Under the Proposed Plan, PHMA focuses on conserving the two key GRSG  
21 meta-populations in the sub-region. The PHMA encompasses areas with the  
22 highest conservation value to GRSG, based on the presence of larger leks,  
23 habitat extent, important movement and connectivity corridors and winter  
24 habitat. IHMA contains additional high value habitat and populations that  
25 provide a management buffer for the PHMA, connect patches of PHMA. The  
26 IHMA encompasses areas of generally moderate to high conservation value  
27 habitat and/or populations and in some CAs includes areas beyond those  
28 identified by USFWS as necessary to maintain redundant, representative and  
29 resilient populations (Priority Areas for Conservation (PACs)). The IHMA are  
30 typically adjacent to PHMA but generally reflect somewhat lower GRSG  
31 population status and/or reduced habitat value due to disturbance, habitat  
32 fragmentation or other factors. GHMA encompasses habitat that is outside of  
33 PHMA or IHMA. It is generally characterized by more marginal habitat and  
34 few, if any, occupied leks or other important seasonal use areas.
  
- 35 • Impacts on GRSG accrue over varying distances from origin depending on the  
36 type and scale of development and the habitat type impacted:
  - 37 ○ Impacts from transmission lines constructed before 2002 are  
38 likely fully manifested. BMPs, RDFs, COAs, and standard  
39 operating procedures are used for analysis and would be  
40 implemented to reduce impacts on GRSG. These are subject

1 to modification based on subsequent guidance and new  
2 science.

3 ○ Ground-disturbing activities could modify habitat and cause  
4 loss or gain of individuals, depending on the size of the area  
5 disturbed, the nature of the disturbance (e.g., anthropogenic  
6 development vs. habitat restoration), and the location of the  
7 disturbance. For example, juniper reduction treatments in  
8 sagebrush steppe disturb the ground but are assumed to  
9 positively modify habitat quality and quantity in the long  
10 term.

11 ○ For analysis purposes, a 4.25-mile (6.9-kilometer) foraging  
12 distance is assumed to adequately encompass possible direct  
13 and indirect effects for both nesting and roosting avian  
14 predators (Boarman and Heinrich 1999; Leu et al. 2008) in  
15 instances where increased predation from human  
16 infrastructure (e.g. power lines, wind turbines,  
17 communication towers, agricultural and urban development)  
18 is a threat.

19 ○ Energy extraction such as oil and gas, geothermal, and plan of  
20 operation mining can cause impacts up to 11.8 miles (19  
21 kilometers) based on direct impacts of field development,  
22 including associated infrastructure, noise, lighting, and traffic  
23 (Johnson et al. 2011; Taylor et al. 2012).

24 ○ Interstate highways at 4.7 miles (7.5 kilometers) and paved  
25 roads and primary and secondary routes can cause impacts at  
26 1.9 miles (3 kilometers) based on indirect effects measured  
27 through road density studies (Connelly et al. 2004; Holloran  
28 2005; Lyon 2000).

29 ○ Site-specific disturbances such as small-scale mining and  
30 mineral material sites can cause impacts at 1.6 miles (2.5  
31 kilometers) based on indirect influence distance from  
32 estimated spread of exotic plants (Bradley and Mustard 2006).

33 • Quantitative impacts are presented for BLM-administered and National Forest  
34 System surface and subsurface only unless otherwise indicated.

35 • Short-term impacts would accrue over a timeframe of up to 10 years. Long-term  
36 impacts would accrue over timeframes exceeding 10 years.

1                   **4.2.2 Nature and Type of Effects**

2                   ***Riparian Areas and Wetlands***

3                   See Livestock Grazing Management, below.

4                   ***Water Resources Management***

5                   See Livestock Grazing Management, below.

6                   ***Vegetation and Habitat Restoration***

7                   Current treatments and active vegetation management typically focus on vegetation  
8                   composition and structure for fuels management, habitat management, and productivity  
9                   manipulation for improving the habitat and forage conditions for ungulates and other  
10                  grazers (Knick et al. 2011). The distribution of these treatments can affect the distribution of  
11                  GRSG and sagebrush habitats by affecting the distribution of suitable cover and forage  
12                  (Manier et al. 2013, p. 169).

13                  GRSG are more productive in higher-quality habitat conditions, including a diversity of  
14                  herbaceous species, vegetative and reproductive health of native grasses, and an abundance  
15                  of sagebrush (Manier et al. 2013, p. 169, Connelly et al. 2000). Residual vegetation cover,  
16                  especially grass and litter, has often been noted as essential for GRSG for concealment  
17                  during nesting and brood-rearing (Sveum et al. 1998; Kirol et al. 2012; Doherty et al. 2014).  
18                  Passive restoration efforts such as adjustments in management practices such as grazing  
19                  systems and seasonal restriction or closures in seasonal-use areas have a reasonable chance  
20                  to improve degraded or altered habitats (Manier et al. 2013, p. 170; Connelly et al. 2004).

21                  Some areas within the Idaho and southwestern Montana sub-region are experiencing severe  
22                  habitat degradation due to the establishment of undesirable annual invasive species which  
23                  have displaced native species, making passive management approaches unsuitable and  
24                  requiring direct manipulation (Connelly et al. 2004).

25                  BLM's Northern Great Basin Rapid Ecoregional Assessment (BLM 2013a) states that  
26                  climate change may worsen the spread of invasive species by increasing the severity of  
27                  droughts, reducing precipitation, or altering wildfire cycles (BLM 2013a). Over the longer  
28                  term, climate change may exacerbate the spread of annual invasive plants and woody plants  
29                  such as juniper, displacing native sagebrush communities. Climate change models indicate  
30                  less precipitation may occur in July through August in lower elevation sites, which may favor  
31                  cheatgrass, which becomes dormant in summer months, over native perennials, which  
32                  depend on summer moisture for growth. Elevated temperatures due to climate change may  
33                  increase the competitive ability of cheatgrass at higher elevations, expanding its range into  
34                  sites where it currently is not widespread. Climate change may increase the spread of woody  
35                  plants such as juniper at higher elevations due to increased precipitation in winter and spring  
36                  and warmer temperatures, which may increase fire risk (BLM 2013a).

37                  Invasive plants alter plant community structure and composition, productivity, nutrient  
38                  cycling, and hydrology, and may competitively exclude native plant populations. In parts of  
39                  the sub-region, invasive species such as cheatgrass or native species such as juniper have  
40                  replaced desirable native shrubs (i.e., sagebrush), perennial bunchgrasses and forbs.

1 Cheatgrass invasion areas typically require active control (e.g., herbicides) and subsequent  
2 seeding of desirable native perennial species may be needed for successful restoration, unless  
3 deep-rooted bunchgrasses are still present in the understory (Miller et al. 2007). Seeding with  
4 non-native perennials may also be necessary, in drier sites. Juniper encroachment requires  
5 active treatment, including manual and mechanical juniper removal. Pinyon pine only occurs  
6 locally in parts of southern Idaho, and has not been identified as a management concern to  
7 date.

8 Cheatgrass competes with native grasses and forbs that are important components of GRSG  
9 habitat. Cheatgrass abundance is negatively correlated with habitat selection by GRSG (Kirol  
10 et al. 2012), indicating that changes in composition and structure associated with cheatgrass  
11 specifically degrade GRSG habitat. Invasion by medusahead (*Taeniatherum caput-medusae*) may  
12 be even worse than cheatgrass, as it is unpalatable to herbivores due to its high silica content,  
13 supports high-frequency wildfire intervals, and requires intensive treatment for restoration  
14 (Davies 2010a, Archer 2001). Invasive species cause direct degradation of sagebrush habitats,  
15 resulting in effects on local GRSG populations by affecting forage, cover quality and  
16 composition, and increased wildfire frequency and intensity, with the potential to cause  
17 complete avoidance (Manier et al. 2013, p. 135).

18 Expansion of conifer woodlands also threatens GRSG populations because woodlands do  
19 not provide suitable habitat and trees can displace shrubs, grasses, and forbs that are  
20 required by GRSG, particularly in shallow-rooted soils (Miller et al. 2007). Conifer expansion  
21 is also associated with increased bare ground and the potential for erosion, as well as an  
22 increase in perch sites for raptors. Juniper encroachment may also represent expansion of  
23 avian predation threats by providing nesting substrate for raptors and corvids. Studies have  
24 shown that GRSG incur population-level impacts at very low levels (as low as 4 percent) of  
25 conifer encroachment (Baruch-Mordo et al. 2013).

26 The VDDT modeling effort is described further in **Appendix X**. Stand replacement wildfire,  
27 mosaic wildfire, overgrazing, insects and disease, and conifer encroachment were  
28 incorporated into the model to quantify changes in GRSG habitat. The modeling effort did  
29 not include changes in habitat conditions associated with climate change or with permitted  
30 activities such as infrastructure development, travel management, or mineral development.  
31 The model also estimated treatment acres required to meet target sagebrush habitat quality  
32 goals. Based on guidelines provided by the GRSG National Technical Team Report (NTT  
33 2011), 70 percent of an area should be in 10 to 30 percent sagebrush canopy cover to meet  
34 GRSG sagebrush habitat objectives. The tables included as part of the vegetation impacts  
35 for each alternative present the percentage of a given GRSG analysis area meeting GRSG  
36 sagebrush habitat objectives by alternative after 10 years and 50 years' time.

### 37 ***Livestock Grazing Management***

38 Livestock grazing is the most widespread land use across the sagebrush biome (Connelly et  
39 al. 2004, pp. 7-29). Livestock grazing can affect soils, biological soil crust, vegetation, riparian  
40 habitat conditions, water, and nutrient availability by consuming or altering vegetation,  
41 redistributing nutrients and plant seeds, trampling soils and vegetation, and disrupting  
42 microbial composition (Connelly et al. 2004). Livestock may also trample nests and disturb

1 GRSG behavior (NTT 2011, p. 14). Livestock grazing is a diffuse form of biotic disturbance  
2 that exerts repeated pressure on a system over many years; unlike point-sources of  
3 disturbance (e.g., fires), effects of grazing are not likely to be detected as disruptions, but as  
4 differences in the processes and functioning of the sagebrush system. Grazing effects are not  
5 distributed evenly because historic practices, management, and animal behavior all lead to  
6 differential use of the range (Manier et al. 2013, pp. 157-168).

7 At improper levels of grazing, impacts can lead to loss of vegetative cover, reduced nesting  
8 habitat quality; reduced forage availability, reduced water infiltration rates, change in  
9 vegetation composition, decreased plant litter, increased bare ground, reduced nutrient  
10 cycling, decreased water quality, increased soil erosion, and reduced overall habitat quality  
11 for wildlife, including GRSG (Manier et al. 2013, pp. 157-159). Grazing practices may  
12 contribute to the spread of invasive weeds in sagebrush ecosystems by reducing cover of  
13 native bunchgrass (Reisner et al. 2013), and may increase desertification or worsen the  
14 impacts of climate change on rangeland (Beschta et al. 2014). Properly managed grazing,  
15 however, may be compatible with GRSG habitat, does not preclude healthy rangelands, and  
16 may reduce wildfire in GRSG habitat by reducing fuel loads in certain circumstances (Strand  
17 and Launchbaugh 2013, Svejcar et al. 2014, NTT 2011, p. 14).

18 Structural range improvements such as fences represent potential movement barriers  
19 (especially woven-wire fences) or predator perches, and are a potential cause of direct  
20 mortality to GRSG due to collision (Stevens et al. 2012; Manier et al. 2013, p. 50).

21 Grazing strategies that promote sagebrush ecosystem health would help to maintain the  
22 desired seasonal GRSG habitat management objectives on the landscape including  
23 herbaceous cover and height metrics, thereby enhancing habitat for GRSG populations  
24 (**Table 2-3**, Seasonal Habitat Desired Conditions for Greater Sage-Grouse).

### 25 ***Fire and Fuels Management***

26 Fire is recognized as a primary threat to GRSG populations in the western half of their  
27 distribution (see Secretarial Order 3336). Within the Snake River Plain floristic province,  
28 which comprises a substantial portion of the sub-region, approximately 37 percent of the  
29 sagebrush area burned between 1980 and 2007 (Baker 2011). Fire is particularly problematic  
30 in sagebrush systems because it kills sagebrush plants and, in some cases, re-burns before  
31 sagebrush has a chance to re-establish.

32 Fuels treatment methods should take into consideration habitat conditions and the presence  
33 or absence of cheatgrass or other invasive species. Avoiding treatments and activities that  
34 remove sagebrush, degrade native herbaceous species, and (or) promote cheatgrass  
35 expansion likely requires a combination of different treatment methods and/or management  
36 actions (Manier et al. 2013, p.81).

37 Actions to reduce the spread of fire in sagebrush can also benefit GRSG. For example,  
38 vegetative fuel breaks have characteristics that disrupt fuel continuity, harbor lower fuel  
39 loads, and have lower volatile compounds and increased moisture content (Pellant 1992).

1 Fuel breaks help provide defensible anchor points for facilitating fire suppression activities  
2 and can allow fires to be compartmentalized, ultimately reducing potential fire size.

3 Grazing may have limited ability to reduce the types of fuels (e.g., cheatgrass) that have the  
4 biggest impact on fire frequency. Intensive livestock grazing is often suggested for  
5 controlling cheatgrass competition. Although targeted grazing may have some applications  
6 for fuels management, it is not effective in reducing cheatgrass competition (Hempy-Mayer  
7 and Pyke 2008).

8 Fire is a primary threat to GRSG populations where increasing exotic annual grasses,  
9 primarily cheatgrass, are resulting in sagebrush loss and degradation (USFWS 2010a, p.  
10 13,932). Cheatgrass can more easily invade and create its own feedback loop in areas that are:  
11 1) dry with understory vegetation cover that is not substantial, or 2) experiencing surface-  
12 disturbing activities (e.g., road construction). It can facilitate short fire return intervals by  
13 outcompeting native herbaceous vegetation with early germination, early moisture and  
14 nutrient uptake, prolific seed production, and early senescence (Hulbert 1955; Mack and  
15 Pyke 1983; Pellant 1996). Furthermore, by providing a dry, fine fuel source during the peak  
16 of fire season, cheatgrass increases the likelihood of fire, which increases the likelihood of  
17 further cheatgrass spread (Pellant 1990). Cheatgrass dominance can also exclude sagebrush  
18 seedlings from establishing due to competition. Fire contributes to the problem by  
19 accelerating the conversion of native, perennial plant communities to annual grasslands,  
20 where those species have a foothold. Without shrubs and a healthy diversity of grasses and  
21 forbs, such annual grasslands will not support GRSG, and populations would likely be  
22 displaced or suffer declines due to increased exposure to predators, loss of forage and cover,  
23 and other factors in burned habitat.

24 Fire risk and the likelihood of perpetuating the cheatgrass-fire cycle in GRSG habitat is  
25 highest in arid, low-elevation areas with Wyoming big sagebrush (*Artemisia tridentata* ssp.  
26 *tridentata*), which dominates the planning area. Ground disturbance, such as roads, facilitates  
27 the establishment and spread of cheatgrass and other invasive weeds (Gelbard and Belnap  
28 2003). While fires do occur within higher elevation mountain big sagebrush (e.g. *Artemisia*  
29 *tridentata* ssp. *naseyana*) habitats, they are typically smaller and more variable in intensity and  
30 these ecological communities typically have a higher resilience to disturbance and a lower  
31 risk of cheatgrass establishment resulting in a shorter recovery time and less effect to GRSG  
32 compared to lower elevations (Chambers et al. 2014, **Appendix D**).

33 Another factor affecting fire in some sagebrush sites is the encroachment of juniper trees or  
34 other conifers, such as Douglas-fir from higher elevations down slope into sagebrush  
35 habitats (Baker 2011; Balch et al. 2012). Wildfires that start in conifer stands can increase in  
36 size and severity with the available heavier fuel, facilitating their spread into Wyoming big  
37 sagebrush stands. Wyoming sagebrush can take 150 years to recover from fire (Cooper et al.  
38 2007). Following fire, sagebrush areas can be opened to invasion by cheatgrass and other  
39 annual grasses, which limit the re-establishment of sagebrush. Increased fire severity leads to  
40 increased soil loss, which in turn facilitates an increase in the abundance of invasive annuals,  
41 resulting in decreased success of rehabilitation efforts. In the Idaho and southwestern  
42 Montana sub-region, several population areas or portions thereof have experienced

1 substantial declines in habitat due to fire (i.e., Jarbidge portion of South Snake River; North  
2 Snake River; Weiser). Depending on the amount of habitat available to the birds, a single fire  
3 can influence a local population's distribution, migratory patterns, and overall habitat  
4 availability (Fischer et al. 1997, p. 89).

5 In degraded GRSG habitats where cheatgrass is dominant under the sagebrush canopy, the  
6 sagebrush may still likely provide adequate winter habitat. However, these areas lack the  
7 understory forb diversity and insect abundance necessary for brood-rearing and could result  
8 in lower chick survival during summer. These areas would also lack the necessary cover for  
9 suitable nesting due to the absence of perennial grasses and forbs., As GRSG habitats  
10 become smaller in scale and less connected to adjacent populations, they become  
11 increasingly susceptible to random events and local extirpation (Knick and Hanser 2011;  
12 Wisdom et al. 2011). In addition, genetically isolated populations could suffer a decrease in  
13 fitness from inbreeding.

14 Fire causes GRSG habitat loss and degradation on an annual basis in portions of the Idaho  
15 and southwestern Montana sub-region. Cheatgrass dominance within portions of the sub-  
16 region has shortened the fire return interval, and exacerbated the loss and degradation of  
17 GRSG habitat. While research and management efforts are focused on developing means of  
18 controlling cheatgrass on a large scale, the only current management actions under the fire  
19 program to minimize the spread of fire in GRSG habitat are fuels treatments, pre-  
20 suppression planning, and effective fire suppression geared toward protecting GRSG habitat.  
21 Reducing the spread of cheatgrass and the scale of wildfire through appropriate conservation  
22 actions associated with other BLM and Forest Service post-fire programs, such as ES&R or  
23 BAER, could also result in more or improved habitat for GRSG.

#### 24 ***Wild Horse and Burro Management***

25 Six horse herd management areas (HMAs) and portions of HMAs occur within or adjacent  
26 to four GRSG population areas in the sub-region including: Southwest Idaho, Weiser,  
27 Mountain Valleys, and South Snake. HMAs occur on 269,800 acres of GRSG habitat in the  
28 sub-region. Within each HMA, an Appropriate Management Level (AML) was established  
29 under which wild horse population levels are managed to meet a Thriving Natural Ecological  
30 Balance (BLM Handbook H-4700-1), and prevent deterioration of the range.

31 Wild horses may alter habitat conditions for GRSG, including reduced total vegetative and  
32 grass abundance and cover, lowered sagebrush canopy cover, increased fragmentation of  
33 shrub canopies, lowered species richness, increased compaction in surface soil horizons, and  
34 increased dominance of unpalatable forbs (Manier et al. 2013, p. 100). In addition, horse  
35 populations over AML can degrade riparian areas, decrease water quantity and quality, and  
36 increase soil erosion, which cumulatively can reduce habitat quality for wildlife, including  
37 GRSG. Effects of wild horses on habitats may also be more pronounced during periods of  
38 drought or vegetation stress (NTT 2011, p. 18).

39 Fences used to manage horse distribution, represent a potential source of direct mortality to  
40 GRSG (Manier et al. 2013). In addition, water must be available year- round in HMAs and  
41 wild horse territories, in compliance with the Wild and Free-Roaming Horses and Burros

1 Act of 1971. This can lead to riparian areas receiving yearlong use by wild horses or riparian  
2 areas being modified with additional fencing and troughs in order to accommodate yearlong  
3 horse use. The range improvements would result in increased potential perch sites for avian  
4 predators, potential drowning hazards, less water available for wildlife, and could have  
5 negative effects on riparian habitat, depending on how each facility is constructed.

### 6 ***Locatable, Leasable, and Salable Minerals Management***

7 Minerals development within the sub-region consists of mining mineral resources at various  
8 scales that require a Notice of Intent when disturbance is 5 acres or less, or Plans of  
9 Operation when the total disturbance will exceed 5 acres, or if the proposed operations meet  
10 one or more of the criteria requiring a Notice of Intent or a Plan of Operations (43 CFR  
11 3809.21 and 36 CFR 228.4). Salable mineral mining in the sub-region is primarily for gravel.  
12 Locatable mineral mining is primarily for gold, silver, and copper, but includes other  
13 minerals such as barite and Oakley stone. Leasable minerals in the sub-region include  
14 commodities such as potash and phosphate. With the exception of the Bear Lake area, the  
15 potential for oil and gas development is low in the sub-region. Development of locatable and  
16 leasable mineral resources typically requires significant infrastructure and human activity for  
17 construction, operation, and maintenance.

18 Mineral extraction of all types in GRSG habitat results in habitat loss caused by construction  
19 of infrastructure and the footprint of the surface facilities/pits or above ground facilities  
20 associated with subsurface operations. Sagebrush communities that are lost or modified in  
21 locations where mine reclamation is not compromised by the presence or introduction of  
22 invasive grasses still may not regain sagebrush cover suitable for GRSG use for 20 to 30  
23 years or longer following interim or final reclamation, depending on scale and site factors  
24 (Knick et al. 2013). GRSG population re-establishment in reclaimed areas may take upwards  
25 of 30 years (Braun 1998). Where compromised by invasive grasses, reclamation may only be  
26 minimally effective, without additional intervention. Necessary infrastructure, including  
27 location, construction, and use of ancillary facilities, staging areas, roads, railroad tracks and  
28 structures such as buildings and power lines causes additional direct and indirect impacts on  
29 GRSG from noise pollution, fugitive dust, human disturbance, increases in predator perch  
30 sites, and weed proliferation, leading to habitat degradation.

31 The industrial activity associated with energy and mineral development produces noise and  
32 human activity that can disrupt the habitat and life-cycle of GRSG. Many studies assessing  
33 impacts of energy development on GRSG have found negative effects on populations and  
34 habitats (Naugle et al. 2011; Taylor et al. 2012). Walker et al. (2007) found that buffer sizes  
35 to 1 mile resulted in an estimated lek persistence of approximately 30 percent, while lek  
36 persistence in areas without oil and gas development averaged 85 percent. Holloran (2005)  
37 found impacts on abundance at a distance between 3 and 4 miles. Coates et al. (2013)  
38 recommended a minimum buffer of 3 miles for protection of GRSG from energy  
39 development impacts. The USGS recently published a scientific review of conservation  
40 buffer distances for GRSG protection from different types of human disturbance (USGS  
41 2014, see **Appendix B**).

1 Noise from industrial activity may disrupt GRSG communication, which is at low-frequency  
2 and potentially masked by low-frequency noise from equipment and vehicles, resulting in  
3 reduced female attendance and yearling recruitment as seen in sharp-tailed grouse (*Pedioecetes*  
4 *phasianellus*; Amstrup and Phillips 1977). The mechanism of how low-frequency noise  
5 affected the birds was not known, but it is known that GRSG depend on acoustical signals  
6 to attract females to leks (Gibson and Bradbury 1985; Gratson 1993; Blickley et al. 2012).  
7 Noise associated with oil and gas development may have played a factor in habitat selection  
8 and a decrease in lek attendance by GRSG in western Wyoming (Holloran 2005). Recent  
9 studies in oil and gas areas suggest GRSG avoid leks exposed to anthropogenic noise  
10 (Blickley et al. 2012; Blickley and Patricelli 2012). Chronic noise pollution can also cause  
11 GRSG to avoid otherwise suitable habitat (Patricelli et al. 2013) and can cause elevated stress  
12 levels in the birds that remain in noisy areas (Blickley et al. 2012).

13 Infrastructure for mining is similar to that required for oil and gas but is more localized in  
14 extent. As revealed by studies on oil and gas development, the interaction and intensity of  
15 effects of habitat loss could cumulatively or individually lead to habitat fragmentation in the  
16 long term (Connelly et al. 2004; Holloran 2005) with negative impacts of fragmentation as a  
17 result of development and associated infrastructure on lek persistence, lek attendance, winter  
18 habitat use, recruitment, yearling annual survival rate, and female nest site choice (Holloran  
19 2005; Aldridge and Boyce 2007; Walker et al. 2007; Doherty et al. 2008).

#### 20 ***Land Uses and Realty Management***

21 Transmission lines and major power lines are widespread throughout the range of GRSG.  
22 GRSG generally respond negatively to increased human infrastructure in sagebrush habitats,  
23 including roads, power lines, and communication towers (Manier et al. 2013, pp. 71-74).  
24 Although transmission and power line construction does not generally result in substantial  
25 direct habitat loss, it would temporarily disturb individual GRSG and habitat along the ROW  
26 due to the associated human activity, equipment, and noise, and would contribute to habitat  
27 fragmentation. In addition, transmission lines can provide perches and nest sites for ravens  
28 and raptors, resulting in indirect negative impacts on GRSG survival and reproduction  
29 (Gillan et al. 2013; Gibson et al. 2013; Lockyear et al. 2103; Coates et al. 2014; Howe et al.  
30 2014). Co-location of transmission lines could reduce impacts by siting new developments in  
31 areas that are previously disturbed. However, co-locating new lines can have indirect impacts  
32 on GRSG such as impeding movement and reducing habitat connectivity (Shirk et al. in  
33 review; Washington Wildlife Habitat Connectivity Working Group 2012). Roads associated  
34 with energy transmission facilities can also reduce the amount and quality of GRSG habitat  
35 or serve as inroads for invasive plants to establish.

36 Following construction, potential GRSG avoidance of tall vertical structures, due to avian  
37 predators perching and nesting on the structures, or due to presence of the structure itself,  
38 may result in habitat exclusion via behavioral response. Although not all studies have found  
39 effects of tall structures on GRSG (Messmer et al. 2013), the tendency of GRSG to fly  
40 relatively low and in low light, puts them at high risk of collision with power lines (Manier et  
41 al. 2013, pp.50-51). The frequency of raptor/GRSG interactions during the breeding season  
42 increased 65 percent and golden eagle interactions alone increased 47 percent in an area  
43 following installation of transmission lines, and nearby lek usage declined 72 percent (Ellis

1 1985, cited in Manier et al. 2013, pp. 50-51). A study of raven occurrence near transmission  
2 lines in southern Idaho found increased raven presence near transmission lines up to 1.4  
3 miles (2.2 km) from the corridor. Ravens preferred sagebrush edge habitats with non-native  
4 vegetation with patchy, exotic vegetation that occurs following disturbance (Coates et al.  
5 2014; Howe et al. 2013).

6 Perch deterrents are often used to reduce the impact of avian predation. Prather and  
7 Messmer (2010) determined that the effectiveness of perch deterrents were limited by the  
8 structure of the power poles and the design and placement of deterrents. In other studies,  
9 equipping poles with perch deterrents has been observed to reduce but not eliminate  
10 perching by corvids and raptors associated with GRSG predation (Lammers and Collopy  
11 2007; Slater and Smith 2010). Similarly, perch-deterrent devices installed following  
12 construction of an 18-mile power transmission line significantly reduced raptor use in  
13 Wyoming (Oles 2007).

14 A west-central Idaho study using spatial statistics and point-pattern simulations found that  
15 GRSG avoided power transmission lines by 600 meters (approximately 0.37 miles; Gillan et  
16 al. 2013). A study of the long-term impacts of the Falcon-Gondor transmission line in  
17 Nevada found strong support for an effect of distance from the power line on nest survival  
18 and female survival, suggesting an impact from increased predation. The study concluded  
19 that placement of transmission lines in GRSG habitat areas may negatively influence long-  
20 term population dynamics (Gibson et al. 2013).

21 In areas managed as ROW/SUA exclusion, the BLM and Forest Service would prohibit all  
22 development of ROWs/SUAs, with some exceptions provided, while in areas managed as  
23 ROW/SUA avoidance, the BLM and Forest Service would consider whether a ROW/SUA  
24 would be allowed on a case-by-case basis. This flexibility may be advantageous where federal  
25 and private land-ownership areas are mixed and exclusion areas may result in more  
26 widespread development on private lands if BLM-administered or National Forest System  
27 lands could not be used. Land tenure adjustments or withdrawals made in GRSG habitat  
28 could reduce the habitat available to sustain GRSG populations, unless provisions were  
29 made to ensure that GRSG conservation remained a priority under the new land  
30 management regime. Land tenure actions designed to decrease fragmentation of GRSG  
31 habitat would help GRSG populations (NTT 2011, p. 12).

32 Collisions with power lines, vehicles, property fencing, and increased predation by raptors  
33 may increase mortality of birds at leks (Connelly et al. 2000a; Lammers and Collopy 2007).  
34 Roads and power lines may also indirectly affect lek persistence by altering productivity of  
35 local populations or survival at other times of the year. GRSG mortality associated with  
36 power lines and roads occurs year round (Aldridge and Boyce 2007). Artificial ponds created  
37 by development (Zou et al. 2006) can support breeding mosquitoes known to vector West  
38 Nile virus (Walker et al. 2007) and elevate risk of mortality in late summer (Walker and  
39 Naugle 2011). GRSG may also avoid otherwise suitable habitat as development increases  
40 (Lyon and Anderson 2003; Holloran 2005; Kaiser 2006; Doherty et al. 2008).

1 Avoidance of development areas should not be considered a simple shift in habitat use, but  
2 rather a reduction in the distribution of GRSG (Walker et al. 2007) because avoidance is  
3 likely to result in true population declines when density dependence, competition, or  
4 displacement of birds into poorer-quality adjacent habitat lowers survival or reproduction  
5 (Holloran and Anderson 2005; Aldridge and Boyce 2007; Holloran et al. 2010). GRSG  
6 exhibit extremely high site fidelity which strongly suggests that unfamiliarity with new  
7 habitats may also reduce survival (Baxter et al. 2008), as evidenced in other grouse species  
8 (Yoder et al. 2004). GRSG avoid other anthropogenic features such as roads, power lines, oil  
9 and gas wells, and buildings (Lyon and Anderson 2003; Pruett et al. 2009). Augmentation of  
10 dwindling GRSG populations by introduction of translocated birds or supplementing  
11 existing populations is often unsuccessful (Naugle et al. 2011; Baxter et al. 2008).

### 12 ***Renewable Energy***

13 Because large-scale development of renewable energy resources is recent compared with oil  
14 and gas, many of the potential impacts of renewable energy on GRSG have not been  
15 studied. However, potential development impacts on GRSG can be anticipated from studies  
16 of oil and gas development on the species (Becker et al. 2009). Recent research has found  
17 that nest and brood survival are negatively affected with proximity to wind turbines, likely as  
18 a result of increased predation (LeBeau 2012; LeBeau et al. 2014). Because GRSG have  
19 evolved in habitats with little vertical structure or other anthropogenic features, tall vertical  
20 structures such as wind turbines may displace GRSG from their normally used habitat  
21 (Johnson and Stephens 2011).

22 Impacts from energy development accrue both locally and cumulatively at the landscape  
23 scale. Accumulated evidence across landscape-scale studies show that GRSG populations  
24 typically decline following oil and gas development (Holloran 2005; Walker et al. 2007;  
25 Doherty et al. 2008). Oil and gas infrastructure and associated human activity have been  
26 shown to adversely affect GRSG populations collectively and in some instances, impacts  
27 have been directly attributed to certain anthropogenic features (e.g., roads, power lines,  
28 noise, and associated infrastructure; Walker et al. 2007; Doherty et al. 2008; Lyon and  
29 Anderson 2003; Holloran 2005; Kaiser 2006; Aldridge and Boyce 2007). Direct impacts of  
30 energy development on GRSG habitats and populations include loss of sagebrush canopy or  
31 nest failure; these effects have been estimated to occur within a 62 m (68 yards) radius from  
32 leks. Indirect effects include habitat degradation or utilization displacement; these effects  
33 have been estimated to occur out to 19 km (11.8 mi) from leks (Naugle et al. 2011).  
34 Population impacts have been observed when leks occur within 4 km (2.5 mi) from a  
35 producing well and when greater than eight active wells occurred within 5 km (3.1 mi) of  
36 leks, or when more than 200 active wells occurred within 18 km (11 mi) of leks. Other  
37 impacts have been documented within varying distances from energy infrastructure and at  
38 different well densities (USGS 2014).

39 Renewable energy development and its infrastructure (e.g., power lines, roads, and  
40 construction activities) may negatively affect GRSG populations via several different  
41 mechanisms. For example, concerns with wind energy development include noise produced  
42 by rotor blades, GRSG avoidance of structures, mortality of GRSG that fly into rotors, and  
43 the presence of new roads and power lines (Connelly et al. 2004; Manier et al. 2013).

1 Mechanisms responsible for cumulative impacts that lead to population declines depend on  
2 the magnitude, frequency, and duration of human disturbance. GRSG may abandon leks if  
3 repeatedly disturbed by raptors perching on power lines or other tall vertical structures near  
4 leks (Ellis 1984), by vehicular traffic on roads (Lyon and Anderson 2003) or by noise and  
5 human activity associated with energy development (Braun et al. 2002; Holloran 2005; Kaiser  
6 2006).

### 7 ***Travel and Transportation Management***

8 The Travel and Transportation program is principally focused on road networks within the  
9 GRSG range. The three types of linear features that comprise the existing transportation  
10 system include roads, primitive roads, and trails. Because roads accommodate year-round  
11 passenger vehicles and volume of traffic is the highest, roads by comparison translate into  
12 the greatest potential for impacts on GRSG and its habitat. Primitive roads are seasonally  
13 passable in many areas and, compared to roads, have a lower traffic volume, lower travel  
14 speeds, and fewer impacts on GRSG. Trails are seasonally passable, have the lowest traffic  
15 volume, and are typically only used by foot travelers, mountain cyclists, equestrians, and  
16 OHVs; thus the fewest impacts on GRSG are expected from trails compared to the other  
17 two feature types.

18 BLM and Forest Service travel management primarily manages public use levels within travel  
19 management zones under the following designations: closed, limited (to existing or  
20 designated roads and trails), or open. Use of roads is predominately associated with  
21 recreational pursuits on BLM-administered or National Forest System lands and permitted  
22 uses, such as by livestock grazing permittees. Areas currently open to cross-country  
23 motorized use would be expected to have greater impacts on GRSG than those areas where  
24 travel is limited to existing roads and trails or closed to motorized use, since there would be a  
25 considerably higher likelihood of disturbance to vegetation, flushing of GRSG, nest  
26 abandonment or destruction, increased wildfire risk and spread of invasive plants and  
27 noxious weeds.

28 GRSG persistence is inversely correlated with road density. Compared with occupied GRSG  
29 range, extirpated range was 60 percent closer to highways and had 25 percent higher road  
30 densities (Manier et al. 2013 citing Wisdom et al. 2011). Within the GRSG range, 95 percent  
31 of the mapped sagebrush habitats are within 1.6 miles (2.5 kilometers) of a mapped road;  
32 density of secondary roads exceeds 3.1 miles per 247 acres (5 kilometers per square  
33 kilometer) in some regions (Knick et al. 2011). Incremental effects of accumulating length of  
34 roads in proximity to leks were apparent rangewide, although limited to major roads (state  
35 and federal highways and interstates). This effect was demonstrated by decreasing lek counts  
36 when there were more than 5 km (3.1 mi) of federal or state highway within 5 km (3.1 mi) of  
37 leks and when more than 20 km (12.4 mi) of highway occurs within an 18-km (11.2-mi)  
38 window (Johnson et al. 2011). Roads have multiple impacts on wildlife in terrestrial  
39 ecosystems, including increased mortality from collision with vehicles; changes in behavior;  
40 loss, fragmentation, and alteration of habitat; spread of exotic species; and increased human  
41 access, resulting in facilitation of additional alteration and use of habitats by humans  
42 (Formann and Alexander 1998; Jackson 2000; Trombulak and Frissel 2000). The effect of

1 roads can be expressed directly through changes in habitat and GRSG populations and  
2 indirectly through avoidance behavior because of noise created by vehicle traffic (Lyon and  
3 Anderson 2003; USFWS 2010a; See **Section 4.2.1** regarding interstates and primary routes).

4 Roads fragment habitat by impeding use of migration corridors or seasonal habitats; facilitate  
5 habitat degradation in the remaining habitats by creating a corridor along which invasive  
6 plants can spread; allow for increased human noise disturbance which can result in GRSG  
7 habitat use avoidance (i.e., functional habitat loss); and increase mammalian and avian  
8 predator abundance (Formann and Alexander 1998, pp. 207-231). Connelly and others  
9 (2004) suggest road traffic within 4.7 miles of leks negatively influences male lek attendance.  
10 Similarly, lek count trends are lower near interstate, federal, or state highways compared with  
11 secondary roads (Johnson et al. 2011), and Connelly and others (2004) reported no leks  
12 within 1.25 miles of an interstate. In general, leks closer to the interstate had higher rates of  
13 decline than leks further away from the interstate. In Montana and southern Canada, as the  
14 length of roads within 2 miles of a lek increased, the likelihood of lek persistence decreased  
15 (Manier et al. 2013).

16 Motorized activities are expected to have a larger footprint on the landscape than non-  
17 motorized users. Cross-country motorized travel would result in increased potential for soil  
18 compaction, loss of perennial grasses and forbs, and reduced canopy cover of sagebrush  
19 (Payne et al. 1983). Long-term losses in sagebrush canopy would likely be the result of  
20 repeated, high frequency, long duration use by cross-country OHV use. Impacts on  
21 vegetation communities would likely be greater during the spring and winter months when  
22 soil conditions are wet and more susceptible to compaction and rutting. In addition, the  
23 chances of wildfire are increased during the summer months when fire dangers are high and  
24 recreation is also at its highest. Noise and increased human presence associated with  
25 construction, use, and maintenance of roads may change GRSG behavior based on the  
26 proximity, magnitude, intensity, and duration.

### 27 ***Special Designations***

28 Special designation areas (e.g., ACECs) may be established to protect GRSG and their  
29 habitat as a relevant or important value. While existing ACECs do not have GRSG as a  
30 relevant or important value, and thus management is not tailored to protect GRSG, some  
31 incidental protection may be conferred in existing ACECs by restricting resource uses  
32 intended to protect other values.

### 33 **4.2.3 Impacts on GRSG and GRSG Habitat Common to All Alternatives**

34 The nature and type of impacts described below are common to all alternatives, but the  
35 context and intensity may vary by alternative.

#### 36 ***Impacts from Vegetation and Soils Management***

37 Vegetation dynamics modeling was completed to describe vegetative changes across all the  
38 alternatives for the short term (10 years) and in the long term (50 years). **Table 4-1**, GRSG  
39 Habitat Condition<sup>1</sup> and Trend Analysis within the Idaho and Southwestern Montana Sub-  
40 region after 10 Years<sup>2</sup>, and **Table 4-2**, GRSG Habitat Condition<sup>1</sup> and Trend Analysis within  
41 the Idaho and Southwestern Montana Sub-region after 50 Years<sup>2</sup>, display these

1 comparisons. Vegetation dynamics modeling is presented separately for the Proposed Plan  
2 in **Section 4.2.7**.

3 ***Impacts from Renewable Energy Management***

4 The magnitude of impacts is different for all alternatives as the acreages of lands managed  
5 for ROWs and zoning designations vary across the alternatives (see **Table 2-3**, Comparative  
6 Allocation Summary of Alternatives, in **Chapter 2**). Acres of avoidance and exclusion areas  
7 for ROWs and SUAs in GRSG habitat would vary by alternative. **Table 4-3**, GRSG Habitat  
8 within Avoidance Areas for ROWs and SUAs in the Idaho and Southwestern Montana Sub-  
9 region, and **Table 4-4**, GRSG Habitat within Exclusion Areas for ROWs and SUAs in the  
10 Idaho and Southwestern Montana Sub-region, show the acreage where ROWs and SUAs  
11 would be restricted under each alternative.

12 ***Impacts from Livestock Grazing Management***

13 Acres available or unavailable (closed) to grazing for each of the alternatives are described in  
14 **Table 4-5**, GRSG Habitat Acres Closed to Grazing in the Idaho and Southwestern Montana  
15 Sub-region.

**Table 4-1**  
**GRSG Habitat Condition<sup>1</sup> and Trend Analysis within the Idaho and Southwestern Montana Sub-region after 10 Years<sup>2,4</sup>**

Analysis Area	Total Acres	Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
Southwest Idaho	5,600,000	62%	63%	61%	63%	63%	63%
South Side Snake	6,768,000	61%	60%	58%	60%	60%	60%
North Side Snake	3,854,000	70%	71%	71%	71%	71%	71%

<sup>1</sup>Percent of analysis area meeting GRSG sagebrush habitat objectives

<sup>2</sup>Existing habitat conditions are estimated from a combination of LANDFIRE and ReGap data sets. These data sets are the best available across both National Forest System and BLM-administered lands, but they include some inaccuracy and error. Interpretation of and evaluation of trends in each population area should consider this. Vegetation modeling data is intended to be an approximation of expected conditions in 50 years. In areas where existing habitat conditions are high, such as 80 to 90 percent, it is not unexpected to see a declining trend in habitat conditions. These conditions can be either a result of overestimating existing conditions or vegetation dynamics driving the trends. The vegetation modeling for each alternative assumes the vegetation treatment rates from Alternative A – No Action. For a description of analysis inputs, see **Appendix X**.

<sup>3</sup>The Mountain Valleys population was divided and modeled as two separate components of the vegetation dynamics model. See **Appendix X** for more details.

<sup>4</sup> Conditions for the Proposed Plan are presented in **Table 4-47**.

**Table 4-2**  
**GRSG Habitat Condition<sup>1</sup> and Trend Analysis within the Idaho and Southwestern Montana Sub-region after 50 Years<sup>2,4</sup>**

Analysis Area	Total Acres	Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F

<sup>1</sup>Percent of analysis area meeting GRSG sagebrush habitat objectives

<sup>2</sup>Existing habitat conditions are estimated from a combination of LANDFIRE and ReGap data sets. These data sets are the best available across both National Forest System and BLM-administered lands, but they include some inaccuracy and error. Interpretation of and evaluation of trends in each population area should consider this. Vegetation modeling data is intended to be an approximation of expected conditions in 50 years. In areas where existing habitat conditions are high, such as 80 to 90 percent, it is not unexpected to see a declining trend in habitat conditions. These conditions can be either a result of overestimating existing conditions or vegetation dynamics driving the trends. The vegetation modeling for each alternative assumes the vegetation treatment rates from Alternative A – No Action. For a description of analysis inputs, see **Appendix X**.

<sup>3</sup>The Mountain Valleys population was divided and modeled as two separate components of the vegetation dynamics model. See **Appendix X** for more details.

<sup>4</sup> Conditions for the Proposed Plan are presented in **Table 4-47**.

Administrative Draft  
Cooperating Agency Review

1 ***Impacts from Travel Management***

2 Acres designated as open, limited, or closed for off-road motorized vehicle use are described  
3 in **Table 4-6**, GRSG Habitat Where Motorized Travel Would Be Limited to Roads,  
4 Designated Roads, and Trails in the Idaho and Southwest Montana Sub-Region.

5 ***Impacts from ACEC Management***

6 Several alternatives identify the potential designation of new ACECs. These areas are  
7 described in **Table 4-7**, GRSG Habitat within BLM ACECs and Forest Service Zoological  
8 Areas in the Idaho and Southwestern Montana Sub-region.

9 **4.2.4 Alternative A**

10 ***Impacts from Vegetation and Soils Management***

11 Under Alternative A, current management implements the Integrated Vegetation  
12 Management Handbook policies (DOI 2008-H-1740-2, Rel.1-1714), Land Health Standards,  
13 Vegetation Treatments Using Herbicides Programmatic EIS (BLM 2007a), and other  
14 policies and plans. The Integrated Vegetation Management Handbook requires an  
15 interdisciplinary and collaborative process to plan and implement vegetation treatments that  
16 improve biological diversity and ecosystem function while promoting and maintaining native  
17 plant communities that are resilient to disturbance and invasive species. Land-health  
18 standards are ecologically based goal statements which include watershed function,  
19 ecological processes, water quality, and habitat quality for threatened and endangered and  
20 special status species (43 CFR 4180.1). Land Health Standards Assessments are used to  
21 establish program priorities, determine the status of current conditions and set the stage for  
22 evaluations that are used to determine achievement or non-achievement of land-health  
23 standards.

24 Implementation of the above policies and plans would improve vegetation condition by  
25 decreasing invasive species, provide for native vegetation establishment in sagebrush habitat,  
26 reduce the risk of wildfire, restore fire-adapted ecosystems and repair lands damaged by fire.  
27 These policies also recognize the need to improve the diversity, resiliency and productivity of  
28 native vegetation health and persistence (BLM 2008g).

29 Conifer expansion is predominant in mountain sagebrush but also occurs within Wyoming  
30 and low sagebrush. Juniper dominance or encroachment is particularly problematic in  
31 portions of the Southwest Idaho and South Side Snake population areas. Douglas-fir or  
32 other conifer encroachment is also an issue locally in the Mountain Valleys, Sawtooth and  
33 Southwest Montana population areas, and possibly others. In all of the population areas,  
34 current treatment rates are not keeping pace with continued conifer encroachment.

35 Mechanical removal of encroaching conifers, primarily juniper species and others such as  
36 Douglas-fir would result in short-term disturbances of soils and sagebrush due to heavy  
37 equipment, skid trails, and temporary roads. Mechanical and manual treatments would also  
38 increase noise, vehicular traffic and human presence. However, once the disturbed area is  
39 recovered, there would be an increase in forage, vegetation cover quality and composition,  
40

Administrative Draft  
Cooperating Agency Review

1 reduction in predator perches, decrease in heavier fuels and fire intensity and a potential  
2 increase in water availability at nearby springs meadows and seeps. Vegetation management  
3 would create mosaic vegetation patterns and natural fuel breaks by promoting healthy,  
4 diverse vegetation communities that generally fuel low-intensity fires.

5 Annual grass expansion and/or repeated fires in low-elevation sagebrush habitat in portions  
6 of the North and South Snake River population areas are outpacing existing treatment or  
7 restoration efforts.

8 Vegetation dynamics modeling shows that, under Alternative A, all of the eight GRSG  
9 analysis areas that are currently meeting GRSG sagebrush habitat objectives in terms of  
10 sagebrush cover on the landscape would continue to meet these objectives in 10 years,  
11 though most would show a decline in the percentage meeting the habitat objectives. This  
12 percentage would continue to drop for most of the GRSG analysis areas after 50 years.  
13 However, several analysis areas, including Southwest Idaho, South Side Snake, and Weiser,  
14 would increase their proportion meeting habitat objectives over this timeframe (See **Tables**  
15 **4-1** and **4-2**).

#### 16 ***Impacts from Livestock Grazing Management***

17 Under Alternative A, 11,073,800 acres of identified PPH and PGH are open for livestock  
18 grazing affecting 98 percent of GRSG habitat within the sub-region. Livestock grazing  
19 would continue to be managed through existing grazing plans, with methods and guidelines  
20 from the existing plans followed to maintain ecological conditions according to Standards  
21 for Rangeland Health, which include maintaining healthy, productive and diverse  
22 populations of native plants and animals. Older LUPs do not contain specific language in  
23 regards to GRSG conservation and livestock management, although many offices are  
24 covered under various conservation strategies for GRSG. Recent LUPs have more specific  
25 language regarding the management of livestock and its relation to GRSG conservation,  
26 including references to state and local GRSG plans. National and state drought policies are  
27 in place and would be followed to minimize impacts on rangelands under drought  
28 conditions. Continuation of these policies would not specifically protect GRSG habitat,  
29 although the policies could provide indirect benefits through more conservative use of  
30 existing sagebrush habitat. Direct impacts on GRSG have been reduced in some areas due to  
31 GRSG-specific management found in some conservation strategies or LUPs.

32 According to National BLM policy, riparian habitats would be managed to achieve PFC. On  
33 National Forest System lands, riparian areas are managed through a combination of  
34 utilization standards and design features discussed/documented each year in the Annual  
35 Operating Instructions. Functional condition of riparian areas and wetlands are considered  
36 in the development of riparian utilization standards. In some cases this management would  
37 require livestock removal or restrictions in riparian areas to reduce impacts caused by  
38 livestock, such as trampling and overuse of riparian areas. Managing for PFC helps to  
39 improve riparian vegetation health through increased production and diversity of vegetation  
40 and helps to improve water retention on those sites. As a result, brood-rearing habitats for  
41 GRSG would be improved or preserved where they are applied.

1 Range improvements would be designed to meet both wildlife and range objectives, and  
2 would include building, modifying or marking fences to permit passage of wildlife and  
3 reduce the chance of bird strikes, use of off-site water facilities, and in some cases  
4 modification or removal or improvements not meeting resource needs. Modifications may  
5 involve moving troughs, adding or changing wildlife escape ramps, or ensuring water is  
6 available on the ground for a variety of different wildlife species. Although not directly  
7 created to protect GRSG, these approaches would protect and enhance GRSG habitat by  
8 reducing the likelihood of surface disturbance in sensitive areas and ensuring brood-rearing  
9 habitat is available to GRSG.

### 10 ***Impacts from Fire and Fuels Management***

11 Within the planning area, all LUPs address fire suppression and fuels management and all  
12 federal lands (Forest Service and BLM) are covered under fire management plans, most of  
13 which address GRSG habitat. The more recent LUPs contain more specific objectives and  
14 management action for suppression and management of fires within sagebrush vegetation  
15 communities and GRSG habitat in accordance with local conservation strategies. Each LUP  
16 supports the development and adherence to a more detailed fire management plan that  
17 outlines priorities and levels of suppression for particular vegetation classes, or resource  
18 protection. Most plans support the objective of re-introducing fire into fire-dependent  
19 ecosystems and utilize the FRCC framework to aid in prioritizing response to wildfires and  
20 determining where fire can be used to meet land management plan objectives. Plans place  
21 priority for suppression on the protection of human life, followed by property and other  
22 important resource values including wildlife, including GRSG and big game.

23 In general, current fire suppression activities, fuels management, post-fire emergency  
24 stabilization and fire restoration efforts focus to a large degree on the protection or  
25 improvement of GRSG habitat. Some LUPs promote the use of native seed for stabilization  
26 and restoration, which may help increase native plant diversity and thereby benefit GRSG,  
27 but this guidance is not consistently applied across the decision area. More direction for the  
28 BLM has been provided in IM 2013-128, which provides habitat maps, guidelines, and  
29 BMPs for wildland fire suppression and fuels management in GRSG habitat.

30 Under Alternative A, wildfires would continue to be especially problematic in several of the  
31 population areas, including North Side Snake, South Side Snake, and Southwest Idaho,  
32 primarily due to lightning and spread of cheatgrass. GRSG habitat would subsequently  
33 continue to be degraded or lost. Small and heavily disturbed populations with dominance of  
34 invasive annual grass understory would be particularly susceptible to these impacts.  
35 Additionally, there may be some direct and indirect effects on individual GRSG from direct  
36 mortality or disturbance due to fire suppression or fuels treatment activities in sagebrush  
37 areas, but this is assumed to be relatively minor, given the tradeoffs.

### 38 ***Impacts from Wild Horse and Burro Management***

39 The Idaho and southwestern Montana sub-region does not contain wild burros but does  
40 contain six wild horse HMAs. Under Alternative A, overall management direction is to  
41 manage populations of wild horses to achieve a thriving natural ecological balance with  
42 respect to wildlife and other uses. Wild horses would continue to be managed on 378,200

1 acres of HMAs, which overlap 228,500 acres of PPH and 41,300 acres of PGH in the sub-  
2 region. Wild horses would be managed at AML, with gathers based on gather schedules,  
3 budgets, or other priorities such as emergency gathers during drought periods. Keeping  
4 horses at AML would reduce overall impacts on vegetation, especially nesting cover and  
5 riparian brood-rearing habitats during periods of drought.

6 ***Impacts from Leasable Minerals Management***

7 Within the sub-region, most BLM-administered and National Forest System lands are open  
8 to oil and gas leasing. Specific closures of areas to leasing, such as ACECs or crucial or  
9 essential wildlife habitat, exist throughout the sub-region.

10 Currently, over 9.5 million acres of GRSG habitat are managed as open to fluid minerals  
11 leasing and over 2.7 million acres of GRSG habitat are closed to fluid minerals leasing.  
12 Lands closed to fluid minerals leasing comprise over 1.7 million acres of PPH and nearly 1  
13 million acres of PGH. Closed areas provide an increased level of protection to GRSG  
14 seasonal habitats because they remove the potential for disturbance and impacts on habitat,  
15 as described in **Section 4.2.2** (see **Table 4-8**, Alternative A: Percent of GRSG Habitat and  
16 Occupied Leks Within Areas Closed or with NSO Stipulations for Oil and Gas Leasing by  
17 Population Area).

**Table 4-8**  
**Alternative A: Percent of GRSG Habitat and Occupied Leks Within Areas Closed or**

Southwest Idaho	23.6%	34
Sawtooth	75.8%	0
Bear Lake	58.9%	6
Weiser	28.9%	0

Source: BLM GIS 2015

18  
19 ***Impacts from Locatable Minerals Management***

20 BLM-administered and National Forest System lands within the sub-region are generally  
21 open to mineral location, causing effects similar to those described in **Section 4.2.2**. There  
22 are specific locatable mineral withdrawals for particular ROWs, designated wilderness areas,  
23 ACECs, and other administrative needs, but none specific to protecting GRSG habitat. All  
24 locatable mineral activities are managed under the regulations at 43 CFR Part 3800 through  
25 approval of a Notice of Intent or a Plan of Operations. Mitigation of effects on GRSG and  
26 its habitat are identified through the NEPA process approving plans of operation. Goals and  
27 objectives for locatable minerals are to provide opportunities to develop the resource while

1 preventing undue or unnecessary degradation of BLM-administered and National Forest  
2 System lands.

3 Lands closed to locatable mineral entry under the General Mining Act of 1872 comprise  
4 over 1.3 million acres of PPH and 433,200 acres of PGH. Current withdrawals provide an  
5 increased level of protection to GRSG seasonal habitats (see **Table 4-9**, Alternative A:  
6 Percent of GRSG Habitat and Occupied Leks Within Existing and Proposed Locatable  
7 Mineral Withdrawals by Population Area).

**Table 4-9**  
**Alternative A: Percent of GRSG Habitat and Occupied Leks Within Existing and Proposed Locatable Mineral Withdrawals by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	5.0%	1
Mountain Valleys	12.7%	30
SW Montana	2.5%	3
North Side Snake	25%	57
South Side Snake	7.7%	8
Southwest Idaho	21.2%	29
Sawtooth	10.6%	0
Bear Lake	8.7%	2
Weiser	5.0%	0

Source: BLM GIS 2015

8  
9 ***Impacts from Salable Minerals Management***  
10 Within the sub-region, most BLM-administered and National Forest System lands are open  
11 to salable mineral material development. Specific closures of areas to salable mineral  
12 materials such as ACECs or crucial or essential wildlife habitat exist throughout the sub-  
13 region.

14 Currently, there are over 1.8 million acres closed to material sales within PPH and PGH  
15 combined. Closed areas provide an increased level of protection to GRSG seasonal habitats  
16 from loss, fragmentation and other impacts discussed in **Section 4.2.2** (see **Table 4-10**,  
17 Alternative A: Percent of GRSG Habitat and Occupied Leks Affected by Closure to Salable  
18 Minerals by Population Area).

**Table 4-10**  
**Alternative A: Percent of GRSG Habitat and Occupied Leks Affected by Closure to Salable Minerals by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	25.3%	1
Mountain Valleys	23.7%	6
SW Montana	22.1%	0
North Side Snake	15.7%	23

**Table 4-10**  
**Alternative A: Percent of GRSG Habitat and Occupied Leks Affected by Closure to Salable Minerals by Population Area**

Population Area	Habitat Area	Occupied Leks
South Side Snake	8.9%	9
Southwest Idaho	18.9%	29
Sawtooth	12.7%	0
Bear Lake	14.4%	1
Weiser	0%	0

Source: BLM GIS 2015

1

2 ***Impacts from Lands Uses and Realty Management***

3 Under Alternative A, all BLM-administered lands are held in retention unless identified for  
4 disposal. Disposal criteria typically include considerations of sensitive or crucial resources  
5 such as wildlife habitat. While older LUPs in the sub-region do not have specific goals  
6 related to GRSG, some newer plans, such as those in Pocatello and Dillon, do have specific  
7 measures related to GRSG disturbance and habitat. Land tenure adjustments would be  
8 subject to current disposal/exchange/acquisition criteria, which include retaining lands with  
9 threatened or endangered species, high quality riparian habitat, or plant and animal  
10 populations or natural communities of high interest. While not explicitly stated in some  
11 existing RMPs, this would likely include retention of areas with GRSG, and would thus  
12 retain occupied habitats under BLM administration. This would reduce the likelihood of  
13 habitat conversion to agriculture, urbanization, or other uses that would remove sagebrush  
14 habitat. Mitigation is typically developed under the NEPA process, and most ROW and  
15 surface developments are subject to limited operation periods or other stipulations in local  
16 GRSG conservation strategies.

17 This alternative designates 1.9 million acres of ROW avoidance areas within existing  
18 PPH/PGH where certain actions would be considered on a case-by-case basis through  
19 subsequent site specific NEPA analysis, including the consideration of mitigation measures  
20 to reduce impacts. This alternative designates over 1 million acres for ROW exclusion within  
21 PPH/PGH where all development would be prohibited. Acres identified as available for  
22 disposal total 749,900 acres of PPH and PGH under Alternative A. Under this alternative,  
23 avoidance areas provide an increased level of protection to habitat and exclusion areas  
24 provide an increased level of protection occupied leks in the sub-region. These management  
25 actions would be expected to reduce both direct and indirect impacts on GRSG.

26 ***Impacts from Renewable Energy Management***

27 In 2005 and 2008, the BLM programmatically amended its LUPs for renewable energy  
28 resources through the Wind Energy PEIS and Geothermal PEIS, respectively. These  
29 programmatic documents outline BLM-administered or National Forest System lands  
30 available and unavailable for these resource uses and provide direction on processing ROWs  
31 and geothermal lease applications, as well as establishing BMPs for conducting these  
32 activities on BLM-administered lands. The BMPs contain some general guidance for

1 addressing GRSG and its habitat. LUPs would continue to have different stipulations for  
2 geothermal resources and under Alternative A, over 7.9 million acres of PPH and PGH  
3 could be open for wind development.

4 Under Alternative A, 1.9 million acres are managed for exclusion and 1.3 million acres are  
5 managed for avoidance of wind energy within existing PPH/PGH. This represents nearly 30  
6 percent of the available PPH and PGH in the planning area being excluded or avoided.  
7 Outside these areas, there would be more impacts on GRSG and their habitat than inside the  
8 areas excluded or avoided.

9 Impacts on GRSG and their habitat from construction and operation of wind energy  
10 facilities are discussed in **Section 4.2.2** above. Management under Alternative A identified  
11 more acres of GRSG habitat available for wind energy and could lead to more impacts,  
12 including habitat degradation, increased predation, and others discussed in **Section 4.2.2**,  
13 compared to the action alternatives (Alternatives B through F).

14 There are 1,028,500 acres of PPH and PGH managed as ROW exclusion and 1,956,200  
15 acres of PPH and PGH managed as ROW avoidance within the sub-region. Proposed  
16 exclusion and avoidance areas provide an increased level of protection to GRSG seasonal  
17 habitats (see **Table 4-11**, Alternative A: Percent of GRSG Habitat and Occupied Leaks  
18 Affected by ROW Exclusion or Avoidance by Population Area).

**Table 4-11**  
**Alternative A: Percent of GRSG Habitat and Occupied Leaks Affected by ROW Exclusion or**  
**Avoidance by Population Area**

Population Area	Habitat Area			Occupied Leaks		
	Exclusion	Avoid with Exclusions	Avoidance	Exclusion	Avoid with Exclusions	Avoidance
East Central Idaho	0.5%	0	11.4%	0	0	0
Mountain Valleys	1.5%	0	14.3%	1	0	17
SW Montana	16.4%	0	30.2%	0	0	1

Weiser	58.6%	0	41.3%	1	0	0

Source: BLM GIS 2015

*Impacts from Geothermal Energy Development*

19  
20 Within the sub-region, most BLM-administered and National Forest System lands are open  
21 to geothermal development. Specific closures of areas to geothermal such as ACECs or  
22 critical or essential wildlife habitat exist throughout the sub-region.  
23

1 Under this alternative, over 9.5 million acres of PPH and PGH would be designated as open  
 2 for geothermal development. This alternative leaves the remaining PPH and PGH closed or  
 3 limited for geothermal development. Closed areas provide an increased level of protection to  
 4 GRSG seasonal habitats (see **Table 4-12** Error! Reference source not found. Error!  
 5 **Reference source not found.**).

**Table 4-12**  
**Alternative A: Percent of GRSG Habitat and Occupied Leaks Within Areas Closed or**  
**with NSO Stipulations for Geothermal Energy by Population Area**

***Impacts from Travel and Transportation Management***

Under current management, Travel Management Areas have not been consistently identified in LUPs beyond the basic allocations of open, closed, and limited. Closed areas are comprised of congressionally designated areas, WSAs, and, as directed, some ACECs. Areas within PPH and PGH that are limited to existing/designated roads include over 2 million acres of National Forest System lands. Under current management, over 700,000 acres of PPH/PGH are closed to motorized vehicles, 7.7 million acres are limited to existing routes for motorized vehicles, and 2.8 million acres are open to all modes of cross country travel (see **Table 4-13**, Alternative A: Percent of GRSG Habitat and Occupied Leaks Affected by Travel Management by Population Area). Lands within the Dillon Field Office are currently restricted to designated routes only.

**Table 4-13**  
**Alternative A: Percent of GRSG Habitat and Occupied Leaks Affected by Travel**  
**Management by Population Area**

Population Area	Habitat Area			Occupied Leaks		
	Open	Limited	Closed	Open	Limited	Closed
East Central Idaho	0.37%	91%	9%	0	2	0
Mountain Valleys	25%	74%	1%	37	99	1
SW Montana	0%	98%	2%	0	40	0

Southwest Idaho	0%	80%	20%	0	126	27
Sawtooth	0%	100%	0%	0	0	0
Bear Lake	0%	100%	0.39%	0	7	0
Weiser	71%	28%	0.41%	0	1	0

Source: BLM GIS 2015

**Impacts from Special Designations Management**

Under Alternative A, the BLM would continue to manage 59 ACECs within the sub-region (Table 4-7). The Forest Service would not manage any ZAs under Alternative A. Existing ACECs likely protect GRSG habitat through use restrictions; these impacts are analyzed under each existing RMP within the planning area. As a result, there would be no additional effects from ACEC or ZA management on GRSG under this alternative.

**4.2.1 Impacts Common to All Action Alternatives**

While the nature and type of effects listed below from each alternative are similar, the impacts may differ by intensity, extent, or context.

**GRSG Habitat Designations**

Each action alternative designates GRSG habitat. Table 4-14, Acres of Designated Habitat Types in the Idaho and Southwestern Montana Sub-region, displays the acres of each habitat designation within each alternative.

**Impacts on USFWS Priority Areas for Conservation**

In 2013, the USFWS identified GRSG priority areas for conservation (USFWS 2013a). The relation of priority areas for conservation to the GRSG habitat designations in each alternative is shown in Table 4-15, Acres of Priority Areas for Conservation within GRSG Analysis Areas in the Idaho and Southwestern Montana Sub-region.

**Mitigation**

Each action alternative includes a mitigation framework. Mitigation does not eliminate direct project effects, its inclusion in projects at the site-specific level is designed to provide an associated benefit to GRSG and eliminate detrimental cumulative effects.

Alternatives B, C, D, and F address mitigation through a Regional Mitigation Strategy (Appendix J). As part of this mitigation strategy, the BLM would establish a Mitigation Implementation Team for each WAFWA MZ. These teams would develop a Mitigation Strategy consistent with the BLM Regional Mitigation Manual Section (1794). The teams will coordinate recommended mitigation strategies between LUP planning areas, WAFWA MZs,

1 and local and state jurisdictions for mitigation consistency. In addition, one of the goals in  
2 Alternative D is to provide for no unmitigated loss to occupied GRSG habitat.

3 Alternative E would utilize an Implementation Task Force to assess project proposals and  
4 their mitigation packages to determine whether to recommend an exemption for the  
5 governor's consideration. This would primarily affect CHZ areas where additional  
6 infrastructure development is restricted with narrow exceptions. Mitigation would be  
7 assessed according to Idaho's Mitigation Framework (**Appendix J**).

Administrative Draft  
Cooperating Agency Review

1 ***Adaptive Management***

2 Each action alternative contains an adaptive management strategy. Effects of Alternatives D  
3 and E strategies are described in the associated section within the alternative impacts section  
4 below.

5 For Alternatives B, C, and F an adaptive management framework is described; however,  
6 specific triggers and resulting actions have not been described. A subsequent adaptive  
7 management plan would be developed that:

- 8 • Identifies science based soft and hard adaptive management triggers applicable to  
9 each population or subpopulation within the planning area
- 10 • Addresses how the multiple scale data from the Monitoring Framework Plan  
11 (**Appendix E**) would be used to gauge when adaptive management triggers are  
12 met
- 13 • Charters an adaptive management working group to assist with responding to  
14 soft adaptive management triggers

15 **4.2.2 Alternative B**

16 PHMA and GHMA would be designated under Alternative B (**Table 4-14**). The BLM and  
17 Forest Service would apply a maximum three percent disturbance cap to human activities in  
18 PHMA. The three percent disturbance cap was recommended in the NTT report and is  
19 designed to minimize impacts on GRSG habitat by limiting disturbances in sensitive habitat  
20 areas. The agencies would implement numerous conservation measures, as described under  
21 the resource headings below, to reduce impacts from human activities in PHMA. Restricting  
22 surface-disturbing activities would reduce the likelihood for habitat loss, fragmentation and  
23 direct disturbance to GRSG.

24 ***Impacts from Vegetation and Soils Management***

25 Under Alternative B, restoration projects would be prioritized in seasonal GRSG habitats  
26 thought to be limiting the distribution and abundance of GRSG. Re-establishment of  
27 sagebrush cover and desirable understory plants would be the highest priority for restoration  
28 efforts. Restoration treatments would incorporate habitat parameters defined by Connelly et  
29 al. 2000, Hagen et al. 2007, and state GRSG conservation plans. Native seed would be  
30 required for restoration treatments and the establishment of designated seed harvest areas  
31 for sagebrush seed collection in fire prone areas. Climate change would be a consideration  
32 when proposing native seed collection. In addition, post-restoration management plans  
33 would be implemented to ensure long-term persistence of vegetation treatments.

34 Alternative B management prescriptions for vegetation and soil applied to PHMAs and  
35 GHMAs would provide greater protection and restoration efforts for GRSG habitat  
36 compared with those under Alternative A. This is because prescriptions under Alternative B  
37 are based on the NTT report recommendations, which were designed specifically for GRSG  
38 conservation.

1 Management under Alternative B would ensure the long-term availability and resiliency of  
2 native seed for restoration treatments by establishing native seed harvest areas which  
3 incorporate climate change effects. This and post-treatment management plans would  
4 improve the success of restoration treatments and the future persistence of GRSG and their  
5 habitat.

6 Vegetation treatment rates would be greater than under Alternative A and would further  
7 reduce the impacts of invasive grasses, affecting the population areas where invasive grasses  
8 are a substantial threat. Treatment rates would further reduce the impacts of conifer  
9 encroachment on the population areas where conifer is a substantial threat. Trends for  
10 habitat at 10 and 50 years would improve compared with Alternative A (See **Tables 4-1** and  
11 **4-2**).

### 12 ***Impacts from Livestock Grazing Management***

13 Under Alternative B, the same number of acres would be open to livestock grazing as under  
14 Alternative A. Agencies, in coordination with permittees, would prioritize a number of  
15 management actions in PHMAs to incorporate GRSG habitat objectives and management  
16 considerations into livestock grazing management, though there would be no change to the  
17 acreage open for grazing or available AUMs unless an allotment is retired from grazing.  
18 Management actions would include developing specific vegetation objectives based on  
19 Ecological Site Descriptions to conserve, enhance, or restore PHMAs habitat and riparian  
20 areas would be managed for proper functioning condition. Vegetation treatments to increase  
21 livestock forage would only be allowed if they conserved, enhanced or restored GRSG  
22 habitat. This alternative would also implement modifications to season of use, numbers of  
23 livestock or livestock types to meet seasonal GRSG requirements based on site-specific  
24 conditions during permit renewal. New water developments would only be authorized when  
25 they would benefit PHMAs. In PHMAs, older developments would also be analyzed in  
26 order to determine if modifications of the system are necessary to maintain the integrity of  
27 the riparian area. Removal, modification, or marking of fences would be considered under  
28 this alternative.

29 This alternative would provide long-term benefits to GRSG through improvements in both  
30 upland and riparian GRSG habitats, and would reduce both short and long-term impacts by  
31 reducing direct impacts on GRSG on their seasonal ranges. However, restriction or removal  
32 of water developments could reduce water availability for GRSG on a site-specific basis.  
33 Compared with Alternative A, Alternative B management actions would further reduce, but  
34 would not eliminate, impacts from grazing on GRSG and their habitat.

### 35 ***Impacts from Fire and Fuels Management***

36 Under Alternative B, impacts on GRSG from fire suppression activities would be largely the  
37 same as Alternative A. On BLM-administered and National Forest System lands, 8.2 million  
38 acres of GRSG habitat would be designated as PHMAs, and 2.8 million acres would be  
39 designated as GHMAs. With regard to fuels management projects, GRSG would benefit  
40 from the direction provided to protect important aspects of habitat within PHMAs (e.g.,  
41 canopy cover). Hazardous fuels projects focused on protecting GRSG habitat would be  
42 prioritized in these areas. Any fuels treatment in sagebrush would carefully consider if there

1 is a net benefit for GRSG prior to implementation, and fuels treatments would not be  
2 allowed in winter habitat. Not allowing fuel treatment in winter habitat may greatly limit the  
3 ability to protect winter habitat from fire.

4 Prescribed fire in low precipitation areas (less than 12 inches) would generally not be  
5 allowed. Post-fire rehabilitation would be conducted using primarily native species, based on  
6 availability and adaptation. Rest from grazing would be required for two full growing  
7 seasons, unless vegetation recovery dictates otherwise. These activities may decrease the  
8 likelihood for fire in GRSG habitats and would help restore GRSG habitat in fire-affected  
9 areas. However, relative to the amount of GRSG habitat that is expected to burn based on  
10 current trends and is outside the control of the BLM or Forest Service, these actions may  
11 provide localized but minimal protections and improvements to the populations in the sub-  
12 region where fire contributes significantly to current declining trends.

13 ***Impacts from Wild Horse and Burro Management***

14 Under Alternative B, wild horses and burros would be managed at AML on the same  
15 number of acres as Alternative A, with gathers prioritized based on PHMA's habitat and  
16 emergency environmental issues. HMA plans, when developed or updated, would  
17 incorporate GRSG habitat objectives. Implementation of any range improvements would  
18 follow the same guidance as identified for livestock grazing in this alternative, including  
19 designing and locating new improvements only where they "conserve, enhance, or restore  
20 GRSG habitat through improved grazing management." Design features could include  
21 developing or modifying water developments to mitigate for West Nile virus, removing or  
22 modifying fences to reduce the chance of bird strikes, or monitoring and treating invasive  
23 species associated with range improvements. Additional range improvements would  
24 specifically address the needs of GRSG. Compared with Alternative A, Alternative B would  
25 prioritize GRSG habitat objectives in HMA plans and base assessment of AMLs on  
26 achieving or maintaining GRSG habitat needs.

27 ***Impacts from Leasable Minerals Management***

28 Management under Alternative B would close 9.1 million acres of PHMA's to leasing. Closed  
29 lands would provide an increased level of protection to habitat associated with leks. (See  
30 **Table 4-16, Alternative B: Percent of GRSG Habitat and Occupied Leks Within Areas**  
31 **Closed or with NSO Stipulations for Oil and Gas Leasing by Population Area**).

**Table 4-16**  
**Alternative B: Percent of GRSG Habitat and Occupied Leks Within Areas Closed or**  
**with NSO Stipulations for Oil and Gas Leasing by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	40%	3
Mountain Valleys	93.1%	159
SW Montana	80.8%	47
North Side Snake	82%	261
South Side Snake	80.2%	157
Southwest Idaho	85%	152

1

2

***Impacts from Locatable Minerals Management***

3

Management under Alternative B would include withdrawals and processes for management. In addition, PHMAs would be recommended for mineral withdrawal and existing mining claims would be subject to validity exams or buy-out. For these reasons, Alternative B would be more protective of GRSG than Alternative A.

4

5

6

7

Lands withdrawn or recommended for withdrawal include 9.3 million acres of PHMAs. Withdrawn lands would provide an increased level of protection to habitat associated with leks (see **Table 4-17**, Alternative B: Percent of GRSG Habitat and Occupied Leaks Affected by Mineral Withdrawal by Population Area).

8

9

10

**Table 4-17**  
**Alternative B: Percent of GRSG Habitat and Occupied Leaks Affected by Mineral Withdrawal by Population Area**

Population Area	Habitat Area	Occupied Leaks
East Central Idaho	25.9%	4
Mountain Valleys	83%	138
SW Montana	52.2%	70
North Side Snake	78.3%	228
South Side Snake	75.3%	167
Southwest Idaho	85.1%	152
Sawtooth	17.2%	0
Bear Lake	85.5%	8
Weiser	43.5%	0

Source: BLM GIS 2015

11

12

***Impacts from Salable Minerals Management***

13

Management under Alternative B would be more protective than Alternative A and would close PHMAs to mineral material sales.

14

15

Alternative B closes 8.7 million acres of PHMAs to mineral material sales. Closed lands would provide an increased level of protection to habitat associated with leks (see **Table 4-**

16

1 **18**, Alternative B: Percent of GRSG Habitat and Occupied Leaks Affected by Closure to  
2 Salable Minerals by Population Area).

**Table 4-18**  
**Alternative B: Percent of GRSG Habitat and Occupied Leaks Affected by Closure to**  
**Salable Minerals by Population Area**

Population Area	Habitat Area	Occupied Leaks
East Central Idaho	8.6%	3
Mountain Valleys	68.9%	159
SW Montana	31.9%	45
North Side Snake	60.8%	252
South Side Snake	58.2%	155
Southwest Idaho	69.9%	152
Sawtooth	7.8%	0
Bear Lake	42.7%	7
Weiser	18.6%	0

Source: BLM GIS 2015

3

4 ***Impacts from Land Uses and Realty Management***

5 Under Alternative B, more habitat would be managed as ROW avoidance (2.5 million acres)  
6 and exclusion (8.4 million acres) areas than under Alternative A. There is an approximate  
7 503,600-acre difference between Alternatives A and B in terms of acres for disposal in  
8 GRSG habitat, with Alternative B having fewer acres available for disposal within PHMA  
9 and GHMA compared to the acres in PPH and PGH. PHMAs would be managed as  
10 exclusion areas for new ROW permits, with some exceptions. Mitigation and restoration  
11 efforts would take place related to existing ROWs in PHMAs. In general habitat, avoidance  
12 areas would be set up in relation to new ROWs, collocating ROWs as much as possible.  
13 Under Alternative B, PHMAs would be retained unless mitigation or land tenure adjustment  
14 would better benefit GRSG habitat. Avoidance areas provide an increased level of  
15 protection to modeled nesting habitat associated with leks representing 64 percent of the  
16 sub-regional population, and exclusion areas provide an increased level of protection to 30  
17 percent of the sub-regional population. In relation to Alternative A, management under  
18 Alternative B would provide fewer direct impacts on GRSG by greatly increasing acreage  
19 subject to ROW avoidance and exclusion and by protection and acquisition of important  
20 GRSG habitats.

21 ***Impacts from Renewable Energy Management***

22 Under Alternative B, impacts from management of lands for wind and solar energy  
23 development would be the same as for Alternative A.

24 ***Impacts from Wind Energy Development on Sub-populations***

25 Alternative B does not specify acreages to set aside specifically for GRSG conservation.  
26 Because no action is specified under Alternative B, the default is that the same action would  
27 be taken for Alternative B as proposed for Alternative A.

1 Within the sub-region, 8.5 million acres of PHMAs and GHMAs would be excluded and 2.3  
 2 million acres of PHMAs and GHMAs would have ROW avoidance for wind energy  
 3 development. This represents 97 percent of the available PHMAs and GHMAs in the  
 4 planning area being excluded or avoided in the planning area. Proposed ROW exclusion and  
 5 avoidance areas provide an increased level of protection to habitat associated with leks (see  
 6 **Table 4-19**, Alternative B: Percent of GRSG Habitat and Occupied Leks Affected by ROW  
 7 Exclusion or Avoidance by Population Area).

**Table 4-19**  
**Alternative B: Percent of GRSG Habitat and Occupied Leks Affected by ROW Exclusion or Avoidance by Population Area**

Population Area	Habitat Area			Occupied Leks		
	Exclusion	Avoid with Exclusions	Avoidance	Exclusion	Avoid with Exclusions	Avoidance
East Central Idaho	0%	15.4%	84.6%	0	1	1
Mountain Valleys	1.5%	80.1%	18.1%	1	131	5
SW Montana	33.6%	49.3%	33.6%	0	38	1
North Side Snake	6.1%	69.9%	23%	5	207	2
South Side Snake	27.1%	69.8%	27.1%	3	157	7
Southwest Idaho	14.8%	63.8%	14.8%	29	123	1
Sawtooth	0.2%	0%	99.8%	0	0	0
Bear Lake	0.6%	88.9%	10.5%	0	6	0
Weiser	41.4%	0%	41.4%	1	0	0

8  
 9 *Impacts from Geothermal Energy Development on Sub-populations*  
 10 Alternative B does not specify acreage to set aside specifically for GRSG conservation.  
 11 Because no action is specified under Alternative B, the default is that the same action would  
 12 be taken for Alternative B as proposed for Alternative A.

13 Within the sub-region, most BLM-administered and National Forest System lands are open  
 14 to geothermal development. Specific closures of areas to geothermal such as ACECs or  
 15 crucial or essential wildlife habitat exist throughout the sub-region.

16 Under this alternative, 2.3 million acres of GHMA would remain open for geothermal  
 17 development. PHMA would be closed to geothermal development (**Table 4-20**).

**Table 4-20**  
**Alternative B: Percent of GRSG Habitat and Occupied Leks Within Areas Closed or with NSO Stipulations for Geothermal Energy by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	39.3%	3

2

***Impacts from Travel and Transportation Management***

3

Under Alternative B, any designated open roads within PHMAs would be managed as limited to existing roads for motorized travel, with the exception of existing closed areas within PHMAs or GHMAs.

4

5

6

Under Alternative B, over 700,000 acres of PHMA and GHMA would be closed to motorized vehicles, over 10 million acres would be limited to existing roads, and 1,350 acres would be open to all modes of cross-country travel (see **Table 4-21**, Alternative B: Percent of GRSG Habitat and Occupied Leks Affected by Travel Management Designations by Population Area).

7

8

9

10

**Table 4-21**  
**Alternative B: Percent of GRSG Habitat and Occupied Leks Affected by Travel Management Designations by Population Area**

Population Area	Habitat Area			Occupied Leks		
	Open <sup>1</sup>	Limited	Closed	Open <sup>1</sup>	Limited	Closed
East Central Idaho	0.5%	87.4%	12.1%	0	2	0
Mountain Valleys	1.5%	97.4%	1.2%	3	133	1
SW Montana	0%	99%	1%	0	40	0
North Side Snake	18.4%	75.5%	6.2%	2	207	5
South Side Snake	0%	80.4%	19.6%	2	162	3
Southwest Idaho	5.1%	91.6%	3.3%	0	126	27
Sawtooth	0%	100%	0%	0	0	0
Bear Lake	0%	99.4%	0.6%	0	6	0
Weiser	41.6%	58.0%	0.4%	0	1	0

Source: BLM GIS 2015

<sup>1</sup>Acres closed to motorized travel represent existing acres closed. No additional areas would be closed under any alternative.

11

1       ***Impacts from Special Designations Management***

2       Impacts from ACEC management under Alternative B are the same as those described for  
3       Alternative A (Table 4-7).

4                   **4.2.3 Alternative C**

5       Under Alternative C, the BLM and Forest Service would manage lands to conserve, enhance,  
6       and restore sagebrush ecosystems. Management actions would be applied to all occupied  
7       GRSG habitats (Table 4-14). Management would focus on removing livestock grazing from  
8       occupied habitats, with most other management similar that to Alternative A. The three  
9       percent disturbance cap would be the same as under Alternative B, but would apply to all  
10      occupied habitat.

11      ***Impacts from Vegetation and Soils Management***

12      Given the limited current distribution of suitable GRSG habitat, management plans that  
13      strategically protect intact sagebrush and restore impacted areas to enhance existing habitats  
14      have the best chance of increasing the amount and quality of GRSG habitat (Manier et al.  
15      2013, p. 171). Management under Alternative C would decrease vegetation treatments  
16      needed to increase the amount and quality of GRSG habitat, compared with Alternative A.  
17      Habitat trends for 10 and 50 years indicate a slight decline, from increased influence of  
18      invasive grasses and continued dominance of conifer, in impacted populations and  
19      subpopulations as compared with Alternative A.

20      Under Alternative C, vegetation management would prioritize the restoration of crested  
21      wheat seedings and focus fuels treatments in areas of urban interface and significant existing  
22      disturbances, establish monitoring sites, require risk assessments, minimize or eliminating the  
23      use of herbicides, address vectors of weed infestations, and require the use of mowers to  
24      remove thatch from meadows and to manage existing fuel breaks.

25      Management prescriptions under Alternative C would focus vegetation treatments in  
26      unoccupied GRSG habitats (e.g., crested wheat grass seeding, urban interface, areas where  
27      livestock management infrastructure is removed, and other areas of significant disturbances).  
28      Broad-scale treatment of invasive grasses would be achieved through natural recovery  
29      following the removal of livestock, and juniper removal projects would be limited.

30      ***Impacts from Livestock Grazing Management***

31      Under Alternative C, all PHMA would be unavailable to livestock use. About 100 percent of  
32      the GRSG populations in the sub-region would be affected. Under this alternative, both  
33      passive and active restoration would occur, including removal of livestock, roads, water  
34      developments, fences, and other range infrastructure that may contribute to GRSG  
35      predators or increase habitat for mosquitoes that may carry the West Nile virus. Additional  
36      active restoration would include reseeding of roads and crested wheatgrass seedings with  
37      native shrubs and grasses.

38      Under Alternative C, impacts on GRSG would be reduced compared with Alternative A in  
39      upland sites. This is because of reduced trampling of nests by livestock during nesting season

1 and increased herbaceous understory vegetation. Under this alternative, the removal of  
2 livestock would result in greater amounts of residual upland cover both in the short term  
3 and long term. Reseeding of crested wheatgrass seedings and roads would reduce and  
4 minimize impacts from invasive species and increase cover of native plant species. Removal  
5 of fencing would reduce the potential of GRSG direct strikes, but in areas where wild horses  
6 and burros are present, riparian damage or nest trampling in brood-rearing habitats may  
7 increase from horses and burros accessing riparian sites. Removal of troughs and other  
8 artificial watering devices would make more water available on the ground for GRSG, their  
9 habitats, and other wildlife species. Additional fencing might be required to separate federal  
10 no-grazing areas from private ranchlands, leading to increased risk of GRSG strikes along  
11 those boundaries.

12 A complete grazing exclusion can also promote exotic annual grass invasion in some  
13 situations. Davies et al. (2009) determined that long-term grazing exclusion followed by fire  
14 resulted in exotic annual grass invasion, while fire following moderate levels of grazing did  
15 not promote invasion. Moderate grazing made the perennial herbaceous component of the  
16 sagebrush plant communities more tolerant of fire (Davies et al. 2009), perhaps due to a  
17 reduction in crown litter (Davies et al. 2010a). Targeted grazing may be a critical tool for  
18 breaking the exotic annual grass-fire cycle by decreasing the probability of fire disturbance  
19 (Diamond et al. 2009). Well-managed livestock grazing may have limited impact (Courtois et  
20 al. 2004) or beneficial effects, including decreased risk of conversion to exotic annual grass  
21 communities (Davies et al. 2009, 2010a). If management under Alternative C were to reduce  
22 ranchers' ability to keep ranches maintained or profitable, they may be sold and developed,  
23 causing loss of habitat (Wilkins et al. 2003). Ultimately, the effects of removing grazing in  
24 GRSG habitats on a landscape scale are unknown, and it is unclear whether complete  
25 removal would improve GRSG habitat or increase population levels.

#### 26 ***Impacts from Fire and Fuels Management***

27 Under Alternative C, impacts on GRSG from wildfire suppression and fuels management  
28 would be the same as Alternative B; 11.1 million acres of GRSG habitat would be designated  
29 as PHMAs. However, this alternative adopts a passive restoration approach relying on a  
30 long-term improvement of habitat conditions by closing PHMAs to livestock grazing. The  
31 alternative does not rely on fuel treatments, such as fuel breaks, to limit the impacts of fire  
32 and limits cheatgrass control to natural restoration over chemical treatment, which is  
33 restricted. The combination of reducing the direct measures to combat invasive species and  
34 limit fire spread would increase the likelihood of continued GRSG habitat decline within the  
35 GRSG populations where fire is a threat.

#### 36 ***Impacts from Wild Horse and Burro Management***

37 Under Alternative C, wild horses would be managed on the same HMA acreage as under  
38 Alternative A. Wild horses would be managed at AML. Use of contraceptives and other  
39 population growth suppression to manage wild horse numbers would be similar to actions  
40 under Alternative A. Management under Alternative C would not allow the use of  
41 helicopters for gathers and would be expected to lead to decreased gather efficiency resulting  
42 in increases of wild horses and burros, making it more difficult to manage wild horses and  
43 burros at AML. Combined with the removal of some fences during active restoration

1 processes related to livestock grazing, wild horses would be expected to range over a larger  
2 area than under Alternative A and would necessitate the need for increased gather outside of  
3 HMA boundaries. To the extent wild horses and burros are present in an area, the increase  
4 in access to fenced riparian and upland habitats and the expected temporary increases in  
5 horses and burros over AML would reduce food and cover for GRSG over time. These  
6 increases also would change water-holding capacities of riparian brood-rearing sites  
7 compared with Alternative A.

8 ***Impacts from Leasable Minerals Management***

9 Leasable Minerals Management under Alternative C would afford the highest level of  
10 protection of all alternatives. Leasable mineral entry would be precluded for all ACECs,  
11 including all PHMA, under this alternative. Closed acreage would include all PMUs in the  
12 sub-region, protecting all occupied or potentially occupied GRSG habitat and increasing the  
13 level of protection to all associate, populations and sub-populations.

14 Management under Alternative C would close PHMA, including split estate (over 20 million  
15 acres in total) to oil and gas leasing. Closure would increase protection of all acres of PHMA  
16 within habitat associated with leks (see **Table 4-22**, Alternative C: Percent of GRSG Habitat  
17 and Occupied Leks Within Areas Closed or with NSO Stipulations for Oil and Gas Leasing  
18 by Population Area).

**Table 4-22**  
**Alternative C: Percent of GRSG Habitat and Occupied Leks Within Areas Closed or**  
**with NSO Stipulations for Oil and Gas Leasing by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	100%	5
Mountain Valleys	100%	164
SW Montana	100%	47
North Side Snake	100%	263
South Side Snake	100%	162
Southwest Idaho	100%	153
Sawtooth	100%	0
Bear Lake	100%	7
Weiser	100%	0

Source: BLM GIS 2015

19  
20 ***Impacts from Locatable Minerals Management***

21 Management under Alternative C would afford the highest level of protection of all  
22 alternatives. Mineral entry withdrawal would be recommended for all ACECs, including all  
23 PHMAs, under this alternative, protecting all occupied or potentially occupied GRSG  
24 habitat and increasing the level of protection to all associated GRSG populations and sub-  
25 populations.

1 Management under Alternative C would recommend withdrawing PHMAs, including split  
 2 estate, from locatable mineral entry (13.3 million acres). Closure would increase protection  
 3 of all acres of PHMA within habitat associated with leks (see **Table 4-23**, Alternative C:  
 4 Percent of GRSG Habitat and Occupied Leks Affected by Mineral Withdrawal by  
 5 Population Area).

**Table 4-23**  
**Alternative C: Percent of GRSG Habitat and Occupied Leks Affected by Mineral Withdrawal by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	100%	9
Mountain Valleys	100%	143
SW Montana	100%	79
North Side Snake	100%	230
South Side Snake	100%	173
Southwest Idaho	100%	153
Sawtooth	100%	0
Bear Lake	100%	8
Weiser	100%	0

Source: BLM GIS 2015

6

***Impacts from Salable Minerals Management***

7 Management under Alternative C would close PHMA to mineral materials sales, providing  
 8 the highest level of protection among the alternatives (same as Alternative B).  
 9

10 Management under Alternative C would close PHMAs, including split estate, to mineral  
 11 materials sales (19.4 million acres in total). Closure would increase protection of all acres of  
 12 PHMA habitat associated with leks (**Table 4-24**, Alternative C: Percent of GRSG Habitat  
 13 and Occupied Leks Affected by Closure to Salable Minerals by Population Area).

**Table 4-24**  
**Alternative C: Percent of GRSG Habitat and Occupied Leks Affected by Closure to Salable Minerals by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	100%	5
Mountain Valleys	100%	164
SW Montana	100%	46
North Side Snake	100%	263
South Side Snake	100%	162
Southwest Idaho	100%	153
Sawtooth	100%	0
Bear Lake	100%	7

**Impacts from Land Uses and Realty Management**

Under Alternative C, ROW avoidance acres would remain the same as under Alternative A. Within PHMA, there are more acres managed as ROW exclusion under Alternative C (11 million acres) than under Alternative A (1 million acres). This difference would provide protections to more of the sub-regional GRSG population than Alternative A. This difference is due to resource use restrictions in all PHMAs as well as potential ACECs. Required buffers of 5 to 10 miles between occupied habitats and wind development in the alternative are also part of the increased acreage. Acres identified for disposal are less than Alternative A. Under Alternative C, all BLM-administered and National Forest System lands in proposed ACECs (all PHMAs) and identified restoration and rehabilitation lands would be retained in public ownership. New corridors or facilities including communication towers would only be allowed in non-habitat areas, with existing towers undergoing reviews for adverse effects. All existing transmission or pipeline corridors would be assessed under this alternative, and ROWs would be amended to require features that enhance GRSG habitat security. This alternative would result in fewer direct or indirect impacts on GRSG and their habitats compared with Alternative A because most effects from the land and realty program would be outside of occupied habitat, and effects within current ROWs would be minimized over time. Additionally, this alternative would prioritize more areas for acquisition compared with Alternative A (see **Table 4-25**, Alternative C: Percent of GRSG Habitat and Occupied Leks Affected by ROW Exclusion or Avoidance by Population Area).

**Table 4-25**  
**Alternative C: Percent of GRSG Habitat and Occupied Leks Affected by ROW Exclusion or Avoidance by Population Area**

Population Area	Habitat Area			Occupied Leks		
	Exclusion	Avoid with Exclusions	Avoidance	Exclusion	Avoid with Exclusions	Avoidance
East Central Idaho	100%	0	0	2	0	0
Mountain Valleys	99.8%	0	0	137	0	0

1 *Impacts from Renewable Energy Management*  
2 Under Alternative C, management of lands for renewable energy development would be the  
3 same as for Alternative B.

4 *Impacts from Wind Energy Development on Sub-populations*  
5 Under Alternative C, management of lands for wind energy development would be the same  
6 as for Alternative B.

7 *Impacts from Geothermal Energy Development on Sub-populations*  
8 Under this alternative, over 20 million acres of PHMA, including split estate, would be  
9 closed to geothermal leasing (Table 4-26).

**Table 4-26**  
**Alternative C: Percent of GRSG Habitat and Occupied Leks Within Areas Closed or with NSO Stipulations for Geothermal Energy by Population Area**

10

11 *Impacts from Travel and Transportation Management*

12 Under Alternative C, any designated open areas within PHMAs would be managed as limited  
13 for motorized travel with the exception of existing closed areas within PHMAs (see Table 4-  
14 27, Alternative C: Percent of GRSG Habitat and Occupied Leks Affected by Travel  
15 Management Designations by Population Area).

**Table 4-27**

<sup>1</sup>Acres closed to motorized travel represent existing acres closed. No additional areas would be closed under any alternative.

1

2

***Impacts from Special Designations Management***

3

Under Alternative C, the BLM would designate 39 new ACECs (**Table 4-7**). Impacts from management of ACECs are as described under **Section 4.2.2**.

4

5

**4.2.4 Alternative D**

6

Alternative D would delineate GRSG management areas into PHMA, IHMA, and GHMA within the sub-region (see **Table 4-14**). GRSG habitat in Idaho would include all three management areas, while habitat in Montana includes only PHMA and GHMA. Management areas in Utah would be all PHMA. PHMA would receive the highest degree of protection from impacts caused by resource uses. The goal would be to retain priority GRSG habitats for each WAFWA management zone (Stiver et al. 2006) across the current geographic range of GRSG, including no net unmitigated loss of GRSG habitat. These habitats would have to be large enough to stabilize populations in the short term and to enhance populations over the long term. There would be additional provisions to protect larger intact areas of sagebrush to reduce fragmentation.

7

8

9

10

11

12

13

14

15

16

***Impacts from Vegetation and Soils Management***

17

Vegetation dynamics modeling shows the same general trend under Alternative D compared with Alternative A (see **Tables 4-1** and **4-2**).

18

19

Under Alternative D, the BLM and Forest Service would prioritize vegetation treatment projects to further improve GRSG abundance and distribution. Factors contributing to higher emphasis include the likelihood of conifer encroachment into GRSG habitat. In addition, the vegetation management tools described in Alternative B would help to reduce encroachment in PHMA and avoid the impacts discussed under **Section 4.2.2**.

20

21

22

23

24

***Impacts from Livestock Grazing Management***

25

Management under Alternative D includes the same provisions as Alternative B, and also prioritizes land health assessments and managing riparian areas and wet meadows toward PFC in priority and medial habitat. These efforts would improve forage and cover in PHMA and IHMA, to sustain nesting GRSG and protect them from population loss due to predation. Together, these efforts would reduce impacts on GRSG from grazing, such as

26

27

28

29

1 loss of nesting cover, described in **Section 4.2.2**, compared with Alternative A. Acreage  
2 closed to grazing under each alternative is shown in **Table 4-5**.

3 ***Impacts from Fire and Fuels Management***

4 Alternative D would implement the same policies as Alternative B to prioritize fire  
5 suppression and restoration in sagebrush areas by using native plants and limiting damage to  
6 sagebrush habitat from wildfire. Alternative D includes additional measures and planning  
7 such as ES&R guidance, preparations in high-risk areas, and additional training for  
8 firefighters to better prepare for fire outbreaks in high-risk areas such as sagebrush. Adaptive  
9 management under Alternative D would expand more restrictive management from PHMAs  
10 to less restrictive IHMAs based on specific and measurable triggers relating to habitat and  
11 population metrics. Overall, Alternative D would reduce impacts from wildfire, similar to  
12 Alternative B.

13 ***Impacts from Wild Horse and Burro Management***

14 Same as Alternative B.

15 ***Impacts from Leasable Minerals Management***

16 Management would be similar to Alternative B but would apply to PHMA, IHMA, and  
17 GHMA (see **Table 2-9**). In unleased areas of PHMA and IHMA, no exploration or leasing  
18 of fluid minerals would be allowed. GHMA would be open to leasing with stipulations.  
19 BMPs and mitigation to protect GRSG would be required in PHMA and IHMA for  
20 locatable minerals and nonenergy leasable minerals. Policies for locatable and salable  
21 minerals are otherwise the same as under Alternative B. In addition, 26 acres of PHMA and  
22 33 acres of IHMA in East-Central Idaho would be closed to nonenergy leasable mineral  
23 leasing in unleased known phosphate lease areas.

24 Management under Alternative D would close 8.8 million acres of PHMA, IHMA and  
25 GHMA to fluid mineral leasing. Closure would increase protection of habitat associated with  
26 leks, which would impact 13 percent of the GRSG population for the sub-region, and by  
27 sub-population (**Table 4-28**, Alternative D: Percent of GRSG Habitat and Occupied Leks  
28 Within Areas Closed or with NSO Stipulations for Oil and Gas Leasing by Population Area).  
29 These approaches would reduce the impacts of mining on GRSG habitat, as described in  
30 **Section 4.2.2**, in ways similar to Alternative B, by closing nearly 9 million acres to fluid  
31 mineral leasing and protecting additional acreage using timing limitations.

**Table 4-28**

**Alternative D: Percent of GRSG Habitat and Occupied Leks Within Areas Closed or  
with NSO Stipulations for Oil and Gas Leasing by Population Area**

<b>Population Area</b>	<b>Habitat Area</b>	<b>Occupied Leks</b>

2

***Impacts from Locatable Minerals Management***

3

4

5

6

7

8

9

10

Alternative D would leave areas open for locatable mineral removal and would require operators to include measures to avoid or minimize adverse effects to GRSG and GSG habitat when 3809 Plans and notices are required (**Table 4-29**). BMPs for locatable minerals removal would be applied to priority, medial, and general areas as COAs in plans of operation. As no additional habitat would be withdrawn from mineral entry, there would continue to be effects on GRSG and their habitat, as described in **Section 4.2.2**. Use of BMPs (see **Appendix B**) under this alternative might reduce these impacts as compared with Alternative A.

**Table 4-29**  
**Alternative D: Percent of GRSG Habitat and Occupied Leks Affected by Mineral Withdrawal by Population Area**

Population Area	Habitat Area	Occupied Leks

**Impacts from Land Uses and Realty Management (Wind and Geothermal Energy)**

Under Alternative D, PHMA, GHMA, and IHMA would be designated ROW avoidance (but not exclusion) areas to allow for management flexibility (Tables 4-3 and 4-4). In PHMA, the BLM and Forest Service would exclude development of larger transmission facilities (greater than 50 kilovolts); wind and solar developments; commercial geothermal development; nuclear, gas, and oil developments; airports; paved and gravel roads; and landfills. Communication sites would not be excluded. In IHMA and GHMA, the BLM and Forest Service would avoid siting these facilities or would co-locate them when possible in order to minimize impacts (see Table 4-31, Alternative D: Percent of GRSG Habitat and Occupied Leks Affected by ROW Exclusion or Avoidance by Population Area).

**Table 4-31**  
**Alternative D: Percent of GRSG Habitat and Occupied Leks Affected by ROW Exclusion or Avoidance by Population Area**

Population Area	Habitat Area			Occupied Leks		
	Exclusion	Avoid with Exclusions	Avoidance	Exclusion	Avoid with Exclusions	Avoidance
East Central Idaho	0.5%	4.4%	95.1%	0	0	2

*Impacts from Travel Management*

Alternative D would limit motorized travel to existing roads, primitive roads and trails on all BLM-administered lands within field offices containing GRSG habitat unless specific open areas have been previously designated to support recreational activities. None of these open areas would overlap PHMA or IHMA areas. Acres where motorized travel would be limited to roads, existing roads, and trails in entire BLM field offices containing GRSG habitat are shown on **Table 4-33**, Alternative D: Percent of GRSG Habitat and Occupied Leks Affected by Travel Management Designations by Population Area.

**Table 4-33**  
**Alternative D: Percent of GRSG Habitat and Occupied Leks Affected by Travel Management Designations by Population Area**

Population Area	Habitat Area			Occupied Leks		
	Open <sup>1</sup>	Limited	Closed	Open <sup>1</sup>	Limited	Closed

<sup>1</sup> Acres closed to motorized travel represent existing acres closed. No additional areas would be closed under any alternative.

1

2

3

4

5

This approach would reduce the likelihood of impacts from infrastructure within GRSG habitat (PHMA, IHMA, and GHMA) and would support comprehensive travel management planning for the entire field office subsequent to this planning effort. Impacts from areas limited to existing roads are as described in **Section 4.2.2**.

***Impacts from Adaptive Management***

Alternative D includes an adaptive management strategy that would apply the more restrictive measures of PHMAs to the IHMA areas if hard adaptive triggers were tripped. In Alternative D, adaptive management is evaluated at the population area scale, so if a population area trips a hard trigger then the IHMA areas within that population area would then be managed as PHMAs on BLM-administered and National Forest System lands, until the habitat or population recovers and the trigger no longer applies. While the management actions and allocations described for this alternative are anticipated to reduce impacts on GRSG, an adaptive management approach is included in the event that habitat or populations continue to decline to the point that hard habitat or population triggers are tripped. **Table 4-34**, Alternative D: Acres of GRSG Habitat and Number of Occupied Leks Affected by Adaptive Management Trigger by Population Area describes the extent of habitat and number of occupied leks on BLM-administered and National Forest System IHMA that would be affected and managed as PHMA, should a trigger be tripped in a particular population area.

**Table 4-34**  
**Alternative D: Percent of GRSG Habitat and Occupied Leks Affected by Adaptive Management Trigger in IHMA by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	5.8%	1
Mountain Valleys	76.6%	4
Southwest Montana	79.9%	0
North Side Snake	48.9%	6
South Side Snake	83.6%	28

1

2 ***Impacts from Special Designations Management***

3 Impacts from ACEC management under Alternative D are the same as those described for  
4 Alternative A (Table 4-7).

5 **4.2.5 Alternative E**

6 Under Alternative E, the BLM and Forest Service would manage to maintain, conserve,  
7 enhance, and restore sagebrush ecosystems. CHZ, IHZ, and GHZ would be designated in  
8 Idaho, with PHMA and GHMA in Montana and PHMA in Utah (Table 4-14). In CHZ and  
9 IHZ, the BLM and Forest Service would incorporate management flexibility to permit high  
10 value infrastructure with appropriate mitigation and best management practices tailored for  
11 the sub-region. Management and impacts are similar to Alternative D, though Alternative E  
12 would require less stringent use restrictions, as the disturbance cap would be applied to fluid  
13 mineral development only and would restrict development to 5 percent disturbance. Further,  
14 Alternative E would designate the least amount of CHZ compared to the other alternatives'  
15 management area designations.

16 ***Impacts from Vegetation and Soils Management***

17 Alternative E categorizes management areas within Idaho into CHZ, IHZ, and GHZ. For  
18 lands within Utah, management areas are categorized as PHMA, and Montana management  
19 areas would be the same as Alternative A (see Table 4-14). CHZ would receive the highest  
20 degree of protection and management would focus on the maintenance and enhancement of  
21 habitats, populations, and connectivity. In important habitat these goals would coexist with  
22 high-value infrastructure projects.

23 Vegetation dynamics modeling shows the same trend under Alternative E compared with  
24 Alternative D; even though habitat condition trends appear to be slightly downward after 50  
25 years, the model projections still show that habitat is meeting desired conditions.

26 Alternative E would maintain the policies described under Alternative A, along with  
27 additional provisions to protect CHZ, IHZ, and GHZ. These habitats would be managed to  
28 prevent invasion. Invasive plants threatening GRSG habitat would be eradicated or  
29 controlled in CHZ and IHZ. Invasive plants would be monitored for three years following a  
30 fire. The policies under Alternative E would reduce the impacts from invasive plants in these  
31 habitats to a limited degree compared with Alternative A, though current management  
32 already addresses this threat.

Under Alternative E, the BLM and Forest Service would prioritize the removal of conifers. This would be accomplished through methods appropriate for the terrain and most likely to facilitate GRSG population and habitat recovery in core and important habitat through methods determined appropriate for the terrain at the site-specific level. In addition, as described in **Section 4.2.6**, CHZ, IHZ, and GHZ would be managed to prevent invasion.

The policies under Alternative E would do more to reduce the impacts from conifer encroachment described under **Section 4.2.2** compared with Alternative A.

**Table 4-35**, Alternative E: Percent of GRSG Habitat Designations and Occupied Leks within each Conservation Area, describes the acres of CHZ, IHZ and GHZ and occupied leks within each conservation area.

**Table 4-35**  
**Alternative E: Percent of GRSG Habitat Designations and Occupied Leks within each Conservation Area**

Population Area	Habitat Area			Occupied Leks		
	CHZ	IHZIH MA	GHZ	CHZ	IHZ	GHZ
Mountain Valleys	41%	32%	27%	64.5	31.8	3.6
Desert	41%	17%	43%	73.3	11.1	15.6
West Owyhee	60%	23%	17%	51.8	39.6	8.6
Southern	29%	33%	38%	82.4	16.9	0.7

Source: BLM GIS 2015

***Impacts from Livestock Grazing Management***

Management under Alternative E would add GRSG guidelines to grazing management plans in core and important habitats. Land health assessments would be prioritized in areas with declining GRSG populations, subject to existing legal requirements, and management changes would be tailored to specifically address GRSG habitat objectives. In core areas, grazing plans could be altered by enhancing grazing in areas with lower habitat value. Acreage closed to grazing is shown in **Table 4-5**. These efforts would reduce impacts from grazing on GRSG, relative to Alternative A.

***Impacts from Fire and Fuels Management***

Alternative E would focus resources to reduce wildfire in sagebrush areas. It would prioritize fire suppression in CHZ, IHZ, and GHZ and would maintain fuel breaks in core and important habitat. Fuels treatments would protect existing sagebrush ecosystems. Fire response times to CHZ and IHZ would be reduced to limit fire damage. Alternative E includes an adaptive management strategy based on population and habitat triggers for each conservation area. These policies may limit the prevalence of wildfire in sagebrush areas and would reduce damage to GRSG habitat; impacts are similar to those described for Alternative B.

1 **Impacts from Wild Horse and Burro Management**

2 Same as Alternative A.

3 **Impacts from Leasable Minerals Management**

4 Alternative E would designate CHZ and IHZ as open to oil and gas leasing subject to an  
5 NSO stipulation. In CHZ in Idaho, Alternative E would stipulate that the Idaho BLM State  
6 Director may waive the stipulation only in situations where the development will not  
7 accelerate and/or cause declines in GRSG populations within the relevant CA, based on the  
8 application of certain criteria. Development would be allowed in important habitat if it  
9 would not cause a decline in GRSG populations. The policy does not state how such an  
10 assurance would be provided in advance of development. Impacts on GRSG from energy  
11 development would be reduced, relative to Alternative A.

12 Under Alternative E, 2.6 million acres would be closed to oil and gas leasing. Closure would  
13 increase protection on habitat associated with leks (**Table 4-36**, Alternative E: Percent of  
14 GRSG Habitat and Occupied Leks Within Areas Closed or with NSO Stipulations for Oil  
15 and Gas Leasing by Population Area).

**Impacts from Land Uses and Realty Management (Wind Energy)**

Under Alternative E, CHZ and IHZ would be identified as ROW avoidance areas (Tables 4-3 and 4-4). The BLM and Forest Service would co-locate new ROWs or SUAs with existing infrastructure. They would aim to remove, bury, or modify existing power lines in these areas when possible. In important habitat areas, new infrastructure could be built if habitat protection criteria were met. In CHZ, no new infrastructure would be permitted, except in-place upgrades. (Table 4-38, Alternative E: Percent of GRSG Habitat and Occupied Leks Affected by ROW Exclusion or Avoidance by Population Area).

**Table 4-38**

5  
 6 **Impacts from Travel Management**  
 7 Alternative E would prioritize travel and transportation planning to minimize impacts on  
 8 GRSG from road travel. It also would reduce the risk of wildfire from cross-country  
 9 motorized travel because motorized vehicles would be restricted to existing routes in CHZ  
 10 and IHZ. Timing and seasonal restrictions would be applied to activities known to disturb  
 11 nesting GRSG while travel management planning is underway. Impacts from roads and  
 12 ROWs in CHZ and IHZ would be reduced, compared with Alternative A. Impacts from  
 13 road construction and use in collocated areas and GHZ are similar to Alternative A. **Table**  
 14 **4-40**, Alternative E: Percent of GRSG Habitat and Occupied Leaks Affected by Travel  
 15 Management Designations by Population Area, describes the percent of habitat and  
 16 occupied leaks affected by travel management decisions in this alternative.

**Table 4-40**

**Impacts from Adaptive Management**

As described in Chapter 2, Alternative E includes an adaptive management strategy composed of soft and hard triggers that are based on population and habitat changes. Each trigger is determined by conservation area, so the strategy is more locally responsive than if triggers were determined on a sub-regional or statewide basis. When a conservation area meets a soft trigger there is no required adaptive response. When a hard trigger is met, the IHZ areas within that conservation area would be managed according to the CHZ regulations primarily impacting the ability to consider infrastructure projects until the habitat or population recovers and the trigger no longer applies. The Implementation Task Force would be engaged in situations where a soft trigger is met or when the cause of meeting the hard trigger is related to wildfire or invasive species or to analyze the secondary threats to determine the appropriate management response. The triggers are based on lek monitoring completed and compiled by IDFG on an annual basis and on habitat change. **Table 4-41**, Alternative E: Percent of GRSG Habitat and Occupied Leaks Affected by Adaptive Management Trigger in IHZ by Population Area, describes the percentage of habitat and percentage of occupied leks that would be affected should a trigger be met in a particular population area.

**Table 4-41**

***Impacts from Special Designations Management***

Impacts from ACEC management under Alternative E are the same as those described for Alternative A (Table 4-7).

**4.2.6 Alternative F**

Management under Alternative F would be largely similar to that described for Alternative B, though with more stringent guidance and restrictive management in sagebrush ecosystems. PHMA, GHMA and RHMA would be designated (Table 4-14). Impacts from implementing the maximum three percent disturbance cap are similar to those described for Alternative B; however, under Alternative F, all surface disturbances (including human disturbance and fire) would count toward this cap. This would further reduce the acreage of vegetation that would be removed or fragmented within all occupied habitat over the long term.

***Impacts from Vegetation and Soils Management***

Management under Alternative F generally would repeat management actions described under Alternative B with exceptions such as reduced treatment of invasive conifer.

Management under Alternative F would provide about the same level of protection as Alternative B or slightly less. Habitat trends for 10 and 50 years would improve compared with Alternative A and would be similar to Alternative B.

Alternative F would maintain the policies described under Alternative A, along with additional provisions to limit invasive weed spread. It would restrict activities that spread invasives and would ensure the health of vegetation and soil in GRSG habitat. Alternative F also includes post-fire treatment of invasives. Alternative F would prioritize restoration, including reducing invasive plants, as described under Alternative B. These policies would reduce impacts from invasive plants, compared to Alternative A, to a limited degree, though current management already addresses this threat.

***Impacts from Livestock Grazing Management***

Management under Alternative F would retain the same number of acres open and the same number of acres closed to livestock grazing as found under Alternative A and, therefore, would affect the same percentage of the sub-region's GRSG population. However, management under Alternative F would be more restrictive than Alternative A, with a 25 percent reduction of grazing in each population area and new water developments using spring or seep sources restricted within GRSG habitat. In addition, all prescriptions related to livestock management would apply to all GRSG habitats.

Alternative F includes a reduction in AUMs calculated by applying a 25 percent reduction to the three-year average of billed use. Management under Alternative F would also require that water developments be analyzed and modified or removed if they are found to be impacting a riparian area. Similar modification or removal standards would be applied to other existing range developments such as fences. No salt or other supplements would be allowed.

1 Ensuring riparian areas are at PFC would be the same as for Alternative A. Compared with  
2 Alternative A, management under Alternative F would provide more indirect benefits to  
3 GRSG. This is because it would increase upland and riparian nesting and brood-rearing  
4 habitat amount and quality by reducing by 25 percent livestock grazing each year. Also, it  
5 would remove certain livestock-related structures such as fences.

6 ***Impacts from Fire and Fuels Management***

7 Impacts would be similar to those under Alternative B, except that a 25 percent reduction in  
8 grazing may increase fuel loads in those areas where grazing no longer occurs. Although  
9 grazing can be an effective tool to reduce fuel loads, research indicates grazing is not  
10 effective in reducing cheatgrass competition (Hempy-Mayer and Pyke 2008). Therefore, fine  
11 fuel loads and fire frequency in cheatgrass-infested GRSG habitat may not be affected by the  
12 absence of grazing.

13 ***Impacts from Wild Horse and Burro Management***

14 Same as Alternative A.

15 ***Impacts from Leasable Minerals Management***

16 Management under Alternative F would close PHMAs and GHMAs to fluid mineral leasing,  
17 including geothermal energy. Quantitative impacts would be the same as for Alternative B.

18 ***Impacts from Locatable Minerals Management***

19 Impacts from locatable minerals management would be the same as for Alternative B.

20 ***Impacts from Salable Minerals Management***

21 Management under Alternative F would close acres to salable minerals removal. Closure  
22 would increase protection on habitat associated with leks (see **Table 4-42**, Alternative D:  
23 Percent of GRSG Habitat and Occupied Leks Affected by Closure to Salable Minerals by  
24 Population Area).

**Table 4-42**  
**Alternative F: Percent of GRSG Habitat and Occupied Leks Affected by Closure to**

Bear Lake	93.3%	7
Weiser	35.4%	0

Source: BLM GIS 2015

25

**Impacts from Land Uses and Realty Management**

Under Alternative F, most GHMAs would be managed as avoidance areas for new ROWs and all PHMAs habitats would be managed as ROW exclusion for new permits with exceptions for co-location of projects within existing footprints and valid, existing rights (Table 4-43). Under this alternative, 8.5 million acres would be managed as ROW exclusion. ROW exclusion would protect over eight times more acres of GRSG habitat than under Alternative A. Management under Alternative F would also include actions to reclaim or modify existing ROWs that may impact GRSG directly (e.g., fences) or indirectly benefit their habitat (e.g., restoring a non-used road). Management under Alternative F would retain public ownership of PHMAs where it benefitted overall GRSG habitat and propose priority habitat for mineral withdrawal. Management under Alternative F would be expected to provide greater direct protections to GRSG than Alternative A due to the larger number of acres under Alternative F being in the ROW exclusion category. Indirect impacts on habitat would be expected to also be less than Alternative A.

**Table 4-43  
Alternative F: Percent of GRSG Habitat and Occupied Leks Affected by ROW Exclusion or Avoidance by Population Area**

Population Area	Habitat Area			Occupied Leks		
	Exclusion	Avoid with Exclusions	Avoidance	Exclusion	Avoid with Exclusions	Avoidance

**Impacts from Renewable Energy Management**

*Impacts from Wind Energy Development*

Same as Alternative B. Under Alternative F, wind energy projects would not be sited within occupied GRSG habitat or within five miles of an active lek. This would result in 8.6 million acres managed as ROW exclusion.

*Impacts from Geothermal Energy Development*

Impacts from geothermal energy management would be the same as presented for Alternative B.

1 **Impacts from Travel and Transportation Management**  
 2 Impacts from travel and transportation management under Alternative F would be similar to  
 3 those described for Alternative B. Acres and leks protected would be slightly different due to  
 4 the management of RHMA under Alternative F (**Table 4-44**).

**Table 4-44**  
**Alternative F: Percent of GRSG Habitat and Occupied Leks Affected by Travel Management Designations by Population Area**

<sup>1</sup>Acres closed to motorized travel represent existing acres closed. No additional areas would be closed under any alternative.

5  
 6 **Impacts from Special Designations Management**  
 7 Under Alternative F, the BLM would designate 17 or 18 new ACECs and the Forest Service  
 8 would designate 12 new ZAs (**Table 4-7**). Impacts from management of ACECs are as  
 9 described under **Section 4.2.2**, and impacts from ZAs are expected to be similar.

10 **4.2.7 Proposed Plan**

11 **Impacts from Lands and Realty Management**

12 Under the Proposed Plan, PHMA and IHMA would be identified as ROW/SUA avoidance  
 13 areas to allow for management flexibility (**Table 4-2**). However, PHMA would be exclusion  
 14 areas specifically for wind and solar developments. In practice, new ROWs/SUAs in PHMA  
 15 would not be allowed except in accordance with the Anthropogenic Disturbance Exception  
 16 Criteria outlined in the Proposed Plan. Transmission lines in PHMA would only be allowed  
 17 as incremental upgrades in existing corridors, and perch deterrents would be used to reduce  
 18 avian predation where appropriate. In IHMA new ROWs/SUAs could be considered if in  
 19 accordance with the IHMA Anthropogenic Disturbance Development Criteria. The BLM  
 20 and Forest Service would co-locate new ROWs or SUAs with existing infrastructure when  
 21 possible. The Proposed Plan provides for a protective buffer from disturbance around leks  
 22 in PHMA, IHMA and GHMA, depending on the type of disturbance, based on the latest  
 23 science (USGS 2014), to be applied at implementation. BLM and Forest Service retain  
 24 management flexibility to route ROWs/SUAs to minimize overall impacts on GRSG habitat.  
 25

1 Existing ROW/SUA corridors are preferred for co-location of new ROWs/SUAs, but could  
2 not be widened more than 50 percent greater than the original footprint. These measures  
3 would protect GRSG and their habitats from fragmentation, disturbance/predation, and  
4 other impacts as described in **Section 4.2.2** associated with ROW construction, operations  
5 and maintenance.

6 There is projected to be no impact from exclusion of solar energy development on National  
7 Forest System land in the planning area as there is limited potential for solar energy  
8 development on these lands.

9 Under the Proposed Plan, land tenure adjustments would include retaining lands with GRSG  
10 habitat. PHMA and IHMA would not be available for disposal and would only be available  
11 for exchanges that increase the extent or provide for connectivity of habitat. Retention of  
12 areas with GRSG would reduce the likelihood of habitat conversion to agriculture,  
13 urbanization, or other uses that would remove sagebrush habitat and potentially impact  
14 sensitive plants. **Tables 4-45** and **4-46** show the percentage of GRSG habitat and occupied  
15 leks affected by major and minor ROW/SUA exclusion or avoidance by population area.

**Table 4-44**

**Impacts from Habitat Restoration and Vegetation Management**

Results from the VDDT are presented in **Table 4-47** below. This modeling effort is described further in **Appendix X**. Stand replacement wildfire, mosaic wildfire, overgrazing, insects and disease, and conifer encroachment were incorporated into the model to quantify changes in GRSG habitat. The modeling effort did not include changes in habitat conditions associated with climate change or with permitted activities such as infrastructure development, travel management, or mineral development. The model also estimated treatment acres required to meet target sagebrush habitat quality goals. Based on guidelines provided by the GRSG National Technical Team Report (NTT 2011), 70 percent of an area should be in 10 to 30 percent sagebrush canopy cover to meet GRSG sagebrush habitat objectives. The tables included as part of the vegetation impacts for each alternative present the percentage of a given GRSG analysis area meeting GRSG sagebrush habitat objectives by alternative after 10 years and 50 years' time.

The acres of treatment proposed in each of the analysis area are necessary to improve or maintain habitat conditions. The proposed plan provides treatment acres by decade sufficient to meet desired habitat conditions (70 percent of the analysis area meeting 10 to 30 percent sagebrush cover) (NTT 2011). The trends reflect the combined treatment acres in both BLM and Forest Service Proposed Plans compared to the treatment rates and types occurring currently under the No Action alternative.

**Table 4-46**  
**Proposed Plan: Modeled Habitat Trends by Analysis Area**

Analysis Area	No Action Modeled <sup>1</sup> Habitat Condition and Trend <sup>2</sup>			Proposed Plan Modeled <sup>1</sup> Habitat Condition and Trend <sup>2</sup>		
	Initial Condition	10 year Condition	50 year Condition	Initial Condition	10 year Condition	50 year Condition
9 (Bear Lake)	84%	77%	67%	84%	80%	73%
18 (East-Central Idaho)	98%	90%	79%	98%	90%	79%
23 (North Side Snake, Mountain Valleys)	85%	78%	73%	85%	79%	70%

**Table 4-46**  
**Proposed Plan: Modeled Habitat Trends by Analysis Area**

Analysis Area	No Action Modeled <sup>1</sup> Habitat Condition and Trend <sup>2</sup>			Proposed Plan Modeled <sup>1</sup> Habitat Condition and Trend <sup>2</sup>		
	Initial Condition	10 year Condition	50 year Condition	Initial Condition	10 year Condition	50 year Condition

19 (Southwest Montana)	98%	90%	81%	98%	91%	81%

Source: Forest Service GIS 2015

<sup>1</sup>The outputs are not absolutes and are bound by the assumptions and limitations of the data.

<sup>2</sup>Habitat condition percentages are the amount of the analysis area that meets 10 to 30 percent sagebrush cover.

1

2

3

4

5

6

7

In the Alternative A model, results show a declining trend in 5 out of 6 of the analysis areas. In Analysis Areas 9 and 26 at 50 years they would be below the desired conditions, meaning less suitable habitat would be available for GRSG than currently exist, which could result in GRSG population declines in those areas. For the other Analysis Areas (18, 23, 25 and 19), GRSG populations should remain stable, absent other factors that may not have been accounted for in the model.

8

9

10

In the Proposed Plan, results indicate all areas would meet or exceed desired conditions based on the vegetation treatment objectives. For all areas GRSG populations should remain stable or improve, absent other factors that may not have been accounted for in the model.

11

12

13

14

15

16

17

18

19

20

21

Conifer removal can provide immediate benefit to GRSG by restoring habitat quality, whereas other vegetation management projects aimed at restoring sagebrush may aid GRSG over the long term, but not provide immediate habitat improvement. Under the Proposed Plan, the BLM and Forest Service would include treatment programs to reduce the likelihood of conifer encroachment and further improve GRSG abundance and distribution. A total of 107,000 acres of BLM-administered lands and 22,000 acres of National Forest System lands would be treated with mechanical means or prescribed fire to reduce conifer encroachment. Conifer removal would facilitate GRSG population and habitat recovery through methods determined appropriate for the terrain at the site-specific level. Thus, the vegetation management tools described in the proposed plan would help to reduce encroachment and improve GRSG habitat.

22

23

24

25

The policies under the Proposed Plan would also reduce the impacts from invasive plants in these habitats compared with Alternative A, and monitoring and mitigation components of the Proposed Plan would help to ensure GRSG seasonal habitat objectives (**Tables 2-3 and 2-6**) are met.

**Impacts from Wildland Fire Management**

The Proposed Plan would focus resources to reduce wildfire in sagebrush areas. It would maintain fuel breaks in PHMA and IHMA. Fire response times to PHMA and IHMA would be reduced to limit fire damage. The recommendations from the BLM Fire and Invasives Assessment Tool (FIAT) (**Appendix D**) will direct field offices to prioritize landscapes for fire prevention and fuels management within GRSG habitat to minimize the risk of wildfire in PHMA and IHMA. Fuels management treatments and post-fire rehabilitation projects in PHMA would focus on maximizing benefits on GRSG habitats using the resistance and resilience concepts in Chambers et al. (2014) coupled with the FIAT assessments. These concepts would reduce impacts from invasive annual grasses and altered fire regimes on the sagebrush ecosystem as well as reduce the rate of conifer encroachment in order to reduce GRSG habitat fragmentation and maintain or re-establish habitat connectivity over the long-term and at a landscape scale. The use of prescribed fire in GRSG habitat would be avoided unless evaluation of site-specific conditions showed a net benefit to GRSG. All of these measures would serve to reduce habitat loss for GRSG.

The Proposed Plan includes an adaptive management strategy based on population and habitat triggers for each conservation area. Adaptive management would expand more restrictive management based on specific and measurable triggers relating to habitat and population metrics, for example, grazing may be restricted in areas adjacent to burns in order to restore habitat capable of supporting GRSG. Enhanced monitoring would be conducted in restoration areas under the Proposed Plan. These policies are designed to limit the prevalence of wildfire in sagebrush areas and would reduce damage to GRSG habitat more than current management.

**Impacts from Leasable Minerals Management**

Under the Proposed Plan, in unleased areas of PHMA and IHMA, an NSO stipulation would be applied without waivers or modifications. In SFAs, NSO stipulations would apply without waiver, exception, or modification. Outside SFAs, exceptions to NSO would be considered under certain criteria. GHMA would be open to leasing with BMPs, RDF, and buffer zones (**Appendices B and C**). Restrictive stipulations would increase protection of habitat associated with leks by avoiding surface disturbance during sensitive times, and would reduce the impacts of mining on GRSG habitat, as described in **Section 4.1.2**. Mitigation requirements would be implemented to ensure a net conservation gain for GRSG. **Table 4-48** shows the percentage of GRSG habitat and occupied leks within areas closed or with NSO stipulations for oil and gas leasing by population area. **Table 4-49** shows the percentage of GRSG habitat and occupied leks within areas closed or with NSO stipulations for geothermal energy by population area.

**Table 4-47**  
**Proposed Plan: Percent of GRSG Habitat and Occupied Leks Within Areas Closed or with NSO Stipulations for Oil and Gas Leasing by Population Area**

***Impacts from Non-Energy Leasable Minerals Management***

Under the Proposed Plan, PHMA areas outside KPLAs would be closed to leasing, while IHMA would be open to leasing in accordance with the Anthropogenic Disturbance Development Criteria, as well as RDFs, BMPs, buffers (based on the USGS (2014) study, and seasonal timing restrictions (**Appendices B and C**). In GHMA, lands will remain available for leasing subject to RDFs, BMPs, buffers, timing restrictions and stipulations. These provisions may have little impact on GRSG because phosphate resources are located primarily in southeastern Idaho in non-habitat areas for GRSG. To the extent that phosphate resources are located in GRSG habitat, the provisions provided under the Proposed Plan would protect the habitat from impacts associated with mineral exploration.

***Impacts from Locatable Minerals Management***

Currently, BLM-administered and National Forest System lands within the sub-region are generally open to locatable mineral development. Mitigation of effects on GRSG and its habitat are identified through the NEPA process approving plans of operation. Goals and

1 objectives for locatable minerals are to provide opportunities to develop the resource while  
2 preventing undue or unnecessary degradation of BLM-administered and National Forest  
3 System lands.

4 These acreages would not change under the Proposed Plan, except in SFAs, where all  
5 acreage would be recommended for withdrawal from locatable mineral entry. In addition,  
6 the Proposed Plan would require operators to include measures to avoid or minimize  
7 adverse effects to GRSG and their habitat when 3809 Plans and notices are required. BMPs  
8 for locatable minerals removal would be applied to PHMA, IHMA and GHMA areas as  
9 COAs in plans of operation. As no additional habitat would be withdrawn from mineral  
10 entry, there would continue to be effects on GRSG and their habitat. Use of BMPs, RDFs  
11 and buffers (**Appendices B and C**) under the Proposed Plan might reduce these impacts as  
12 compared with Alternative A. **Table 4-50** shows the percentage of GRSG habitat and  
13 occupied leks affected by mineral withdrawal by population area.

14  
**Table 4-49**  
**Proposed Plan: Percent of GRSG Habitat and Occupied Leks Within Existing and**  
**Proposed Locatable Mineral Withdrawals by Population Area**

Population Area	Habitat Area	Occupied Leks

16  
17 ***Impacts from Salable Minerals Management***

18 Under the Proposed Plan, PHMA would be closed to new development while IHMA would  
19 be open subject to Anthropogenic Disturbance Development Criteria. Closure would  
20 increase protection on habitat associated with leks and GRSG habitat across the broader  
21 landscape (**Table 4-4**). In addition, buffer zones, RDFs and BMPs (**Appendices B and C**)  
22 associated with development in GRSG habitat would provide improved protection from  
23 disturbance associated with salable mineral development. **Table 4-51** shows the percentage  
24 of GRSG habitat and occupied leks affected by closure to salable minerals by population  
25 area.

**Table 4-50**  
**Proposed Plan: Percent of GRSG Habitat and Occupied Leks Affected by Closure to Salable Minerals by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	22.6%	1
Mountain Valleys	61.5%	127
SW Montana	68.9%	45
North Side Snake	44.7%	210
South Side Snake	39.8%	84
Southwest Idaho	68.3%	141
Sawtooth	12.7%	0
Bear Lake	59.4%	5

***Impacts from Travel and Transportation Management***

The Proposed Plan would prioritize travel planning to designate open and closed areas. In the meantime, it would limit motorized travel to existing roads and trails on all BLM-administered lands within field offices containing GRSG habitat, unless specific open areas have been previously designated to support recreational activities. Negative impacts would occur on a small scale in open areas. Timing and seasonal restrictions would be applied to activities known to disturb nesting GRSG while travel management planning is underway.

Under the Proposed Plan, impacts from roads and ROWs/SUAs in PHMA and IHMA would be reduced, compared with Alternative A. Impacts from road construction and use in co-located areas and GHMA are similar to Alternative A. **Table 4-52** shows the percentage of GRSG habitat and occupied leks affected by travel management designations by population area.

**Table 4-51**  
**Proposed Plan: Percent of GRSG Habitat and Occupied Leks Within Each Travel Management Designation by Population Area**

Population Area	Habitat Area			Occupied Leks		
	Open <sup>1</sup>	Limited	Closed	Open <sup>1</sup>	Limited	Closed

<sup>1</sup>Acres closed to motorized travel represent existing acres closed. No additional areas would be closed under any alternative.

***Impacts from Livestock Grazing Management***

Under current management, 11,073,800 acres of identified GRSG habitat are open for livestock grazing (**Table 4-5**). Livestock grazing is managed through existing grazing plans, with methods and guidelines from the existing plans followed to maintain ecological conditions according to Standards for Rangeland Health, which include maintaining healthy, productive and diverse populations of native plants and animals. Direct impacts on GRSG have been reduced in some areas due to GRSG-specific management found in some conservation strategies or LUPs.

Range improvements are designed to meet both wildlife and range objectives, and include building, modifying or marking fences to permit passage of wildlife and reduce the chance of bird strikes. Modifications may involve moving troughs, adding or changing wildlife escape ramps, or ensuring water is available on the ground for a variety of different wildlife species. Although not directly created to protect GRSG, these approaches would protect and enhance GRSG habitat by diverting livestock away from sensitive areas, thereby reducing the likelihood of surface disturbance in these areas.

Management under the Proposed Plan would add GRSG guidelines to grazing management plans in PHMA, IHMA, and GHMA. Land health assessments would be prioritized in SFAs and PHMA, and management changes would be tailored to specifically address GRSG habitat objectives. When an allotment becomes vacant, voluntary retirement of the allotment or grazing preference would be considered in PHMA if it would benefit GRSG habitat. In addition, the NEPA analysis for renewals and modifications of livestock grazing permits that include lands within SFAs and PHMAs will include specific management thresholds based on GRSG habitat objectives. Defined responses will allow the authorizing officer to make adjustments to livestock grazing without conducting additional NEPA. **Table 4-5** shows acres closed to grazing under the Proposed Plan, compared to current management. Allotment retirement would remove any grazing effects to GRSG habitat in the retired allotment.

Structural range improvements not beneficial to GRSG would be limited in GRSG habitat to reduce the likelihood of additional disturbance. Similar efforts would apply to AML re-evaluations in HMA for wild horse and burro populations. HMA would not be increased in PHMA or in IHMA without consideration of GRSG habitat objectives. Together, these efforts would reduce impacts on GRSG from grazing, such as loss of nesting cover, compared with Alternative A.

1 **Impacts from Special Designations Management**

2 Impacts would be the same as under Alternative A (current management); no additional  
3 special designations would be created under the Proposed Plan.

4 **Impacts from Anthropogenic Disturbance Management, Adaptive Management, and**  
5 **Coordination**

6 While the management actions described for the Proposed Plan are anticipated to reduce  
7 impacts on GRSG, the adaptive management approach is included in the event that habitat  
8 or populations continue to decline to the point that triggers are met. In that event, more  
9 restrictive measures could be applied. The goal of adaptive management is to detect effects  
10 on GRSG and take action in an appropriate timeframe to effectively offset impacts.

11 In Idaho, the Proposed Plan would incorporate an adaptive management strategy composed  
12 of soft and hard triggers that are based on population and habitat changes. BLM and Forest  
13 Service would utilize population information collected and maintained by the Idaho  
14 Department of Fish and Game to track and identify population changes to assess the  
15 population trigger in the adaptive management approach. Triggers would be determined by  
16 Conservation Area, making the strategy more locally responsive than if triggers were  
17 determined on a sub-regional or statewide basis. When a soft trigger is met, the response  
18 would be additional evaluation. When a hard trigger is met, IHMA areas within that  
19 Conservation Area would be managed as PHMA, impacting the consideration of  
20 infrastructure projects until the habitat or population recovers and the trigger no longer  
21 applies. Hard triggers include a 20 percent decline of nesting and/or wintering habitat within  
22 PHMA or IHMA compared to an established baseline within a Conservation Area.  
23 **Appendix G** provides more detail on the adaptive management approaches, triggers and  
24 responses. The use of adaptive management would benefit GRSG by limiting disturbance to  
25 habitat in PHMA and IHMA in Idaho. **Table 4-53** shows the percentage of GRSG habitat  
26 and occupied leks affected by adaptive management triggers by population area.

27  
28 **Table 4-52**  
**Proposed Plan: Percent of GRSG Habitat and Occupied Leks Affected by Adaptive**  
**Management Trigger in IHMA by Population Area**

Population Area	Habitat Area	Occupied Leks
East Central Idaho	0%	0
Mountain Valleys	73%	35
SW Montana	0%	0
North Side Snake	54.8%	30
South Side Snake	80.9%	92
Southwest Idaho	37.4%	13
Sawtooth	0%	0
Bear Lake	29%	3
Weiser	0%	0

Source: BLM GIS 2015

1  
2 To limit overall anthropogenic disturbance to GRSG habitat, BLM and Forest Service would  
3 impose a cap to limit anthropogenic disturbance to 3 percent of habitat, as calculated within  
4 the BSU and project analysis area. This would reduce disturbance on both the local and  
5 landscape scales. The BSU is defined as the nesting and wintering habitat within PHMA and  
6 IHMA within a Conservation Area. The use of BSUs to calculate disturbance is more  
7 protective of GRSG because it assesses disturbance on a finer scale than would be possible  
8 using GRSG PACs.

9 The anthropogenic disturbance cap excludes habitat disturbance from wildfire because  
10 wildfire is already factored into the soft and hard habitat triggers. In Idaho, disturbance is  
11 measured by direct footprint or by ROW/SUA width, while in Montana disturbance is  
12 measured using the Disturbance Density Calculation Tool (**Appendix G**). The management  
13 area map and BSU baseline map would be re-evaluated every five years. In PHMA, the  
14 Anthropogenic Disturbance Exception Criteria would apply stringent criteria to any  
15 potential exceptions to the disturbance cap. These criteria would apply in addition to the  
16 Anthropogenic Disturbance Development Criteria that apply in IHMA. No disturbance cap  
17 would apply in GHMA or GRSG brood-rearing habitat and migration corridors. BSUs  
18 include only nesting and wintering habitat.

19 The impact of the disturbance cap would differ by Conservation Area. In some areas,  
20 projected disturbance would not approach the cap, and would avoid impacts to GRSG  
21 habitat using buffers (**Appendix B**), co-location of disturbance, other management under  
22 the Proposed Plan. The implementation of the anthropogenic disturbance cap represents an  
23 additional regulatory safeguard to maintain GRSG populations and habitat within BSUs. The  
24 mitigation requirements under the Proposed Plan would further reduce harm to GRSG from  
25 development. Adherence to GRSG habitat objectives (**Tables 2-3** and **2-6**) in mitigation and  
26 monitoring would ensure that restoration efforts improve nesting and wintering habitat for  
27 GRSG.

28 Coordination among agencies under the Proposed Plan will allow for effective, integrated  
29 management of GRSG to achieve desired habitat and population conditions and to  
30 maximize available funding. Coordination will occur among federal agencies, between  
31 federal agencies and the States of Idaho and Montana, and between agencies and tribes,  
32 private landowners and communities to develop consistent approaches for monitoring and  
33 facilitate effective GRSG conservation.

#### 34 **4.3 Vegetation**

##### 35 **4.3.1 Methods and Assumptions**

###### 36 ***Indicators***

37 Indicators of impacts on vegetation are as follows:

###### 38 *Upland, Riparian and Wetland Vegetation*

- 39 • Acres and condition of vegetation communities

- Extent of sagebrush fragmentation

*Noxious Weeds and Invasive Species*

- Change (increase, decrease, or no change) in the likelihood for noxious weed or invasive species introduction or spread
- Change (increase, decrease, or no change) in the estimated acres of conifer encroachment

**Assumptions**

The analysis includes the following assumptions:

- All plant communities would be managed to achieve a mix of species composition, cover, and age classes across the landscape, except in site-specific situations where nonnative plantings are used for livestock grazing in order to provide rest or deferment to native vegetation.
- The degree of impact attributed to any one disturbance or series of disturbances would be influenced by several factors. These are location in the watershed; the type, time, and degree of disturbance; existing vegetation; precipitation; and mitigating actions applied to the disturbance.
- Noxious and invasive weeds would continue to be introduced and spread as a result of ongoing vehicle traffic in and out of the planning area, recreation, wildfire, wildlife and livestock grazing and movements, and surface-disturbing activities.
- Activities that would disturb soils could cause wind and/or water erosion, topsoil loss, and soil compaction, which could affect the ability of vegetation to regenerate. Resulting impacts could include lowered plant vigor and growth rate, altered or disrupted pollination, and increased susceptibility to disease. Impacts may vary depending on the sensitivity of certain species, functional group and vegetation community.
- Ecological health and ecosystem functioning depend on vegetative cover, species diversity, nutrient cycling and availability, water infiltration and availability, and percent cover of weeds.
- Climate fluctuation would continue to influence the health and productivity of plant communities annually.

Short-term effects would occur over two years or less, and long-term effects would occur over longer than two years.

1                   **4.3.2 Nature and Type of Effects**

2                   GRSG rely on sagebrush ecosystems for all aspects of their life cycle. Typically, a range of  
3                   sagebrush community composition within the landscape, including variations in subspecies  
4                   composition, codominant vegetation, shrub cover, herbaceous cover, stand age, are needed  
5                   to meet seasonal and interseasonal requirements for food, cover, nesting, and wintering  
6                   habitats. The landscape required for GRSG may be up to 40 square miles. Thus, conserving  
7                   and managing GRSG is as much about the ecology, management, and conservation of large,  
8                   intact sagebrush ecosystems as it is about the dynamics and behaviors of the populations  
9                   themselves (Manier et al. 2013, p. 7).

10                  Historically, sagebrush-dominated vegetation was one of the most widespread habitats in the  
11                  country, but its expanse has been fragmented, lost, or altered by invasive plants and human  
12                  disturbance (NTT 2011, p.4). Protection of GRSG habitat would involve restrictions and  
13                  limitations on activities that contribute to the spread of invasive species, fire, and other  
14                  surface disturbance. It also would involve management of vegetation to promote healthy  
15                  sagebrush and understory vegetation to support GRSG.

16                  ***Vegetation Management and Habitat Protection***

17                  In addition to landscapes with large, intact patches of sagebrush, GRSG require high-quality  
18                  habitat conditions. These conditions are a diversity of herbaceous species, vegetative and  
19                  reproductive health of native grasses, and an abundance of sagebrush. These requirements  
20                  make management for high condition in seasonally important habitats essential (Manier et al.  
21                  2013, pp. 181-182). Management plans that protect intact sagebrush and restore impacted  
22                  areas strategically to enhance existing habitats (for example, connectivity of intact sagebrush)  
23                  have the best chance of increasing the amount and quality of sagebrush cover (Manier et al.  
24                  2013, p.183). This is because of the limited distribution of suitable sagebrush habitats and  
25                  the cost of habitat restoration. Sagebrush-promoting vegetation treatments will enhance  
26                  native vegetation and overall ecosystem productivity, while reducing the distribution of  
27                  invasive species and some woody species.

28                  Invasive plants can alter plant community structure and composition, productivity, nutrient  
29                  cycling, and hydrology. They could competitively exclude native plant populations. In  
30                  particular, invasive plants can reduce and eliminate vegetation that GRSG use for food and  
31                  cover, resulting in habitat loss and when infestations occur on large scales may result in  
32                  fragmentation. They also could increase the risk of wildfire caused by the spread of invasive  
33                  plants such as cheatgrass (*Bromus tectorum*), which has increased the frequency and intensity of  
34                  fires (Balch et al. 2012). An assortment of nonnative annuals and perennials and native  
35                  conifers are currently invading sagebrush ecosystems.

36                  Expansion of conifer woodlands, especially juniper (*Juniperus* spp.) present a threat to GRSG  
37                  because they do not provide suitable habitat; mature trees can displace shrubs, grasses, and  
38                  forbs through direct competition for resources. Juniper expansion is also associated with  
39                  increased bare ground and increased potential for erosion. Mature trees may offer perch and  
40                  nest sites for raptors; thus, woodland expansion may also represent expansion of predation  
41                  threat, similar to perches on power lines and other structures (Manier et al. 2013, pp. 152-  
42                  154).

1 To reduce juniper expansion, current vegetation treatments and active vegetation  
2 management typically focus on manipulation of vegetation composition and/or structure.  
3 These techniques are used to improve fuels management, fire suppression, and habitat  
4 management, by removing invasive plants or using surface soil stabilization to increase  
5 productivity. Conifer removal treatments are more likely to succeed if perennial grasses and  
6 forbs are a component of the pre-treatment understory (Miller et al. 2007, p. 32). Locally and  
7 regionally, the distribution of these treatments can affect the distribution of GRSG and  
8 sagebrush habitats (Manier et al. 2013, pp. 179-185). Vegetation treatments would have  
9 short-term effects on vegetation from vegetation removal and disturbance but would result  
10 in long-term improvements in habitat condition by reducing invasive species and  
11 fragmentation and increasing diversity and productivity

12 Management of vegetation resources to protect GRSG would alter vegetation communities  
13 by promoting diversity, healthy reproductive native grasses and sagebrush productivity and  
14 vigor. Treatments designed to prevent encroachment of nonnative species or conifers would  
15 alter the condition of native vegetation communities. They would do this by changing the  
16 species richness, composition, and frequency of species within plant communities. Habitat  
17 connectivity for GRSG could also be increased through vegetation manipulation designed to  
18 restore vegetation, particularly sagebrush overstory cover.

19 Vegetation manipulation in the riparian zone, such as weed treatments and native plantings,  
20 would improve the condition of the riparian vegetation community. It also would improve  
21 or maintain plant vigor and hydrologic function.

22 Protection of sagebrush habitat through restrictions on uses, such as closure to mineral  
23 development or OHV use, or exclusion of ROWs, would support GRSG. Such use  
24 restrictions would reduce damage to native vegetation communities and individual native  
25 plant species. Likewise, use restrictions would minimize habitat fragmentation and would be  
26 more likely to retain contiguous sagebrush habitat, naturally developed sagebrush growth  
27 form, existing age class distribution, and sagebrush recruitment within these areas. Use  
28 restrictions could also minimize the spread of invasive species by limiting human activities  
29 that cause soil disturbance or seed introductions. Specific impacts from restrictions on  
30 certain uses, such as minerals, lands and realty, and grazing, are described in more detail  
31 under their respective headers below.

### 32 **Wildland Fire**

33 Wildfires likely played an important role historically in creating a mosaic of areas dominated  
34 by herbaceous species (recently disturbed) and mature sagebrush (less-frequently disturbed).  
35 Nevertheless, current and past land use patterns have restricted the system's ability to  
36 support natural wildfire regimes. Slow rates of regrowth and recovery of vegetation,  
37 particularly sagebrush, after wildfire, as well as high rates of anthropogenic disturbance, and  
38 conversion to invasive annual grasses, are largely responsible for the accumulating  
39 displacement and degradation of the sagebrush ecosystem (Manier et al. 2013, pp. 133-144).

40 Fire can be particularly damaging to sagebrush ecosystems. Big sagebrush does not resprout  
41 after a fire but is replenished by wind-dispersed seed from adjacent unburned stands or seeds

1 in the soil. Depending on the species and the size of a burn, sagebrush can reestablish itself  
2 within five years of a burn, but a return to a full pre-burn community cover can take 15 to 30  
3 years or longer (Manier et al. 2013, pp. 133-134). ES&R (for BLM-administered lands) and  
4 BAER (for National Forest System lands) would reduce the potential effects of invasive  
5 species by providing the best opportunities for vegetation to reestablish following wildland  
6 fires and compete with the natural strengths invasive species have compared to native  
7 species. Re-seeding with native plants and long-term monitoring to ensure the production of  
8 GRSG cover and forage plants assists with vegetation recovery (NTT 2011, pp. 25-26).

9 Fire suppression may be used to maintain habitat for GRSG (NTT 2011, pp. 25-26). When  
10 management reduces wildland fire frequency the indirect impact is that vegetation ages  
11 across the landscape, and early successional vegetation communities are diminished. Fire  
12 suppression may preserve the condition of some vegetation communities, as well as habitat  
13 connectivity. This is particularly important in areas where fire frequency has increased as a  
14 result of invasive annual grass invasion and where landscapes are highly fragmented. Fire  
15 suppression can also lead to increased fuel loads, which can lead to more severe or larger  
16 fires in the long term. Fire also increases opportunities for invasive species, such as  
17 cheatgrass, to expand (Brooks et al. 2004); fire suppression can indirectly limit this  
18 expansion.

19 Controlled burning may be prescribed to treat fuel buildup, remove invasive annuals, and  
20 can assist in the recovery of sagebrush habitat in some vegetation types, such as in juniper  
21 woodlands and conifer-encroached mountain sagebrush communities (NTT 2011, pp. 25-26;  
22 Manier et al. 2013, p. 71). Prescribed fire may be an important management option in these  
23 areas, increasing spatial heterogeneity and reducing tree cover and fuel continuity (Manier et  
24 al. 2013, p. 71).

### 25 ***Lands and Realty***

26 Permitted activities, such as construction of utility ROWs or SUAs, involve vegetation  
27 removal. This reduces the condition of native vegetation communities and individual native  
28 plant species, alters age class distribution, increases fragmentation, and encourages the  
29 spread of invasive species. Construction could compact soils, which would inhibit natural  
30 revegetation by hindering root growth in areas without reclamation. It also would reduce  
31 plant vigor, making plants more susceptible to disease, drought, and insect attack. In most  
32 cases soils in reclaimed areas would be ripped and seeded during interim or final reclamation  
33 (NTT 2011, pp. 12-13).

34 Different types of ROWs or SUAs would impact vegetation in different ways. Aboveground  
35 linear and underground ROWs or SUAs, such as transmission lines or pipelines, would  
36 temporarily remove vegetation during construction, but areas would be reclaimed or restored  
37 after construction. Vegetation would be permanently removed for construction of surface  
38 linear ROWs or SUAs, such as roads. Furthermore, since aboveground and surface linear  
39 ROWs or SUAs may extend for many miles, vegetation communities could be fragmented  
40 and encourage the spread of invasive species. Aboveground ROWs or SUAs and wind  
41 energy projects would remove vegetation during the life of the project, often lasting several  
42 decades, but areas would be restored after the ROW or SUA is decommissioned.

1 ROW or SUA exclusion areas would prohibit all development of ROWs or SUAs.  
2 Prohibiting ROWs or SUAs in exclusion areas would directly protect vegetation from  
3 disturbance and removal. In ROW or SUA avoidance areas, the BLM and Forest Service  
4 would consider on a case-by-case basis whether a ROW or SUA should be allowed. This  
5 flexibility may be advantageous where federal and private landownership areas are mixed and  
6 exclusion areas may result in more widespread development on private lands.

7 Acquisitions, disposals, or land exchanges to reduce the fragmentation of GRSG habitat  
8 could improve the BLM and Forest Service's ability to implement management to increase  
9 vegetation diversity, ecological health, and land health standards. In addition, retention of  
10 federal lands would prevent sagebrush removal associated with land conversion to  
11 agricultural or urban uses.

### 12 ***Mineral Resources***

13 While not a large threat in the Idaho and Southwestern Montana Sub-region, mineral  
14 development requires construction of roads, well pads, wells and other infrastructure which  
15 result in the removal of vegetation (Manier et al. 2013, pp. 90-104). Surface disturbance  
16 associated with mineral development often removes vegetation, reduces the condition of  
17 native vegetation communities, increases fragmentation, and encourages the spread of  
18 invasive species, particularly if pre-disturbance vegetation is composed of deep-rooted  
19 perennial bunchgrasses and/or biological soil crusts (NTT 2011, pp. 19-20; Reisner et al.  
20 2013, p. 1047; Deines et al. 2007, p. 31). Vegetation is typically removed for a period of time  
21 during the course of mining. When mining is completed, the areas are reclaimed using seed  
22 mixes chosen by the BLM or Forest Service. The remaining vegetation could have reduced  
23 vigor or productivity due to mechanical damage, soil compaction, and dust. Impacts would  
24 not occur in areas closed to mineral leasing or development.

### 25 ***Recreation***

26 Recreation in GRSG habitat can be benign, but casual use at excessive levels may degrade  
27 sagebrush vegetation from such activities as camping, hiking, bird watching, bicycling, OHV  
28 riding, hunting, and rock climbing site access. Potential impacts from casual recreation  
29 include trampling, soil compaction, erosion, invasive plant spread, and fugitive dust  
30 generation (Knick et al. 2011). Recreation can also increase the potential for wildfire caused  
31 by invasive plant spread or human error (Knick et al. 2011). Most impacts occur in easily  
32 accessible areas and in areas open to cross-country travel, particularly motorized use.  
33 Restrictions on recreation in GRSG habitat would limit damage to the vegetation  
34 communities that comprise this habitat by directly reducing vegetation disturbance from  
35 trampling, motorized vehicles, dust, and spread of invasive species. Such restrictions could  
36 involve seasonal area closures or limitations on the number of users or types of uses  
37 permitted, particularly OHV use (NTT 2011, p. 12).

38 There would likely be negligible impacts on vegetation from management associated with  
39 recreation under all alternatives.

1       ***Travel and Transportation***

2       Road and trail construction divides and fragments vegetation and causes erosion and  
3       nutrient leaching. The use of roads creates soil compaction and allows the spread of human  
4       disturbance, including wildfire and invasive plant species (USFWS 2010a, pp. 19-21; Manier  
5       et al. 2013, pp. 71-90). Invasive species can outcompete sagebrush and other vegetation  
6       essential for GRSG survival. Invasives also increase wildfire frequency, further contributing  
7       to loss of habitat (Balch et al. 2012).

8       The more areas that are seasonally or permanently closed to off-road motorized vehicle use,  
9       the fewer impacts on vegetation from surface disturbance. In areas open to OHV use,  
10       vehicle and human trampling of vegetation, soil compaction, and spread of dust and weeds  
11       would be expected. Impacts would be reduced, but not eliminated, in areas limited to  
12       existing routes.

13       ***Livestock Grazing***

14       Livestock grazing is the most widespread land use across the sagebrush landscape (Connelly  
15       et al. 2004, pp. 7-29). Livestock grazing can affect soils, vegetation health, species  
16       composition, and water and nutrient availability by consuming vegetation, redistributing  
17       nutrients and seeds, trampling soils and vegetation, and disrupting microbial systems  
18       (Connelly et al. 2004 Ch. 7; NTT 2011, p. 14).

19       Livestock grazing has been described as a diffuse form of disturbance that exerts repeated  
20       pressure over many years on a system; unlike point sources of disturbance (e.g., fires). Thus,  
21       effects of grazing are not likely to be detected as disruptions but as differences in the  
22       processes and functioning of the sagebrush, riparian, and wetland systems.

23       Grazing effects are not distributed evenly because historic practices, management plans and  
24       agreements, and animal behavior all lead to differential use of the range (Manier et al. 2013,  
25       pp. 157-168). Livestock often use riparian and wetland areas for water and shade, which  
26       could reduce riparian community condition and hydrologic function.

27       Water developments, roads, and structural range improvements associated with livestock  
28       grazing would remove vegetation over the long term and could introduce weeds to  
29       rangelands. Livestock would congregate around water developments, compacting soil and  
30       trampling nearby vegetation, and making reestablishment of native vegetation difficult in the  
31       surrounding area. However, water developments would divert livestock use away from  
32       riparian and wetland areas and thus reduce such impacts in these areas.

33       At unsustainable levels, grazing can lead to loss of vegetation cover, reduced water  
34       infiltration rates and nutrient recycling, decreased plant litter and water quality, and increased  
35       bare ground and soil erosion (Manier et al. 2013, pp. 157-159). Depending on the level of  
36       utilization and timeframe, livestock grazing can reduce resistance to invasive annual grasses  
37       by decreasing bunchgrass abundance, shifting bunchgrass composition, and reducing  
38       biological soil crusts (Reisner et al. 2013, p. 1044). Land health evaluations are used to assess  
39       rangeland condition and help to identify where changing grazing management would be  
40       beneficial. Grazing may also affect the extent and behavior of fires in sagebrush-dominated

1 ecosystems, both on annual and decadal scales. Over annual timeframes, grazing can reduce  
2 the amount of herbaceous fine fuels, including cheatgrass, forbs, and small twigs of woody  
3 plants. Grazing can reduce fire spread and intensity by removing understory vegetation,  
4 reducing the amount of fuel, and accelerating the decay of litter through trampling. Over  
5 decadal timeframes, livestock grazing can change the relative proportions of shrubs,  
6 perennial grasses, and annual grasses, altering the fuel composition (Strand et al. 2014, p. 50).

7 Management of grazing systems that aim to protect sagebrush and riparian ecosystems  
8 would enhance vegetation by allowing more plant growth, increase plant vigor, reduce  
9 trampling and introduction of exotic and undesirable species. Conversely, livestock grazing  
10 concentrated in certain areas would increase surface-disturbing impacts in those areas.

11 The Forest Service will incorporate grazing guidelines (**Table 2-6**) into term grazing permits  
12 that will likely improve vegetation structures in GRSG seasonal habitat on grazing  
13 allotments.

#### 14 ***Special Designations***

15 Special designations (e.g., ACECs, Wilderness, and WSAs) and other conservation measures  
16 may be established to protect vegetation in GRSG habitat as a relevant or important value.  
17 While existing ACECs, Wilderness, WSAs and other special designations do not have GRSG  
18 habitat as a relevant or important value, some incidental protection may be conferred to  
19 vegetation in existing ACECs by restricting resource uses intended to protect other values.

#### 20 **4.3.3 Impacts on Vegetation Common to All Alternatives**

21 The nature and type of impacts described below are common to all alternatives, but the  
22 context and intensity may vary by alternative.

23 Under all alternatives, the Integrated Vegetation Management Handbook policies would be  
24 followed and would provide guidance on which treatments and chemicals can be used.  
25 Applying these policies would improve vegetation management in sagebrush habitat, thereby  
26 likely improving vegetation conditions in these areas.

27 In general, impacts from recreation are similar among all alternatives, as dispersed casual  
28 recreation would continue throughout the planning area.

29 There would be no impacts common to all alternatives from lands and realty management,  
30 habitat restoration and vegetation management, wildland fire management, mineral resource  
31 management, livestock grazing management, or ACEC management.

#### 32 **4.3.4 Alternative A**

33 While GRSG may be protected under existing provisions of some LUPs, in general,  
34 Alternative A relies on management guidance that does not reflect the most up-to-date  
35 science regarding GRSG. Some of the older land use plans lack a landscape-level approach  
36 to land planning.

1 There is no consistently applied vegetation management across all land use plans, though  
2 Idaho and Montana Standards for Rangeland Health incorporate objectives for maintaining,  
3 improving, or restoring vegetation communities, particularly sagebrush and riparian and  
4 wetland habitats. As a result, there is general direction to preserve and improve vegetation  
5 communities; however, discrete human disturbances, such as road construction and mineral  
6 and ROW development, would continue. This could result in a number of impacts on  
7 vegetation, as described under **Section 4.3.2**.

#### 8 ***Impacts from Lands and Realty Management***

9 Under Alternative A, lands and realty management would continue, with some areas  
10 identified as ROW avoidance and ROW exclusion (**Table 4-54**, Acres of Sagebrush  
11 Vegetation within ROW Avoidance Areas in the Idaho and Southwest Montana Sub-Region,  
12 and **Table 4-55**, Acres of Sagebrush Vegetation within ROW Exclusion Areas in the Idaho  
13 and Southwest Montana Sub-Region). Impacts on areas chosen for ROWs are similar to  
14 those described under Section 4.3.2 and would include loss and degradation of upland  
15 vegetation communities, and the potential for increased spread of noxious weeds.

#### 16 ***Impacts from Habitat Restoration and Vegetation Management***

17 Under Alternative A, the BLM and Forest Service would continue to incorporate habitat  
18 restoration and vegetation objectives in management actions as described in the existing  
19 LUPs. This may improve vegetation conditions and increase the amount of native vegetation  
20 in areas, depending on the application of existing LUPs across the sub-region. In particular,  
21 the BLM and Forest Service would manage for the benefit of vegetation that provides  
22 wildlife forage, forbs, and sagebrush. Native species would be used when possible, but not  
23 required, allowing for some introduced species in areas where they are necessary for site  
24 stabilization. This approach would provide for habitat restoration, reduce noxious weeds,  
25 and improve the condition of vegetation communities to the extent possible under existing  
26 resource allocations.

#### 27 ***Impacts from Wildland Fire Management***

28 Under Alternative A, projects would be designed to minimize the size of wildfires and to  
29 prevent the further loss of sagebrush. In addition, prescribed burning may be used in  
30 support of resource management objectives, such as restoring grassland or shrubland,  
31 reducing conifer encroachment, or increasing age-class variety. As a result, vegetation  
32 condition and desired species composition would be improved in certain areas. Further,  
33 chemical weed treatments applied following prescribed burns would limit the expansion of  
34 weeds or invasive species in the burned area and would facilitate revegetation of native  
35 species. Impacts from fire on vegetation, described under **Section 4.3.2**, would continue  
36 under Alternative A.

Administrative  
Cooperating Agency

1       ***Impacts from Nonenergy Leasable Minerals Management***

2       Acres of sagebrush closed to nonenergy leasable mineral leasing under Alternative A are  
3       shown in **Table 4-56**, Acres of Sagebrush Vegetation Closed to Non-energy Leasable  
4       Mineral Leasing in the Idaho and Southwest Montana Sub-Region1. Impacts from  
5       nonenergy leasable development on vegetation, including loss and degradation of upland  
6       vegetation and increased potential for invasive plant spread, as described under **Section**  
7       **4.3.2**, would continue to occur in areas open to leasing and development.

8       ***Impacts from Locatable Minerals Management***

9       Impacts from locatable mineral development on vegetation, as described under **Section**  
10       **4.3.2**, would continue to occur in areas open to development.

11       ***Impacts from Salable Minerals Management***

12       Acres of sagebrush closed to mineral material disposal under Alternative A are shown in  
13       **Table 4-56**, Acres of Sagebrush Vegetation Closed to Mineral Materials Disposal in the  
14       Idaho and Southwestern Montana Sub-region1. Acres are not available for National Forest  
15       System lands. Impacts from salable mineral development on vegetation, as described under  
16       **Section 4.3.2**, would continue to occur in areas open to development.

17       ***Impacts from Fluid Minerals Management***

18       Acres of sagebrush closed to fluid mineral leasing under Alternative A are shown in **Table**  
19       **4-5**Table 4-578, Acres of Sagebrush Vegetation Closed to Fluid Mineral Leasing in the Idaho  
20       and Southwestern Montana Sub-region. Seasonal timing restrictions and lek buffers may be  
21       applied in certain areas, as described in the existing LUPs, to reduce impacts from mineral  
22       leasing or development, but these stipulations would not be applied consistently across the  
23       planning area. Impacts from fluid mineral development on vegetation, as described under  
24       **Section 4.3.2**, may occur in areas open to leasing and development.

25       ***Impacts from Travel and Transportation Management***

26       Impacts from OHV use would continue under Alternative A in areas that would be open to  
27       cross-country use and would be reduced in areas limited to existing roads (**Table 4-59**, Acres  
28       of Sagebrush Vegetation Limited to Existing Roads in the Idaho and Southwest Montana  
29       Sub-Region). Route and trail modifications would be considered on a case-by-case basis.  
30       Impacts on vegetation from travel would continue, including damage to upland vegetation,  
31       fragmentation, and potential for spread of invasive plants, as described under **Section 4.3.2**.

32       ***Impacts from Livestock Grazing Management***

33       Livestock grazing would continue to occur under Alternative A, with no change in acres  
34       open or closed to grazing (**Table 4-60**, Acres of Sagebrush Vegetation Closed to Livestock  
35       Grazing in the Idaho and Southwestern Montana Sub-region). Rangelands would continue  
36       to be managed to conform to the Idaho Standards for Rangeland Health or similar  
37       guidelines; thus, vegetation communities would continue to be maintained and improved to  
38       some extent across the planning area. Changes and adjustments would be considered on a  
39       case-by-case basis and would incorporate grazing standards and guides to evaluate the ability

Administrative Draft  
Cooperating Agency Review

1 to meet desired conditions. Under current LUPs, riparian and wetland areas would be  
2 managed to maintain or attain PFC or forest plan standards and guidelines, and rangelands  
3 would be managed to attain Rangeland Health Standards. These standards would benefit  
4 vegetation condition and limit fragmentation.

### 5 ***Impacts from Special Designations Management***

6 Under Alternative A, the BLM would continue to manage 59 ACECs within the sub-region  
7 (**Table 4-61**, Acres of Sagebrush Vegetation within BLM ACECs and Forest Service  
8 Zoological Areas in the Idaho and Southwestern Montana Sub-region1). The Forest Service  
9 would not manage any ZAs under Alternative A. Existing ACECs likely protect vegetation  
10 through use restrictions; these impacts are analyzed under each existing RMP within the  
11 planning area. As a result, there would be no additional effects from ACEC or ZA  
12 management on vegetation under this alternative.

### 13 **4.3.5 Alternative B**

14 Under Alternative B, the BLM and Forest Service would manage lands to conserve, enhance,  
15 and restore sagebrush ecosystems. Direct protection of sagebrush habitat to support GRSG  
16 would limit or modify uses in this habitat type, improving the acreage and condition of  
17 desired vegetation communities. Restrictions on resource uses such as ROW and mineral  
18 development would reduce damage to native vegetation communities and individual native  
19 plant species in areas that are important for regional vegetation diversity and quality.  
20 Likewise, use restrictions would minimize loss of connectivity and would be more likely to  
21 retain existing age class distribution within these areas. Use restrictions could also minimize  
22 the spread of invasive species by limiting human activities that disturb soil or introduce  
23 seeds.

24 PHMA and GHMA would be designated (**Table 4-14**). Acres of each vegetation community  
25 within GRSG management areas are presented in **Table 4-62**, Acres of Annual Grassland  
26 within GRSG Analysis Areas in the Idaho and Southwestern Montana Sub-region through  
27 **Table 4-67**, Acres of Perennial Grassland within GRSG Analysis Areas in the Idaho and  
28 Southwestern Montana Sub-region, and are split out by GRSG analysis area. These tables  
29 demonstrate the differences in the size of GRSG management areas by alternative and the  
30 relative differences in the acreage of each vegetation community within these areas. The  
31 BLM and Forest Service would apply a maximum three percent disturbance cap to human  
32 activities in PHMA. The three percent disturbance cap was recommended in the NTT report  
33 and is designed to minimize impacts on GRSG habitat by limiting disturbances in sensitive  
34 habitat areas. The agencies would implement numerous conservation measures, as described  
35 under the resource headings below, to reduce impacts from human activities in PHMA.  
36 Restricting surface-disturbing activities would reduce the likelihood for vegetation removal,  
37 degradation, or fragmentation and would maintain the acreage and condition of sagebrush  
38 vegetation.

Administrative Draft  
Cooperating Agency Review

1       ***Impacts from Lands and Realty Management***

2       Identifying GHMA as ROW avoidance and PHMA as ROW exclusion areas would reduce  
3       impacts on vegetation, as described under **Section 4.3.2**. In addition, the BLM and Forest  
4       Service would restore ROWs that are no longer in use. This would increase the extent and  
5       connectivity of sagebrush habitats and reduce the spread of weeds to these areas over the  
6       long term. Lands would be retained in federal ownership, with limited exceptions, which  
7       would reduce fragmentation, as described under **Section 4.3.2**.

8       ***Impacts from Habitat Restoration and Vegetation Management***

9       Under Alternative B, habitat restoration and vegetation management actions would improve  
10       GRSG habitat. It would do this by restricting activities that degrade sagebrush communities,  
11       while promoting and prioritizing those activities that improve sagebrush communities and  
12       prioritizing restoration to benefit GRSG habitat. The BLM and Forest Service would require  
13       the use of native seeds as a component and would design post-restoration management to  
14       ensure the long-term persistence of restoration. In addition, the BLM and Forest Service  
15       would consider climate change when determining species for restoration. Together, these  
16       management actions would alter vegetative communities by increasing sagebrush height,  
17       herbaceous cover, and vegetation productivity.

18       Treatments designed to prevent encroachment of trees and nonnative species would alter the  
19       condition of native vegetation communities by changing the density, composition, and  
20       frequency of species within plant communities. Habitat connectivity for GRSG could be  
21       increased over the planning timeframe through vegetation manipulation designed to restore  
22       vegetation, particularly sagebrush overstory cover.

23       Vegetation manipulations in riparian areas, such as weed treatments, native plantings, and  
24       erosion control in the channel, would improve the acreage and condition of the riparian  
25       vegetation community, individual riparian species, and hydrologic functionality. The result of  
26       this would be to attain PEC or forest plan standards and guidelines.

27       ***Impacts from Wildland Fire Management***

28       Fuels treatments under Alternative B would be designed to protect sagebrush ecosystems by  
29       maintaining sagebrush cover, applying seasonal restrictions and protections for winter range,  
30       and requiring use of native seeds as a component of restoration. Post-fuels treatments, ESR,  
31       and BAER management would be designed to ensure long-term persistence of seeded areas  
32       and native plant restoration areas. While the risk of wildfire in sagebrush areas would  
33       continue, these management actions would help to restore sagebrush vegetation and prevent  
34       degradation or destruction of sagebrush from wildfire. Furthermore, emphasizing the use of  
35       native seeds and noninvasive species would reduce the likelihood for weed invasion in  
36       burned or treated areas.

37       The BLM and Forest Service would also prioritize suppression in PHMA, which would  
38       retain the existing conditions and trends of vegetation in these areas. Impacts from fuels  
39       treatments, ESR/BAER, and suppression are similar to those described under **Section 4.3.2**.

1       ***Impacts from Nonenergy Leasable Minerals Management***

2       Under Alternative B, PHMA would be closed to future nonenergy leasable mineral leasing  
3       (**Table 4-56**) and RDFs would be required on existing leases. This would prevent removal,  
4       fragmentation, and other impacts on vegetation associated with nonenergy leasable mineral  
5       development in unleased areas and would reduce impacts in leased areas.

6       ***Impacts from Locatable Minerals Management***

7       In addition to withdrawing acres from locatable mineral entry, the BLM and Forest Service  
8       would make applicable BMPs (see **Appendix B**) required design features on 3809 plans and  
9       Plans of Operation in PHMA. These actions would reduce the likelihood that vegetation  
10      would be removed, degraded, or fragmented in these areas and would reduce the likelihood  
11      that weeds could be introduced or spread as a result of locatable mineral development.

12      ***Impacts from Salable Minerals Management***

13      In addition to closing PHMA to mineral material sales, the BLM and Forest Service would  
14      restore salable mineral pits no longer in use. Over the long term, closures would protect  
15      existing vegetation from removal, degradation, fragmentation, and nonnative invasive species  
16      introduction or spread. Restoration would increase the extent of vegetation and depending  
17      on the location could remove nonnative invasive species and reduce fragmentation.

18      ***Impacts from Fluid Minerals Management***

19      In addition to acres closed to fluid mineral leasing (**Table 4-57**), the BLM and Forest Service  
20      would require numerous conservation measures in PHMA. Impacts are similar to those  
21      described for Locatable Minerals Management, above. Over the long term, closures and  
22      NSO stipulations would protect vegetation from removal, degradation, fragmentation, and  
23      nonnative invasive species introduction or spread in unleased areas. Conservation measures  
24      would help to reduce such impacts in leased areas. Restoration would improve the condition  
25      and increase the extent of vegetation and depending on the location could remove nonnative  
26      invasive species and reduce fragmentation. Geophysical exploration could disturb vegetation  
27      or spread weeds, but it would be unlikely to remove substantial amounts of vegetation.

28      ***Impacts from Travel and Transportation Management***

29      Under Alternative B, motorized travel would be limited to existing roads, primitive roads,  
30      and trails within PHMA (**Table 4-59**). Management actions would also reduce new route  
31      construction and restore roads, primitive roads, and trails not designated under future travel  
32      management plans. These actions would reduce the likelihood of impacts caused by roads, as  
33      described under **Section 4.3.2**, and would increase the acreage and connectivity of sagebrush  
34      vegetation.

35      ***Impacts from Livestock Grazing Management***

36      Under Alternative B, the BLM and Forest Service would not change permitted AUMs  
37      compared to Alternative A (**Table 4-60**). However, the BLM and Forest Service would  
38      implement a number of management actions in PHMA, including prioritizing land health  
39      assessments or similar grazing evaluations in GRSG habitat, to incorporate GRSG habitat  
40      objectives and management considerations into livestock grazing management and to  
41      improve the condition of vegetation in GRSG habitat areas. These actions include

1 completing land health assessments or similar grazing evaluations, taking into consideration  
2 grazing methods and systems to reduce impacts on GRSG habitat, improving management  
3 of riparian areas and wet meadows, and evaluating existing introduced perennial grass  
4 seedings, water developments, and structural range improvements. Such measures would  
5 help to improve vegetation condition of rangeland and riparian and wetland areas. They also  
6 could reduce the likelihood of nonnative invasive species introduction or spread. Together,  
7 these efforts would improve consistency of management across the sub-region and would  
8 reduce impacts from grazing on vegetation, described in **Section 4.3.2**.

9 ***Impacts from Special Designations Management***

10 Impacts from ACEC management under Alternative B are the same as those described for  
11 Alternative A (**Table 4-61**).

12 **4.3.6 Alternative C**

13 Under Alternative C, the BLM and Forest Service would manage lands to conserve, enhance,  
14 and restore sagebrush ecosystems. Management actions would be applied to all occupied  
15 GRSG habitats (**Table 4-14**). Management would focus on removing livestock grazing from  
16 occupied habitats, with most other management similar that to Alternative A. A three  
17 percent disturbance cap would be the same as under Alternative B but would be applied to  
18 all occupied habitat.

19 ***Impacts from Lands and Realty Management***

20 Lands and realty management under Alternative C would be similar to that described for  
21 Alternative B, but ROW exclusion areas would be designated in all occupied habitats and  
22 ACECs (**Table 4-55**). In addition, all occupied habitat, ACECs, and restoration areas would  
23 be retained in federal ownership. These actions would protect vegetation from removal,  
24 degradation, and fragmentation in protected areas. Impacts from ROW exclusion areas and  
25 retention of federal lands would be as described under **Section 4.3.2**.

26 ***Impacts from Habitat Restoration and Vegetation Management***

27 Management under Alternative C would be similar to that described under Alternative A,  
28 though with an increased focus on restoration. Impacts are similar to those described for  
29 Alternative A, though impacts may be reduced in areas where vegetation is restored to the  
30 reference state of the appropriate ecological site description.

31 ***Impacts from Wildland Fire Management***

32 Impacts from wildland fire management under Alternative C are similar to those described  
33 for Alternative A.

34 ***Impacts from Nonenergy Leasable Minerals Management***

35 Impacts from nonenergy leasable minerals management under Alternative C are the same as  
36 those described under Alternative B, but would include more acres in PHMA (**Table 4-56**).  
37 These management changes would prevent impacts on vegetation associated with nonenergy  
38 leasable mineral development in unleased areas, described in **Section 4.3.2**, and reduce  
39 impacts in leased areas.

1       ***Impacts from Locatable Minerals Management***

2       Impacts from locatable minerals management under Alternative C are the same as those  
3       described under Alternative A.

4       ***Impacts from Salable Minerals Management***

5       Impacts from salable minerals management under Alternative C are the same as those  
6       described under Alternative A (**Table 4-56**).

7       ***Impacts from Fluid Minerals Management***

8       Impacts from fluid minerals management under Alternative C are similar to those described  
9       for Alternative B, although all occupied habitat would be closed to leasing (**Table 4-57**).

10       ***Impacts from Travel and Transportation Management***

11       Impacts from travel and transportation management under Alternative C are the same as  
12       those described under Alternative A (**Table 4-59**).

13       ***Impacts from Livestock Grazing Management***

14       Under Alternative C, livestock grazing would be removed from all occupied GRSG habitats  
15       (**Table 4-60**). The effects of livestock exclusion would depend on climate, soils, fire history,  
16       and disturbance and grazing history (Strand and Launchbaugh 2013, p. 10). While studies  
17       have examined the effects of reducing or changing livestock grazing, limited literature is  
18       available on the effects of completely removing livestock grazing. Grazing is associated with  
19       direct and indirect impacts on vegetation, as described under **Section 4.3.2**. Grazing may  
20       reduce resistance to invasion from cheatgrass (Reisner et al. 2013, p. 9), reduce water  
21       infiltration, increase soil compaction and erosion, and decrease water quality (Braun 1998  
22       and Dobkin et al. 1998 in USFWS 2010, p. 13939).

23       Ceasing grazing could relieve these impacts and allow for recovery of native understory  
24       perennials and an increase in sagebrush and herbaceous vegetation cover (Strand and  
25       Launchbaugh 2013, pp. 6-7). This recovery would enhance habitat components important to  
26       nest success, including cover and forage by increasing the insect population. Other research  
27       suggests that understory herbaceous productivity may not increase in depleted sagebrush  
28       ranges when grazing is removed (Beck and Mitchell 2000, p. 995). Furthermore, in some  
29       areas, passive restoration may not be sufficient to improve GRSG habitat and active  
30       restoration may be necessary (Davies et al. 2011).

31       Riparian and wetland areas that have been altered by grazing-associated water developments  
32       would be restored, potentially increasing the acreage and improving the condition of these  
33       vegetation communities. However, impacts from wildlife use and from wild horses and  
34       burros, where present, on riparian and wetland areas would continue.

35       In the short term, this alternative would result in more residual herbaceous biomass, which  
36       may result in some smaller fires under less severe conditions. It may also result in more  
37       crown die-out of bunchgrasses that burn hotter due to retained crown fuel. Evidence  
38       suggests that the potential role of grazing on fire behavior is limited under extreme burning  
39       conditions, such as low fuel moisture and relative humidity, high temperature, and wind

1 speed (Strand and Launchbaugh 2013, p. 16). Ultimately, the effect of removing grazing on  
2 fire spread, severity, and intensity would depend on weather, fuel characteristics, landscape  
3 features, and other factors.

#### 4 ***Impacts from Special Designations Management***

5 Under Alternative C, the BLM would designate 39 new ACECs (**Table 4-61**). Impacts from  
6 management of ACECs are as described under **Section 4.3.2**.

#### 7 **4.3.7 Alternative D**

8 Under Alternative D, the BLM and Forest Service would manage lands to conserve,  
9 enhance, and restore sagebrush ecosystems. Management and impacts would be similar to  
10 Alternative B, though Alternative D would incorporate more flexibility and adaptive  
11 management applied to resource uses to account for sub-regional conditions. PHMA,  
12 IHMA, and GHMA would be designated (**Table 4-14**). The BLM and Forest Service would  
13 require a no net unmitigated loss of PHMA and IHMA and would implement numerous  
14 conservation measures to reduce impacts from human activities in PHMA. This would  
15 reduce the likelihood for vegetation removal, degradation, or fragmentation.

16 However, by including a rule set to release areas from PHMA, IHMA, GHMA protection,  
17 some vegetation communities that do not provide habitat for GRSG could receive less  
18 protection under this alternative and could be subject to removal, damage, or reduced  
19 condition caused by human disturbances. At the implementation level, impacts would be  
20 analyzed on a site-specific basis.

#### 21 ***Impacts from Lands and Realty Management***

22 Under Alternative D, PHMA would be ROW avoidance, with exclusions for wind and solar  
23 development. A number of uses would not be allowed, such as large transmission facilities,  
24 fluid mineral development, and paved and graded gravel roads. IHMA and GHMA would be  
25 designated as ROW avoidance areas for all infrastructure (**Table 4-54**). Impacts from  
26 designating ROW exclusion and avoidance areas are as described under **Section 4.3.2**;  
27 impacts from land tenure decisions are similar to those described for Alternative B.

#### 28 ***Impacts from Habitat Restoration and Vegetation Management***

29 Management under Alternative D would be similar to that described for Alternative B,  
30 though with additional measures to prioritize vegetation rehabilitation. They would  
31 incorporate design features that would improve the success of rehabilitation projects and  
32 strategically plan for wildfire suppression. Together, these management actions would  
33 improve the likelihood for sagebrush rehabilitation and prevention of catastrophic wildfires  
34 that would destroy sagebrush vegetation over the long term.

#### 35 ***Impacts from Wildland Fire Management***

36 Wildfire management under Alternative D would be similar to that described for Alternative  
37 B, with additional management flexibility to respond to sub-regional conditions and  
38 management, and guidance incorporated to tailor management to specific vegetation  
39 communities. The BLM and Forest Service would prioritize wildfire suppression planning

1 and would consider targeted grazing to reduce fine fuels throughout the decision area.  
2 Together, these actions would improve wildfire management, given the limited resources  
3 available, and would target those areas that need most protection. As a result, the likelihood  
4 for wildfire would be reduced and subsequent impacts on vegetation from wildfire described  
5 under **Section 4.3.2** would also be reduced.

#### 6 ***Impacts from Nonenergy Leasable Minerals Management***

7 Under Alternative D, PHMA and IHMA would be closed to nonenergy leasable mineral  
8 leasing with exceptions for modifications (**Table 4-56**). GHMAs are available for leasing  
9 subject to applicable timing restrictions and lease stipulations. RDFs and restoration would  
10 be required on existing leases in all GRSG habitat. This would reduce impacts on vegetation  
11 associated with nonenergy leasable mineral development in unleased and leased areas, as  
12 described under **Section 4.3.2**.

#### 13 ***Impacts from Locatable Minerals Management***

14 Acres open to locatable mineral development under Alternative D would be the same as  
15 those described for Alternative A. However, no net unmitigated loss of habitat would be  
16 allowed under this alternative. This measure, along with BMPs (see **Appendix B**), would  
17 reduce impacts on vegetation and would restore habitat, thereby reducing the impacts  
18 described under Alternative A.

#### 19 ***Impacts from Salable Minerals Management***

20 Under Alternative D, no new authorizations would be approved within 1.86 miles (3 km) of  
21 an occupied lek. RDFs and timing limitations would be applied to newly authorized  
22 disposals throughout the decision area, and reclamation bonding would be required (**Table**  
23 **4-56**). Impacts on vegetation, such as those described under **Section 4.3.2**, could occur from  
24 authorizations outside of the 1.86-mile (3 km) buffer from leks, although RDFs would  
25 reduce impacts.

#### 26 ***Impacts from Fluid Minerals Management***

27 Under Alternative D, low or no potential areas in PHMA and IHMA would be closed to  
28 fluid mineral leasing (**Table 4-57**). Areas of moderate and high potential would be open to  
29 leasing, subject to CSU, timing limitations, and an NSO stipulation within 0.6 miles (1 km)  
30 of an occupied lek. Geophysical exploration would be allowed, subject to timing limitations.  
31 Impacts on vegetation, such as those described under **Section 4.3.2**, could occur from  
32 development on leases outside of the 0.6-mile (1 km) buffer from leks, although RDFs  
33 would reduce impacts.

#### 34 ***Impacts from Travel and Transportation Management***

35 Impacts from travel and transportation management under Alternative D are similar to those  
36 described under Alternative B, though with increased flexibility to provide for high quality  
37 and sustainable travel routes and administrative access (**Table 4-59**). As such, there may be  
38 increased impacts on the acreage of vegetation in areas where new routes are created.  
39 Impacts in these areas are as described under **Section 4.3.2**.

1       ***Impacts from Livestock Grazing Management***

2       Under Alternative D, the BLM and Forest Service would maintain the same number of acres  
3       open to grazing as under Alternative A (**Table 4-60**). Impacts from livestock grazing  
4       management under Alternative D are similar to those described for Alternative B. However,  
5       under Alternative D, PHMA would receive the highest priority, subject to legal  
6       requirements, for completion of land health assessments. Also, the BLM and Forest Service  
7       would restrict authorizations of new water developments and would evaluate introduced  
8       perennial grass seedings. The BLM and Forest Service would incorporate measures to reduce  
9       impacts from trailing and would consider using grazing to achieve fuels management  
10       objectives throughout the decision area. Together these measures would reduce the impacts  
11       from grazing described under **Section 4.3.2**.

12       ***Impacts from Special Designations Management***

13       Impacts from ACEC management under Alternative D are the same as those described for  
14       Alternative A (**Table 4-61**).

15               **4.3.8 Alternative E**

16       Under Alternative E, the BLM and Forest Service would manage to maintain, conserve,  
17       enhance, and restore sagebrush ecosystems. CHZ, IHZ, and GHZ would be designated  
18       (**Table 4-14**). In CHZ and IHZ, the BLM and Forest Service would incorporate  
19       management flexibility to permit high value infrastructure with appropriate mitigation and  
20       best management practices tailored for the sub-region. Management and impacts are similar  
21       to Alternative D, though Alternative E would require less stringent use restrictions and  
22       would designate the least amount of CHZ, compared to the other alternatives' management  
23       area designations.

24       ***Impacts from Lands and Realty Management***

25       Under Alternative E, CHZ and IHZ would be designated as ROW avoidance areas, although  
26       the BLM and Forest Service would allow for more exceptions for development in IHZ  
27       (**Table 4-54**). This could increase the likelihood for impacts on vegetation, such as  
28       disturbance, removal, or fragmentation. Impacts from designation of ROW avoidance areas  
29       are as described under **Section 4.3.2**. Alternative E does not provide guidance for land  
30       tenure decisions in GRSG habitat, so there would be no associated effects on vegetation.

31       ***Impacts from Habitat Restoration and Vegetation Management***

32       Development of a restoration strategy for vegetation management at the implementation  
33       stage would help focus priorities on the areas and communities identified as most pertinent  
34       to restoring sagebrush and GRSG habitat. Native vegetation would be used for restoration  
35       to the extent practicable. These measures would increase the acreage and extent of sagebrush  
36       vegetation over the long term. Invasive species would be controlled for three years after  
37       wildfire treatments, which would reduce the likelihood of invasive weeds to be introduced or  
38       spread into recently burned areas.

1       ***Impacts from Wildland Fire Management***

2       Alternative E provides guidance to reduce wildfire response time, create fuel breaks, and  
3       improve the wildfire suppression baseline. The goal is to maintain habitat to support 73 to  
4       95 percent of breeding male GRSG by implementing fire breaks, re-seeding burned areas,  
5       establishing Rangeland Fire Protection Associations within CHZ and IHZ, and offsetting  
6       habitat losses to wildfire, according to the Governor's Office of Species Conservation letter  
7       dated July 1, 2013 (Governor's Office of Species Conservation 2013). Completion of a  
8       response time analysis would help focus suppression resources and activities to help reduce  
9       the size and extent of wildfires in CHZ. Targeted grazing would be allowed in IHZ. These  
10      actions would improve the likelihood for fire suppression and would reduce the likelihood  
11      for fire, thereby protecting existing vegetation. However, this alternative does not provide  
12      much guidance regarding other fuel treatments and ESR, which could limit the success of  
13      fire suppression and regrowth of desired vegetation after a fire.

14      ***Impacts from Nonenergy Leasable Minerals Management***

15      Alternative E does not provide guidance on nonenergy leasable minerals management, and  
16      as such, impacts on vegetation are expected to be similar to those described for Alternative  
17      A (Table 4-56).

18      ***Impacts from Locatable Minerals Management***

19      Alternative E does not provide guidance on locatable minerals management, and as such,  
20      impacts on vegetation are expected to be similar to those described for Alternative A.

21      ***Impacts from Salable Minerals Management***

22      Alternative E does not provide guidance on salable minerals management, and as such,  
23      impacts on vegetation are expected to be similar to those described for Alternative A (Table  
24      4-56).

25      ***Impacts from Fluid Minerals Management***

26      Under Alternative E, the BLM and Forest Service would apply an NSO stipulation on leases  
27      in CHZ, which would reduce the likelihood of surface-disturbing activities and vegetation  
28      removal in these areas. No additional areas would be closed to leasing (Table 4-57), but a  
29      five percent disturbance cap would apply to fluid mineral impacts only. Fluid mineral leasing  
30      would be authorized in IHZ under certain conditions, and vegetation could be disturbed,  
31      removed, or fragmented in the areas where development would occur.

32      ***Impacts from Travel and Transportation Management***

33      Under Alternative E, the completion of travel management planning would be prioritized  
34      and would seek to minimize disturbance to GRSG and their habitat. Prior to completion of  
35      travel planning, vehicles would be restricted to existing routes and new roads would be  
36      discouraged or re-routed where possible (State of Idaho 2012). No immediate road closures  
37      would occur (Table 4-59).

38      ***Impacts from Livestock Grazing Management***

39      Impacts from livestock grazing management under Alternative E are similar to those  
40      described for Alternative D, though with an increased emphasis on flexibility to respond to

1 sub-regional conditions and adaptive management in grazing management (**Table 4-60**).  
2 These measures could further reduce impacts on vegetation, depending on where and how  
3 they were applied.

#### 4 ***Impacts from Special Designations Management***

5 Impacts from ACEC management under Alternative E are the same as those described for  
6 Alternative A (**Table 4-61**).

#### 7 **4.3.9 Alternative F**

8 Management under Alternative F would be largely similar to that described for Alternative B,  
9 though with more stringent guidance and restrictive management in sagebrush ecosystems.  
10 PHMA, GHMA and RHMA would be designated (**Table 4-14**). Unique to Alternative F, an  
11 area would be considered successfully restored only if GRSG used the area.

12 Impacts from implementing the maximum three percent disturbance cap are similar to those  
13 described for Alternative B; however, under Alternative F, all surface disturbances (including  
14 human disturbance and fire) would count toward this cap. This would further reduce the  
15 acreage of vegetation that would be removed or fragmented within all occupied habitat over  
16 the long term.

#### 17 ***Impacts from Lands and Realty Management***

18 Impacts from designation of ROW exclusion areas are similar to those described under  
19 Alternative B (**Table 4-55**). Impacts from land tenure decisions are similar to those  
20 described under Alternative B, though Alternative F would not allow for exceptions to  
21 disposal criteria. This would reduce management flexibility and could have implications for  
22 vegetation connectivity.

#### 23 ***Impacts from Habitat Restoration and Vegetation Management***

24 Impacts from habitat restoration and vegetation management under Alternative F are similar  
25 to those described for Alternative B.

#### 26 ***Impacts from Wildland Fire Management***

27 Impacts from wildland fire management under Alternative F are similar to those described  
28 for Alternative B. Alternative F would require exclusions of grazing post-fire. This would  
29 reduce grazing pressure on and trampling of ESR seedings, thus improving the likelihood of  
30 native vegetation restoration post-fire.

#### 31 ***Impacts from Nonenergy Leasable Minerals Management***

32 Impacts from nonenergy leasable minerals management under Alternative F are the same as  
33 those described for Alternative B (**Table 4-56**).

#### 34 ***Impacts from Locatable Minerals Management***

35 Impacts from locatable minerals management under Alternative F are the same as those  
36 described for Alternative B.

1       ***Impacts from Salable Minerals Management***

2       Impacts from salable minerals management under Alternative F are the same as those  
3       described for Alternative B (**Table 4-56**).

4       ***Impacts from Fluid Minerals Management***

5       Impacts from fluid minerals management under Alternative F are the same as those  
6       described for Alternative B (**Table 4-58**).

7       ***Impacts from Travel and Transportation Management***

8       Impacts from travel and transportation management under Alternative F are similar to those  
9       described for Alternative B, though there would be fewer impacts on vegetation under  
10       Alternative F (**Table 4-59**), because no new road construction would be allowed within 4  
11       miles (6.4 km) of leks in PHMA, and mitigation of impacts from route construction would  
12       be required.

13       ***Impacts from Livestock Grazing Management***

14       Impacts from livestock grazing management under Alternative F are similar to those  
15       described for Alternative B, though Alternative F would require a 25 percent reduction in  
16       AUMs and would incorporate more stringent guidance and restrictive measures. This  
17       reduction could further reduce impacts on vegetation by reducing grazing pressure across  
18       the decision area. The total acreage open to grazing would be the same as for Alternative B  
19       (**Table 4-60**).

20       ***Impacts from Special Designations Management***

21       Under Alternative F, the BLM would designate one of two sub-alternatives: F1, which would  
22       designate all PPH as an ACEC, and F2, which would designate a subset of PPH as an ACEC  
23       (**Table 4-61**). Impacts from management of ACECs are as described under **Section 4.3.2**  
24       and impacts from ZAs are expected to be similar.

25       **4.3.10 Proposed Plan**

26       Under the Proposed Plan, the BLM and Forest Service would manage lands to conserve,  
27       enhance and restore GRSG habitat and the sagebrush ecosystem upon which GRSG  
28       populations depend. Direct protection of sagebrush habitat to support GRSG would limit or  
29       modify uses in this habitat type, improving the acreage and condition of desired vegetation  
30       communities. Restrictions on resource uses such as ROW and mineral development would  
31       reduce damage to native vegetation communities and individual native plant species in areas  
32       that are important for regional vegetation diversity and quality. Likewise, use restrictions  
33       would minimize fragmentation and would be more likely to retain existing age class  
34       distribution within these areas. Use restrictions could also minimize the spread of invasive  
35       species by limiting human activities that disturb soil or introduce seeds.

36       Management and impacts would be similar to Alternatives D and E, though the Proposed  
37       Plan would incorporate robust strategies and approaches to GRSG management, including  
38       wildfire management, adaptive management, mitigation, and monitoring (**Appendices D, G,**  
39       **J, and E**). PHMA, IHMA, and GHMA would be designated, and 3.8 million acres of SFAs  
40       would be managed. Acres of each vegetation community within GRSG habitat management

1 areas are presented in **Table 4-62** through **4-68**. Limiting anthropogenic  
2 disturbances to 3 percent at both the BSU and project levels would reduce the likelihood for  
3 vegetation removal, degradation, or fragmentation and would maintain the acreage and  
4 condition of sagebrush vegetation on both the local and landscape scales. Anthropogenic  
5 disturbances in PHMA and IHMA would be mitigated to a no net loss of Key habitat  
6 standard, thereby preserving the potential for these areas to provide GRSG habitat. In  
7 addition, the BLM and Forest Service would implement numerous conservation measures  
8 such as BMPs, RDFs, and buffers (**Appendix B**) to reduce impacts from human activities in  
9 PHMA and IHMA. This would reduce the likelihood for vegetation removal, degradation, or  
10 fragmentation and reduce the likelihood for weed introduction or spread.

### 11 ***Impacts from Lands and Realty Management***

12 Under the Proposed Plan, PHMA would be designated as ROW exclusion areas and IHMA  
13 would be ROW avoidance areas for solar, wind, nuclear, and hydropower energy  
14 development as well as commercial service airports and landfills. ROW avoidance areas  
15 would also be designated for major and minor ROWs in PHMA and IHMA. GHMA in  
16 Montana would have similar protections. Such restrictions would have impacts on vegetation  
17 as described under **Section 4.3.2** (**Tables 4-54 and 4-55**). Additional requirements to meet  
18 the Anthropogenic Disturbance Exception Criteria (for PHMA in Idaho), Anthropogenic  
19 Disturbance Development Criteria (for PHMA and IHMA in Idaho), the project/action  
20 screen and mitigation process in Montana, mitigation requirements, and application of the  
21 disturbance cap, RDFs, BMPs, and buffers would further reduce the likelihood for impacts  
22 on vegetation by requiring additional conditions to be met and reducing overall disturbance.

23 Retention and acquisition of GRSG habitat would reduce fragmentation of vegetation  
24 communities, as described under **Section 4.3.2**.

### 25 ***Impacts from Habitat Restoration and Vegetation Management***

26 Under the Proposed Plan, habitat restoration and vegetation management actions would aim  
27 to achieve certain vegetation objectives to improve GRSG habitat. It would do this by  
28 restricting activities that have the potential to degrade sagebrush communities, such as  
29 prescribed fire, while promoting and prioritizing those activities that improve sagebrush  
30 communities and prioritizing restoration and rehabilitation to benefit GRSG habitat. The  
31 BLM and Forest Service would require the use of native seeds as a component of most  
32 restoration activities and would design post-restoration management to ensure the long-term  
33 persistence of restoration. Together, these management actions would alter vegetative  
34 communities by increasing herbaceous cover and vegetation productivity. Strategically  
35 planning for wildfire suppression would prevent catastrophic wildfires that would destroy  
36 sagebrush vegetation over the long term.

37 Over a 10-year period, mechanical treatments on 77,000 acres, prescribed fire on 30,000  
38 acres, and grass restoration treatments on 620,000 acres designed to prevent and reduce  
39 encroachment of conifers and nonnative species would alter the condition of native  
40 vegetation communities by changing the density, composition, and frequency of species  
41 within plant communities. Habitat connectivity for GRSG could be increased over the

1 planning timeframe through vegetation manipulation designed to restore vegetation,  
2 particularly sagebrush overstory cover.

### 3 ***Impacts from Wildland Fire Management***

4 A comprehensive strategy for wildland fire management would be implemented under the  
5 Proposed Plan, including the FIAT (**Appendix D**). The assessment would identify priority  
6 habitat areas and management strategies to reduce the threats to GRSG from invasive annual  
7 grasses, wildfires, and conifer expansion. It would incorporate recent scientific research on  
8 resistance and resilience of Great Basin ecosystems as well as interdisciplinary team  
9 knowledge. Potential management strategies include proactive measures such as fuels  
10 management and habitat restoration and recovery, and reactive measures such as fire  
11 operations and post-fire rehabilitation. Together, these actions would improve wildland fire  
12 management, given the limited resources available, and would target those areas that need  
13 most protection. As a result, the likelihood for wildfire would be reduced and subsequent  
14 impacts on vegetation from wildfire, particularly vegetation that meets GRSG habitat  
15 requirements, described under **Section 4.3.2** would also be reduced. Further, providing  
16 adequate rest from livestock grazing would improve the likelihood that ESR seedlings would  
17 stabilize the site, compete effectively against invasive annuals, and successfully establish  
18 native vegetation over the long term.

### 19 ***Impacts from Non-Energy Leasable Minerals Management***

20 Acres of sagebrush closed to non-energy leasable mineral leasing under the Proposed Plan  
21 are shown in **Table 4-56**. Application of the disturbance cap, mitigation requirements, and  
22 closures in PHMA and restrictions in IHMA and GHMA outside of KPLAs would prevent  
23 or reduce the removal, fragmentation, and other impacts as described in **Section 4.3.2** on  
24 vegetation associated with non-energy leasable mineral development. Impacts, including loss  
25 and degradation of upland vegetation and an increased potential for invasive plant spread, as  
26 described under **Section 4.3.2**, would continue to occur in areas open to non-energy leasable  
27 mineral leasing and development.

### 28 ***Impacts from Locatable Minerals Management***

29 Under the Proposed Plan, SFAs would be recommended for withdrawal from the General  
30 Mining Act of 1872; if withdrawn, this action would result in the protection of vegetation in  
31 these areas from removal and disturbance caused by locatable minerals management. In  
32 addition, RDFs and BMPs would be applied as Conditions of Approval, which would reduce  
33 impacts on vegetation and would restore habitat, thereby reducing the impacts described  
34 under Alternative A.

### 35 ***Impacts from Salable Minerals Management***

36 Acres of sagebrush closed to salable mineral development under the Proposed Plan are  
37 shown in **Table 4-57**. Prohibitions on new salable mineral development in PHMA would  
38 prevent new impacts on vegetation in these areas. Requirements to meet the anthropogenic  
39 disturbance criteria in IHMA, adhere to the disturbance cap, and implement mitigation,  
40 RDFs, BMPs, and buffers in IHMA and GHMA would reduce vegetation removal,  
41 fragmentation, and other impacts associated with salable mineral development as described

1 in **Section 4.3.2**. Restoration would increase the extent of vegetation and depending on the  
2 location could remove nonnative invasive species and reduce fragmentation.

### 3 ***Impacts from Fluid Minerals Management***

4 Acres of sagebrush closed to fluid mineral leasing under the Proposed Plan are shown in  
5 **Table 4-58**. Protections for vegetation would be greatest in SFAs which would be subject to  
6 an NSO stipulation without waivers, exceptions, or modifications. Vegetation would also be  
7 highly protected in PHMA and IHMA, which would be subject to an NSO stipulation with  
8 one exception. As a result, the NSO stipulation, anthropogenic disturbance criteria,  
9 mitigation requirement, disturbance cap, RDFs, BMPs, and buffers would be the primary  
10 mechanisms to prevent or reduce the removal, fragmentation, and other impacts on  
11 vegetation associated with fluid mineral development in unleased areas. Impacts, including  
12 loss and degradation of upland vegetation and an increased potential for invasive plant  
13 spread, as described under **Section 4.3.2**, would continue to occur in areas open to fluid  
14 mineral leasing and development.

### 15 ***Impacts from Travel and Transportation Management***

16 Under the Proposed Plan, motorized travel would be limited to existing roads, primitive  
17 roads, and trails within Idaho BLM field offices (**Table 4-59**). Management actions would  
18 also close areas adversely affected by off-highway vehicles and Travel Management Plans  
19 would be developed. These actions would reduce the likelihood of impacts caused by roads,  
20 as described under **Section 4.3.2**, and would increase the acreage and connectivity of  
21 sagebrush vegetation.

### 22 ***Impacts from Livestock Grazing Management***

23 Under the Proposed Plan, the BLM and Forest Service would maintain the same number of  
24 acres open to grazing as under Alternative A (**Table 4-60**). However, the BLM and Forest  
25 Service would implement a number of management actions to meet vegetation objectives in  
26 SFAs and PHMAs, including prioritizing the review and processing of grazing  
27 permits/leases in SFAs, particularly in areas not meeting land health standards that also  
28 contain riparian areas, including wet meadows. Further, BLM would prioritize land health  
29 assessments in GRSG habitat, incorporate GRSG habitat objectives and management  
30 considerations into livestock grazing management, improve the condition of vegetation in  
31 GRSG habitat areas, and incorporate grazing into adaptive management considerations.  
32 Such measures would help to improve vegetation condition of rangeland and riparian and  
33 wetland areas. They also could reduce the likelihood of nonnative invasive species  
34 introduction or spread through improved grazing management and changes implemented  
35 resulting from land health assessments. Together, these efforts would improve consistency  
36 of management across the sub-region and would reduce impacts from grazing on vegetation,  
37 described in **Section 4.3.2**.

38 The Forest Service will incorporate grazing guidelines (**Table 2-6**) into term grazing permits  
39 that will likely improve vegetation structures in GRSG seasonal habitat on grazing  
40 allotments.

1       ***Impacts from Special Designations Management***

2       Under the Proposed Plan, the BLM would continue to manage 59 ACECs within the sub-  
3       region (**Table 4-61**). The Forest Service would not manage any ZAs under the Proposed  
4       Plan. Existing ACECs likely protect vegetation through use restrictions; these impacts are  
5       analyzed under each existing RMP within the planning area. As a result, there would be no  
6       additional effects from ACEC or ZA management on vegetation under this alternative.

7       ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and***  
8       ***Coordination***

9       Implementing an anthropogenic disturbance cap at both the BSU and project levels would  
10      limit vegetation removal in GRSG habitat at the site and landscape scales. The BLM and  
11      Forest Service would also require no net loss of Key habitat. This would help to maintain the  
12      extent and condition of sagebrush habitat throughout the sub-region, but could displace  
13      development into other vegetation types, causing increased impacts to these communities.  
14      Co-location requirements in the Anthropogenic Disturbance Exception and Development  
15      Criteria would limit fragmentation and may also limit weed spread since development would  
16      occur in previously disturbed areas.

17   **4.4 Wild Horse and Burro Management**

18           **4.4.1 Methods and Assumptions**

19           ***Indicators***

20           Indicators of impacts on wild horses and burros are as follows:

- 21           • Changes in permitted Appropriate Management Levels (AMLs)
- 22           • Changes in allotted forage (AUMs)
- 23           • Prohibitions or limitations on the construction or maintenance of structural and  
24           nonstructural range improvements
- 25           • Modifications to or removal of structural range improvements

26           ***Assumptions***

27           The analysis includes the following assumptions:

- 28           • Horses and burros depend on the herbaceous component of a shrub/grass plant  
29           community. Declines in grasses and forbs are adverse and increases are  
30           beneficial. Vegetation treatments, such as prescribed burns or weed control, can  
31           enhance the plant community composition and forage availability.
- 32           • Water is the primary resource associated with wild horse distribution, and water  
33           developments can improve wild horse distribution.

- 1 • Fences and other disturbances can restrict wild horse movement and access.  
2 Fences are sometimes necessary to restrict horse distribution to areas inside  
3 HMAs or to protect sensitive resources within HMAs.
  
- 4 • No forage is allocated to wild horses and burros found on lands outside of  
5 HMAs. The BLM has the responsibility to remove wild horses and burros found  
6 outside of HMAs
  
- 7 • The scheduling for wild horse and burro gathers to remove excess animals is  
8 influenced by a national priority process. Factors affecting gather priorities are  
9 determinations of excess horses and overpopulations, wild horse and range  
10 condition, annual appropriations, litigation and court orders, emergency  
11 situations, such as disease, weather, and fire, availability of contractors, the  
12 market for adoption, and long-term holding availability for unadoptable excess  
13 horses.
  
- 14 • Wild horse and burro distribution is influenced by season, climatic conditions,  
15 water and forage availability, and population size.
  
- 16 • There are no HMAs in the southwest Montana portion of the sub-region.  
17 Therefore, impacts described apply to Idaho only.
  
- 18 • There are no wild burros in Idaho or southwest Montana, so impacts apply only  
19 to wild horses.

#### 20 4.4.2 Nature and Type of Effects

21 All HMAs are managed for AML. Initially, AML is established in RMPs at the outset of  
22 planning and is adjusted based on monitoring data through revision of HMA Plans and  
23 subsequent land use plan amendment. Priorities for gathering excess wild horses and burros  
24 to maintain AML are based on population inventories, resource monitoring objectives,  
25 gather schedules, and budgets. Gathers are also conducted in emergency situations when the  
26 health of the population is at risk due to lack of forage or water and, in some situations,  
27 wildland fire.

28 Development activities such as mineral extraction, recreation, and construction within ROW  
29 may impact wild horse populations in the following ways:

- 30 • Reduce forage availability
- 31 • Disturb wild horses
- 32 • Prohibit the ability of wild horses to move freely across HMAs
- 33 • Limit ability to perform management activities (for example, energy  
34 development infrastructure may impact the ability to conduct helicopter  
35 gathers)

1 Implementing management to protect GRSG generally involves reducing or otherwise  
2 restricting land uses and activities. Limiting these activities to protect GRSG would also  
3 protect forage for wild horses and would limit human and surface disturbance.

4 Conversely, there could be impacts on wild horses and the ability to support AMLs when  
5 management options for HMAs are restricted. Impacts from range improvement restrictions  
6 vary based on type of range improvement affected. Restrictions on fences would improve  
7 wild horse habitat by allowing free range, while limiting projects that could enhance forage  
8 and water availability could limit future options to manage for current AML.

9 Implementing management for the following resources would have negligible or no impact  
10 on wild horse and burro management and are therefore not discussed in detail: air quality,  
11 visual resources, cultural resources, wilderness characteristics, socioeconomics, special  
12 designation management, and tribal interests.

#### 13 **4.4.3 Impacts Common to All Alternatives**

14 Under all alternatives except Alternative F, management actions for wild horses and burros  
15 would not result in direct changes to HMA status, to AMLs within designated HMAs, or  
16 acreage designated as HMAs. Impacts under all alternatives, with the exception of  
17 Alternative F, would be limited to any future changes that may result in AML and/or acreage  
18 adjustment as well as reconsideration of HMA status that are based on achievement of  
19 GRSG habitat objectives for improving habitat conditions.

20 Under all alternatives, management actions would not result in direct acreage designated as  
21 HMAs. Approximately 269,700 acres of HMAs would fall within GRSG habitat, although  
22 the acres within a specific GRSG management area designation (such as a PHMA) with  
23 associated management varies by alternative.

24 The Forest Service does not manage any wild horses or burros within the planning area, so  
25 no impacts would occur on National Forest System lands.

#### 26 ***Impacts from Energy and Mineral Development***

##### 27 *Impacts from Nonenergy Leasable Minerals Management*

28 There are expected to be minimal impacts from nonenergy leasable minerals on wild horses  
29 and burros across all alternatives due to a lack of leases in GRSG habitat.  
30

##### 31 *Impacts from Coal Management*

32 No economically viable coal resources are found in Idaho. Under the Dillon RMP, a plan  
33 amendment would be required to lease coal. As a result, coal development in the project area  
34 and related impacts on wild horses and burros are likely to be limited under all alternatives.

##### 35 ***Impacts from Recreation and Visitor Services Management***

36 Under all alternatives, motorized vehicles would be limited to existing roads and trails,  
37 thereby limiting the impacts on wild horses and burros from dispersed travel. Site-specific

1 travel management planning could, when completed, reduce the potential for conflicts  
2 between wild horses and burros and travel management.

#### 3 **4.4.4 Alternative A**

4 No PHMA or GHMA would be designated for GRSG under this alternative. Wild horse and  
5 burro management would be determined by management in current RMPs in the planning  
6 area.

##### 7 ***Impacts from Vegetation Management***

8 Under Alternative A, restoration would continue in the planning area, with long-term  
9 benefits to forage for horses and burros. Vegetation could be managed to improve forage,  
10 and impacts on WHB from vegetation management would likely be minimal. Management  
11 actions for invasive species would continue under the direction of current management  
12 plans, with the focus on areas not meeting land health standards or desired conditions.

##### 13 ***Impacts from Wild Horse and Burro Management***

14 Under Alternative A, all HMAs are managed for AML and for healthy populations to  
15 achieve a thriving natural ecological balance with respect to wildlife, livestock use, and other  
16 multiple uses. All adjustments to HMAs, HMA plans, and priorities of gathers would  
17 continue to be based on monitoring data. As a result, impacts on wild horses under  
18 Alternative A would depend on the site-specific conditions as reported in monitoring data.

19 While most HMAs in the sub-region contain GRSG habitat within a sagebrush vegetation  
20 community, prioritizing wild horses and burro gathers to maintain AML is not based on  
21 GRSG habitat needs. Nevertheless, this is implicit in the congressional directive to maintain  
22 a thriving natural ecological balance.

##### 23 ***Impacts from Wildland Fire Management***

24 Under Alternative A, mechanical treatments, prescribed fires, and other treatments would be  
25 used to prevent conifer encroachment and remove undesirable annual grass and weed  
26 species. These actions could improve forage for wild horses and burros in the long term.  
27 Although most of the LUPs do not provide specific direction for fire suppression in GRSG  
28 habitat, protection of GRSG habitat during suppression has taken center stage in planning  
29 and operational discussions due to large fire in PPH and PGH in 2007 and 2012. Therefore,  
30 the risk of forage loss in these areas may be lower than in non-GRSG habitats.

##### 31 ***Impacts from Livestock Grazing/Range Management***

32 Under Alternative A, grazing permits, including grazing systems, permitted AUMs, and  
33 allotment boundaries, would be modified as necessary to conform to Standards and  
34 Guidelines for Livestock Grazing Management. Range improvements, including fences,  
35 vegetation treatments, and water developments, would be allowed in the decision area when  
36 needed to support grazing or to improve livestock distribution.

37 Levels of conflict with wild horses and burros would vary throughout the planning area  
38 based on individual RMP management and levels of grazing. Water developments for

1 livestock would likely be maintained and may provide a source of water for horses and  
2 burros.

### 3 ***Impacts from Recreation Management***

4 Under this alternative, there would be no new restrictions to SRPs in the decision area;  
5 therefore, horses and burros could be disturbed by recreation in the planning area. Some  
6 limited potential for disturbance from general recreation is possible, as described under  
7 nature and type of impacts, above.

### 8 ***Impacts from Travel Management***

9 Under Alternative A, as under all alternatives, motorized travel would be limited to  
10 designated routes, and site-specific travel management planning on BLM-administered lands  
11 would be developed, limiting disturbance to horses and burros.

### 12 ***Impacts from Lands and Realty Management***

13 Under Alternative A, the impacts on wild horses and burro management continue to be the  
14 same as those identified in the individual RMP documents. Under Alternative A, there would  
15 be approximately 1 million acres of ROW exclusion and 1.9 million acres of avoidance areas  
16 in the decision area; no new ROW exclusion or avoidance areas would be created. Wild  
17 horses and burros could be disturbed from development of ROWs. For these reasons, this  
18 alternative would have the highest potential for impacts from lands and realty on WHB  
19 management; however, access to HMAs for gathers would be the least restricted.

### 20 ***Impacts from Mineral Materials (Salables) Management***

21 In general, Alternative A is the least restrictive on energy and mineral development of all  
22 alternatives. As a result, the indirect impacts of development on wild horses and burros,  
23 including spread of noxious weeds and disturbance of horses or burros, are the greatest  
24 under this alternative.

## 25 **4.4.5 Alternative B**

### 26 ***Impacts from Vegetation Management***

27 Under Alternative B, restoration projects in PH would be designed to benefit GRSG and  
28 based on the likelihood of success, with reestablishment of sagebrush cover as the highest  
29 priority. Projects to remove nonnative species and improve habitat would likely improve  
30 forage conditions and water quality for wild horses in the long term. However, should  
31 management require increased fences to protect vegetation for GRSG, this could limit wild  
32 horse and burro movement and access to riparian areas and reduce water availability. This  
33 could result in potential need for reduction of wild horses and burro numbers within an  
34 HMA in order to meet vegetation objectives for GRSG.

### 35 ***Impacts from Wild Horse and Burro Management***

36 Under Alternative B, management actions would require examination of herd management  
37 plans, AML levels, and range improvements or other NEPA and management activities for  
38 wild horses and burros in light of GRSG habitat objectives and potential impacts on GRSG  
39 habitat, particularly in PHMA. This could potentially result in changes to wild horse and  
40 burro management and AMLs should objectives for GRSG habitat not align with

1 management objectives for wild horse management. In many cases, however, management  
2 actions to improve GRSG habitat would also improve wild horse rangeland conditions (for  
3 example, conifer removal and noxious weed control would improve forage conditions for  
4 wild horses and burros).

5 If water developments required modification to meet GRSG objectives or new  
6 developments were not permitted, water availability could be reduced. This could result in  
7 the potential need to reduce wild horse and burro numbers or develop alternative water  
8 sources within the HMA, particularly during periods of drought.

9 ***Impacts from Wildland Fire Management***

10 Fuels projects and fire suppression to protect sagebrush ecosystems and associated PHMA  
11 would benefit wild horses and burros where HMAs overlap this habitat. This would be due  
12 to a reduction in the likelihood of high intensity wildfire. However, temporary or long-term  
13 management changes to wild horses and burros, such as reduction in AML, or fencing  
14 blocking access to forage may be necessary to achieve and maintain the desired project  
15 objectives post-fire.

16 ***Impacts from Livestock Grazing/Range Management***

17 Management to conserve, enhance, or restore GRSG habitat that benefit livestock forage  
18 would generally also benefit wild horses and burros within GRSG in the long term.  
19 Modifying or eliminating livestock watering sites could reduce water availability for wild  
20 horses and burros. This could result in the need to reduce wild horse and burro numbers or  
21 develop alternative water sources within specific HMAs, especially during periods of  
22 drought.

23 ***Impacts from Recreation and Visitor Services Management***

24 In PHMA, motorized travel would be limited to existing roads and trails on BLM-  
25 administered and National Forest System lands. Travel plans (to be completed) would  
26 analyze PHMA for the need for road closures, and limitations would be implemented during  
27 development of new roads. Some reduction in routes, and limitations on new routes would  
28 occur compared to Alternative A in PHMA. This could impact the ability to conduct gathers  
29 of wild horses and burros for population control. These limits also could increase the time  
30 and costs of gathers if they are not covered by administrative exceptions. However, limits to  
31 travel would also decrease any disturbance of horses and burros from OHV use.

32 Under Alternative B, limits on SRPs in PHMA would reduce any conflicts between  
33 recreation and wild horse and burro management.

34 ***Impacts from Lands and Realty Management***

35 Under Alternative B, no new ROW authorizations would be permitted in PHMA unless the  
36 development would occur within the existing developed footprint This action would likely  
37 reduce devolvement in HMAs overlapping PHMA as compared to Alternative A, indirectly  
38 reducing related disturbance to wild horses and burros.

1       ***Impacts from Energy and Mineral Management***

2       Under Alternative B, additional restrictions would be put on mineral development, as  
3       compared to Alternative A. Lands in PHMA would be recommended for withdrawal from  
4       mineral entry for locatable minerals, closed to mineral materials removal, and closed to new  
5       leasing for fluid minerals. For currently leased parcels, NSO stipulations would be applied in  
6       PHMA and around leks. As a result, disturbance of wild horses and burros from mineral  
7       development would be minimized in PHMA.

8                   **4.4.6   Alternative C**

9       ***Impacts from Vegetation Management***

10       Habitat restoration actions and related impacts in PHMA would be similar to that described  
11       in Alternative B. In addition, restoration proposed under Alternative C includes removing  
12       water developments. This could reduce available water in HMAs and result in the need to  
13       reduce wild horse and burro AML within an HMA in occupied habitat in order to meet  
14       vegetation objectives for GRSG.

15       ***Impacts from Wild Horse and Burro Management***

16       Impacts are as discussed under Alternative A.

17       ***Impacts from Wildland Fire Management***

18       Impacts are similar to those discussed under Alternative B.

19       ***Impacts from Livestock Grazing/Range Management***

20       Elimination of livestock grazing in occupied habitat would provide additional forage for wild  
21       horses and burros where HMAs overlap these habitats. This would occur by reducing  
22       competition for forage in these areas.

23       Elimination of livestock watering sites or failure to maintain water developments could  
24       reduce water availability. As a result, developments would be limited, and ability to manage  
25       for AML could be impacted for HMAs in occupied habitat, particularly in drought  
26       conditions.

27       ***Impacts from Recreation and Visitor Services Management***

28       Impacts from recreation management are similar to those discussed under Alternative A.  
29       Travel management impacts would be as discussed under Alternatives B.

30       ***Impacts from Lands and Realty Management***

31       Under Alternative C, new ROWs for corridors would be sited in non-habitat and bundled  
32       with existing corridors to the maximum extent possible. As a result, disturbance from  
33       development and related impacts on wild horses and burros management would be reduced  
34       compared to Alternative A.

35       ***Impacts from Energy and Mineral Management***

36       Impacts from mineral materials would be similar to those described under Alternative B for  
37       existing fluid mineral leases and locatable saleable and nonenergy leasable minerals. No new  
38       fluid-mineral leases would be issued in PHMA. As a result, the chance of disturbance of wild

1 horses and burros form development of these resources would be reduced as compared to  
2 Alternative A.

#### 3 4.4.7 Alternative D

##### 4 ***Impacts from Vegetation Management***

5 Under Alternative D, vegetation rehabilitation would emphasize projects to achieve the  
6 greatest improvement in GRSG abundance and distribution. This includes sites with greater  
7 likelihood of success. Reconnecting and expanding native plant communities would be an  
8 objective across all GRSG habitat types; restoring seasonal habitats would be emphasized in  
9 both PHMA and IHMA. As discussed in Alternative B, these management actions could  
10 improve wild horse and burro forage in the long term. For example, measures to replace  
11 annual grasses with perennial grasses would also reduce interannual variability in forage  
12 quantity.

13 Impacts would likely occur if wild horses and burros are found to be factors in GRSG  
14 habitat not achieving or moving toward achieving objectives, in which case the adjustment  
15 of wild horse and burro populations would be considered and could result in the reduction  
16 of AMLs in some HMAs in the long term. Post-restoration management requirements could  
17 impact horse movement if fences were installed. In addition, should access to water sources  
18 be restricted, ability to manage for AML could be affected.

##### 19 ***Impacts from Wild Horse and Burro Management***

20 Under Alternative D, as in Alternative B, HMPAs would be amended to incorporate GRSG  
21 habitat objectives; therefore changes may be required to AMLs or wild horse and burro  
22 management in the long term in PHMA, IHMA and GHMA should these objectives not be  
23 met by current AMLs or management.

24 In addition, under Alternative D, no HMA expansion would be permitted in PHMA. Under  
25 IHMA habitat expansion may be permitted if impacts on GRSG as well as alternative areas  
26 of expansion are examined first. These actions would limit the ability to sustainably manage  
27 for increasing population of horses and potentially necessitate additional gathers to reduce  
28 herd sizes, at increased cost for management of the program.

##### 29 ***Impacts from Wildland Fire Management***

30 Under Alternative D, post-fire and restoration management would be undertaken to ensure  
31 long-term persistence of seeded or pre-burn native plants. It may also require short- or long-  
32 term change to wild horse and burro management. Fencing to exclude livestock from post-  
33 burn areas could impact the ability of horses to roam freely. If exclusion reduces horses'  
34 ability to access water sources, ability to manage for AML could be affected. The degree of  
35 impacts would be determined by the location, size, and intensity of fires in GRSG habitat  
36 but would be increased over those in Alternative B. because all GRSG habitat types would  
37 be included.

1       ***Impacts from Livestock Grazing/Range Management***

2       Grazing management actions and impacts on wild horses and burros would be similar to  
3       those described in Alternative B. Under Alternative D, however, allotments containing  
4       PHMA would be prioritized for permit renewal, followed by IHMA and finally GHMA;  
5       impacts on wild horse and burro would occur in HMAs overlapping these habitat areas in  
6       this sequence.

7       Water developments under Alternative D would be limited as compared to Alternative A, as  
8       only projects that would maintain, benefit or have neutral effect on PHMA would be  
9       allowed and modification or removal of existing developments may be required. As  
10      described for Alternative B, this could result in impacts on the ability to manage for AML,  
11      particularly under drought conditions.

12      ***Impacts from Recreation Management and Visitor Services***

13      Under Alternative D, motorized travel would be limited to designated roads, primitive roads,  
14      and trails, at a minimum. However, any play area designated for OHV use would remain  
15      open, with the potential to disturb or disrupt wild horse and burro movement in these areas.  
16      Seasonal restrictions for authorized activities could impact the ability of to-access herds for  
17      gatherers.

18      ***Impacts from Lands and Realty Management***

19      Under Alternative D, new ROW and land use authorizations would be avoided whenever  
20      possible, with a goal of no net loss of GRSG habitat. ROW avoidance areas in PHMA,  
21      IHMA, and GHMA, as well as the exclusion of larger facilities in PHMA, would somewhat  
22      limit the indirect impacts of development on wild horses and burros in the avoidance and  
23      exclusion areas. Impacts would still occur in non-habitat HMAs.

24      Similarly, management actions prohibiting solar and wind development in PHMA and  
25      imposing restrictions on development in IHMA and avoidance areas in GHMA would limit  
26      any impacts of disturbance from development of these resources. However, this may shift  
27      impacts to non-habitat HMAs.

28      ***Impacts from Mineral Materials (Salables) Management***

29      Under Alternative D, some degree of mineral development would be allowed, with measures  
30      to avoid or mitigate impacts on GRSG. Specifically, new fluid minerals and undeveloped  
31      nonenergy mineral leases would be allowed in all GRSG habitat types, with BMPs applied.  
32      Similarly, mineral materials would be allowed to be leased in all habitat types, with  
33      stipulations. As a result of the flexibility in management for PHMA, unlike that in  
34      Alternative B, there is some potential for mineral development in PHMA and related  
35      impacts on disturbance of wild horses and burros; however, the impacts would likely be  
36      minimal and lower than those under Alternative A. Within IHMA and GHMA, the degree of  
37      disturbance from or conflicts with wild horses and burros from energy and mineral  
38      development would also be lower than that under Alternative A.

1                   **4.4.8 Alternative E**

2                   ***Impacts from Vegetation Management***

3                   Impacts from habitat restoration are as described under Alternative A. Similarly,  
4                   management actions of invasive species would likely be similar to Alternative A, with a focus  
5                   on actions in CHZ and IHZ. Short-term impacts on wild horses and burros would be  
6                   minimal, with a chance for long-term improvement of forage.

7                   ***Impacts from Wild Horse and Burro Management***

8                   Under Alternative E, management actions for wild horses and burros and related impacts  
9                   would be as discussed under Alternative A.

10                  ***Impacts from Wildland Fire Management***

11                  Under Alternative E, management actions for wildfire include an emphasis on fire  
12                  suppression and reduction in fire risk in CHZ, IHZ, and GHZ. As a result, the risk of  
13                  ignition and spread of fire in occupied GRSG habitat would be reduced, thereby reducing  
14                  the impacts of fire on HMAs in GRSG habitat. The risk of fire spread in HMAs in other  
15                  habitat could increase, should limited resources be allocated for GRSG habitat.

16                  ***Impacts from Livestock Grazing/Range Management***

17                  Under Alternative E, management actions for livestock grazing would be based on GRSG  
18                  population trends and focused on CHZ and IHZ. Adjustments would be applied at a site-  
19                  specific level and specifically tailored to achieve objectives. As a result, changes to  
20                  management and associated impacts would be limited. Impacts on wild horse and burro  
21                  management would therefore be most likely to occur in CHZ and IHZ but would be limited  
22                  in nature.

23                  Avoiding construction of new fences within 1.2 miles (2 km) of leks could reduce barriers to  
24                  wild horse and burro movement as compared to Alternative A. Considering GRSG habitat  
25                  needs and risks when designing and locating new water developments may limit water  
26                  developments which could result in a need to reduce AMLs in HMAs where alternative water  
27                  sources are not available, especially in drought situations.

28                  ***Impacts from Recreation Management and Visitor Services***

29                  Impacts would be similar to those described under Alternative B. Seasonal and site-specific  
30                  limits on OHV travel in GRSG habitat could impact management options for gathers;  
31                  however, administrative access allowances may limit impacts. These restrictions also could  
32                  limit disturbances on wild horses and burros from other recreational users.

33                  ***Impacts from Lands and Realty Management***

34                  Under Alternative E, ROW avoidance areas in CHZ and IHZ, as well as the exclusion of  
35                  new infrastructure in CHZ, would somewhat limit the indirect impacts of development and  
36                  associated disturbance on wild horses and burros.

1       ***Impacts from Energy and Minerals Mineral Management***

2       Impacts from mineral and energy development are generally the same as those described  
3       under Alternative A. Fluid mineral development would have some additional restrictions  
4       applied to limit disturbance; therefore, the likelihood of development and associated  
5       disturbance would be reduced in areas with potential for these resources.

6                       **4.4.9 Alternative F**

7       ***Impacts from Vegetation Management***

8       Management actions under this alternative are similar to those described under Alternative  
9       B. For invasive species management, activities that spread invasives would be restricted. As  
10      described under the range management section, restrictions on water developments may  
11      apply, with potential impacts on wild horses and burros. However, there is the potential that  
12      less water would be necessary under Alternative F, due to the reduction in AMLs in the  
13      planning area.

14      ***Impacts from Wild Horse and Burro Management***

15      Under Alternative F, AMLs would be directly reduced by 25 percent for all HMAs within  
16      PHMA and GHMA. This would result in a reduction of the established AMLs for all HMAs  
17      that are located entirely or partially within mapped occupied GRSG habitat. As a result of  
18      AML reduction under Alternative F, costs of wild horse and burro management would  
19      increase, due to a need for additional horse gathers for removal and/or population growth  
20      suppression treatments. Location specific population reductions and impacts on particular  
21      HMAs would be determined at implementation and likely related to land health and current  
22      population size.

23      Other management actions for horse and burros and related impacts are similar in nature to  
24      those described under Alternative B.

25      ***Impacts from Wildland Fire Management***

26      Impacts from Wildland Fire Management are similar to those described under Alternative B  
27      and all action alternatives; actions to suppress and control the spread of wildfire under  
28      Alternative F could decrease the risk of disturbance from wildfire for HMAs in GRSG  
29      habitat. HMAs outside of GRSG habitat would be at a lower priority level for fire  
30      suppression efforts, and may have higher risk of loss of forage from fire.

31      Closures in place for livestock grazing post-fire until woody and herbaceous cover achieve  
32      GRSG habitat objectives could result in long-term (10 to 50 years or longer) exclusion from  
33      burned sites and barrier to movement for wild horses and burros, as it would generally take  
34      more than a decade to reestablish adequate Wyoming sage cover in low precipitation areas.  
35      The level of impacts would depend on locations, size, and intensity of wildfire in GRSG  
36      habitat in relation to location of HMAs.

37      ***Impacts from Livestock Grazing/Range Management***

38      Under Alternative F, 25 percent of the area in PHMA/GHMA open to livestock grazing  
39      would be rested each year and utilization would be limited to 25 percent of current levels;  
40      therefore AUMs for livestock would correspondingly be reduced. As described in

1 Alternative C, a reduction in areas available for livestock grazing could result in additional  
2 forage available for wild horses and burros. In addition, a prohibition on new water  
3 developments and requirements to make modifications, including potential dismantling of  
4 developments would be in place. As a result, there would likely be impacts on the availability  
5 of water sources for wild horses and burros. This could result in impacts on the ability to  
6 manage for AML, particularly for those HMAs with no alternate water source. Alternative F  
7 also calls for avoiding all new structural range developments in occupied GRSG habitat,  
8 unless independent peer-reviewed studies show that the range improvement structure  
9 benefits GRSG. In practice, this would result in few range developments being approved.  
10 The lack of new fences would benefit wild horses and burros by reducing barriers to  
11 movement across the range.

#### 12 ***Impacts from Recreation and Visitor Services Management***

13 Impacts are similar to those described under Alternative B.

#### 14 ***Impacts from Energy and Minerals Management***

15 Under Alternative F, no new mining claims would be allowed, and salable minerals sales  
16 would be prohibited in PHMA. Therefore, there would be limited potential from  
17 development-related disturbance of these resources on wild horses and burros. Impacts  
18 from leased fluid minerals are the same as those described under Alternative A. New leasing  
19 in PHMA and GHMA would be limited, so there is some limited opportunity for  
20 disturbance from development of these resources.

### 21 **4.4.10 Proposed Plan**

#### 22 ***Impacts from Lands and Realty Management***

23 Under the Proposed Plan, restrictions on disturbance would be prioritized based on GRSG  
24 habitat. The greatest restrictions on ROW development would occur in the HMAs within  
25 SFAs followed by PHMAs and IHMAs. While these restrictions would provide for the  
26 greatest protection of wild horse forage and water sources and would limit disturbance in  
27 SFAs, it would still allow development in areas outside of occupied GRSG habitat.

28 Under the Proposed Plan, PHMA and IHMA would be managed as ROW avoidance areas,  
29 but would be subject to RDFs, BMPs buffers, and a seasonal timing limitation, resulting in  
30 limited new development in GRSG habitat. As a result, disturbance of wild horses and  
31 forage from development activities, as discussed under *Nature and Type of Effects*, would be  
32 limited in GRSG habitat.

33 Implementing the GRSG mitigation strategy and monitoring framework under the Proposed  
34 Plan would ensure that this increased level of protection of forage and water resources and  
35 reduction of wild horse harassment would be maintained for HMAs within GRSG habitat.

#### 36 ***Impacts from Habitat Restoration and Vegetation Management***

37 Under the Proposed Plan, vegetation rehabilitation would emphasize projects in areas with  
38 potential to improve GRSG habitat. Conifer removal and noxious weed control as identified  
39 in **Tables 2-5** and **2-7** or the prioritization for treatment/restoration projects as identified in

1 the Wildfire, Invasive Annual Grasses and Conifer Expansion Assessment approach would  
2 improve forage conditions for wild horse in the long-term. In the short term, prescribed  
3 burns or other treatments may temporarily reduce available forage or disturb horses, but due  
4 to the restrictions on these activities, impacts are likely to be limited.

5 Implementing the GRSG mitigation strategy and monitoring framework responses under the  
6 Proposed Plan would ensure that this increased level of protection of forage and water  
7 resources and reduction of wild horse and burro harassment would be maintained.

8 Management changes in restoration or rehabilitation area could be required to maintain or  
9 improve GRSG habitat. This could result in potential need for reduction of wild horses and  
10 burro numbers within an HMA in order to meet vegetation objectives for GRSG.

### 11 ***Impacts from Wildland Fire Management***

12 Fuels projects and fire suppression to protect sagebrush ecosystems and associated GRSG  
13 habitat would benefit wild horses where HMAs overlap this habitat due to a reduction in the  
14 likelihood of high intensity wildfire.

15 Under the Proposed Plan, management actions for wildfire include an emphasis on fire  
16 suppression and reduction in fire risk in PHMA and IHMA with potential for reduction in  
17 fire risk and related disturbance of wild horses and forage in these areas. Wildland Fire,  
18 Invasive Annual Grasses and Conifer Expansion Assessments' identification of priority  
19 areas/treatment opportunities for fuels management, fire management, and restoration  
20 would further define areas for fire management activities. These actions may result in site-  
21 specific temporary exclusions of wild horses or reduced forage, but would help to reduce the  
22 likelihood of catastrophic wildfire and subsequent disturbance of wild horses and reduction  
23 of forage in the long-term.

24 Should HMAs contain high fire risk areas that are outside of the identified priority treatment  
25 areas, then these non-priority areas could be at an increased risk for wildfire, as treatment  
26 and suppression activities would be focused elsewhere. Impacts to forage or herd dispersal  
27 could occur in these areas if fires occur. Temporary or long-term management changes to  
28 wild horse management, such as emergency gathers, reduction in AML, or fencing blocking  
29 access to forage or water may be necessary to achieve and maintain the desired GRSG  
30 objectives post-fire. The degree of impacts would be determined by the location, size, and  
31 intensity of fires in GRSG habitat. Fencing to exclude livestock from post-burn areas could  
32 impact the ability of horses to roam freely. If exclusion reduces horses' ability to access water  
33 sources, ability to manage for AML could be affected, and animals may be removed from the  
34 range temporarily if adequate forage and alternate water sources cannot be supplied.

### 35 ***Impacts from Energy and Minerals Development***

36 Under the Proposed Plan energy and mineral development would have additional  
37 restrictions applied to limit disturbance on GRSG habitat as compared to Alternative A.  
38 Restrictions on development would be prioritized with the greatest restrictions in SFAs  
39 followed by PHMA, IHMA and GHMA. As a result the likelihood of development and  
40 associated disturbance of wild horses would be reduced in areas with potential for these

1 resources (with the most reduction in SFAs followed by PHMA, IHMA and GHMA) as  
2 compared with Alternative A. Due to the limited conflicts between wild horse management  
3 and energy development under existing conditions, however, impacts would be negligible.

4 ***Impacts from Travel and Transportation Management***

5 Under the Proposed Plan motorized travel would be limited to existing roads, primitive  
6 roads, and trails in PHMA and IHMA unless already designed as limited or closed. As a  
7 result, disturbance of wild horses and their forage and water sources from recreational traffic  
8 would be reduced as compared to Alternative A. Under the Proposed Plan, temporary  
9 closures would also be permitted as determined necessary for resource protection which  
10 would further reduce disturbance to wild horses and forage.

11 Specific implementation-level criteria to protect GRSG would also be applied, further  
12 limiting location of new roads and volume of traffic on new and existing roads. Site-specific  
13 travel management planning could, when completed, reduce the potential for conflicts  
14 between wild horses and recreation.

15 ***Impacts from Livestock Grazing Management***

16 Management to conserve, enhance, or restore GRSG habitat that benefits livestock forage  
17 would generally also benefit wild horses within GRSG habitat in the long term.

18 Livestock grazing permits and leases would be processed and land health assessment would  
19 occur in allotments most in need of habitat improvement with an emphasis on allotments in  
20 GRSG habitat, with SFAs prioritized over PHMA and then IHMA. As a result, range  
21 conditions for both livestock and wild horses overlapping these allotments should be  
22 improved concurrent with this priority order.

23 Modifying or eliminating livestock watering sites could reduce water availability for wild  
24 horses. This could result in the need to reduce wild horse numbers or develop alternative  
25 water sources within specific HMAs, especially during periods of drought.

26 ***Impacts from Wild Horse and Burro Management***

27 Under the Proposed Alternative, HMAPs would be amended to incorporate GRSG habitat  
28 objectives; therefore changes may be required to AMLs or wild horse and burro  
29 management in the long term in SFAs, PHMA and IHMA should these objectives not be  
30 met by current AMLs or management. The level of such changes or the specific HMA(s) in  
31 which changes may occur would be determined at implementation and would be influenced  
32 by site specific habitat conditions and land health.

33 Acres of SFA, PHMA, IHMA and GHMA in each HMA are displayed in **Table 4-69**,  
34 Proposed Plan GRSG Management Areas by HMA, below.

**Table 4-68**  
**Proposed Plan GRSG Management Areas by HMA**

HMA	Associated Conservation Area	SFA (acres)	PHMA (acres)	IHMA (acres)	GHMA (acres)
Black Mountain	West Owyhee	0	0	46,300	0
Challis	Mountain Valleys	109,400	104,800	51,400	250
Fourmile	Mountain Valleys	0	0	0	16,000
Hardtrigger	West Owyhee	0	0	60,200	0
Sands Basin	West Owyhee	0	0	9,500	0
Saylor Creek	West Owyhee	0	0	0	0

12

13

Prioritization of gathers within HMAs would directly and indirectly impact wild horses. SFAs would take priority for gathers, followed by PHMA and IHMA. The Challis HMA is the only HMA that falls within a SFA and would have the highest standing priority for gathers each year to maintain animals within the established AML. This focused management strategy would ensure that AML is maintained along with the necessary forage for the horses in this HMA; however it may increase the number of gathers needed and other intensive management to maintain AML thereby potentially increasing the disturbance to the populations as well as possible disruption of herd dynamics. This prioritized management strategy could also reduce ability to gather animals from lower prioritized HMAs and puts HMAs that fall within the lowest priority at risk for overpopulation; however, under this LUPA, provisions would allow for exceptions as needed for herd health-limiting impacts.

14

15

16

17

18

19

20

21

Authorization of new or modification of existing livestock watering sites that benefit or conserve PHMAs, IHMAs, and GHMAs within conservation areas would be expected to provide alternate sources of water for wild horses. Elimination of fencing or existing water sources that may be identified as impacting PHMAs and IHMAs could reduce or eliminate water availability resulting in a change in horse distribution and potential need for reduction of wild horse and burro numbers within an HMA. In addition, without adequate water sources, wild horses would be expected to stray outside HMAs in search of water, increasing cost of gathers for removal of nuisance animals outside HMAs or that occupy private land.

22

23

24

25

26

Finally, the BLM would continue to coordinate with professionals from other federal and state agencies, researchers at universities and others to utilize and evaluate new management tools (e.g. population growth suppression, inventory techniques and telemetry) for implementing the wild horse and burro program in order to ensure practical and efficient management of wild horses within AML while protecting GRSG habitat.

31

***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and Coordination***

Placing a 3 percent cap on anthropogenic disturbance at the BSU and project levels would generally result in a reduction in development in GRSG habitat and a related reduction in disturbance of wild horses. Anthropogenic disturbances in PHMA and IHMA would

1 additionally be mitigated to ensure a net conservation gain to GRSG habitat which indirectly  
2 protects wild horse forage.

3 Within a Conservation Area, if adaptive management soft triggers are met and wild horses  
4 are found to be factors in GRSG habitat not achieving or moving toward achieving  
5 objectives, the adjustment of wild horse and burro populations would be considered and  
6 could result in the reduction of AMLs in some HMAs in the long term.

7 Increased coordination between the BLM and Forest Service and adjacent land owners,  
8 federal and state agencies, local governments, tribes, communities, other agencies, Resource  
9 Advisory Councils, public land permit holders and non-governmental organizations would  
10 directly impact the conservation of GRSG habitat which would indirectly conserve forage  
11 for wild horses.

## 12 4.5 Wildland Fire Management

### 13 4.5.1 Methods and Assumptions

#### 14 *Indicators*

15 Indicators of impacts on wildland fire management are as follows:

- 16 • Alteration of vegetative cover that is likely to result in a  
17 substantial shift in fire regime condition class (FRCC) across the  
18 planning area
- 19 • A substantial change in the likelihood or severity of wildfire,  
20 based on level of restrictions on uses that may introduce sources  
21 of ignition
- 22 • Management actions that substantially inhibit a response to  
23 wildfire or appropriate treatments to prevent wildfire

#### 24 *Assumptions*

25 The analysis includes the following assumptions:

- 26 • The spread of invasive annuals (e.g., cheatgrass) has lengthened  
27 the fire season in many parts of the planning area. These species  
28 often cure sooner than native perennial species and are more  
29 prone to ignition. Therefore, actions that reduce the spread or  
30 footprint of invasive annuals or restore perennial vegetation  
31 communities would reduce the frequency and intensity of  
32 wildfires, while reducing wildfire management costs.
- 33 • Fuels treatments using chemical methods to control invasive  
34 annuals are likely to be the most effective in reducing fine fuels  
35 and fire intensity and severity.
- 36 • Fire is an important functional natural disturbance in many of  
37 the ecological systems found in the planning area.

- In many cases, a direct relationship exists between fuel loading and potential fire intensity and severity.

#### 4.5.2 Nature and Type of Effects

Impacts on wildfire management result from changes in fire frequency and intensity and the ability to employ fire-suppression methods, both of which would affect management of fire and related costs within the planning area. As discussed in **Section 3.7**, most of the lands in the decision area have moderate to high levels of departure from historic conditions and related fire risk. Actions that change condition class from highly altered ecosystems to one closer to historical conditions could reduce the risk of key ecosystem loss, as well as decrease fire risk and management costs in the long term.

Many different resource uses may introduce additional ignition sources into the planning area. This increases the probability of wildfire occurrence and the need for fire-suppression activities. Fire intensity can be affected by activities that decrease fuel loading, such as vegetation treatments and timber product harvesting, and activities that alter the composition and structure of vegetation communities. High-intensity fires generally result in a greater loss of vegetation cover, changes to soil chemistry, damage to root structures, and a greater ability for nonnative species to become established (Verma and Jayakumar 2012).

Transportation and travel management can impact fire frequency by changing the level of risk of human-caused ignitions. The risk of ignition is increased where travel is less restrictive, particularly where motorized vehicles travel cross-country. All forms of travel encourage the spread of invasive weeds, particularly cheatgrass, which can shift fire regimes and increase fire behavior potential. Conversely, if management were to restrict access, wildfire risk may decrease. In addition, transportation management may impact fire suppression; when routes are closed and rehabilitated, they become unavailable for response to wildfires, limiting access opportunities.

Similarly, the level and type of recreation permitted can impact fire risk. Increased recreation may increase the probability of unintentional fires from human-caused ignitions and the need for fire suppression. Recreation management may reduce this risk by providing targeted activities and outcomes.

Surface disturbance caused by development would generally contribute to the modification of the composition and structure of vegetation communities (including increases in noxious weed proliferation) around developed areas. This would then be more likely to fuel high-intensity fires, which could increase program costs because of the increased potential for fire.

Lands and realty actions may indirectly result in development and associated fire risk. For example, issuing ROWs can result in indirect impacts by increasing the risk of human-caused ignition should transmission lines, renewable energy projects, or other development be constructed.

Likewise, the development of energy and minerals may increase the risk of wildfires by introducing new ignition sources (Shlisky et al. 2007). Associated facilities, infrastructure, and

1 transmission lines can increase fire and fuels program costs, while decreasing fire  
2 management flexibility to respond to sub-regional conditions with regard to suppression  
3 options. Energy development also poses hazards to firefighters, including unknown toxins,  
4 facility protection, evacuation of industry personnel, and dangerous overhead power lines.  
5 Fire programs could incur additional costs to train firefighting personnel for emergency  
6 situations associated with energy development.

7 Additional limitations on mineral development would have an indirect effect of decreased  
8 fire. This would be due to less development, fewer vehicles, and less construction  
9 equipment, all of which would serve to decrease the chance of human ignition. Development  
10 of federal minerals underlying nonfederal lands may impact fire management on BLM-  
11 administered and National Forest System lands when developed. This is particularly the case  
12 when ownership is in a patchwork pattern, as fires ignited on nonfederal lands may quickly  
13 spread onto and impact BLM- administered and National Forest System lands.

14 Invasive species establishment or increase may follow construction and could impact fire  
15 management actions through increased risk of fire and need for fire management. If  
16 treatments in annual infested areas use an approved herbicide, those treatments would  
17 generally experience greater levels of success.

18 Prioritizing fuels treatments in areas dominated by invasive species would reduce the  
19 frequency and intensity of wildfire. The spread of invasive species, which cure earlier in the  
20 spring or summer, has lengthened the fire season in many parts of the planning area. If these  
21 areas revert to a perennial dominated community, the fire season would generally be  
22 shortened by two to four months, depending on moisture, weather, and other factors.

23 Biological treatments can impact the ability to manage fire as a natural process through  
24 changes in fine fuels availability (e.g., grasses). For example, livestock grazing temporarily  
25 reduces fuel loads, so retiring allotments may increase fuels in specific sites. Conversely,  
26 increasing AUMs could reduce fuel loads. However, grazing could spread invasive species.  
27 Mowing or herbicide applications may be better suited for long-term fuels management  
28 goals.

29 Vegetation and weed treatments that decrease standing vegetation could decrease the  
30 intensity of wildfires and allow fires to be more easily controlled. For example, efforts to  
31 reduce incursion of nonnative annual grasses (primarily cheatgrass) and proliferation of other  
32 noxious and invasive weeds would promote healthy plant communities and an associated  
33 lower risk of high-intensity wildfire (USGS 2006). Used appropriately, prescribed fire would  
34 be compatible with noxious weed control; however, the presence of noxious weeds and the  
35 potential of weeds to spread after a prescribed fire would need to be monitored on a site-  
36 specific basis; herbicide applications may be warranted to assist in successful treatments.  
37 Conversely, management actions that retain shrub and cover may increase fuel loading and  
38 the likelihood and intensity of wildfire.

39 Management actions that are intended to improve, create, or reestablish healthy ecological  
40 conditions in various vegetation types benefit the fire and fuels program in the long term.

1 They do this by promoting the most efficient use of fire and fuels management program  
2 resources. Conversely, prioritizing fire suppression can limit management options and  
3 increase costs for fire management programs.

4 Special designations, such as ACECs and sensitive resource management, can restrict fuels  
5 treatments on a site-specific basis. For example, in areas where preservation of particular  
6 species or habitats is emphasized, management options and fuels treatments may be limited.  
7 Conversely, restrictions on resource uses, such as travel and mineral extraction, in special  
8 designations areas could reduce fire risk in these locations.

9 Implementing management for the following resources would have negligible or would have  
10 no impact on wildfire management; therefore they are not discussed in detail: air quality, soil  
11 resources, water resources, cultural resources, paleontological resources, visual resources,  
12 wilderness characteristics, cave and karst resources, forestry, socioeconomics, and  
13 environmental justice.

#### 14 **4.5.3 Impacts on Wildland Fire Management Common to All Alternatives**

15 The nature and type of impacts described below are common to all alternatives, but the  
16 context and intensity may vary by alternative.

17 Impacts on wildland fire management common to all alternatives include changes in fire  
18 frequency and intensity, and the ability to use fire suppression methods, all of which would  
19 affect management of fire within the planning area. Many different resource uses may  
20 introduce additional ignition sources into the planning area, which increases the probability  
21 of wildfire occurrence and the need for fire suppression.

22 Fire intensity can be affected by activities that decrease fuel loading, such as vegetation  
23 treatments and timber product harvesting, and activities that alter the composition and  
24 structure of vegetation communities. High-intensity fires generally result in a greater loss of  
25 vegetation cover, changes to soil chemistry, damage to root structures, and a greater ability  
26 for nonnative species to become established. Resource and special designation restrictions  
27 may limit fire suppression tactics and fuels treatment methods.

#### 28 ***Impacts from Lands and Realty Management***

29 Under all alternatives, issuance of power line ROWs would increase access and program  
30 costs because of the increased potential for fire in the ROW. There may also be slightly  
31 higher risk of human-caused ignitions from construction, maintenance, and use of power  
32 line ROWs. As new ROWs are developed, additional fuels treatments are necessary to  
33 address potential impacts from wildland fires.

34 Critical infrastructure ROW corridors would need maintenance throughout their life to keep  
35 vegetation at a level that would moderate fire behavior and allow for some protection from  
36 an unplanned wildfire. Vegetation maintenance would ensure that critical infrastructure  
37 would not fail at a time of need, such as during a wildfire.

1       ***Impacts from Habitat Restoration and Vegetation Management***

2       Under all alternatives, the BLM and Forest Service would manipulate vegetation, use  
3       prescribed fire or manage unplanned wildfire for LUP objectives. This would affect the  
4       wildfire management program by reducing costs and potential for large, damaging wildland  
5       fires.

6       Vegetation treatments could also reduce fuel loading, which would affect fire intensity and  
7       allow fires to be more easily controlled.

8       ***Impacts from Invasive Species Management***

9       Under all alternatives, invasive species treatments could reduce fuel loading, which would  
10      affect fire intensity and allow fires to be more easily controlled.

11      ***Impacts from Wildland Fire Management***

12      Under all alternatives, management actions that are intended to improve, create, or  
13      reestablish healthy ecological conditions in various vegetation types would benefit the fire  
14      and fuels program. They would do this by promoting the most efficient use of fire and fuels  
15      fire management program resources. In addition, allowing a range of fuel treatment options  
16      and the possibility of unplanned wildfire for resource benefit provides needed management  
17      flexibility to reduce large fire costs and achieve fire and fuels goals and objectives.

18      ***Impacts from Minerals Management***

19      The development of minerals resources may increase the risk of wildfires by introducing new  
20      ignition sources, although initial mine development also removes fuel sources by stripping  
21      the immediate area of vegetation. Facilities, infrastructure, and transmission lines can  
22      increase fire and fuels program costs, while decreasing fire management flexibility with  
23      regard to suppression options. Energy development also poses hazards to firefighters,  
24      including unknown toxins, facility protection, evacuation of industry personnel, and  
25      dangerous overhead power lines. Fire programs could incur additional costs to train  
26      firefighting personnel for emergencies associated with energy development.

27      The road infrastructure supporting energy and minerals development would provide  
28      increased accessibility to remote areas for fire suppression. Roads also provide fuel breaks in  
29      the event of wildfire.

30      ***Impacts from Recreation and Visitor Services Management***

31      Under all alternatives, restrictions on recreation use would decrease the potential for human-  
32      caused ignition.

33      Transportation and recreation access also increase the risk of human-caused ignitions. All  
34      forms of travel encourage the spread of invasive weeds, particularly cheatgrass, which can  
35      shift fire regimes and increase fire behavior potential. When routes are closed and  
36      rehabilitated, they become unavailable for response to wildfires, limiting access opportunities  
37      and potentially delaying fire management actions.

1 ***Impacts from Livestock Grazing Management***

2 Under all alternatives, livestock grazing may reduce fuels loading in certain areas. The impact  
3 would be greatest where grass fuel types are the main carrier of the fire.

4 **4.5.4 Alternative A**

5 ***Impacts from Lands and Realty Management***

6 Current impacts would continue as would the increased risk of human-caused ignitions  
7 where power line ROWs are developed and operated.

8 ***Impacts from Habitat Restoration and Vegetation Management***

9 Vegetation management and weed treatments would continue to decrease both standing and  
10 downed vegetation (i.e., fuel load) across the planning area. This would decrease the intensity  
11 of wildfires and allow them to be more easily controlled. These activities would also modify  
12 the composition and structure of vegetation communities by creating mosaic vegetation  
13 patterns and natural fuel breaks and by promoting healthy, diverse vegetation communities  
14 that generally fuel low-intensity fires. Specifically, efforts to reduce the incursion of  
15 nonnative annual grasses (primarily cheatgrass), the encroachment of shrubby vegetation, the  
16 buildup of biomass in forested areas, and the proliferation of noxious and invasive weeds  
17 would help to achieve this effect. Similarly, treatments for habitat improvement and forage  
18 would reduce fuels and reduce the likelihood for stand-replacing fire.

19 ***Impacts from Invasive Species Management***

20 On average, the planning area would continue to experience a five- to seven-month fire  
21 season due to invasive annuals curing earlier than the perennial vegetation and being prone  
22 to ignition. Without targeted management actions in GRSG habitat to convert vegetation  
23 communities back to a perennial dominated community, there would continue to be an  
24 increased risk of wildfire over a longer period of time each year.

25 ***Impacts from Wildland Fire Management***

26 The wildland fire management program would continue to be impacted by the spread of  
27 invasive annuals, which results in a longer fire season and the need for more resources to  
28 respond. There would also be a continued decrease in the hazardous fuels reduction  
29 program's ability to maintain reactive suppression and rehabilitation efforts in the wildland-  
30 urban interface (WUI).

31 ***Impacts from Nonenergy Leasable Minerals Management***

32 Current impacts would continue and nonenergy mineral development would continue to  
33 pose an ignition risk.

34 ***Impacts from Locatable Minerals Management***

35 Current impacts would continue and locatable mineral extraction would continue to pose an  
36 ignition risk.

37 ***Impacts from Salable Minerals Management***

38 Current impacts would continue and mineral material disposal activities would continue to  
39 pose an ignition risk.

1       ***Impacts from Unleased Fluid Minerals Management***

2       Unleased fluid minerals management would continue to have no detrimental impact on fire  
3       risk or management because there would be no surface-disturbing activities from fluid  
4       mineral leasing or development.

5       ***Impacts from Leased Fluid Minerals Management***

6       Current impacts would continue and fluid mineral development would continue to pose an  
7       ignition risk.

8       ***Impacts from Recreation and Visitor Services Management***

9       Recreation use would continue to increase the risk of human-caused ignitions, especially in  
10      areas with high visitation.

11      ***Impacts from Livestock Grazing Management***

12      Grazing would continue to reduce fuels loading in certain areas. Impacts on the wildland fire  
13      management program would continue to be greatest where grass fuel types are the main  
14      carrier of the fire.

15      ***Impacts from Special Designations Management***

16      Current impacts would continue, and there would be less management flexibility for fuels  
17      treatments and wildfire response in existing ACECs.

18                   **4.5.5 Alternative B**

19      Management under Alternative B would focus on restrictions on resource uses and  
20      protection for and enhancement of sagebrush habitat. In general, this would reduce the risk  
21      of human-caused ignitions and would encourage a return to historic FRCC in sagebrush  
22      habitat. Use restrictions could also minimize the spread of invasive species by limiting  
23      human activities that disturb the soil disturbance or introduce seeds. This would likely  
24      reduce the frequency and intensity of wildfire. However, restrictions on response to wildfire  
25      could limit management options and increase costs for fire management programs.

26      ***Impacts from Lands and Realty Management***

27      Limiting new development in PHMA to existing footprints would reduce opportunities for  
28      human-caused ignitions. The rest of the decision area would continue to experience current  
29      levels of risk for human-caused ignitions and the resultant shift in FRCC.

30      ***Impacts from Habitat Restoration and Vegetation Management***

31      Prioritizing the reestablishment of sagebrush cover would promote a shift towards historic  
32      FRCC in sagebrush ecosystems. Vegetation treatments could reduce fuel loading, which  
33      would affect fire intensity and allow fires to be more easily controlled. Vegetation treatments  
34      also create early seral stage vegetation communities, which generally fuel low-intensity fires.

35      Active restoration of cheatgrass infestation areas in PHMA would result in less frequent or  
36      intense wildfires as native perennial species are reestablished.

1       ***Impacts from Invasive Species Management***

2       An increased potential for invasive species treatments in grazing allotments in PHMA would  
3       decrease the intensity of wildfires and allow fires to be more easily controlled.

4       ***Impacts from Wildland Fire Management***

5       Designing and implementing fuel breaks to protect existing sagebrush would discourage  
6       further shifts away from historic FRCC in these areas.

7       Using livestock in certain cases to reduce fine fuels would reduce the likelihood and severity  
8       of wildfire.

9       In PHMA, prioritizing suppression in GRSG habitat immediately after fire, and then  
10      property, could limit management options and increase costs for the fire management  
11      program. However, the focus on suppression could also limit expansion of cheatgrass  
12      because fire increases opportunities for invasive species, such as cheatgrass, to expand  
13      (Brooks et al. 2004).

14     As a last resort in PHMA, the use of prescribed fire for fuel breaks that would disrupt the  
15     fuel continuity across the landscape could be considered in stands where cheatgrass is a  
16     minor component in the understory. Although this action would only be undertaken if all  
17     other treatment options have been explored, it would reduce the likelihood and severity of  
18     wildfire.

19     If livestock grazing, travel management, and other activities were to affect the success of  
20     restoration projects, management could be changed to encourage a higher success rate. This  
21     would help stabilize shifts in FRCC and reduce the likelihood and severity of wildfire by  
22     implementing more successful restoration projects across the planning area.

23     ***Impacts from Nonenergy Leasable Minerals Management***

24     Prohibiting new leases in PHMA would reduce opportunities for human-caused ignitions.  
25     The rest of the decision area would continue to experience current levels of risk for human-  
26     caused ignitions and the resultant shift in FRCC.

27     ***Impacts from Locatable Minerals Management***

28     If PHMA is withdrawn from mineral entry, there would be fewer opportunities for human-  
29     caused ignitions.

30     ***Impacts from Salable Minerals Management***

31     Restoring salable mineral pits in PHMA would result in a temporary increase in the potential  
32     for human-caused ignitions. However, prohibiting mineral material sales in PHMA would  
33     reduce opportunities for human-caused ignitions over the long term.

34     Indirect impacts would reduce invasive species when salable mineral pits are restored. This  
35     would reduce the frequency and intensity of wildfire and promote the establishment of  
36     native perennial species that are less combustible.

1 ***Impacts from Unleased Fluid Minerals Management***

2 Closing PHMA to leasing and letting existing leases expire would reduce future  
3 opportunities for human-caused ignitions. Geophysical exploration, especially when using  
4 overland travel, could temporarily increase the potential human-caused ignitions.

5 Over the long term, closures would protect against nonnative invasive species introduction,  
6 which would reduce the frequency and intensity of wildfire.

7 ***Impacts from Leased Fluid Minerals Management***

8 Conservation measures in PHMA, including prohibiting new surface occupancy, would limit  
9 increased risk for human-caused ignitions.

10 ***Impacts from Recreation and Visitor Services Management***

11 Limiting special uses in PHMA to those that are neutral or beneficial to GRSG could result  
12 in use restrictions that may reduce the risk of human-caused ignitions.

13 ***Impacts from Livestock Grazing Management***

14 Potential restrictions on grazing, including retiring allotments, in PHMA could increase fine  
15 fuels and thus the severity of wildfires.

16 Evaluating, and potentially introducing, exotic grass seedings could increase the risk of  
17 wildfire, depending on the attributes of and range where the grass species is introduced.

18 Limiting the types of range improvements allowed in PHMA would decrease opportunities  
19 for human-caused ignitions during construction or maintenance.

20 ***Impacts from Special Designations Management***

21 Impacts are the same as under Alternative A.

22 **4.5.6 Alternative C**

23 The complete removal of livestock grazing would reduce weed spread via livestock vector  
24 and could increase fire intensity due to heavier fuel loads from lack of fuel removal. In the  
25 short term, fuel buildup might lead to bigger fires, while in the long term, if weed spread  
26 were reduced, fewer fires may result. Ultimately, the effect of no grazing on fire frequency  
27 would be dependent on weather conditions at the time of ignition.

28 ***Impacts from Lands and Realty Management***

29 Limiting development in occupied habitat to existing footprints would reduce opportunities  
30 for human-caused ignitions. The rest of the decision area would continue to experience  
31 current levels of risk for human-caused ignitions and the resultant shift in FRCC.

32 ***Impacts from Habitat Restoration and Vegetation Management***

33 Impacts are similar to those under Alternative B.

1       ***Impacts from Invasive Species Management***

2       There are no management actions for invasive species management, and impacts are the  
3       same as under Alternative A.

4       ***Impacts from Wildland Fire Management***

5       Impacts are similar to those under Alternative B, except that occupied habitat would be  
6       managed in good or better ecological condition to reduce the unnatural frequency and  
7       intensity of wildfire. In addition, removing grazing from GRSG habitat would limit the  
8       effectiveness of RFPAs because there would be fewer ranchers to serve as first responders  
9       and engage in implementing comprehensive fuel break strategies.

10       ***Impacts from Nonenergy Leasable Minerals Management***

11       Impacts are the same as under Alternative B.

12       ***Impacts from Locatable Minerals Management***

13       Impacts are the same as under Alternative B.

14       ***Impacts from Salable Minerals Management***

15       Impacts are similar to those under Alternative B.

16       ***Impacts from Unleased Fluid Minerals Management***

17       Impacts are similar to those under Alternative B.

18       ***Impacts from Leased Fluid Minerals Management***

19       Impacts are similar to those under Alternative B.

20       ***Impacts from Recreation and Visitor Services Management***

21       Impacts are similar to those under Alternative A.

22       ***Impacts from Livestock Grazing Management***

23       Eliminating grazing from the decision area would increase some pressures on the wildland  
24       fire management program, while lessening others. In either case, the impact would be  
25       greatest where grass fuel types are the main carrier of the fire. For example, in areas  
26       dominated by grass fuel types, there would be no reduction in fine fuels, and the frequency  
27       and intensity of wildfires would increase. However, because the prohibition on grazing  
28       would reduce weed spread, some areas, in conjunction with efforts to reintroduce perennial  
29       vegetation, may experience a shorter fire season and less frequent or intense wildfires.

30       ***Impacts from Special Designations Management***

31       Restrictions associated with the management of 39 new ACECs (covering 3.1 million acres  
32       of GRSG habitat) may limit fire suppression tactics and fuels treatment methods. ACEC  
33       designations may also result in fewer human ignitions due to restrictive management actions.

34               **4.5.7 Alternative D**

35       With an emphasis on balancing resources and resource use among competing human  
36       interests, land uses, and the conservation of natural resources, this alternative would reduce

1 FRCC shift and would result in a more natural (i.e., historic) frequency and intensity of  
2 wildfire.

### 3 ***Impacts from Lands and Realty Management***

4 Certain uses would be excluded in PHMA, reducing the type of development allowed in  
5 those areas. This restriction would limit opportunities for human-caused ignitions. There  
6 would be no similar restrictions in IHMA or GHMA, meaning the reduction in ignitions  
7 would be confined to a smaller area than under other alternatives.

### 8 ***Impacts from Habitat Restoration and Vegetation Management***

9 Alternative D proposes a more defined set of tools for wildfire management than other  
10 alternatives. In most instances, Alternative D allows for management flexibility to respond to  
11 sub-regional conditions in designing fuels treatments and response to wildfire. For example,  
12 in PHMA the use of chemical, mechanical, and seeding treatments with appropriate plant  
13 materials is emphasized to prevent the dominance of invasive weeds. This would allow a  
14 greater success of those treatments. Using mechanical and chemical treatments to prepare  
15 areas in FRCC2 and FRCC3 for prescribed fire would have a similar impact.

16 Strategic wildland fire planning would help return PHMA to historic FRCC and natural fire  
17 intensities and intervals. Key actions driving this impact are as follows:

- 18 • Strategically placed fire-resistant vegetation or green-strip  
19 seedings
- 20 • Strategically placed pretreated areas that reduce fine fuels by  
21 such practices as mowing vegetation along roadsides,  
22 implementing grazing strategies, and applying herbicides
- 23 • Planned wildfire suppression tactics in important GRSG habitat

24 Prioritizing wildfire suppression in PHMA and conducting burn-out/backfiring operations  
25 in a manner that minimizes the loss of sagebrush may have limited ability to restore historic  
26 FRCC in PHMA.

### 27 ***Impacts from Invasive Species Management***

28 Education, inventory, prevention, control, rehabilitation, and monitoring would be  
29 emphasized. By limiting the spread of invasive species, more GRSG-occupied habitat would  
30 be retained as a perennial-dominated community, which has a shorter fire season than those  
31 communities characterized by invasive annuals (which cure earlier in the year and are more  
32 prone to ignition).

### 33 ***Impacts from Wildland Fire Management***

34 Wildland fire management under Alternative D is similar to Alternative B, with additional  
35 management flexibility and guidance incorporated to tailor management to specific  
36 vegetation communities. The BLM and Forest Service would prioritize wildfire suppression  
37 planning and would consider targeted grazing to reduce fine fuels in PHMA. As a result,  
38 FRCC shift would be reduced and the frequency and intensity of wildland fire would be

1 more natural. This is because post-fuel, restoration, and ESR management would be  
2 designed to ensure long term persistence of seeded or pre-burn native plants.

3 Likewise, several actions would improve the success of fuels treatments in PHMA.  
4 Specifically, ensuring chemical applications are used in fuels treatments and pretreating areas  
5 to reduce fine fuels through mechanical treatments, grazing strategies, chemical or biological  
6 application would dramatically improve the fuel program's ability to improve GRSG habitat  
7 conditions.

8 When reseeding following fire, using species varieties that are adapted to a warmer climate  
9 may, in combination with potential climate change, reduce potential for unnatural levels of  
10 fire frequency and intensity.

11 Stationing first response firefighting resources to higher fire occurrence areas would reduce  
12 response time.

13 ***Impacts from Nonenergy Leasable Minerals Management***

14 Seasonal limitations and restrictions on development near leks would reduce the potential  
15 for human-caused ignitions.

16 ***Impacts from Locatable Minerals Management***

17 Valid claims would require additional mitigation within GRSG habitat, likely resulting in site-  
18 specific improvements to FRCC and wildfire intensity and frequency.

19 ***Impacts from Salable Minerals Management***

20 The types of impacts are similar to those under Alternative B, except that prohibitions on  
21 mineral material disposal would extend only to areas around occupied leks. This would  
22 reduce the area where there would be lower risk of human-caused ignitions.

23 ***Impacts from Unleased Fluid Minerals Management***

24 There would be several measures (e.g., TL and NSO stipulations and RDFs) restricting  
25 surface disturbance that would reduce the potential for human-caused ignitions.

26 ***Impacts from Leased Fluid Minerals Management***

27 Allowing exploration and drilling on leased areas in IHMA from July through November  
28 would increase the risk of human-caused ignitions. Off-site mitigation requirements for new  
29 developments in PHMA could encourage a return to historic FRCC in areas where  
30 mitigation is implemented.

31 ***Impacts from Recreation and Visitor Services Management***

32 Restricting SRPs in sensitive seasons or in PHMA could result in temporary and site-specific  
33 reductions in human-caused ignitions.

34 Minimizing adverse recreation effects on GRSG within recreation management areas that  
35 overlap PHMA could result in use restrictions that may reduce the risk of human-caused  
36 ignitions.

1       ***Impacts from Livestock Grazing Management***

2       Impacts are similar to those under Alternative B.

3       ***Impacts from Special Designations Management***

4       Impacts are the same as under Alternative A.

5                   **4.5.8   Alternative E**

6       Alternative E focuses primarily on management for the threats of wildfire, invasive species,  
7       and large infrastructure projects. Secondly it focuses on the threats of livestock grazing  
8       management and infrastructure, West Nile virus, and recreation. It recommends use of an  
9       adaptive management approach and implementation of triggers or thresholds that adjust  
10      zone criteria. Guidance to reduce wildfire response time, create fuel breaks, and improve the  
11      wildfire suppression baseline would increase demand on the wildland fire management  
12      program; however, it would result in long-term improvements in FRCC and lowered risk of  
13      wildfire.

14      ***Impacts from Lands and Realty Management***

15      Impacts are similar to those under Alternative B.

16      ***Impacts from Habitat Restoration and Vegetation Management***

17      Development of a restoration strategy for vegetation management would help focus  
18      priorities on the areas and communities identified as most pertinent to restoring sagebrush  
19      and GRSG habitat. This would constrain or reverse the current trend toward areas becoming  
20      dominated by invasive annuals that are more prone to ignition.

21      Native vegetation would be used for restoration to the extent practicable. In addition,  
22      invasive species would be controlled for three years after wildfire treatments. Together, these  
23      actions would reduce the likelihood for weed invasion in burned or treated areas, thus  
24      reducing the frequency and intensity of wildland fires.

25      In Utah, reducing or eliminating the spread of invasive species, particularly cheatgrass, after a  
26      wildfire, is a high priority. If the spread of cheatgrass is slowed or stopped, these areas would  
27      be at lower risk for intense large-scale fires.

28      ***Impacts from Invasive Species Management***

29      This alternative promotes active and aggressive control of invasive species, which would  
30      likely reduce the likelihood of large-scale wildfires.

31      Eradicating or controlling invasive weeds in GHMA may help some areas revert to perennial  
32      vegetation types, which would shorten the fire season and reduce the risk of large-scale  
33      wildfires.

34      Weed treatments in IHMA and GHMA would decrease fuel loads and vegetation density  
35      across these areas. Management flexibility would decrease the intensity of wildfires and allow  
36      them to be more easily controlled. Likewise, in IHMA, the use of chemical and mechanical

1 methods to eradicate or control invasive species would result in more successful treatments  
2 and long-term reduction in fire frequency and intensity.

3 ***Impacts from Wildland Fire Management***

4 Reducing the number and size of wildfires in PHMA (in accordance with updated IM 2013-  
5 128) would allow for more efficient management of wildfire program resources and would  
6 reduce risks to firefighters and public safety. The adaptive construct of Governor's  
7 Alternative provides a mechanism to protect GRSG from habitat loss due to wildfire. The  
8 short-term use of triggers and zones will provide the time to develop more proactive  
9 measures that demonstrate long-term success on the landscape. Fuel breaks will be  
10 implemented in priority areas to minimize the size of wildfires and reduce need for  
11 firefighting resources.

12 Close coordination with federal, state, and private firefighting personnel, local fire  
13 departments and local expertise, such as RFPAs, will improve strategies for initial attack and  
14 developing comprehensive fuel break strategies to minimize and reduce the size of wildfires  
15 threatening the PHMA and IHMA following ignition. The employment of specific, more  
16 aggressive wildlife and invasive species management practices to prevent further  
17 encroachment into the PHMA and IHMA should be driven by local planning efforts at the  
18 field office and ranger district level. The creation of RFPAs will ensure better and faster  
19 initial attack on wildfires threatening the PHMA and IHMA through the employment of  
20 additional trained firefighters and resources in rural parts of the GRSG Management Area.  
21 This management action is more likely to be used on areas with high fuel loads that are at a  
22 high risk of fire threatening PHMA and IHMA.

23 ***Impacts from Nonenergy Leasable Minerals Management***

24 There would be over 2 million acres of GRSG habitat closed to leasing and nonenergy  
25 minerals development. This would prevent any human-caused ignitions in this area. In areas  
26 open to leasing there would be multiple restrictions (e.g., timing, locational, and a five  
27 percent disturbance cap within nesting, winter, or other habitat in priority habitats) on  
28 development that would reduce the potential for human-caused ignitions.

29 ***Impacts from Locatable Minerals Management***

30 Impacts are the same as under Alternative A.

31 ***Impacts from Salable Minerals Management***

32 Impacts in Idaho are the same as under Alternative A. In Utah, restrictions near leks and  
33 during certain times of the year would reduce the potential for human-caused ignitions.

34 ***Impacts from Unleased Fluid Minerals Management***

35 Impacts in Idaho are the same as under Alternative A. In Utah, restrictions near leks and  
36 during certain times of the year would reduce the potential for human-caused ignitions.

1       ***Impacts from Leased Fluid Minerals Management***

2       Impacts in Utah are similar to those under Alternative A. In PHMA and IHMA in Idaho,  
3       restrictions on development would result in the same type of impacts as described under  
4       Alternatives B and D.

5       ***Impacts from Recreation and Visitor Services Management***

6       There would be numerous site-specific and seasonal restrictions on recreation facilities and  
7       activities near leks and during nesting, winter, and other priority habitats. These restrictions  
8       would limit human activity and the associated ignition risks.

9       ***Impacts from Livestock Grazing Management***

10       Targeted grazing would be allowed to reduce fine fuels, resulting in less need for mechanical  
11       or chemical fuels treatments. However, efforts to reduce grazing in PHMA and IHMA may  
12       increase fuels loading if they overlap with areas where grass fuel types are the main carrier of  
13       fire.

14       In Idaho PHMA, improving management of livestock in existing disturbed sites (e.g.,  
15       seedings or cheatgrass sites) would complement hazardous fuels reduction program efforts,  
16       especially if the targeted grazing were to occur in the WUI.

17       ***Impacts from Special Designations Management***

18       Impacts are the same as under Alternative A.

19               **4.5.9 Alternative F**

20       Alternative F closely mirrors management direction proposed in Alternative B but prescribes  
21       additional and more restrictive conservation measures. These measures would generally  
22       reduce the risk of human-caused ignitions but may reduce management flexibility for fuels  
23       treatments and other actions to reduce the long-term risk of wildfire.

24       ***Impacts from Lands and Realty Management***

25       Impacts are similar to those described under Alternative B; however, Alternative F would  
26       not allow for exceptions to disposal criteria, which would reduce management flexibility and  
27       could have implications for fuels treatment effectiveness. Managing priority areas as  
28       exclusion areas for new ROW permits would reduce the amount of ROW development and  
29       associated risk for human-caused ignitions.

30       ***Impacts from Habitat Restoration and Vegetation Management***

31       Impacts are the same as those described under Alternative C.

32       ***Impacts from Invasive Species Management***

33       There would be little emphasis on treatments or other methods of invasive species control  
34       and consequently a greater risk for increased fuel load and vegetation density across the  
35       decision area. Areas dominated by invasive annuals would experience a longer fire season,  
36       increasing wildfire management costs.

1       ***Impacts from Wildland Fire Management***

2       Wildland fire management under Alternative F would be similar to Alternative B, though  
3       Alternative F would require post-fire exclusion of grazing. Constructing livestock enclosures  
4       to monitor fire restoration progress would lead to more efficient fire restoration methods  
5       and associated improvements in wildland fire program resource allocations. Mowing grass in  
6       any fuel break may be less effective than other mechanical methods. This could result in less  
7       of a reduction in large fire costs than under other alternatives where there is greater  
8       management flexibility.

9       Impacts from RFPAs would be similar to those described under Alternative E, but their  
10      effectiveness may be limited due to a 25 percent reduction in grazing that will result in fewer  
11      ranchers to serve as first responders.

12      ***Impacts from Nonenergy Leasable Minerals Management***

13      Impacts are the same as under Alternative B.

14      ***Impacts from Locatable Minerals Management***

15      Impacts are the same as under Alternative B.

16      ***Impacts from Salable Minerals Management***

17      Impacts are the same as under Alternative B.

18      ***Impacts from Unleased Fluid Minerals Management***

19      Allowing existing leases to expire would reduce the long-term potential for human-caused  
20      ignitions. Geophysical exploration, especially when using overland travel, could temporarily  
21      increase the potential human-caused ignitions.

22      ***Impacts from Leased Fluid Minerals Management***

23      Impacts are the same as under Alternative B.

24      ***Impacts from Recreation and Visitor Services Management***

25      Impacts are the same as under Alternative B.

26      ***Impacts from Livestock Grazing Management***

27      Impacts are the same as Alternative B except that AUMs would be reduced, meaning  
28      impacts from livestock grazing may decrease in intensity. The exact location of reduction in  
29      AUMs and related impacts from livestock grazing would be determined at project  
30      implementation.

31      ***Impacts from Special Designations Management***

32      Designating 17 or 18 new ACECs and 12 new ZAs encompassing up to over 1 million acres  
33      of GRSG habitat would result in impacts similar to those under Alternative C, but they  
34      would occur over a larger area.

1       **4.5.10 Proposed Plan**

2       With an emphasis on balancing resources and resource use among competing human  
3       interests, land uses, and the conservation of natural resources, the proposed plan would  
4       reduce FRCC shift and would result in a more natural (i.e., historic) frequency and intensity  
5       of wildfire.

6       ***Impacts from Lands and Realty Management***

7       Certain uses would be excluded in PHMA and avoided in IHMA, reducing the type of  
8       development allowed in those areas. These restrictions would limit opportunities for human-  
9       caused ignitions. There would be no similar restrictions in GHMA, meaning the reduction in  
10      ignitions would be confined to a smaller area than under some other alternatives.

11      ***Impacts from Habitat Restoration and Vegetation Management***

12      The proposed plan uses a more defined set of tools for wildfire management than other  
13      alternatives. In most instances, the proposed plan allows for management flexibility to  
14      respond to sub-regional conditions in designing fuels treatments and response to wildfire.  
15      For example, in PHMA the use of chemical, mechanical, prescribed fire and seeding  
16      treatments with appropriate plant materials is emphasized to prevent the dominance of  
17      invasive weeds. This would allow a greater success of those treatments.

18      Strategic wildland fire planning would help return PHMA to historic FRCC and natural fire  
19      intensities and intervals. Key actions driving this impact are as follows:

- 20           • Strategically placed fuel breaks instead of fire-resistant vegetation or green-strip  
21           seedings
- 22           • Strategically placed pretreated areas that reduce fine fuels by such practices as  
23           mowing vegetation along roadsides, implementing biological treatments, seeding  
24           perennial species, and applying herbicides
- 25           • Planned wildfire suppression tactics in important GRSG habitat

26      Prioritizing wildfire suppression in PHMA and conducting burn-out/backfiring operations  
27      in a manner that minimizes the loss of sagebrush may have limited ability to restore historic  
28      FRCC in PHMA.

29      Education, inventory, prevention, control, rehabilitation, and monitoring would be  
30      emphasized. By limiting the spread of invasive species, more GRSG-occupied habitat would  
31      be retained as a perennial-dominated community, which has a shorter fire season than those  
32      communities characterized by invasive annuals (which cure earlier in the year and are more  
33      prone to ignition).

34      ***Impacts from Wildland Fire Management***

35      Wildland fire management under the proposed plan is similar to Alternatives B and D, with  
36      additional management flexibility and guidance incorporated to tailor management to  
37      specific vegetation communities. The BLM and Forest Service would prioritize wildfire  
38      suppression planning and would consider fuels management treatments to reduce invasive

1 species in GRSG habitat. As a result, FRCC shift would be reduced and the frequency and  
2 intensity of wildland fire would be more natural. This is because post-fuel, restoration, and  
3 ESR management would be designed to ensure long term persistence of seeded or pre-burn  
4 native plants.

5 The Proposed Plan would include GRSG Wildfire, Invasive Annual Grasses and Conifer  
6 Expansion Assessment (**Appendix D**). This assessment process sets the stage for identifying  
7 important GRSG occupied habitats and baseline data layers important in defining and  
8 prioritizing GRSG habitats. It would determine potential landscape scale management  
9 strategies by considering resilience to disturbance, resistance to invasive annual grasses, and  
10 GRSG landcover requirements. The management strategies considered in the assessment to  
11 increase GRSG habitat at landscape scales included; conservation, prevention, restoration,  
12 and monitoring and adaptive management. The strategies are adapted for fire operations  
13 (preparedness, suppression, and prevention activities), fuels management, post-fire  
14 rehabilitation, and habitat restoration.

15 Creating and maintaining effective fuel treatments in strategic locations, prioritizing  
16 suppression of fires, in accordance with the GRSG Wildfire, Invasive Annual Grasses and  
17 Conifer Expansion Assessment (**Appendix D**), for conservation and protection during fire  
18 operations and fuels management decision-making. Compared to Alternative D, this would  
19 reduce the size and intensity of wildland fires but would result in an increase in both fuels  
20 management and fire suppression costs.

21 Likewise, several actions would improve the success of fuels treatments in PPMA.  
22 Specifically, ensuring chemical applications are used in fuels treatments and pretreating areas  
23 to reduce invasive species through biological and mechanical treatments and chemical or  
24 biological application would dramatically improve the fuel program's ability to improve  
25 GRSG habitat conditions.

26 When reseeding following fire, using species varieties that are adapted to a warmer climate  
27 may, in combination with potential climate change, reduce potential for unnatural levels of  
28 fire frequency and intensity.

29 Stationing first response firefighting resources closer to higher fire occurrence areas would  
30 reduce response time.

31 Rural fire protection coordination would be stronger under the proposed plan than under  
32 any other alternative. Developing and implementing Rangeland Fire Protection Associations  
33 in coordination with the state would result in a more consistent inter-agency approach to  
34 wildland fire management. As a result, each agency's fire management team would deploy  
35 resources in a consistent manner, helping the BLM's fire and fuels program operate more  
36 efficiently.

37 Management under the Proposed Plan would prescribe added measure for analysis of  
38 prescribed fire and alternate uses of prescribed fire through site specific NEPA analysis. The  
39 proposed plan includes added measures for fuels treatment effectiveness and post fire

1 rehabilitation activities and monitoring. These added measures would increase both fuels  
2 management planning and post fire rehabilitation costs, but would increase the awareness  
3 and encourage partnerships with other agencies and resource programs.

4 ***Impacts from Non-Energy Leasable Minerals Management***

5 Seasonal limitations and restrictions on development in PHMA and in IHMA and GHMA  
6 outside of known phosphate leasing areas would reduce the potential for human-caused  
7 ignitions.

8 ***Impacts from Locatable Minerals Management***

9 Valid claims would require additional mitigation within GRSG habitat, likely resulting in site-  
10 specific improvements to FRCC and wildfire intensity and frequency. Recommending SFAs  
11 for withdrawal from mineral entry would have similar impacts if those lands are withdrawn.

12 ***Impacts from Salable Minerals Management***

13 Restoring salable mineral pits in GRSG habitat would result in a temporary increase in the  
14 potential for human-caused ignitions. Restoration would reduce invasive species, though.  
15 Over the long term, this would reduce the frequency and intensity of wildfire and promote  
16 the establishment of native perennial species that are less combustible.

17 ***Prohibiting mineral material sales in PHMA would also reduce opportunities for***  
18 ***human-caused ignitions over the long term.***  
19 ***Impacts from Fluid Minerals***  
20 ***Management***

21 There would be several measures (e.g., TL and NSO stipulations and RDFs) restricting  
22 surface disturbance that would reduce the potential for human-caused ignitions. These  
23 restrictions would be most effective in SFAs where waivers, exceptions, and modifications  
24 would not be allowed for the NSO stipulation. Not allowing modifications or waivers to  
25 NSO stipulations in PHMA would also likely reduce the potential for human-caused  
26 ignitions in those areas. COAs on post-leasing activity would have a similar impact on the  
27 fire and fuels program. Applying CSU stipulations and timing limitations in GHMA would  
28 be less effective at reducing the potential for ignitions because development would be  
restricted but not prohibited.

29 ***Impacts from Livestock Grazing Management***

30 Potential restrictions on grazing, including retiring allotments, in PHMA could increase fine  
31 fuels and thus the severity of wildfires.

32 Evaluating, and potentially introducing, exotic grass seedings could increase the risk of  
33 wildfire, depending on the attributes of and range where the grass species is introduced.

34 Limiting the types of range improvements allowed in PHMA would decrease opportunities  
35 for human-caused ignitions during construction or maintenance.

36 ***Impacts from Special Designations Management***

37 Current impacts would continue, and there would be less management flexibility for fuels  
38 treatments and wildfire response in existing ACECs.

1       ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and***  
2       ***Coordination***

3       Anthropogenic disturbance excludes habitat disturbance from wildfire and fuels  
4       management activities; therefore the wildland fire and fuels program will retain management  
5       flexibility and a greater chance to meet goals and objectives over the life of the plan. The 3  
6       percent anthropogenic disturbance cap should limit human-caused ignitions in GRSG  
7       habitat over the long-term and decrease the probability of wildfire occurrence and the need  
8       for fire-suppression activities. Coordination with other land management agencies and  
9       landowners may promote improved habitat conditions across land management boundaries,  
10      thus improving the efficiency and effectiveness of fire and fuels treatments across the  
11      landscape. Additionally, implementation of the Wildfire, Invasive Annual Grasses and  
12      Conifer Expansion Assessment will improve wildland fire management across the landscape  
13      via improved coordination across agencies.

14   **4.6   Livestock Grazing/Range Management**

15               **4.6.1   Methods and Assumptions**

16               ***Indicators***

17               Indicators of impacts livestock grazing/range management are as follows:

- 18                       • Changes in permitted AUMs in areas open to livestock grazing
- 19                       • Changes in the kind of livestock permitted on allotments
- 20                       • Prohibitions or limitations on the construction or maintenance  
21                       of structural and nonstructural range improvements
- 22                       • Modifications to or removal of structural range improvements
- 23                       • Closures of areas to livestock grazing for the life of the plan
- 24                       • Changes to the timing, duration, intensity or frequency of  
25                       permitted use, including temporary closures
- 26                       • Changes in livestock management requirements
- 27                       • Changes in quality or availability of forage and water for  
28                       livestock

29               ***Assumptions***

30               The analysis includes the following assumptions:

- 31                       • All new and renewed leases and permits would be subject to  
32                       terms and conditions determined to be necessary by the  
33                       authorizing officer to achieve the applicable management and  
34                       GRSG habitat objectives for BLM and National Forest System  
35                       lands and to meet land health standards for BLM lands and  
36                       desired conditions on National Forest System lands (see **Tables**  
37                       **2-3** and **2-6**).

- The construction and maintenance of range improvements would continue in the decision area, and would vary according to the constraints imposed by each alternative. New range improvements would be subject to limitations and may require additional maintenance, as defined in the plan. Range improvements are generally intended to improve livestock distribution and management, which would maintain or improve rangeland health and could benefit the forage base and wildlife and GRSG habitat.
- By definition in this plan, livestock grazing and construction and maintenance of associated range improvements are not considered to be surface-disturbing activities and are not included in the calculations for the disturbance threshold under Alternatives B, C, F, and the Proposed Plan, but it could affect the surface in areas where livestock concentrate, such as near water sources. Construction and maintenance of range improvements may result in limited temporary vegetation disturbance.
- If the ability to construct range improvements is limited, livestock grazing management options would be reduced.
- Livestock grazing directly affects specific GRSG habitat objective attributes, and does not affect, or only indirectly affects other GRSG habitat objectives. Modification of livestock grazing to benefit GRSG would be designed and implemented based upon meeting or making progress towards habitat objectives that are affected by livestock grazing. Modification or cessation of livestock grazing alone may not be adequate to make progress towards meeting habitat objectives, depending upon site history, current conditions, and the habitat objectives not being met.

#### 4.6.2 Nature and Type of Effects

Impacts on livestock grazing are generally the result of activities that affect forage production, areas open to grazing, the class of livestock, the season of use and timing, the ability to construct and maintain range improvements, and impacts from human disturbance, including disruption of livestock movement or unwanted dispersal. Key types of impacts are detailed below.

Protecting GRSG habitat may directly affect livestock grazing if management requires limitations to areas open to grazing or available AUMs, modification of grazing strategies, or changes to season of use. This could increase the time and costs to permittees and lessees. For example, management actions to enhance habitat for GRSG could affect livestock

1 grazing by restricting grazing intensity or season of use, closing areas to grazing, or changing  
2 livestock rotation patterns in order to maintain residual herbaceous cover in sagebrush  
3 habitat (NTT 2011). The listed restrictions could also decrease opportunities for grazing, or  
4 even overall grazing operation viability (e.g., if no spring grazing areas are available).

5 However, managing vegetation to benefit GRSG may indirectly benefit livestock grazing by  
6 increasing herbaceous vegetation productivity and improving forage in the long term. This  
7 would be the case especially where current conditions are not meeting land health standards.  
8 For example, in allotments with a history of intensive grazing, transitions in the composition  
9 of sagebrush communities may have occurred that have reduced cover or forage for GRSG  
10 (Cagney et al. 2010) and forage for livestock. When grazing management is modified to  
11 promote health and vigor of the herbaceous community and meet sage-grouse habitat  
12 objectives, this may also result in increased amounts of palatable livestock forage. In general,  
13 when forage is abundant and easily available, livestock performance is higher; diverse or  
14 heterogeneous rangeland vegetation is also associated with improved livestock performance  
15 (Bailey 2005).

16 Some areas would not make progress towards meeting sage-grouse habitat objectives  
17 through modification or even cessation of livestock management due to dominance of non-  
18 native vegetation, recurring wildfire, and/or inadequate seedbanks of desirable species, and  
19 would require additional active restoration, such as reseeding native grasses and forbs or  
20 controlling invasive species or fire suppression. Effects of restoration and fire suppression  
21 actions on livestock grazing are addressed in the corresponding sections of this EIS.

22 Managing livestock grazing so that riparian and wetland systems maintain proper functioning  
23 condition (PFC) is required for BLM lands. Unregimented livestock grazing can have  
24 adverse impacts on riparian and wetland ecosystems (Armour et al. 1991); therefore,  
25 managing these ecosystems can directly impact livestock grazing through excluding livestock  
26 at specific sites, increasing herding, adding range improvements (such as cross fences and  
27 water gaps), and adjusting season of use and livestock numbers. Improvements in riparian  
28 and wetland conditions benefit grazing livestock by indirectly providing cleaner and more  
29 reliable water sources and more dependable forage availability. The BLM has been  
30 implementing grazing management to make progress towards PFC in riparian and wetland  
31 areas since at least 1997; however additional impacts to livestock grazing could occur as  
32 additional riparian/wetland management needs are identified and implemented.

33 Protecting water quality and watershed health is a requirement of standards and guidelines as  
34 well as state and federal water quality standards. If additional management needs are  
35 identified and implemented, changes could be required in livestock management, such as  
36 deferring or shortening grazing periods, adding range improvements, excluding grazing from  
37 riparian areas, establishing riparian pastures, and increasing livestock herding. In areas  
38 requiring exclusion of livestock or other restriction on livestock management, these  
39 limitations could have economic impacts to permittees and lessees as a result of reduced  
40 AUMs or livestock numbers, changes in season that impact overall ranch operations, or  
41 increased livestock management costs such as increased herding.

1 Recreation can affect livestock grazing directly through human disturbance and indirectly  
2 through rangeland degradation. Direct disturbance can include undesired animal dispersing  
3 or trespassing due to recreationists leaving gates open as well as animal displacement,  
4 harassment, or injury from collisions or shooting. Direct disturbance can also include  
5 damage to range improvements, particularly from the use of recreational vehicles or from  
6 sport shooting. Disturbance could occur during the hunting season due to increased  
7 presence of people, vehicles, and noise. Limitations on recreation in GRSG habitat could  
8 indirectly benefit livestock by reducing direct disturbances, but could also concentrate use in  
9 grazing allotments outside GRSG habitat, leading to more conflicts in those areas.

10 Other direct long-term recreation impacts include disturbance caused by increased levels of  
11 human activities. The degree of impacts would vary with the intensity of recreation (that is,  
12 large numbers of people attending an event under a special recreation permit (SRP) use  
13 would likely have a higher level of disturbance than frequent use by a small number of  
14 visitors), the timing of recreation (for example, livestock could be more susceptible to  
15 disturbance during calving or lambing periods), and location of recreation in the allotment  
16 (for example, disturbance could be more problematic if it occurs near areas frequented by  
17 livestock, such as water sources or salt licks). As stated above, limitations on recreation in  
18 GRSG habitat could indirectly benefit livestock by reducing direct disturbances.

19 Limits on construction or use of transportation routes may affect livestock grazing practices.  
20 Road construction may cause loss of forage, harassment, and displacement; thus, reduction  
21 of these activities may benefit livestock by reducing disturbances. Closing roads or trails not  
22 used for livestock management would also increase forage availability when the area is  
23 rehabilitated or when natural rehabilitation occurs. Limitations on cross-country travel may  
24 impact permittees' and lessees' ability to effectively manage livestock if administrative access  
25 is not granted for allotment management purposes. Travel management actions for GRSG  
26 protection generally involve increased limitations or restrictions on vehicular travel.

27 Wildfire alters sagebrush habitat because sagebrush takes a long time to regenerate and  
28 invasive annual grasses such as cheatgrass are adapted to frequent wildfire. In the absence of  
29 a robust perennial grass component, invasive annual grasses are likely to dominate these  
30 systems following wildfire (NTT 2011). Wildland or prescribed fire would remove vegetation  
31 and forage over the short term; however, they can increase forage a few years post-fire as  
32 herbaceous vegetation increases and woody vegetation is removed or reduced. Impacts on  
33 livestock operations could also occur when agency policies require a rest period following  
34 post-fire rehabilitation and before grazing is reintroduced.

35 Changes in wildfire suppression and fuels management to protect GRSG habitat would have  
36 varying effects on livestock grazing. Measures to protect sagebrush habitat might reduce the  
37 spread of wildfire and the associated disruption to grazing during suppression and post-fire  
38 rehabilitation activities. Use of livestock to manage fuel loads may provide some increased  
39 opportunities for grazing at a site-specific scale and on a temporary basis.

40 The management of habitat for GRSG using natural disturbance regimes, such as fire, and  
41 using vegetative treatments to achieve biodiversity objectives and improve plant community

1 resilience could also benefit livestock grazing in the long term by maintaining a balance of  
2 seral stages that provide a heterogeneous forage base. In general, removing encroaching  
3 junipers benefits livestock grazing by maintaining the herbaceous components of the treated  
4 area.

5 Restrictions on ROWs or land transfers may indirectly impact grazing by reducing  
6 construction impacts from developing these ROWs (such as dust, displacement, and  
7 introduction of noxious weeds). Lands and realty actions taken to protect GRSG habitat  
8 would involve avoiding or excluding ROWs (e.g., for power lines, pipelines, and other  
9 structures) or land transfers in GRSG habitat. These measures could slightly decrease  
10 disturbance in these areas. However, the areas outside of GRSG habitat to which ROWs  
11 development may be relocated could see an increase in construction-related effects and  
12 associated disturbance or displacement of livestock.

13 Energy and mineral development could impact grazing. During the exploration and testing  
14 phase of mineral development, the footprint of disturbance is usually small and localized;  
15 therefore, minimal acres available for grazing would be directly impacted. However, during  
16 the exploration phase, impacts on livestock dispersal and trespass could occur, increasing  
17 time and cost to permittees and lessees. Outside of the exploration and testing phase,  
18 surface-disturbing mineral development directly affects areas of grazing in the short term  
19 during construction of well pads, roads, pipelines, and other facilities. A potential impact is  
20 an increased potential for the introduction and proliferation of noxious weeds that lack the  
21 nutritional value needed for productive grazing practices. Mining can also introduce heavy  
22 metals into the environment, where they can concentrate in forage plants, or contaminate  
23 waters, possibly impacting livestock health (Fessler 2003). Other potential impacts are  
24 changes in available forage, limits on livestock movement, harassment, and temporary  
25 displacement of livestock. In the long term, a smaller amount of grazing acreage is  
26 permanently lost from mining following rehabilitation. Improving roads associated with  
27 mineral development could facilitate livestock management operations by maintaining or  
28 improving access to remote locations within allotments. Properly implemented BMPs and  
29 reclamation mitigation measures would likely maintain rangeland health and forage levels for  
30 livestock. Reducing mineral development in GRSG habitat could reduce potential impacts  
31 on grazing, described above.

32 Changes in livestock grazing management could impact grazing opportunities in a variety of  
33 ways. For example, implementing particular livestock grazing management requirements to  
34 benefit GRSG could affect livestock grazing by increasing operators' costs or changing  
35 required management actions. Some management requirements may result in short-term and  
36 long-term increased costs or decreased AUMs for some permittees and lessees due to the  
37 following:

- 38 • Implementation of modification of a grazing strategy
- 39 • Change in season-of-use or livestock class
- 40 • Construction or modification of range improvements, when ability to  
41 disperse livestock is impacted

- Viability of existing operations could be compromised if seasons or areas of use are eliminated or severely restricted from grazing

These management requirements could result in economic impacts on individuals and the community at large, both direct and indirect. For example, if a ranch were dependent seasonally on forage on BLM and National Forest System lands, a reduction or elimination of AUMs on BLM and National Forest System lands may affect the entire ranching operation by reducing the total amount of available forage (Torell et al. 2002). Socioeconomic effects of changes in livestock grazing are discussed in more detail in the socioeconomics section of this EIS.

Some management changes may require a short-term output of cost for permittees and lessees and/or agencies but will result in long-term benefits. For example, construction of range improvements to improve livestock distribution and allow for uniform use of the rangeland would generally enhance rangeland health in the long term; however, it would have short-term costs. Constructing off-site water sources and fencing riparian and spring sources could keep livestock away from sensitive riparian areas and provide a cleaner more reliable source of water for livestock; however, it would represent an increased cost for permittees and lessees. Other requirements could increase annual operating costs, such as increased time feeding animals on private land, transporting animals to alternate grazing lands, more complex pasture rotations or herding requiring increased labor and fuels costs for moving animals, or annually maintaining let-down fences. In instances where an allotment is closed to grazing or AUMs reduced to meet GRSG objectives, the permittee or lessee may be eligible for compensation for the value of range improvement projects constructed under a range improvement permit or cooperative agreement, in accordance with 43 CFR 4120.3-6(c), and 36 CFR 222.6 (a).

ACECs may be designated to protect sensitive habitat for the benefit of GRSG. Grazing availability would depend on the designated ACEC management objectives. Restrictions could include reducing grazing in the ACEC and limiting the class of livestock animal or the season of use, duration, or location that livestock are allowed to graze.

#### **4.6.3 Impacts on Livestock Grazing Common to All Alternatives**

The nature and type of impacts described below are common to all alternatives, but the context and intensity may vary by alternative. Impacts on livestock grazing as described below are the same regardless of the alternative selected.

##### ***Impacts from Energy and Mineral Development***

###### *Impacts from Nonenergy Leasable Minerals Management*

There are expected to be minimal impacts from nonenergy leasable minerals on livestock grazing across all alternatives due to a lack of leases in GRSG habitat.

1 *Impacts from Coal Management*

2 No economically viable coal resources are found in Idaho. Under the Dillon RMP, a plan  
3 amendment would be required to lease coal. As a result, coal development in the project area  
4 and related impacts on range management are likely to be limited under all alternatives.

5 *Impacts from Recreation and Visitor Services Management*

6 Under all alternatives, motorized vehicles would be limited to existing roads and trails,  
7 thereby limiting the impacts on livestock grazing from dispersed travel as discussed under  
8 **Section 4.5.2**. Access to authorized agency uses, such as grazing allotments, would not be  
9 impacted under any alternative. Site-specific travel management planning could, when  
10 completed, reduce the potential for conflicts between range management and travel  
11 management.

12 **4.6.4 Alternative A**

13 No management areas would be designated for GRSG under this alternative. In general  
14 Alternative A would be the least restrictive alternative on resource uses, including livestock  
15 grazing. This alternative would also be the least restrictive for other resource uses and  
16 associated development. Therefore, there is an increased chance of disturbance from mineral  
17 development, recreation, and other uses, as compared to action alternatives.

18 *Impacts from Lands and Realty Management*

19 Under Alternative A, there would be approximately 1 million acres of ROW exclusion and  
20 1.9 million acres of avoidance areas in the decision area; no new ROW exclusion or  
21 avoidance areas would be created. Livestock could be disturbed from development of  
22 ROWs, as discussed under **Section 4.5.2**. For these reasons, this alternative would have the  
23 highest potential for impacts from lands and realty on range management; however, access  
24 to range improvements for maintenance would be the least restricted.

25 *Impacts from Habitat Restoration and Vegetation Management, Including Invasive*  
26 *Species Management*

27 Under Alternative A, restoration would continue in the planning area, with long-term  
28 benefits to livestock forage. Vegetation could be managed to improve forage, and impacts  
29 on range management from vegetation management would be minimal; however, these  
30 actions could require adjustment to livestock grazing management. Management actions for  
31 invasive species would continue under the direction of current management plans, with the  
32 focus on areas not meeting land health standards or desired conditions.

33 *Impacts from Wildland Fire Management*

34 Under Alternative A, mechanical treatments, prescribed fires, and other treatments would be  
35 used to prevent conifer encroachment and remove undesirable annual grass and weed  
36 species. These actions could improve forage in the long term. Although most of the LUPs  
37 do not provide specific direction for fire suppression in GRSG habitat, protection of GRSG  
38 habitat during suppression has become a priority in planning and operational discussions due  
39 to large fires in GRSG habitat in 2007 and 2012. Therefore, the risk of forage loss in these  
40 areas may be lower than in non-GRSG habitats.

1 A minimum rest period from livestock grazing of two growing seasons would typically be  
2 required after any major vegetative disturbance, including wildfire, for BLM-administered  
3 and National Forest System lands. Specific timing and the type of rest would be determined  
4 at the site-specific environmental assessment phase for all lands in the planning area. As a  
5 result, livestock grazing would typically be excluded from areas following a fire to some  
6 extent. Impacts on and costs and time for permittees and lessees would depend on the  
7 location of the fire in relation to grazing allotments, as well as the size and severity of the  
8 fire. Overall, impacts of required rest are likely to be minimal, compared to the action  
9 alternatives.

#### 10 ***Impacts from Energy and Mineral Development***

11 In general, Alternative A is the least restrictive on energy and mineral development of all  
12 alternatives. As a result, the indirect impacts of development on livestock grazing, including  
13 spread of noxious weeds and disturbance of livestock, are the greatest under this alternative.

#### 14 ***Impacts from Locatable Minerals Management***

15 Under Alternative A, 1.7 million acres of the decision area would be withdrawn from mineral  
16 entry. Impacts on range management would not occur in this area.

#### 17 ***Impacts from Salable Minerals Management***

18 Under Alternative A, 1.8 million acres of the decision area would be closed to mineral  
19 materials disposal. Impacts on range management would not occur in this area.

#### 20 ***Impacts from Unleased Fluid Minerals Management***

21 Under Alternative A, 2.7 million acres in the decision area would be closed to leasing.  
22 Alternative A would have the highest number of BLM-administered and National Forest  
23 System lands open to fluid mineral leasing with standard terms and conditions; therefore,  
24 conflicts between grazing and mineral development would be more likely to occur in this  
25 area.

#### 26 ***Impacts from Leased Fluid Minerals Management***

27 The Idaho BLM has four federal oil and gas leases. No drilling or exploration has occurred  
28 on any of the leases, nor has any activity been proposed; therefore, minimal impacts on  
29 livestock grazing are anticipated.

#### 30 ***Impacts from Recreation and Visitor Services Management***

31 Under this alternative, there would be no new restrictions to SRPs in the decision area;  
32 therefore, livestock could be disturbed by recreation in the planning area. Some limited  
33 potential for disturbance from general recreation is possible, as described under **Section**  
34 **4.5.2.**

35 Under Alternative A, as under all alternatives, motorized travel would be limited to  
36 designated routes, and site-specific travel management planning on BLM-administered lands  
37 would be developed, limiting disturbance to livestock. In addition, OHV use on National  
38 Forest Lands within the planning area is limited to roads, trails, and areas that have been  
39 designated through a transportation planning process; therefore, impacts on disturbance of

1 livestock or access to allotments from travel management are the same across all alternatives  
2 for National Forest System lands.

### 3 ***Impacts from Livestock Grazing Management***

4 Under Alternative A, livestock grazing would be allowed on approximately 11,730,785 acres  
5 in the planning area. This includes approximately 8,898,400 acres and 1,080,200 AUMs on  
6 BLM-administered lands within GRSG Habitat and 1,915,900 acres of National Forest  
7 System lands in GRSG habitat (see **Table 4-70**, Overview Comparison of Impacts on Range  
8 Management by Alternative within GRSG Habitat). AUM calculations are not available for  
9 National Forest System lands. While livestock grazing is currently permitted throughout the  
10 planning area, the population areas with the most acres open to grazing are Mountain  
11 Valleys, North Side Snake, and Southwest Idaho. Each has close to 2 million acres of BLM-  
12 administered lands open to grazing within occupied GRSG habitat in the planning area.

13 Note that outside of GRSG habitat in the planning area there are an additional  
14 approximately 2,832,339 acres and 374,202 permitted AUMs on BLM-administered lands  
15 and 7,700,600 acres on National Forest System lands. Livestock management decisions on  
16 these lands are not made in this document.

17 All leases and permits under Alternative A would continue to be required to meet or make  
18 progress toward meeting standards defined in the Idaho Standards for Rangeland Health and  
19 Guidelines for Livestock Grazing Management and the Standards for Rangeland Health and  
20 Guidelines for Livestock Grazing Management for Public Lands Administered by the  
21 Bureau of Land Management for Montana and the Dakotas for BLM-administered lands.  
22 Achievement or significant progress toward achievement would continue to be evaluated.  
23 Grazing permits, including grazing systems, permitted AUMs, and allotment boundaries,  
24 would be modified as necessary at this point to conform to Standards and Guidelines for  
25 Livestock Grazing Management. This would be the case if grazing were determined to be the  
26 causal factor for a standard not being achieved, as required by regulation on BLM-  
27 administered lands. As a result, any changes to grazing management would occur on a rolling  
28 basis following the determination.

29 On National Forest System lands, allotments with grazing permits would be required to  
30 meet or be moving toward desired conditions, as defined in the LRMP, or as described in an  
31 agency NEPA decision for the allotment. Permits would be reviewed and amended as  
32 needed and rangeland conditions would be assessed during site-specific NEPA analysis  
33 based on the Forest Allotment NEPA schedule.

**Table 4-69**  
**Overview Comparison of Impacts on Range Management by Alternative within GRSG Habitat**

	BLM-Administered Lands by GRSG Population Area																
	Alt. A	Alt. B		Alt. C	Alternative D			Alternative E		Alternative F			Proposed Plan				
	All GRSG Habitat	GHMA	PHMA	PHMA	GHMA	IHMA	PHMA	PHMA	GHMA	IHMA	GHMA	PHMA	RHMA	GHMA	IHMA	PHMA	SFA
<b>BLM</b>																	
Acres open to grazing	8,898,400	1,831,200	7,024,000	0	1,874,400	1,109,700	5,914,200	2,444,600	2,314,300	4,124,600	1,831,200	7,024,000	482,600	2,111,900	2,669,000	1,000,400	3,397,000
Permitted AUMs	1,080,200	253,700	821,600	0	258,600	146,800	674,800	338,900	259,700	480,600	253,700	821,600	57,200	258,500	314,500	138,800	372,000

Open to grazing <sup>1</sup>	1,915,900	824,800	924,900	0	991,500	254,900	667,000	446,300	880,500	356,400	825,800	925,200	140				

BLM GIS 2015

<sup>1</sup> AUMs are not available for National Forest System lands

34

Administrative Draft  
Cooperating Agency Review

1 Lands would be maintained and restored to maintain healthy native plant and animal species.  
2 Changes to rangeland management would be directed first to allotments not meeting one or  
3 more of the land health standards or desired conditions. On approximately 61 of the 2,220  
4 allotments assessed on BLM-administered lands, on 660,900 acres, standards are not being  
5 achieved due to livestock management. Management actions have not yet been taken to  
6 make progress toward meeting standards. See **Section 3.8**, Livestock Grazing. Similarly, the  
7 focus in riparian areas and wetlands would be to improve functioning-at-risk and  
8 nonfunctioning riparian areas and wetlands toward PFC. As described under **Section 4.5.2**,  
9 managing riparian habitat can directly impact livestock grazing by excluding livestock at  
10 specific sites, increasing herding, adding range improvements (such as cross fences and water  
11 gaps), and adjusting season and duration of use and livestock numbers. Such changes in  
12 grazing management options may increase time or costs for lessees and permittees.

13 Measures for GRSG and other sensitive species habitat under Alternative A are limited to  
14 requirements for “habitat suitable to maintain suitable viable populations” (under the Idaho  
15 standard), or “habitat as necessary to maintain a viable and diverse population of native plant  
16 and animal species, including special status species,” (under the Montana standards). This  
17 alternative would not direct the BLM or Forest Service to manage certain areas more  
18 intensively for GRSG habitat objectives; therefore, impacts on grazing in GRSG habitat are  
19 similar to those throughout the planning area.

20 Range improvements, including fences, vegetation treatments, and water developments,  
21 would be allowed in the decision area when needed to support grazing or to improve  
22 livestock distribution, allowing for management options for lessees and permittees. Fences  
23 would be constructed to protect and benefit livestock and wildlife, but no specific provisions  
24 are included for GRSG, so additional costs could be limited.

25 Under drought conditions under Alternative A, grazing use could be adjusted, as necessary,  
26 in accordance with BLM IM 2013-094. There would be potential impacts on authorized  
27 AUMs and management options, with increased time and costs for permittees and lessees if  
28 any changes were implemented on BLM-administered lands.

### 29 ***Impacts from Special Designations Management***

30 Under Alternative A, 59 existing ACECs containing over 460,000 acres of occupied GRSG  
31 habitat would be maintained. Impacts on range management would be as described under  
32 **Section 4.5.2**.

#### 33 **4.6.5 Alternative B**

34 Occupied GRSG habitat would be classified into PHMA and GHMA under this alternative,  
35 and impacts would primarily occur on range management in PHMA due to restrictions on  
36 resource uses.

### 37 ***Impacts from Lands and Realty Management***

38 Under Alternative B, no new ROW authorizations would be permitted in PHMA unless the  
39 development would occur within the existing developed footprint. As a result, indirect

1 impacts on livestock grazing from disturbance would be limited in this area and would  
2 decrease, compared to Alternative A.

3 ***Impacts from Habitat Restoration and Vegetation Management, Including Invasive***  
4 ***Species Management***

5 Under Alternative B, restoration projects in PHMA would be designed to benefit GRSG and  
6 based on the likelihood of success, with reestablishment of sagebrush cover as the highest  
7 priority. Projects to remove nonnative species and improve habitat would likely be in line  
8 with current grazing management practices and could improve livestock forage in the long  
9 term. Impacts could occur on range management when objectives for range management did  
10 not match those for GRSG habitat. Post-restoration management requirements could also  
11 result in changes to grazing systems or range management, with a resulting potential for an  
12 increase in costs and time for permittees and lessees.

13 Actions for invasive species management are similar to that described under Alternative A,  
14 with a greater focus on restoration and potential for impacts on grazing management in  
15 PHMA.

16 ***Impacts from Wildland Fire Management***

17 Under Alternative B, fire suppression would be prioritized when PHMA is threatened. As a  
18 result, there is potential for fewer disturbances to grazing due to fewer wildfires. Fires  
19 burning outside of PHMA or GHMA may increase in size when they are prioritized for  
20 suppression after fires burning in PHMA and GHMA. This could slightly increase the  
21 disturbance to grazing outside of GRSG habitat.

22 Post-fire management actions to restore habitat could result in impacts on range  
23 management. Under this alternative, management activities may be adjusted to support  
24 successful restoration, which could temporarily or permanently reduce grazing in areas  
25 reseeded post-fire. The level of impacts would depend on size, location, and intensity of fire  
26 and on the related level of restoration needed.

27 Fuels management projects to reduce fine fuels include the use of targeted livestock grazing.  
28 This could result in site-specific temporary increases in available forage in PHMA, but  
29 impacts are likely to be minimal overall.

30 ***Impacts from Energy and Mineral Development***

31 Under Alternative B, additional restrictions would be put on mineral development, as  
32 compared to Alternative A. Lands in PHMA would be recommended for withdrawal from  
33 mineral entry for locatable minerals, closed to mineral materials removal, and closed to new  
34 leasing for fluid minerals. For currently leased parcels, NSO stipulations would be applied in  
35 PHMA and around leks. As a result, disturbance of range management from mineral  
36 development would be minimized in PHMA.

37 ***Impacts from Recreation and Visitor Services Management***

38 In PHMA, motorized travel would be limited to existing roads and trails on BLM-  
39 administered and National Forest System lands. Travel plans (to be completed) would

1 analyze PHMA for the need for road closures, and limitations would be implemented during  
2 development of new roads. Some reduction in routes, limitations on new routes, and  
3 upgrades to existing routes would be added, compared to Alternative A. This could  
4 indirectly reduce livestock disturbance in PHMA. If restrictions on cross-county travel were  
5 to apply to permittees and lessees, access to allotments and the ability to effectively manage  
6 livestock may be impacted.

7 SRPs in PHMA would be limited when they were found to have negative impacts on GRSG;  
8 therefore, overall SRPs may be reduced with potential benefits to livestock grazing due to  
9 decreased disturbance.

### 10 ***Impacts from Livestock Grazing Management***

11 Under Alternative B, no management actions would result in direct changes to acres open to  
12 grazing and permitted AUMs (**Table 4-69**, Overview Comparison of Impacts on Range  
13 Management by Alternative within GRSG Habitat). In the long term, livestock grazing in  
14 PHMA may be reduced under Alternative B, compared to Alternative A, in order to  
15 conform to GRSG habitat objectives. However, the impacts would be site-specific and likely  
16 occur gradually.

17 This alternative provides GRSG habitat objectives, which will be incorporated into permit  
18 and lease renewals; therefore, impacts would occur at a site-specific level during the renewal  
19 process. Completion of land health assessments would be prioritized within PHMA on  
20 BLM-administered allotments. As a result, impacts on range management would be most  
21 likely to occur in these areas. Retirement of allotments would be an option in PHMA,  
22 resulting in potential reductions in AUMs in the planning area. Compensation for authorized  
23 range improvements would be provided, as appropriate.

24 Vegetation treatments that benefit livestock forage could only be completed if these  
25 treatments would also conserve, enhance, or improve GRSG habitat; therefore, the  
26 management options in PHMA could be reduced and the ability to fully use permitted  
27 AUMs could be impacted. On BLM-administered lands, land health assessments using  
28 ecological site descriptions (where available) would be required to determine if standards of  
29 rangeland health and GRSG habitat objectives were being met.

30 Under drought conditions, as under Alternative A, grazing management changes may be  
31 implemented; however, under Alternative B the focus would be on adjusting management in  
32 PHMA; therefore, impacts would be more likely to occur in this area.

33 Under Alternative B, riparian areas would be managed for PFC or similar standards at a  
34 minimum within PHMA. There could be limitations on grazing within these areas, increased  
35 use of fencing and herding, seasonal limitations on grazing, creation of water developments,  
36 or other measures to manage distribution of livestock so that pressure on these systems is  
37 limited. This could increase costs or time for permittees and lessees.

1 In the long term, livestock grazing in PHMA is likely to be reduced under Alternative B in  
2 order to conform to GRSG habitat objectives and other resource concerns. The timing and  
3 degree of reduction would depend on permit renewal timing and site-specific conditions.

4 Structural range improvements, such as fences and enclosures, in PHMA under Alternative  
5 B would be allowed but would have to be designed to conserve or enhance GRSG habitat.  
6 In addition, some fences would require marking, alternative siting, or other design features  
7 to lessen risk for GRSG impacts, so the cost of building or maintaining these structures may  
8 be increased, compared to Alternative A.

9 Similarly, new water developments from diverting spring or seep sources would be permitted  
10 only when GRSG habitat would also benefit and so would be limited. Permittees and lessees  
11 may not be able to fully use permitted AUMs if water were limited on a given allotment.  
12 Overall, water improvements and fences are likely to be removed or modified to some  
13 extent under this alternative, resulting in decreased grazing or shifts in grazing use patterns in  
14 the long term.

#### 15 ***Impacts from Special Designations Management***

16 No new ACECs or ZAs would be designated under Alternative B, so impacts would be as  
17 described under Alternative A.

#### 18 **4.6.6 Alternative C**

19 Alternative C would be the most restrictive on grazing management; no grazing would be  
20 authorized in occupied GRSG habitat following a two-year notice to cancel existing permits  
21 and leases, or portions thereof. Impacts from all other resources and resource uses on  
22 livestock grazing under Alternative C would be limited due to the limited permitted grazing  
23 outside of occupied habitat.

#### 24 ***Impacts from Lands and Realty Management***

25 Impacts are as described under Alternative B but would apply to all occupied habitat.  
26 Impacts on livestock grazing are minimal due to lack of grazing in all occupied GRSG  
27 habitat.

#### 28 ***Impacts from Habitat Restoration and Vegetation Management, Including Invasive 29 Species Management***

30 Management actions and impacts are similar to that described in Alternative B, with some  
31 additional restrictions on removing sagebrush cover to improve forage production. Impacts,  
32 however, are limited due to the lack of authorized grazing in occupied habitat.

#### 33 ***Impacts from Wildland Fire Management***

34 Impacts from wildland fire management are minimal under Alternative C due to the lack of  
35 permitted grazing in occupied habitat.

#### 36 ***Impacts from Energy and Mineral Development***

37 Management would be similar to that described under Alternative B. Impacts from all energy  
38 and mineral development would be minimal due to lack of grazing in occupied habitat.

1       ***Impacts from Recreation and Visitor Services Management***

2       Management would be the same as Alternative B but would apply to all occupied habitat.  
3       Impacts are minimal due to lack of grazing in occupied habitat.

4       ***Impacts from Livestock Grazing Management***

5       Alternative C would remove livestock grazing from all allotments in occupied habitat, a 100  
6       percent reduction from Alternative A (see **Table 4-69**, Overview Comparison of Impacts on  
7       Range Management by Alternative within GRSG Habitat). Grazing would be permitted  
8       outside of GRSG habitat on a total of approximately 2,875,600 acres, with 379.100  
9       permitted AUMs on BLM -administered lands. Acres and AUMs are not available for  
10       National Forest System lands.

11       Removing grazing from all occupied habitat would result in economic impacts on permittees  
12       and lessees. As discussed under **Section 4.5.2**, permittees and lessees would be faced with  
13       reducing AUMs for their operations or locating replacement forage. This could have higher  
14       costs or limited availability with related impacts on individual leases and permits as well as  
15       the local community. Closures to grazing would also disrupt the viability of current seasonal  
16       rotations or other management strategies that use combinations of federal, state, and private  
17       lands and potentially reduce the value of private lands used for grazing. If ranches are not  
18       maintained or profitable, they could be sold and may be developed (Wilkins et al. 2003).

19       Existing structures under Alternative C could be required to be modified or removed if they  
20       are determined to have a high risk of GRSG strike. In addition, management actions would  
21       allow no new water developments, and existing water developments could be removed. It is  
22       unclear if there would be a concerted effort to remove any or all livestock management  
23       infrastructure under this alternative. However, permittees and lessees who have investments  
24       on federal lands in occupied habitat that would be impacted could be compensated.  
25       Compensation for BLM permittees and lessees with authorized range improvements would  
26       be provided as appropriate, based on requirements specified in 43 CFR 4120.3-6(c). Under  
27       certain limited circumstances, Forest Service permittees would be compensated in  
28       accordance with 36 CFR 222.6(a). BLM and Forest Service investments in range  
29       infrastructure could also be impacted under this alternative, as structures no longer are  
30       maintained and go into disrepair. Furthermore, fencing may be required to prevent livestock  
31       from trespassing onto lands where grazing is excluded.

32       Removing range improvements and water developments on occupied habitat would also  
33       further restrict management options. Permittees and lessees who rotate pastures between  
34       private and federal lands may need to construct additional water developments and realign  
35       fences to keep livestock on private pastures, thereby increasing time and costs. Fencing  
36       density could increase in areas where federal, state, and private lands are interspersed and are  
37       grazed in common.

38       As a result of removing grazing from occupied habitat, there is also the potential for  
39       increased conflicts between grazing and other resources and resource uses on lands of other  
40       surface ownership, should livestock grazing increase in this area.

1       ***Impacts from Special Designations Management***

2       Under Alternative C, 39 new ACECs encompassing approximately 3.1 million acres of  
3       occupied GRSG habitat would be designated in the planning area, a tenfold increase over  
4       Alternative A. Impacts would, however, be limited since grazing would be prohibited from  
5       occupied habitat on BLM-administered and National Forest System lands.

6                       **4.6.7   Alternative D**

7       Occupied habitat is categorized into three categories, PHMA, IHMA and GHMA medial,  
8       and general, with associated management. Impacts for livestock grazing would be focused in  
9       PHMA and IHMA.

10       ***Impacts from Lands and Realty Management***

11       Under Alternative D, new ROW and land use authorizations would be avoided whenever  
12       possible, with a goal of no net loss in GRSG habitat. ROW avoidance areas in PHMA,  
13       IHMA, and GHMA, as well as the exclusion of larger facilities in PHMA, would somewhat  
14       limit the indirect impacts of development on grazing in the avoidance and exclusion areas.  
15       Impacts would still occur in nonhabitat allotments.

16       Similarly, management actions prohibiting solar and wind development in PHMA and  
17       imposing restrictions on development in IHMA and avoidance areas in GHMA would limit  
18       any impacts of disturbance from development of these resources. However, this may shift  
19       impacts on nonhabitat allotments.

20       ***Impacts from Habitat Restoration and Vegetation Management, Including Invasive***  
21       ***Species Management***

22       Under Alternative D, vegetation rehabilitation would emphasize projects to achieve the  
23       greatest improvement in GRSG abundance and distribution. This includes sites with greater  
24       likelihood of success, as discussed under Alternative B. Reconnecting and expanding native  
25       plant communities would be an objective across all GRSG habitat types; restoring seasonal  
26       habitats would be emphasized in both PHMA and IHMA.

27       As discussed in Alternative B, these management actions would likely be in line with current  
28       grazing management practices and could improve livestock forage in the long term. Impacts  
29       could occur on range management when objectives for range management do not match  
30       those for GRSG habitat. Post-restoration management requirements could also change  
31       grazing or other range management systems. This could increase costs and time for  
32       permittees and lessees. Most management actions and related impacts on grazing would be  
33       applied across all three habitat types, so they would be similar to those discussed in  
34       Alternative B but increased in intensity.

35       Cooperative planning would be used to develop and implement habitat restoration projects,  
36       so local permittees and lessees would have the opportunity to provide input into the  
37       implementation process. This would allow for results that could limit impacts on grazing  
38       management or improve habitat for both GRSG and livestock.

1 ***Impacts from Wildland Fire Management***

2 Under Alternative D, post-fire and restoration management would be undertaken to ensure  
3 long-term persistence of seeded or pre-burn native plants. It may also require short- or long-  
4 term change to grazing management. Management actions for post-fire restoration may  
5 reduce livestock grazing, with related impacts on permittees' and lessees' ability to fully use  
6 permitted AUMs. The degree of impacts would be determined by the location, size, and  
7 intensity of fires in GRSG habitat but would be increased over those in Alternative B. This is  
8 because all GRSG habitat types (priority, medial, and general) would be included.

9 Using grazing to manage fine fuels would also be considered in PHMA, IHMA, and GHMA,  
10 following certain conditions. Grazing management would be implemented strategically on  
11 the landscape. It would directly involve the minimum footprint and grazing intensity  
12 required to meet fuels management objectives and to conform to grazing standards and  
13 guidelines. As a result, additional site-specific opportunities for targeted grazing may be  
14 available, but these are likely to be limited and short term; thus, the overall impact in the  
15 planning area would be minimal.

16 ***Impacts from Energy and Mineral Development***

17 Under Alternative D, some degree of mineral development would be allowed, with measures  
18 to avoid or mitigate impacts on GRSG. Specifically, new fluid minerals and undeveloped  
19 nonenergy mineral leases would be allowed in all GRSG habitat types, with BMPs applied.  
20 Similarly, mineral materials would be allowed to be leased in all habitat types, with  
21 stipulations. As a result of the flexibility in management for PHMA, unlike that in  
22 Alternative B, there is some potential for mineral development in PHMA and related  
23 impacts on disturbance of livestock; however, the impacts would likely be minimal and lower  
24 than that under Alternative A. Within IHMA and GHMA, the degree of disturbance from or  
25 conflicts with grazing from energy and mineral development would also be lower than that  
26 under Alternative A.

27 ***Impacts from Recreation and Visitor Services Management***

28 Under Alternative D, motorized travel would be limited to existing roads, primitive roads,  
29 and trails, at a minimum. All open play areas designated for OHV use are outside GRSG  
30 habitat; these would remain open, with the potential to disturb livestock or disrupt livestock  
31 movement in these areas. This would be due to gates left closed or open inappropriately.  
32 Seasonal restrictions for authorized activities could impact the ability of permittees and  
33 lessees to access and manage allotments.

34 ***Impacts from Livestock Grazing Management***

35 Grazing would be allowed on all lands identified as available, as under Alternative A (see  
36 **Table 4-69**, Overview Comparison of Impacts on Range Management by Alternative within  
37 GRSG Habitat).

38 Grazing management action and impacts are similar to those described in Alternative B.  
39 There would be prioritized implementation of grazing systems or permit modifications to  
40 meet habitat objectives in areas that are not meeting these objectives. This would result in a  
41 moderate decline in permitted grazing over time as permits are modified to incorporate

1 GRSG objectives at renewal. Under Alternative D, however, allotments containing PHMA  
2 would be prioritized for permit renewal, followed by IHMA and finally GHMA; impacts on  
3 range management would occur in this sequence. In addition, all allotments with federally  
4 threatened and endangered species may also be prioritized for permit renewal ahead of  
5 GRSG habitat; therefore, impacts on range management could also occur in these areas.

6 Under Alternative D, additional measures would be applied to limit impacts of trailing  
7 livestock on leks and structural range improvements on GRSG. This would result in some  
8 additional potential for increased time and costs for management.

9 Retiring grazing permits, as described under Alternative B, would be considered where  
10 grazing privileges are relinquished or the allotment is vacant in all GRSG habitat types. As a  
11 result, total areas open to grazing may be reduced in the long term.

12 During droughts, under Alternative D, grazing management would be adjusted, as under  
13 Alternatives A and B, with the emphasis on providing sufficient food and cover for GRSG.  
14 Impacts would depend on site-specific resource conditions.

#### 15 ***Impacts from Special Designations Management***

16 No new ACECs or ZAs would be designated under Alternative D, so impacts are as  
17 described under Alternative A.

#### 18 **4.6.8 Alternative E**

19 Under Alternative E, GRSG habitat would be separated into CHZ, IHZ, and GHZ, with the  
20 priority on allotment renewal in CHZ and IHZ where populations are declining.  
21 Management changes, if required, would be tailored to specifically address habitat objectives  
22 that need improvement, and the impacts on other resources or resource uses, such as  
23 wildland fire management, would be examined. As a result, impacts on livestock  
24 management may be limited, compared to other action alternatives, due to the increased  
25 flexibility to address site-specific needs.

#### 26 ***Impacts from Lands and Realty Management***

27 Under Alternative E, ROW avoidance areas in CHZ and IHZ, as well as the exclusion of  
28 new infrastructure in CHZ, would somewhat limit the indirect impacts of development on  
29 grazing.

#### 30 ***Impacts from Habitat Restoration and Vegetation Management, Including Invasive*** 31 ***Species Management***

32 Impacts from habitat restoration are as described under Alternative A. Similarly,  
33 management actions of invasive species would likely be similar to Alternative A, with a focus  
34 on actions in CHZ and IHZ. Short-term impacts on grazing are minimal, with a change for  
35 long-term improvement of forage.

#### 36 ***Impacts from Wildland Fire Management***

37 Under Alternative E, management actions for wildfire include an emphasis on fire  
38 suppression and reduction in fire risk in CHZ, IHZ, and GHZ, with potential for reduction

1 in fire risk and related disturbance in these areas. As under Alternatives B and D, actions  
2 include targeted livestock grazing to reduce fine fuels and invasive species and to maintain  
3 fuel breaks, particularly in areas with high fuel loads with high risk of wildfire threatening the  
4 CHZ and IHZ. This action could result in some site-specific temporary increases in available  
5 forage, but location and levels would be unpredictable; thus, impacts are minimal overall.

#### 6 ***Impacts from Energy and Mineral Development***

7 Impacts from mineral and energy development are generally the same as those described  
8 under Alternative A. Fluid mineral development would have some additional restrictions  
9 applied to limit disturbance; therefore, the likelihood of development and associated  
10 disturbance would be reduced in areas with potential for these resources.

#### 11 ***Impacts from Recreation and Visitor Services Management***

12 Impacts are similar to those described under Alternative B. On BLM-administered and  
13 National Forest System lands, restrictions on motorized use on existing routes before travel  
14 planning and seasonal restrictions on activities that could disturb nesting GRSG could  
15 impact the ability of permittees and lessees to access and manage allotments.

#### 16 ***Impacts from Livestock Grazing Management***

17 Under Alternative E, Grazing would be allowed on all lands identified as available, as under  
18 Alternative A (see **Table 4-70**, Overview Comparison of Impacts on Range Management by  
19 Alternative within GRSG Habitat). Management actions and impacts would be based on  
20 GRSG population trends and focused on CHZ and IHZ. Allotments would be prioritized  
21 for permit renewal where populations of GRSG are. Changes to grazing management and  
22 associated impacts are most likely to occur in these areas.

23 Existing grazing management would be maintained unless the current grazing system does  
24 not meet GRSG habitat objectives and there is compelling information that changing the  
25 system would enhance habitat. Specifically, management actions in this alternative state that  
26 where population and habitat triggers are being maintained within a Conservation Area, this  
27 shows that the current grazing system is adequate to maintain viable GRSG populations and  
28 therefore absent compelling information, no further changes to BLM grazing systems would  
29 be required pursuant to Standard 8 (Threatened And Endangered Plants And Animals) of  
30 the Idaho Standards for Rangeland Health and Guidelines for Livestock Grazing  
31 Management, with respect to GRSG. Modifications to grazing management would continue  
32 to be implemented, however, where Standards 2 (Riparian Areas and Wetlands) and 4  
33 (Native Plant Communities) are not being met, or where Standard 8 is not being met for  
34 other species.

35 Adjustments would be applied at a site-specific level and specifically tailored to achieve  
36 objectives. As a result, changes to management and associated impacts would be limited. In  
37 addition, altering grazing systems within allotments may be possible under this alternative.  
38 This includes enhanced grazing opportunities in some areas with introduced seedings or  
39 areas with lower value to GRSG, such as GHZ. This limits overall impacts.

1 Under Alternative E, some additional limitations would apply to structural range  
2 improvements, as compared to Alternative A. This could increase the time or costs for  
3 construction and maintenance of improvements or could impact the ability to distribute  
4 livestock. These restrictions are more flexible than those under other action alternatives.  
5 They include avoiding construction of new fences within 1.2 miles (2 km) of leks and  
6 considering GRSG habitat needs and risks when designing and locating new water  
7 developments.

8 The location and level of adjustment needed to management cannot be determined and may  
9 change over time, lending some instability to the range management program. This is  
10 because of the unpredictable nature of areas that may be targeted for grazing management  
11 revision under this alternative (based on local GRSG population levels).

#### 12 ***Impacts from Special Designations Management***

13 No new ACECs or ZAs would be designated under Alternative E, so impacts are as  
14 described under Alternative A.

#### 15 **4.6.9 Alternative F**

16 As in Alternative B, all occupied habitat would be categorized into PHMA and GHMA, with  
17 potentially other restoration areas, each with associated management. Although grazing  
18 would be permitted under this alternative, the level of authorized grazing would be reduced  
19 by removing 25 percent of average billed AUMs in occupied GRSG habitat, following a two-  
20 year notice to cancel existing permits and leases, or portions thereof. In addition, the ability  
21 to construct improvements and other management options would be limited, with impacts  
22 on permittees and lessees.

#### 23 ***Impacts from Lands and Realty Management***

24 The type of impacts are as described under Alternative A, although the level of impacts  
25 would be reduced due to the reduction in authorized grazing.

#### 26 ***Impacts from Habitat Restoration and Vegetation Management, Including Invasive 27 Species Management***

28 Management actions under this alternative are similar to those described under Alternative B  
29 but include additional restrictions on removing sagebrush cover to improve forage. As such,  
30 management options may be further limited. However, there is the potential that less forage  
31 improvement would be necessary under Alternative F for livestock grazing purposes, due to  
32 the reduction in authorized grazing in the planning area.

33 For invasive species management, activities that spread invasives would be restricted. As  
34 described under the range management section for this alternative, restrictions on range  
35 improvements may apply, with potential impacts on permittees and lessees.

1 ***Impacts from Wildland Fire Management***

2 As for all action alternatives, actions to suppress and control the spread of wildfire under  
3 Alternative F could decrease the risk of disturbance from wildfire in GRSG habitat. Fires  
4 outside of GRSG habitat would be at risk of decreased suppression efforts.

5 Under Alternative F, measures to protect GRSG habitat post-fire could impact range  
6 management. Livestock grazing would be excluded from burned areas until woody and  
7 herbaceous vegetation meet GRSG objectives, which could result in long-term (10 to 50  
8 years or longer) exclusion from burned sites. It would generally take more than a decade to  
9 reestablish adequate Wyoming sage cover in low precipitation areas. The level of impacts  
10 would depend on locations, size, and intensity of wildfire in GRSG habitat in relation to the  
11 location and level of authorized grazing. Requirements to include livestock exclosures to  
12 monitor fire restoration progress are anticipated to have negligible impacts, due to the  
13 limited size of exclosures.

14 ***Impacts from Energy and Mineral Development***

15 Under Alternative F, no new mining claims would be allowed, and salable minerals sales  
16 would be prohibited in PHMA. Therefore, there would be limited potential from  
17 development-related disturbance of these resources.

18 Impacts from leased fluid minerals are the same as those described under Alternative A.  
19 New leasing in PHMA and GHMA would be limited, so there is some limited opportunity  
20 for disturbance from development of these resources.

21 ***Impacts from Recreation and Visitor Services Management***

22 Impacts are similar to that described under Alternative B. In addition, seasonal camping  
23 closures within 4 miles (6.4 km) of active leks could impede implementation of required  
24 livestock movement and trailing activities.

25 ***Impacts from Livestock Grazing Management***

26 Under Alternative F, management actions and impacts would occur in all occupied habitat.  
27 The reduction in authorized grazing in GRSG occupied habitat, while not as complete as  
28 under Alternative C, would include a 25 percent reduction below AUMs levels typically  
29 billed by permittees. While allotment-specific impacts would be determined at the  
30 implementation level, overall, livestock grazing levels would be reduced in the decision area.  
31 Estimated AUMs under Alternative F are 689,962.

32 In some cases, this may involve loss of permitted grazing for individual allotments and, in  
33 other cases, may involve reduction of permitted grazing levels for allotments. These  
34 management actions would potentially require permittees to reduce grazing or locate  
35 alternative sources of forage, with potential for economic impacts on as discussed in  
36 Alternative C.

37 Where grazing is permitted, management would be similar to that described in Alternative B,  
38 with the addition of other protective measures for GRSG habitat (such as increased  
39 prohibitions on grazing after fire and restriction on all vegetation treatments). As a result,

1 management options would be limited and time and costs for permittees would be increased  
2 as compared to Alternative A.

3 In addition, management actions would allow no new water developments or other  
4 structural range improvements. Prohibitions on new improvements could also limit the  
5 ability to effectively distribute livestock, resulting in indirect increases in time and costs for  
6 permittees. These actions are likely to further limit the abilities of permittees and lessees to  
7 fully use permitted AUMs and would increase time and cost for management.

#### 8 ***Impacts from Special Designations Management***

9 Under Alternative F, 17 or 18 new ACECs and 12 new ZAs encompassing up to over 1  
10 million acres of occupied GRSG habitat, would be designated in the planning area. This  
11 would be a 22-fold increase over Alternative A. Impacts would, however, be reduced in areas  
12 where grazing is reduced.

#### 13 **4.6.10 Proposed Plan**

14 Under the Proposed Plan, GRSG habitat would be separated into SFAs, PHMA, IHMA, and  
15 GHMA, with the priority on allotment renewal in SFAs and PHMA in areas not currently  
16 meeting land health standards. Management changes, if required, would be tailored to meet  
17 GRSG habitat objectives.

#### 18 ***Impacts from Lands and Realty Management***

19 Under the Proposed Plan, PHMA and IHMA would be managed as ROW avoidance areas,  
20 but would be subject to RDFs, BMPs and a seasonal timing limitation, resulting in limited  
21 new development in GRSG habitat. Similarly, management actions would prohibit solar and  
22 wind development in PHMA, impose restrictions on development in IHMA, and classify  
23 GHMA as avoidance areas.

24 The Proposed Plan would include a cap on anthropogenic disturbance; the 3-percent  
25 disturbance cap on discrete anthropogenic disturbances would be applied in PHMAs at both  
26 the BSU and project levels. Anthropogenic disturbances in PHMA and GHMA would be  
27 also mitigated to ensure a net conservation gain to GRSG. In addition, conservation  
28 measures would be implemented in PHMA and GHMA such as adaptive management and  
29 defined monitoring protocols (**Appendices G and E**), RDFs, and lek buffers (**Appendix B**).

30 As a result, disturbance of livestock from development activities, as discussed in **Section**  
31 **4.6.2**, including disturbance of forage or unwanted dispersal of livestock, would be limited in  
32 GRSG habitat.

33 Under the Proposed Plan on National Forest System lands, special use authorizations, land  
34 ownership adjustments, and land withdrawals would limit the direct and indirect impacts of  
35 development and surface disturbance on rangelands where livestock grazing is permitted,  
36 thereby maintaining forage availability.

1       ***Impacts from Habitat Restoration and Vegetation Management***

2       Impacts under the Proposed Plan habitat from vegetation management would be similar to  
3       those discussed under Alternative D. The Proposed Plan would also include additional  
4       measures such as conifer removal, improved management of wet meadows, and  
5       implementation of RDFs. In addition, specific vegetation objectives in PHMA have been  
6       identified in the Proposed Plan based on vegetation modeling, including targets of  
7       approximately 77,000 acres identified for mechanical treatments, 30,000 acres of prescribed  
8       fire and 620,000 acres for annual grass treatment to meet GRSG objectives on BLM Lands  
9       (see **Table 2-5**). As vegetation treatments are implemented, livestock grazing may be  
10      modified temporarily or permanently to help ensure treatment success and progress towards  
11      meeting GRSG habitat objectives. However, in most cases, treatments (e.g., conifer  
12      removal) would maintain or improve forage conditions in the long term. Conversion of  
13      cheatgrass to sagebrush-steppe may reduce overall amounts of forage available, but would  
14      increase perennial bunchgrasses, which provide higher nutritional quality, and produce more  
15      consistent amounts of forage from year to year.

16      ***Impacts from Wildland Fire Management***

17      Under the Proposed Plan, impacts from wildland fire management would be similar to those  
18      described for Alternative D. Management actions would include an emphasis on fire  
19      suppression and reduction of fire risk in PHMA and IHMA, with potential for reduction in  
20      long term fire risk and related loss of livestock forage in these areas. Specific requirements  
21      include burn plans prior to use of prescribed fire in GRSG habitat and assessment of  
22      management needs based on local conditions as detailed in **Appendix D**. Wildfire, Invasive  
23      Annual Grasses and Conifer Expansion Assessments would also identify priority  
24      areas/treatment opportunities for fuels management, fire management, and restoration.

25      As discussed under Alternative D, targeted grazing could result in some site-specific  
26      temporary increases in available forage, but location and levels would be unpredictable and  
27      temporary; thus, impacts overall impacts on available forage would be minimal.

28      Under the Proposed Plan, GRSG habitat objectives would be incorporated into Emergency  
29      Stabilization and Burned Area Emergency Rehabilitation plans in accordance with the  
30      Restoration/Rehabilitation Strategy developed as a result of the Wildfire, Invasive Annual  
31      Grasses and Conifer Expansion Assessments. Management activities may be altered to meet  
32      objectives. As a result, grazing could be modified or excluded from restoration sites until  
33      GRSG objectives were met. However, incorporation of objectives would be based on site  
34      capability and potential and therefore would vary on a site-specific basis; site-specific  
35      changes to grazing management required would be determined at implementation.

36      In addition, grazing management may be adjusted on sites adjacent to burned areas to  
37      mitigate the impact of a wildfire on GRGS populations. As a result, some permittees may be  
38      impacted by both exclusion of livestock from a burned area and reduction of grazing or  
39      changes to management in adjacent allotments. Specific management changes and intensity  
40      of impacts would vary based on site specific conditions and wildfire occurrences.

1 As discussed in **Section 4.6.2**, fuels projects and fire suppression to protect sagebrush  
2 ecosystems and associated GRSG habitat would benefit livestock grazing where areas  
3 available to grazing overlap this habitat, due to a long term reduction in the likelihood of  
4 high intensity wildfire. Short term fuels reduction projects may result in temporary reduction  
5 in available forage on a site-specific basis. Under the Proposed Plan on National Forest  
6 System lands, measures to protect GRSG habitat from fire and associated fire operations  
7 would be beneficial to livestock grazing, especially in the 12-inch or less precipitation zone,  
8 because it would help prevent expansion of non-native invasive species such as cheatgrass.  
9 Although management to suppress and control the spread of wildfire under the Proposed  
10 Plan would decrease the risk of disturbance from wildfire in GRSG habitat, fires outside of  
11 GRSG habitat would possibly be at risk of decreased suppression efforts. Management  
12 direction to protect GRSG habitat from fire in higher elevation sagebrush habitats (i.e.,  
13 mountain big sagebrush) could indirectly negatively impact livestock grazing in the long-term  
14 as sagebrush potentially increases and forage production decreases.

### 15 ***Impacts from Energy and Mineral Development***

16 Similar to Alternative D, under the Proposed Plan, fluid mineral development would be  
17 permitted in GRSG habitat, with measures limiting surface disturbance. Specifically, SFAs,  
18 PHMA and IHMA would be available for leasing with NSO stipulations. GHMAs would be  
19 available with CSU stipulations. SFAs would be recommended for withdrawal from locatable  
20 mineral entry and PHMAs would be closed to mineral material leasing.

21 In addition, the Proposed Plan would include a 3 percent cap on anthropogenic disturbance  
22 applied in PHMAs at both the BSU and project levels. These measures, combined with the  
23 RDFs, buffers, and mitigation, would help to reduce potential disturbance of livestock  
24 forage and livestock as compared to Alternative A. Due to the limited conflicts between  
25 livestock grazing management and energy development under existing conditions, impacts  
26 would be minimal.

27 On National Forest System lands, management direction prohibiting solar and wind  
28 development in PHMA and imposing restrictions on development in IHMA would limit any  
29 impacts associated with ground disturbances from development of these resources. This  
30 management direction would limit the direct impacts of development and surface  
31 disturbances on existing rangelands, which would be beneficial to livestock grazing.

32 Under the Proposed Plan on National Forest System lands, new fluid mineral leases would  
33 require a no surface occupancy stipulation in priority habitat and controlled surface use and  
34 timing restrictions in general habitat. New leases would be prioritized in non-habitat first and  
35 then in the least suitable habitat for GRSG.

36 For existing leases under the Proposed Plan on National Forest System lands, leaseholders  
37 would be required to avoid and minimize surface disturbing and disruptive activities in  
38 priority habitat for leases that are not yet developed. In addition, reclamation plans would be  
39 designed to restore habitat to desired conditions described in **Table 2-6**. Fluid mineral

1 operations would be mitigated in priority habitat to reduce soil compaction to improve  
2 vegetation reestablishment and keep GRSG habitat disturbance to a minimum.

3 Surface disturbances would also be prohibited for unleased coal mines in priority habitat as  
4 well as other mitigation measures to reduce disturbances for leased coal mines and associated  
5 facilities. Locatable mineral, non-energy leasable, and mineral material operations in priority  
6 habitat would be mitigated to protect GRSG habitat.

7 Minerals management direction under the Proposed Plan on National Forest System lands  
8 would not impact livestock grazing in priority and general GRSG habitats because  
9 development and surface disturbance would be limited and the potential from development  
10 related disturbance of rangeland and forage resources would be reduced.

### 11 ***Impacts from Travel and Transportation Management***

12 Under the Proposed Plan, motorized travel would be limited to existing roads, primitive  
13 roads, and trails. Ability of permittees to access range improvements for maintenance or to  
14 utilize motorized vehicles to gather livestock could be impacted, as exceptions for  
15 administrative access would generally be granted only at permit renewal if not provided for  
16 within existing grazing permits or leases, potentially increasing time and costs of these  
17 management activities. Seasonal restrictions on motorized use could further impact ability of  
18 permittees to access allotments for management. Limitations on motorized travel could also  
19 reduce any conflicts between livestock and recreation, as discussed in **Section 4.6.2**,

20 Under the Proposed Plan, temporary closures would also be permitted as determined  
21 necessary for resource protection. Closures would further reduce disturbance livestock but  
22 have the potential to impact ability of permittees to access allotments and livestock using  
23 motorized vehicles. Under the Proposed Plan on National Forest System lands new road or  
24 trail and construction would be prohibited in GRSG habitat, and road construction within  
25 riparian and mesic meadows would be restricted. This direction would be beneficial to  
26 livestock grazing, indirectly improving forage production and improving overall rangeland  
27 conditions. However, impacts from roads and transportation would still occur in areas  
28 outside of priority and general GRSG habitats, which could indirectly impact grazing  
29 conditions through increased development.

### 30 ***Impacts from Livestock Grazing Management***

31 Grazing would be allowed on all lands identified as available as under Alternative A (see  
32 **Table 4-70**, Overview Comparison of Impacts on Range Management by Alternative within  
33 GRSG Habitat), although limited areas may be closed through site-specific decisions to meet  
34 habitat objectives.

35 Grazing management actions and impacts are similar to those described in Alternatives B  
36 and D. As described in Alternative D, the effect of grazing management practices on  
37 attainment of GRSG habitat objectives would be determined through the range health  
38 evaluation process. Management designed to meet applicable habitat objectives would be  
39 incorporated into BLM into grazing permits and leases through allotment management  
40 plans, permit renewals, and into Forest Service permits through the Forest Service NEPA

1 processes, with consideration for local objectives and site potential. Similar to Alternatives B  
2 and D, a moderate decline in permitted grazing is anticipated over time as permits are  
3 modified to meet objectives. In addition, the proposed plan would require analysis of  
4 management thresholds based upon habitat objectives within SFAs and PHMA, which may  
5 trigger modifications to annual grazing authorizations and/or grazing permits or leases  
6 within the term of the renewed grazing permit if monitoring data indicate that grazing  
7 management implementation is not resulting in expected progress towards meeting habitat  
8 objectives. When alternatives that implement thresholds and triggers are selected for grazing  
9 permits, implementation of the identified modifications within the life of 10-year grazing  
10 permits reduces operational certainty for permittees, and may impact their ability to plan and  
11 implement an economically feasible ranch or business plan. Because of this, magnitude of  
12 impacts to livestock grazing would be relatively higher for allotments within SFAs and  
13 PHMA.

14 Under the Proposed Plan, priority for land health assessment and permit renewal would  
15 include SFAs first followed by PHMAs outside the SFAs. Precedence will be given to  
16 existing permits/leases in these areas not meeting Land Health Standards, with focus on  
17 those containing riparian areas, including wet meadows. Changes in management would  
18 follow this priority order.

19 Existing grazing management would be maintained unless the current grazing system does  
20 promote applicable GRSG habitat objectives (**Table 2-6**, desired Seasonal Habitat  
21 Conditions), or if changes are needed to meet Standards and Guidelines or other resource  
22 objectives. Adjustments to grazing management or authorized grazing use level would be  
23 applied on a site specific basis and tailored to achieve objectives for GRSG based on habitat  
24 type in the areas assessed (i.e. breeding, nesting, wintering, etc.) as detailed in **Table 2-6**.  
25 Site-specific review of seasonal habitat type would be required as part of the land assessment  
26 process; quantitative analysis of current GRSG seasonal habitat conditions of allotments is  
27 not available and is likely to change over time based on precipitation patterns, wildfire  
28 occurrence, and other factors. Acres within nesting habitat may be likely to require changes  
29 to grazing management, due to the desired conditions for this habitat type, including  
30 perennial grass height of at least 7 inches, while acres in brood-rearing habitat may require  
31 adjustments to meet PFC and promote diversity and abundance of GRSG preferred forbs.  
32 The level and intensity of impacts would vary on a site-specific basis; changes in  
33 management would be commensurate with the scale and magnitude of deficiencies in  
34 meeting habitat objectives as caused or contributed to by ongoing livestock management.  
35 The scale and extent of modifications to grazing would also vary based upon the  
36 relationships of allotments and pastures to seasonal habitat patches and the scale of grazed  
37 areas not meeting habitat objectives. Modifications in use of grazing areas outside of the  
38 target habitat may also occur in order to develop logical and feasible grazing systems (e.g. if  
39 the season of use is modified in one pasture containing nesting habitat, this may necessitate  
40 changes in season of use in all pastures in the allotment to coordinate grazing use and  
41 livestock movements).

1 Under the Proposed Plan, as under other alternatives, BLM grazing preference may be  
2 voluntarily relinquished, and grazing on Forest Service allotments may be waived without  
3 preference. Under the Proposed Plan, the BLM or Forest Service may determine whether  
4 AUMs associated with relinquished grazing preference or waived allotments should be  
5 retired, remain available for livestock grazing or be used for other resource management  
6 objectives per WO IM 2013-184. This may result in long term reduction of overall available  
7 AUMs, with potential for economic impacts on local communities that depend on livestock  
8 grazing. Economic impacts are further discussed in **Section 4.22**, Socioeconomic impacts. If  
9 AUMs associated with relinquished grazing preference are maintained as a forage reserve for  
10 use by permittees who are displaced by wildfire or restoration activities, disruption of  
11 livestock operations could be decreased over the long-term.

12 Under the Proposed Plan some additional limitations would apply to structural range  
13 improvements, as compared to Alternative A, including limitations on fence construction  
14 and tall structures near occupied leks, as detailed in project RDFs and BMPs (**Appendix B**).  
15 New and existing structural range improvements would be required to have a neutral effect  
16 or conserve, enhance, or restore GRSG. These restrictions could increase the time or costs  
17 for construction and maintenance of improvements but should allow sufficient flexibility  
18 that permittees could utilize range improvements to effectively manage livestock.

19 Under the Proposed Plan on National Forest System lands, livestock grazing would be  
20 managed to achieve or maintain desired conditions in GRSG seasonal habitats as described  
21 in **Table 2-6**. Livestock grazing would also be managed in order to maintain residual  
22 perennial grass height to provide for adequate GRSG nesting cover according to the  
23 guidelines described in **Table 2-6**.

24 Current direction for livestock grazing under Alternative A is generally less restrictive than  
25 direction described under the Proposed Plan, therefore, grazing use guidelines under the  
26 Proposed Plan would directly impact livestock grazing management on National Forest  
27 System lands. Impacts could include modification of grazing strategies or rotation schedules,  
28 changes to the season of use, changes to kind and class of livestock, closure of a portion of  
29 an allotment, or reduction of livestock numbers. Implementation of this management  
30 direction could result in the reduction of AUMs on some allotments, and possibly overall  
31 operation viability. The level and intensity of impacts could vary on a site specific basis with  
32 permitted grazing likely decreasing moderately over time as permits are modified to achieve  
33 desired conditions and meet annual grazing use guidelines.

34 Implementation of Forest Service grazing guidelines could also directly impact permittees by  
35 increasing the amount of time permittees spend to manage livestock on National Forest  
36 System lands as well as the total costs to a livestock operation. Impacts would occur at the  
37 allotment scale as management direction is incorporated into permits, allotment management  
38 plans, and annual operating instructions.

39 Grazing use guidelines under the Proposed Plan on National Forest System lands would  
40 impact about 264 allotments, 1,409,546 acres, and 454,376 AUMs in nesting and brood  
41 rearing seasonal habitats within active grazing allotments. Under the Proposed Plan on

1 National Forest System lands sheep camps would not be located within 1.2 miles from the  
2 perimeter of a lek during lekking season and trailing of livestock during breeding and nesting  
3 seasons would be minimized during breeding and nesting seasons. This management  
4 direction would result in the need to modify grazing practices with increased costs for  
5 permittees in these areas.

6 Additional constraints under the Proposed Plan on National Forest System lands would also  
7 apply to structural range improvements in priority GRSG habitat compared to Alternative A.  
8 These include prohibiting fence construction or reconstruction within 1.2 miles from the  
9 perimeter of occupied leks unless the collision risk can be mitigated through design features  
10 or markings, not constructing new permanent livestock facilities (e.g., windmills, water tanks,  
11 corrals) within 1.2 miles from the perimeter of occupied leks, and not constructing water  
12 developments in priority habitat unless they are beneficial to GRSG.

13 Prohibitions on new structural improvements could limit the ability of permittees to  
14 effectively distribute livestock resulting in increases in time and costs to permittees and  
15 potentially the full use permitted AUMs. Although these constraints could increase the  
16 amount of time permittees spend to manage livestock on National Forest System lands, it  
17 should allow sufficient flexibility that permittees could continue to utilize structural range  
18 improvements to effectively distribute livestock.

19 Under the Proposed Plan, the Forest Service would consider closure of grazing allotments,  
20 pastures, or portions of pastures, or managing the allotment as a forage reserve as  
21 opportunities as opportunities arise where removal of livestock would enhance the ability to  
22 achieve desired habitat conditions as described in **Table 2-6**. These actions would occur  
23 according to applicable regulations and, if implemented, would result in the reduction of  
24 overall available AUMs.

25 Managing livestock grazing to achieve the desired conditions in **Table 2-6** and livestock use  
26 guidelines in **Table 2-8** may indirectly benefit rangeland conditions by increasing vegetation  
27 productivity and increasing forage in the long term. This in turn would provide managers  
28 and permittees better management options, especially on those allotments where livestock  
29 numbers are approaching a sustainability threshold or during drought and other disturbances  
30 such as wildfire.

### 31 ***Impacts from Special Designations Management***

32 No new special designation areas are proposed under the Proposed Action, therefore no  
33 impacts would occur to livestock grazing management.

### 34 ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and*** 35 ***Coordination***

36 Livestock grazing and related range improvements are not included as anthropogenic  
37 disturbances in calculation of the anthropogenic disturbance cap, therefore, no direct  
38 impacts would occur to livestock grazing management as a result of the cap. Limitations of  
39 Anthropogenic disturbance would generally result in a reduction in development in GRSG

1 habitat and a related reduction in disturbance of livestock and would maintain livestock  
2 forage.

3 If adaptive management triggers are met and livestock management is identified as a  
4 contributing factor, then short-term adjustment of management would be required as  
5 identified in the Adaptive Grazing Management Response, **Appendix G**. Accelerated  
6 assessment of suspected habitat deficiencies would be conducted and used to identify  
7 management actions that would be implemented to ensure that livestock grazing is not  
8 contributing to further declines in the long-term within the affected Conservation Area  
9 While management changes may be implemented in the short-term on allotments where  
10 habitat is meeting GRSG habitat objectives, as discussed under livestock grazing  
11 management impacts, impacts would be limited in scale to that determined necessary to  
12 mitigate impacts in the short-term while site-specific assessments and management actions  
13 are identified and implemented. Conservation areas that have tripped adaptive management  
14 triggers would be prioritized for HAF, rangeland health assessments and review of grazing  
15 permits.

#### 16 **4.7 Travel Management**

17 This section discusses impacts on travel and transportation management from proposed  
18 BLM and Forest Service management actions. Existing conditions concerning travel and  
19 transportation management are described in **Section 3.10**.

20 Travel and transportation management supports and helps achieve the objectives of other  
21 resource programs, particularly such resource uses as recreation, mineral development, and  
22 lands and realty. At the resource management planning level, impacts on travel and  
23 transportation management occur when management restricts travel access, such as by  
24 closing an area to motorized travel.

25 Since travel management decisions impact other resource areas—for example, closing or  
26 limiting travel to protect sensitive soil resources—impacts of travel management actions on  
27 other resources and uses are discussed in the respective resource sections of this chapter.  
28 Accordingly, while impacts on travel and transportation management from other program  
29 areas do occur and are considered as part of transportation management planning, this  
30 section does not address the impacts on travel and transportation management from other  
31 resources and resource uses.

##### 32 **4.7.1 Methods and Assumptions**

###### 33 ***Indicators***

34 Indicators of impacts on travel and transportation management from BLM and Forest  
35 Service management to protect GRSG are changes in the following:

- 36 • The acreages designated as open, limited, or closed to motorized  
37 travel
- 38 • The types and timing of transportation activities occurring on  
39 routes that could impact GRSG or its habitat

1        ***Assumptions***

2        In addition to the assumptions in **Section 4.1.1**, this analysis includes the following  
3        assumptions:

- 4                    • The BLM recognizes roads, primitive roads, and trails as the  
5                    three types of linear features that comprise the existing  
6                    transportation system. These features are formally recognized  
7                    based on an inventory of the planning area. Some routes may be  
8                    designated for specific uses in a travel management plan. Other  
9                    linear features used for transportation but not formally  
10                    designated or recognized are considered linear disturbances.  
11                    These features are not part of the BLM transportation system  
12                    (BLM 2006b).
- 13                    • Some primitive roads and trails in the northern portion of the  
14                    planning area and higher elevations may not be used during  
15                    GRSG lekking and wintering seasons because they are not  
16                    passable, while those in the southern part of planning area and  
17                    in lower elevation areas may receive higher use.
- 18                    • The demand for general access to travel routes on BLM-  
19                    administered and National Forest System lands would remain  
20                    steady or increase over the life of the LUPs.
- 21                    • The BLM and Forest Service acknowledge that snow machines  
22                    and mechanized access in the snow is expanding, but generally  
23                    occurs in higher elevations areas where there is consistent snow  
24                    pack and less GRSG habitat.
- 25                    • Administration of updated agency travel management policy,  
26                    rules, and planning and design guidelines is improving public  
27                    land travel systems, making them more sustainable while  
28                    decreasing potential impacts on resources.
- 29                    • OHV use will continue to increase and with this increase the  
30                    potential for resource and user conflict may increase.
- 31                    • The designation of individual routes is an implementation level  
32                    process and typically follows the planning process.
- 33                    • Travel systems are dynamic and will be changed through  
34                    subsequent implementation-level planning.
- 35                    • Implementation of a travel management plan would include  
36                    increased public education, signing, enforcement, and resource  
37                    monitoring in regard to travel management.

1 **4.7.2 Nature and Type of Effects**

2 Impacts on travel and transportation management are those that restrict or enhance travel,  
3 such as managing areas as closed or limited to off-highway motorized travel or restrict where  
4 new routes can be created and existing ones expanded.

5 **Table 4-71**, OHV Area Designations by Alternative, summarizes motorized travel  
6 designation by alternative.

**Table 4-70**  
**OHV Area Designations by Alternative**

		Alt. A	Alt. B	Alt. C	Alt. D	Alt. E	Alt. F	Proposed Plan
BLM	Open	2,880,300	254,800	50	50	1,783,000	254,800	3,360
	Limited to existing routes	5,725,000	8,798,000	8,563,300	8,605,300	6,815,800	8,798,000	8,856,100
	Closed	711,400	716,800	706,200	711,400	707,900	716,800	710,600
Forest Service	Limited to designated routes	2,040,700	1,861,800	1,861,900	2,040,700	1,867,000	1,861,800	1,560,700

Source: BLM GIS 2015

7  
8 Management actions that prohibit cross-country motorized travel would minimize the  
9 creation of new transportation linear disturbances, enabling BLM and Forest Service travel  
10 management actions to manage and improve access on linear features in the transportation  
11 system.

12 Restrictions on new route construction or expansion of existing routes would direct users  
13 elsewhere in the transportation network, potentially impacting those areas from the added  
14 activity. Additionally, management actions that restrict future route construction, including  
15 adaptive management strategies that prohibit future disturbance upon reaching a disturbance  
16 cap, would arbitrarily limit the ability of the transportation system manager to accommodate  
17 increased travel demands over time or address minimization techniques (i.e. affects to  
18 wildlife per criteria b, 8340.1). Conflicts among route users could increase if the existing  
19 network becomes congested.

20 Implementing management for all other resources and uses would have negligible or no  
21 impact on comprehensive travel and transportation management; therefore they are not  
22 discussed in detail.

### 4.7.3 Impacts on Travel Management Common to All Alternatives

The nature and type of impacts described below are common to all alternatives, but the context and intensity may vary by alternative.

Under all alternatives the BLM would defer travel management route designations to a separate process following the current LUPA process. As such, for each alternative, the BLM would maintain current management of areas closed to cross-country motorized travel and would manage varying acreages as limited to existing routes. The Forest Service has already undertaken a route designation process. As a result, motorized travel is limited to designated routes on National Forest System lands under all alternatives. Areas of disturbance associated with these designated routes vary slightly by alternative. **Table 4-71, OHV Area Designations by Alternative**, summarizes the total areas open, limited, and closed to cross-county motorized travel by alternative.

### 4.7.4 Alternatives Analysis

In accordance with 43 CFR 8342.1, current BLM management limits motorized travel to existing roads and trails within portions of the planning area, while allowing cross-country travel in other areas. Under Alternative A, the BLM and Forest Service would maintain current levels of travel management, as identified in the existing planning documents. For example, BLM-administered lands currently designated as open to cross-country OHV use (over 2.8 million acres) would continue to be managed as such. Motorized travel on National Forest System lands would continue to be limited to designated routes. There would be no new restrictions on GRSG habitat management and no change in impacts on travel management.

Under Alternative B, the BLM would limit motorized travel to existing roads and trails in PHMA. Motorized travel on National Forest System lands would continue to be limited to designated routes with a total disturbance area of over 2 million acres. The area designation change on BLM-administered lands from open to limited would reduce cross-country access in those portions of PHMA that were previously managed as open. Applications for upgrading or realigning routes would be required to meet certain design, location, and mitigation criteria intended to protect GRSG habitat. These requirements may preclude the construction of some new routes but would be unlikely to reduce access across the decision area.

Alternative B would also require increased signs and education alerting OHV users of limitations on cross-country travel. It would add processing requirements for transportation-related projects in GRSG habitat. Signs and education would likely improve travel management by reducing user and resource conflicts; added processing requirements could increase the time needed to approve new projects and result in site-specific increases in congestion if portions of the current route system become overcrowded. Alternative B's restrictions on OHV travel would make active livestock management more difficult because of the difficulty of access to the allotments.

1 Alternative C would result in the greatest reduction in access, when compared to Alternative  
2 A. For example, under Alternative C, motorized cross-country travel would be prohibited in  
3 all GRSG habitats. Additionally, in PHMA, new road construction within 4 miles (6.4 km) of  
4 active leks would be prohibited. Upgrading existing routes where it would damage occupied  
5 GRSG habitat would also be precluded. Together, these actions would result in site-specific  
6 losses of opportunity for motorized travel, future route construction, and improved access.  
7 Similar to Alternative B, Alternative C's restrictions on OHV travel would make active  
8 livestock management more difficult because of the difficulty of access to the allotments.

9 Under Alternative D, motorized travel in PHMA would be limited to existing routes on  
10 BLM-administered lands and designated routes on National Forest System lands.  
11 Undesignated routes would be designated as part of a future travel management planning  
12 process. There would be no areas within GRSG habitat managed as open to cross-country  
13 OHV travel under Alternative D, which would reduce cross-country access in areas  
14 previously managed as open. In those areas managed as limited to existing routes, impacts  
15 on travel and transportation management under Alternative D are the same as Alternative B  
16 and are consistent with **Section 4.6.2**. Similar to Alternative B, Alternative D's restrictions  
17 on OHV travel would make active livestock management more difficult because of the  
18 difficulty of access to the allotments.

19 Impacts under Alternative E are the same as under Alternative A, while impacts under  
20 Alternative F are the same as under Alternative B.

### 21 ***Impacts from Travel and Transportation Management***

22 Impacts from limiting motorized travel to existing routes on 99 percent (10,416,800 acres) of  
23 the planning area would be consistent with those described in the ***Nature and Types of***  
24 ***Effects***.  
25

26 During subsequent travel management planning, the designation of individual routes would  
27 allow BLM to manage the types of travel on individual routes to avoid impacts on GRSG  
28 and its habitat. Restricting motorized travel on roads and primitive roads in lower elevations  
29 of the planning area would result in greater effects on travel opportunities because these  
30 routes are passable year-round and have higher traffic volumes.

31 Seasonal restrictions to minimize impacts on GRSG and its habitat would prevent road  
32 maintenance and could make certain roads impassable until the required maintenance could  
33 be performed.

34 RDFs for roads and travel management would likely limit the number of routes in GRSG  
35 habitat, but would enhance the long-term condition of routes available for public and/or  
36 permitted use by requiring design features to ensure routes accommodate their anticipated  
37 uses. Best practices for decommissioning routes would likewise direct traffic to higher-  
38 quality routes that remain open for use and will adequately facilitate access over the long  
39 term.

1       ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and***  
2       ***Coordination***

3       If there is a future decline in GRSG or its habitat and the decline is attributable to travel  
4       management, the BLM would evaluate management alternatives that could result in more  
5       restrictions on travel and decrease travel opportunities.

6       Where re-routing new roads is required to avoid GRSG impacts (habitat and/or  
7       disturbance), those actions could result in longer roads with overall greater surface  
8       disturbance.

9       If the 3 percent disturbance cap within a BSU is reached, new surface disturbance within the  
10      BSU would be prohibited, thus preventing new road development. In these areas, the BLM  
11      and Forest Service would be unable to accommodate additional travel demand until the  
12      disturbance falls below the disturbance cap.

13   **4.8   Lands and Realty**

14      BLM-administered and National Forest System lands are used for a variety of purposes.  
15      Major focus areas for the lands and realty program include land use authorizations, land  
16      tenure adjustments, and land withdrawals. The Forest Service completes landownership  
17      adjustments (purchase, exchange, donation, and ROW acquisition), while the BLM conducts  
18      land tenure adjustments (exchanges, disposals, and acquisitions).

19      This section discusses impacts on lands and realty from proposed management actions of  
20      other resources and resource uses. Existing conditions concerning lands and realty are  
21      described in **Section 3.11**.

22                   **4.8.1   Methods and Assumptions**

23           ***Indicators***

24           Indicators of impacts on lands and realty are as follows:

- 25                   • Acres of BLM-administered and National Forest System surface  
26                   ownership, which include federal surface with private minerals,  
27                   in the planning area.
- 28                   • Acres of BLM-administered and National Forest System surface  
29                   ownership affected by ROW and Special Use Authorization  
30                   (SUA) allocations (i.e., exclusion, avoidance, open).
- 31                   • Acres of BLM-administered and National Forest System surface  
32                   ownership affected by ROW and SUA restrictions (e.g., BMPs,  
33                   RDFs, seasonal restrictions, buffers).
- 34                   • Acres/miles of designated ROW corridors open to ROW and  
35                   SUA development in the planning area.
- 36                   • Number, acres, type, and density of surface-disturbing ROWs,  
37                   SUAs, and leases in the planning area.

- Acres of potential land tenure adjustments (i.e., lands identified as suitable for disposal, acquisition, or exchange) in the planning area.

#### ***Assumptions***

This analysis includes the following assumptions:

- Authorized ROWs, SUAs, permits and leases would continue to be managed subject to valid existing rights.
- Mitigation by burying power lines, collocation, or including design features (e.g., perch deterrents) reduces impacts on GRSG.
- The demand for both energy- and non-energy ROWs/SUAs is anticipated to remain steady or gradually increase over time.
- No utility-scale (20 MW) solar energy ROWs/SUAs are anticipated due to low solar energy potential.
- Activities proposed or approved for mineral exploration or development have potential implications for lands and realty decisions for associated ROWs/SUAs.
- Collocation does not eliminate the potential for new temporary or permanent surface disturbance.
- The BLM and Forest Service would continue to manage all previously withdrawn lands as withdrawn from entry, appropriation, or disposal under the public land laws. Withdrawals would be reviewed as needed and recommended for extensions, modifications, revocations, or terminations. All existing withdrawals initiated by other agencies would be continued unless the initiating agency, BLM, or the Forest Service requests that the withdrawal be extended, modified, revoked, or terminated.
- Any lands that become unencumbered by withdrawals or classifications will be managed according to the decisions made in this LUPA. If the LUPA has not identified management prescriptions for these lands, they will be managed the same as adjacent or comparable public lands within the decision area.
- Designated utility corridors have a higher probability for development because of their designation in existing land use plans.
- Upgrades to existing power lines will occur within existing designated corridors, unless an alternate route benefits GRSG.

1                   **4.8.2 Nature and Type of Effects**

2           BLM and Forest Service management of resources and uses affects the lands and realty  
3           program by increasing or decreasing the BLM and Forest Service lands and realty programs'  
4           ability to carry out land use authorization or land tenure/land ownership adjustment actions.  
5           Effects on the lands and realty program are typically the result of management that excludes  
6           or avoids ROWs or SUA in certain areas, requires stipulations on land use activities, or  
7           applies criteria for land tenure actions.

8           Forest Service land use plan prescriptions are similar to BLM exclusion and avoidance areas.  
9           Prescriptions can restrict or prohibit certain uses in a planning area. The Forest Service  
10          grants SUAs, while the BLM grants ROWs on their respective agency lands. In addition,  
11          each agency issues permits, easements and leases. The Forest Service completes  
12          landownership adjustments (purchase, exchange, donation, and ROW acquisition), while the  
13          BLM conducts land tenure adjustments (withdrawals, disposals through sale or exchange,  
14          and acquisitions through purchase or exchange)

15          Within a BLM ROW exclusion area, the authorization of new ROWs is not allowed under  
16          any conditions; SUA authorizations would be prohibited on National Forest System lands. A  
17          ROW avoidance area may be available for ROW location but requires special stipulations  
18          such as resource surveys and reports, construction and reclamation engineering, long-term  
19          monitoring, special design features, special siting requirements, timing limitations, regional  
20          mitigation, and rerouting. Such stipulations could restrict project location or delay the  
21          availability of an energy supply by delaying or restricting construction of pipelines,  
22          transmission lines, or renewable energy projects. Additionally, such stipulations could limit  
23          future access, delay or increase the cost of energy supplies, or delay or restrict  
24          communications service availability. As a result of such stipulations, alternative routes may  
25          need to be identified and selected to protect GRSG habitat and there may be increased  
26          processing time and costs due to the potential need to relocate facilities or due to greater  
27          design, mitigation, and siting requirements.

28          Management that restricts ROW development in a certain area will eventually increase the  
29          concentration of ROW development in adjacent areas where restrictions are not present.  
30          Increased ROW density can limit new siting options in non-restricted areas, decrease service  
31          reliability to rural areas, increase conflict among facilities, and intensify impacts on other  
32          resources and uses.

33          Co-locating infrastructure in existing ROWs, corridors, or existing disturbed areas reduces  
34          land-use conflicts, limits disturbance to the smallest footprint, and limits impacts to greater  
35          sage-grouse or their habitats. Co-location policies also clarify the preferred locations for  
36          utilities, and potentially simplifying processing on BLM-administered and National Forest  
37          System lands. However, collocating can limit options for infrastructure development and  
38          could reduce network redundancy and potentially affect service reliability in some areas.

39          Land tenure and landownership adjustments are intended, among other things, to maintain  
40          or improve the landownership pattern for the protection and management of resources,

1 including management of GRSG habitat. Land disposal, exchange, purchase, or sale can  
2 result in a more contiguous decision area, thus increasing the efficiency of BLM and Forest  
3 Service management. However, while consolidation may be beneficial for certain resources  
4 and uses, it may not necessarily reduce effects on GRSG habitat.

5 Implementing management for the following resources would have negligible or no impact  
6 on lands and realty management and are not discussed in detail: travel and transportation  
7 management, recreation, range management, locatable minerals, non-energy leaseables,  
8 mineral split estate, fire and fuels management, habitat restoration and vegetation  
9 management, and ACECs.

#### 10 **4.8.3 Impacts on Lands and Realty Common to All Alternatives**

11 The nature and type of impacts described below are common to all alternatives, but the  
12 context and intensity may vary by alternative.

##### 13 ***Impacts from Recreation and Visitor Services***

14 BLM and Forest Service management goals and objectives are to preserve a desired setting  
15 and recreation experience for users within SRMAs and developed recreation sites. Land uses  
16 in the SRMAs and developed recreation sites should not conflict with recreation uses. Under  
17 all alternatives, the BLM and Forest Service would continue to evaluate land use  
18 authorizations on a case-by-case basis in the special recreation areas and near recreation sites  
19 so as to avoid conflicting uses.

##### 20 ***Impacts from Special Designations Management***

21 Under all alternatives, the BLM and Forest Service would continue to manage existing  
22 special designation areas according to the existing LUP designations. Limiting ROW  
23 development in special designation areas impacts the ability of the BLM and Forest Service  
24 to accommodate ROW authorization demands within the planning area. This is particularly  
25 the case in locations where special designation areas separate energy sources (e.g., wind or  
26 geothermal) from likely demand centers. Routing transmission lines around exclusion areas  
27 could result in longer ROWs with greater surface disturbance and extended processing times.

#### 28 **4.8.4 Alternative A**

##### 29 ***Sage-Grouse Management***

30 GRSG management actions have been incorporated in the Dillon Field Office and for the  
31 Beaverhead/Deerlodge and Caribou National Forests. Within these areas, impacts on the  
32 lands and realty program are as follows:

- 33 • Additional siting criteria for ROWs proposed next to leks or within breeding or  
34 nesting habitat
- 35 • Required design features for certain types of infrastructure
- 36 • Extended processing times to review ROW applications for compliance with  
37 GRSG habitat management objectives

1 In the portions of the planning where land use plans do not contain GRSG management  
2 actions, there would be no impacts on lands and realty under Alternative A.

### 3 ***Impacts from Travel and Transportation Management***

4 Under Alternative A, existing transportation routes would continue to provide motorized  
5 access to ROW infrastructure and communication sites for construction and maintenance.  
6 Refer to **Section 4.6** for further analysis.

### 7 ***Impacts from Lands and Realty***

#### 8 *Land Use Authorizations*

9 Under Alternative A, 1,956,200 acres on both BLM-administered and National Forest  
10 System would continue to be managed as ROW avoidance areas, and 1,028,500 acres would  
11 continue to be managed as ROW exclusion. Within exclusion areas, new ROW development  
12 would be prohibited, which would prevent the lands and realty program from approving  
13 new applications within these areas. All other lands within the decision area would continue  
14 to be open for ROW development. Alternative A would not prevent the BLM or Forest  
15 Service from accommodating future demand for ROW development within the planning  
16 area.  
17

18 BLM-administered and National Forest System lands would continue to be available for  
19 multiple-use and single-use communication sites and road access ROW authorizations on a  
20 case-by-case basis, in accordance with Title V of FLPMA, 43 CFR Part 2800 regulations, and  
21 Section 704(c) of the Telecommunications Act of 1996 (47 USC 332). All ROW applications  
22 would be reviewed using the criteria of collocating new ROWs within or next to existing  
23 ROWs wherever practical to avoid the proliferation of separate ROWs.

#### 24 *Wind and Solar ROWs*

25 Wind and solar energy projects would be permitted through the ROW permitting process.  
26 For wind and solar energy development under Alternative A, the BLM would manage  
27 1,715,800 acres as ROW exclusion and 320,200 acres as ROW avoidance. The Forest Service  
28 would continue to manage 227,700 acres as closed to new wind and solar use authorizations,  
29 while new wind and solar development would be avoided on 1,018,900 acres on National  
30 Forest System lands.

31 ROW exclusion and avoidance designations decrease the amount of BLM-administered and  
32 National Forest System land available for new development. Under Alternative A, the BLM  
33 and Forest Service management would provide sufficient opportunities to accommodate  
34 future wind and solar energy development within the planning area. Therefore, there would  
35 be little to no impacts on wind or solar energy development under Alternative A. (Refer to  
36 **Section 4.8.2** for impact analysis regarding geothermal resources)

#### 37 *Withdrawals*

38 There would continue to be 4,032,400 acres of land withdrawals in the planning area,  
39 including 2,224,100 acres in GRSG habitats.

1       ***Impacts from Special Designations Management***

2       Under Alternative A, nine ACECs would continue to be managed primarily as ROW  
3       exclusion. This would affect ROW permit application processing times, available  
4       development locations, and design standards for proposed ROWs on approximately 426,700  
5       acres within the planning area. Refer to **Section 4.12**, Special Designations, for further  
6       analysis.

7                       **4.8.5 Alternative B**

8       ***Sage-Grouse Management***

9       Management actions under Alternative B to protect GRSG habitat would impact lands and  
10      realty by closing areas to ROW authorizations, additional criteria for land exchanges, and  
11      limitations on new mineral development and road construction. Primary impacts under  
12      Alternative B are from the designation of an additional 7.3 million acres as ROW exclusion  
13      and an additional 582,800 acres as ROW avoidance, compared to Alternative A.

14     In exclusion areas, the BLM and Forest Service would be prohibited from approving new  
15     ROW development. In avoidance areas, development would be allowed only if certain siting  
16     and design requirements could be met. ROW restrictions under Alternative B would  
17     substantially reduce the ability of the BLM and Forest Service to accommodate demand for  
18     interstate and intrastate gas pipelines and electric transmission lines, wind and solar energy  
19     development, fiber optic lines, and communication sites.

20      ***Impacts from Travel and Transportation Management***

21      Impacts from travel and transportation management under Alternative B are the same as  
22      under Alternative A. Proposed action under Alternative B to prioritize travel management  
23      planning in PHMA, which would design and designate a travel system that minimizes  
24      adverse effects on GRSG habitat, is an activity-level process and would be accompanied by  
25      separate environmental review and documentation. Refer to **Section 4.6** for further analysis.

26      ***Impacts from Lands and Realty***

27                       ***Land Use Authorizations***

28      Under Alternative B, 8.3 million acres would be designated as ROW exclusion. Neither the  
29      BLM nor the Forest Service would authorize new ROWs in these areas unless the  
30      infrastructure could be located entirely within an existing ROW footprint. Additionally, 2.5  
31      million acres would be designated ROW avoidance. As noted above in **Section 4.7.2**,  
32      managing GRSG habitat as ROW exclusion or avoidance would prevent the BLM and  
33      Forest Service from accommodating new ROW development in those areas.

34      With a continuing demand for new ROWs in the planning area, including major interstate  
35      and intrastate electrical transmission lines, gas pipelines, and communication ROWs,  
36      developments would be diverted to adjacent private or state lands or would be prevented  
37      altogether. Development on adjacent lands could result in direct and indirect impacts on  
38      GRSG populations and habitat (e.g., vehicle traffic on roads crossing BLM-administered and  
39      National Forest System lands). This would be the case especially if the development is close  
40      to GRSG habitat on BLM-administered or National Forest System lands.  
41

1 If new ROW development, particularly interstate electrical transmission, fiber optic, and gas  
2 pipelines, could not be feasibly developed due to ROW exclusions on BLM-administered  
3 and National Forest System lands in the planning area, then energy and communication  
4 development opportunities needed to meet a growing demand would be reduced until  
5 alternative routes or technology could be developed.

6 Within avoidance areas, the BLM and Forest Service would continue to process ROW  
7 applications but would require additional requirements before authorizing the ROW.  
8 Supplemental design criteria and siting limitations would decrease the level of future ROW  
9 development in avoidance areas.

10 Additionally, under Alternative B, the BLM and Forest Service would take advantage of  
11 opportunities to remove, bury, or modify existing power lines. Limitations on new ROWs  
12 and aboveground lines, such as transmission lines and pipelines, could restrict the availability  
13 of energy or service availability and reliability for communication systems.

#### 14 *Wind and Solar ROWs*

15 Under Alternative B, utility-scale wind and solar energy would be excluded on 8.5 million  
16 acres and would be avoided on 2.3 million acres. ROW exclusion and avoidance decreases  
17 the BLM's and Forest Service's ability to accommodate new wind and solar energy  
18 development in GRSG habitats. However, impacts would occur only in areas statewide that  
19 are considered developable, such as locations where wind speeds are greater than 23 feet [7  
20 meters] per second). Therefore, excluding or avoiding wind and solar energy development in  
21 GRSG habitat would reduce but not eliminate renewable energy development potential  
22 within the sub-region.

#### 23 *Land Tenure and Landownership*

24 The BLM and Forest Service would retain administration of public land in PHMA.  
25 Exceptions would be where land tenure adjustments would result in more contiguous federal  
26 ownership patterns or where disposal accompanied by a habitat mitigation agreement or  
27 conservation easement would result in more effective management of GRSG habitat.  
28 Impacts would be consistent with those described in **Section 4.7.2**.

#### 29 *Withdrawals*

30 Under Alternative B, land withdrawals in PHMA and GHMA would total 2,223,100 acres.  
31 Additionally, the BLM or Forest Service would recommend all PHMA for mineral  
32 withdrawal. However, withdrawal would be subject to Congress's approval. The BLM or  
33 Forest Service would not recommend approval of withdrawals for reasons other than  
34 mineral activity. In withdrawn areas, BLM-administered or National Forest System lands  
35 would not be available for mineral extraction for a defined period. Impacts on mineral  
36 development are described in **Sections 4.8** through **4.11**.

#### 37 *Impacts from Special Area Designations*

38 Under Alternative B there would be no impacts from ACECs or ZAs on lands and realty.

1                                   **4.8.6 Alternative C**

2                   ***Sage-Grouse Management***

3 Management actions under Alternative C to protect GRSG habitat would impact lands and  
4 realty through by designating over 10 million additional acres as ROW exclusion, compared  
5 to Alternative A. A ten-fold increase in ROW exclusion area would result in the most ROW  
6 restrictions of any alternative. It would prevent the BLM and Forest Service from  
7 accommodating demand for new transmission lines, gas pipelines, communication sites,  
8 wind energy facilities, and other types of ROWs. Additional management prescriptions for  
9 land tenure and road construction would further constrain BLM-administered and National  
10 Forest System lands and realty program functions in GRSG habitat.

11                   ***Impacts from Travel and Transportation Management***

12 Impacts from travel and transportation management under Alternative C would prohibit  
13 new road construction within four miles (6.4 km) of active leks. The proposed management  
14 under Alternative C would limit new road construction on BLM-administered and National  
15 Forest System lands throughout occupied habitat. Limitations on road construction would  
16 reduce the number of new road ROW applications submitted to the BLM. The limitations  
17 would make certain areas impractical for new ROW authorizations, particularly in areas  
18 where there are few or no ROWs or roadways. Refer to **Section 4.6** for further analysis.

19                   ***Impacts from Lands and Realty***

20  
21                   ***Land Use Authorizations***

22 Under Alternative C, all occupied habitat (11.1 million acres) would be designated as ROW  
23 exclusion. The BLM and Forest Service would not authorize new ROWs in exclusion areas  
24 unless the infrastructure could be located in an existing ROW. Impacts under Alternative C  
25 are similar to Alternative B except that under Alternative C exclusion areas would apply to a  
26 larger land area. Therefore, Alternative C would further reduce opportunities for  
27 communication facilities, gas pipelines, fiber optic cables, electrical transmission lines, and  
28 similar ROW development. There is a continuing demand for these ROWs in the planning  
29 area to meet energy and communication needs outside the planning area; Alternative C  
30 would reduce the ability of the BLM and Forest Service lands and realty programs from  
31 meeting those needs.

32                   ***Wind and Solar ROWs***

33 Management of 11.1 million acres as exclusion for utility-scale wind and solar energy  
34 development would eliminate the BLM and Forest Service's ability to accommodate any new  
35 wind or solar energy demand on that portion of GRSG habitat. ROW exclusions would also  
36 inhibit development on adjacent private and state land where transmission infrastructure  
37 would be needed across BLM-administered or National Forest System lands.

38                   ***Land Tenure and Landownership***

39 Under Alternative C, the BLM and Forest Service would retain public ownership in PHMA,  
40 with no exceptions. Impacts would be consistent with those described in **Section 4.7.2**.

1        *Withdrawals*

2        Under Alternative C, the total acres of land withdrawals are the same as under Alternative A.  
3        However, GRSG-occupied habitat, would be withdrawn from mineral entry. Impacts under  
4        Alternative C from withdrawals are the same as under Alternative B, except that mineral  
5        withdrawal would apply to all GRSG habitat. Refer to **Sections 4.8** through **4.11** for further  
6        analysis related to mineral development.

7        ***Impacts from Special Designations Management***

8        Under Alternative C, the BLM would designate 39 new ACECs, equivalent to approximately  
9        3.1 million acres. No Forest Service ZAs would be designated. Management for the ACECs  
10       would be tailored to protect the relevant and important values (i.e., GRSG habitat) for which  
11       the ACECs would be designated. All lands within the ACECs would be managed as ROW  
12       exclusion, which would prohibit new ROW development in those areas. Under Alternative  
13       C, infrastructure development and other ROWs would be directed to adjacent BLM-  
14       administered or National Forest System lands or to private lands. Alternative F would result  
15       in an overall reduction in new land use authorizations. New land use authorizations would  
16       be further reduced if ROW applicants could not find suitable alternative development  
17       locations outside ACECs. Refer to **Section 4.12**, Special Designations, for further analysis.

18                    **4.8.7 Alternative D**

19        ***Sage-Grouse Management***

20        Management proposed under Alternative D would enable the BLM and Forest Service to  
21        accommodate certain types of ROW development, because there would be no exclusion  
22        areas. However, it would exclude ROWs for large infrastructure development, such as  
23        electrical transmission lines greater than 50kV, and renewable energy testing and generation,  
24        on over 6.2 million acres. In addition, there would also be 2 million more acres of ROW  
25        avoidance areas, compared to Alternative A. Under Alternative D, the BLM-administered  
26        and National Forest System lands and realty programs would be prevented from  
27        accommodating any new demand for electrical transmission or renewable energy  
28        development in exclusion areas. A large increase in avoidance areas, even if Alternative D  
29        would require no absolute exclusion areas, would affect the ability of the BLM and Forest  
30        Service to grant new ROWs in GRSG habitat.

31        ***Impacts from Travel and Transportation Management***

32        Impacts from travel and transportation management under Alternative D are the same as  
33        under Alternative B. Refer to **Section 4.6** for further analysis.

34        ***Impacts from Lands and Realty***

35                    *Land Use Authorizations*

36        Alternative D would designate over 1 million acres as ROW exclusion for all ROW types,  
37        similar to Alternative A. However, it would also exclude large transmission lines, renewable  
38        energy ROWs, and new roadways on 6.2 million acres. An additional 3.9 million acres would  
39        be managed as ROW avoidance for all ROW types.  
40

1 Alternative D would impact the BLM-administered and National Forest System lands and  
2 realty programs by reducing their ability to authorize ROWs, such as electrical transmission  
3 lines greater than 50kV, within PHMA. Within avoidance areas, additional stipulations for  
4 the development of electrical transmission lines could result in the denial of projects that  
5 cannot meet ROW grant requirements to protect GRSG habitat. Limitations on electrical  
6 transmission line development, renewable energy development, and new roadways under  
7 Alternative D would be similar to Alternative C and are consistent with **Section 4.7.2**.  
8 Impacts on other types of ROWs and land use permits, such as electrical distribution lines,  
9 communication sites, fiber optic lines, pipelines, and water infrastructure, would result when  
10 an applicant could not find a suitable location outside avoidance or exclusion areas or could  
11 not meet the design and placement criteria for an ROW or other land use permit within an  
12 avoidance area. For communication facilities in particular, stipulations in avoidance areas  
13 could diminish the effectiveness of the communication infrastructure to the point where the  
14 development would not be practical, resulting in an impact on that type of infrastructure  
15 development and the communication network.

#### 16 *Wind and Solar ROWs*

17 Alternative D would exclude wind and solar energy testing and generation facilities on 6.7  
18 million acres in GRSG habitat. These types of ROWs would be avoided on an additional 4.3  
19 million acres in GRSG habitat. Impacts on wind energy ROWs would be consistent with  
20 **Section 4.7.2**. While excluding or avoiding wind and solar energy development in GRSG  
21 habitat would reduce development potential, impacts are concentrated primarily in areas  
22 south of Twin Falls and near Pocatello, where average wind speeds are greater than 23 feet  
23 (7 meters) per second (NREL 2009). This is the typical threshold for utility-scale wind  
24 energy to occur (NREL 2012). Therefore, Alternative D would reduce but not eliminate  
25 wind energy development potential within the sub-region. Impacts on solar energy  
26 development would be negligible due to a lack of solar potential in the planning area.

#### 27 *Land Tenure and Landownership*

28 Under Alternative D, the BLM and Forest Service would retain public ownership in all  
29 GRSG habitats, except where there is mixed ownership and land tenure adjustment would  
30 promote a more contiguous land pattern in GRSG habitat. Management actions to retain  
31 public ownership would increase land management efficiency, as described in **Section 4.7.2**.

#### 32 *Withdrawals*

33 There are no impacts from withdrawals under Alternative D.

#### 34 ***Impacts from Special Designations Management***

35 Under Alternative D, there are no impacts from ACECs or ZAs on lands and realty.

### 36 **4.8.8 Alternative E**

#### 37 ***Sage-Grouse Management***

38 Management actions under Alternative E to protect GRSG habitat would impact lands and  
39 realty through a 5.3 million-acre increase in ROW avoidance areas, compared to Alternative  
40 A. ROW avoidance criteria would impact the lands and realty program by limiting the areas  
41 where new ROW authorizations could be approved without supplemental siting and design

1 criteria to protect GRSG habitat. Avoidance criteria would reduce the number of ROW  
2 applications, increase processing times for applications submitted for projects in avoidance  
3 areas, and direct new development to adjacent lands, where fewer restrictions would be  
4 present.

### 5 ***Impacts from Travel and Transportation Management***

6 Impacts from travel and transportation management under Alternative E are the same as  
7 Alternative A. Refer to **Section 4.6** for further analysis.

### 8 ***Impacts from Lands and Realty***

#### 9 *Land Use Authorizations*

10 Under Alternative E, 7.3 million acres in CHZ and IHZ would be designated as ROW  
11 avoidance, while 979,100 acres would continue to be managed as ROW exclusion. New  
12 infrastructure would be prohibited in priority habitat, unless the infrastructure could be  
13 collocated in an existing ROW footprint and the infrastructure is critical for meeting  
14 increasing demands. Limitations on new infrastructure outside existing ROWs and ROW  
15 stipulations for avoidance areas would prevent the BLM and Forest Service from  
16 accommodating additional demand for ROW development within CHZ and in IHZ. This  
17 could result in ROW applications being denied. With the expected demand for new ROWs  
18 in the planning area, particularly interstate and intrastate electrical transmission and gas  
19 pipeline ROW developments, new ROW development could be diverted to adjacent private  
20 or state lands. If new ROW development could not be feasibly developed there would be a  
21 reduction in energy and communication development opportunities to meet growing  
22 demand.  
23

#### 24 *Wind and Solar ROWs*

25 Alternative E would continue to exclude wind and solar energy testing and generation  
26 facilities on 1.8 million acres, while avoiding these types of ROWs on 2.6 million acres.  
27 Alternative E would further restrict wind and solar ROWs through the use of triggers,  
28 stipulations, and BMPs. Avoiding or excluding wind and solar energy development would  
29 reduce or eliminate development potential, especially in areas considered to have  
30 developable (i.e., average wind speeds greater than 23 feet [7 meters] per second) wind  
31 resources. Impacts on solar energy development are negligible due to a lack of solar potential  
32 in the planning area.

#### 33 *Land Tenure and Landownership*

34 There are no impacts on lands and realty from land tenure requirements under Alternative E.

#### 35 *Withdrawals*

36 There are no impacts from withdrawals under Alternative E.

### 37 ***Impacts from Special Designations Management***

38 Under Alternative E, there are no impacts from ACECs or ZAs on lands and realty.

1                   **4.8.9 Alternative F**

2                   ***Sage-Grouse Management***

3 Management actions under Alternative F to protect GRSG habitat would impact lands and  
4 realty by designating over 7 million additional acres as ROW exclusion, compared to  
5 Alternative A. Similar to Alternative B and consistent with **Section 4.7.2**, ROW exclusion  
6 areas under Alternative F would restrict the BLM and Forest Service from accommodating  
7 demand for new transmission lines, gas pipelines, communication sites, wind energy  
8 facilities, and other types of ROWs.

9                   ***Impacts from Travel and Transportation Management***

10 Impacts from travel and transportation management under Alternative F are the same as  
11 under Alternative A. Refer to **Section 4.6** for further analysis.

12                   ***Impacts from Lands and Realty***

13 Alternative F would designate 8.4 million acres as ROW exclusion and 2.5 million acres as  
14 avoidance. By not authorizing new ROWs in exclusion areas, the ability of the BLM and  
15 Forest Service to accommodate the demand for land use authorizations would be  
16 diminished. Impacts are consistent with **Section 4.7.2** and would result in an overall decline  
17 in energy or service availability and reliability, when compared to Alternative A.

18                   ***Wind and Solar ROWs***

19 Alternative F would exclude wind and solar energy testing and generation facilities on 2.3  
20 million acres in GRSG habitat. These types of ROWs would be avoided on 486,100 acres.  
21 Impacts on wind energy ROWs under Alternative F are similar to Alternative B and are  
22 consistent with **Section 4.7.2**. While excluding or avoiding wind and solar energy  
23 development in GRSG habitat would reduce development potential, impacts would be  
24 concentrated in areas with average wind speeds greater than 23 feet (7 meters) per second  
25 since this is the typical threshold needed for utility-scale wind energy to occur (NREL 2012).  
26 Therefore, Alternative F would reduce but not eliminate wind energy development potential  
27 within the sub-region. Impacts on solar energy development are negligible due to a lack of  
28 solar potential in the planning area.

29                   ***Land Tenure and Landownership***

30 There are no impact on lands and realty from land tenure requirements under Alternative F.

31                   ***Withdrawals***

32 There are no impacts from withdrawals under Alternative F.

33                   ***Impacts from Special Designations Management***

34 Under Alternative F, the BLM would designate 17 or 18 new ACECs and Forest Service  
35 would designate 12 new ZAs, encompassing up to 1 million acres. Management for the  
36 ACECs and ZAs would be tailored to protect the relevant and important values (i.e., GRSG  
37 habitat) for which the ACECs and ZAs would be designated. All lands within the ACECs  
38 and ZAs would be managed as ROW exclusion, which would prohibit new ROW  
39 development in those areas. Under Alternative F, infrastructure development and other  
40 ROWs would be directed to adjacent BLM-administered or National Forest System lands or

1 to private lands. Alternative F would result in an overall reduction in new land use  
2 authorizations. These would be further reduced if ROW applicants could not find suitable  
3 alternative development locations outside ACECs or ZAs. Refer to **Section 4.12**, Special  
4 Designations, for further analysis.

#### 5 **4.8.10 Proposed Plan**

6 The Proposed Plan would enable the BLM and Forest Service to accommodate a portion of  
7 the anticipated future demand for ROW development, while conserving and enhancing  
8 GRSG habitat. The most notable impacts on the Lands and Realty program under the  
9 Proposed Plan would occur in PHMA. In addition to managing PHMA as avoidance areas  
10 for future land use authorizations, including ROWs, leases, and permits, the Proposed Plan  
11 would require land use authorizations to:

- 12 • Achieve a net conservation gain to GRSG,
- 13 • Incorporate RDFs,
- 14 • Avoid tall structures within key GRSG habitat areas,
- 15 • Meet noise requirements,
- 16 • Abide by lek buffer requirements, and
- 17 • Avoid disturbing more than 3 percent of any BSU in PHMA (and IHMA in  
18 Idaho).

19 Collectively, these GRSG conservation management actions would increase mitigation  
20 requirements for land use authorizations that could result in more complex project designs,  
21 potentially exclude infrastructure placement in the most cost effective locations, and  
22 potentially result in overall greater development costs. A corresponding effect could be a  
23 reduction in the number of authorization applications received for activities in PHMA (and  
24 IHMA in Idaho) and longer, more complicated review periods for those that are proposed in  
25 PHMA. Implementation of the GRSG habitat conservation management actions listed  
26 above would also place NSO stipulations on fluid mineral development in PHMA and  
27 IHMA, which would further reduce the demand for new ROW development in those areas.

28 Less restrictive management for new land use authorizations in GHMA and in GRSG  
29 habitat outside BLM-administered and National Forest System lands would allow for more  
30 ROW/SUA development, leases, and permits in those areas compared to PHMA. However,  
31 because the Proposed Plan would still require discretionary surface-disturbing land use  
32 actions to achieve a net conservation gain, incorporate RDFs, and abide by lek buffers,  
33 project proponents in GHMA could seek less restrictive locations outside GRSG habitat or,  
34 if located in GHMA, potentially incur added costs and longer project review periods.

#### 35 ***Impacts from Lands and Realty Management***

##### 36 *Land Use Authorizations*

37 Unless a new ROW/SUA is proposed within an existing designated corridor (**Figure 2-7**),  
38 which the BLM and Forest Service would manage as open (but still subject to the

1 disturbance cap), new major and minor ROW/SUA development would be avoided in  
2 PHMAs and IHMAs (8,365,000 acres). Within PHMA and IHMA, there are a total of 59,900  
3 acres of designated corridors. New development proposed within and outside corridors  
4 would be subject to RDFs, and disturbance mitigation requirements.

5 Management of PHMA and IHMA as avoidance, combined with RDFs have the potential to  
6 increase project costs and could result in a greater proportion of new development occurring  
7 outside PHMA and IHMA. Concentrating new development in corridors, GHMA, and non-  
8 habitat areas could lead to higher density of ROW/SUA development in those areas with  
9 impacts consistent with the **Nature and Types of Effects**.

10 The Boardman to Hemingway and Gateway West projects are exempt from the proposed  
11 plan decision to designate PHMA/GHMA as an avoidance area (Proposed Plan decisions  
12 LR-1, LR-5 and LR-13). The projects are also exempt from the proposed GRSG screening  
13 criteria, RDFs, buffers, tall structure requirements, and disturbance cap requirements  
14 identified in Chapter 2.

15 The Obama Administration identified these transmission projects as priority projects, as part  
16 of the President's commitment to job creation and modernizing America's Infrastructure.  
17 These transmission projects were two of seven projects identified for expedited permit  
18 review and federal agency coordination among an interagency Rapid Response Team for  
19 Transmission (RRTT) established to foster coordination, expedite simultaneous permitting  
20 processes and resolve permitting challenges, while ensuring appropriate environmental  
21 reviews.

22 The BLM is currently processing the application for the Boardman to Hemingway and  
23 Gateway West projects, both high-voltage transmission lines, which include alternatives  
24 through this avoidance area/GRSG habitat. The BLM is analyzing conservation measures  
25 for GRSG as part of the review process for Boardman to Hemingway and Gateway West.

26 Boardman to Hemingway and Gateway West are analyzed in detail in the cumulative impacts  
27 section of this plan.

28 Although existing designated corridors would be considered first for new ROW  
29 development in GRSG habitat areas, because corridors are typically located adjacent to  
30 existing infrastructure, power companies are reluctant to locate new infrastructure in those  
31 areas given redundancy concerns. New ROW development would be likely in corridors  
32 where those corridors provide a cost effective, direct route to demand centers that also avoid  
33 conflicts with populated areas. If an area outside PHMA and IHMA provide this option,  
34 then a developer would likely pursue that route instead of placing within a corridor.

35 In GHMA, 1,764,500 acres on BLM-administered lands would be open for proposals for  
36 new major and minor ROW/SUA development, while only major ROWs in Montana  
37 (828,100 acres) would be avoided. RDFs for new ROW/SUAs in general habitat could  
38 further deter development in those areas resulting in a greater likelihood for development in

1 non-habitat areas. Any decline in new ROW and SUA development applications in general  
2 habitat would be less than in PHMA and IHMA.

3 The overall proposed increase in ROW restrictions under the Proposed Plan could affect the  
4 BLM and Forest Service's ability to accommodate the demand for new linear energy-related  
5 ROW development. Compared to Alternative A, energy suppliers under the Proposed Plan  
6 could have fewer options to place new transmission lines without costly route adjustments  
7 or design modifications.

#### 8 *Wind and Solar*

9 BLM and Forest Service management of PHMA as ROW/SUA exclusion areas for wind  
10 and solar would prevent the development of new utility-scale wind and solar energy  
11 generation facilities on 6,352,300 acres of GRSG habitat. Due to low solar energy potential  
12 in the planning area, there would be negligible to no impacts on solar energy development.  
13 Because wind resources in the planning area are sufficient to support utility-scale wind  
14 energy development, excluding wind energy ROW/SUAs in PHMA would restrict the BLM  
15 and Forest Service ability to accommodate future demand. Projects currently proposed  
16 would not be authorized. Excluding wind energy development in PHMA and avoiding it in  
17 IHMA would distribute new development to GHMA and non-habitat areas where fewer  
18 restrictions would apply. Demand for new transmission lines, access roads, and related  
19 ancillary features to serve new wind generation projects on non-habitat or private lands  
20 could result in new ROW/SUA applications in GRSG habitat. Where transmission lines,  
21 access roads, and related ancillary features would cross PHMA and IHMA, management of  
22 those areas as ROW/SUA avoidance areas could deter or prevent wind energy development  
23 on non-habitat or private lands.

24 Although GHMA would be open for proposals for new wind development on BLM-  
25 administered lands, RDFs and requirements to achieve a net conservation gain to GRSG  
26 (e.g. buffers, disturbance mitigation, and tall structure restrictions) could affect wind  
27 development by limiting the number of turbines per project and the ability to access  
28 generation sites. Where wind development on private land or non-habitat requires new  
29 access roads, RDFs for roadways, including requirements to use existing roads, could limit  
30 access and subsequent energy development opportunities on private land or non-habitat  
31 areas.

#### 32 *Other Land Use Authorizations*

33 Excluding landfills and commercial service airports in PHMAs and avoiding them in IHMA  
34 would shift any new development and associated disturbance to GHMA or non-habitat  
35 areas. However, because there is little to no demand for these uses within GRSG habitat,  
36 managing PHMA as exclusion for these uses is not anticipated to affect the BLM lands and  
37 realty program or hinder future refuse disposal or air services opportunities in the planning  
38 area. Landfill areas, even if transferred to non-federal ownership, would be considered a  
39 disturbance.

40 In all GRSG habitat areas, restrictions on temporary (less than 3 years on BLM-administered  
41 lands and limited to 1 year on National Forest System lands) authorizations (e.g., apiaries and

1 filming) would be subject to seasonal or timing restrictions and mitigation requirements  
2 regarding habitat loss. Seasonal or timing restrictions on temporary uses could prevent those  
3 uses during certain times of year (e.g., lekking season) and could prevent the BLM and the  
4 Forest Service from accommodating demand for those uses.

5 Impacts from management of water development ROW/SUAs would be minimal. Seasonal  
6 timing restrictions may temporarily limit the use of some water developments with minimal  
7 to no long-term impacts.

#### 8 *Land Tenure*

9 Land tenure actions would be allowed in PHMA and IHMA if they can demonstrate a net  
10 conservation gain to GRSG. Allowing certain land tenure actions could create a more  
11 contiguous decision area and increase short- and long-term land management efficiency, as  
12 described in the **Nature and Types of Effects**. Land exchanges or disposal to remove low-  
13 quality habitat from BLM-administered land and National Forest System land would also  
14 increase efficiency where those lands are isolated and difficult to manage.

15 Recommending SFAs for mineral withdrawal would decrease the overall long-term demand  
16 for ROWs/SUAs to support mineral development. The recommended withdrawal would be  
17 for locatable minerals only and not result in a land withdrawal. The BLM and Forest Service  
18 would retain their respective ownership and primary management responsibilities.

#### 19 *Impacts from Salable Minerals Management*

20 Closing PHMAs to new salable mineral authorizations would decrease the need for new  
21 ROWs/SUAs to serve those uses. It also would require source material for maintenance of  
22 existing gravel road ROWS to be obtained from existing sites in PHMA and IHMA, or  
23 existing or expanded sites in GHMA or non-habitat. If the amount of source material is  
24 insufficient to properly maintain the road, access via those roadways to valid existing  
25 ROW/SUAs (e.g., transmission lines) and leases (e.g., communication sites) could be  
26 impacted. Requiring existing sites to be subject to RDFs and GRSG conservation measures  
27 (e.g. buffers, disturbance mitigation, and seasonal timing restrictions) could impact the ability  
28 of the sites to remain open and the availability of source material.

#### 29 *Impacts from Leased Fluid Minerals Management*

30 Restrictions on surface occupancy for new fluid mineral development in PHMAs and  
31 IHMAs could decrease the potential for new fluid mineral development in those areas and  
32 subsequently the demand for associated ROWs/SUAs to serve those uses. Surface-  
33 disturbing activities could be shifted, additional protective measures could be required, and  
34 extraction delays could occur.

#### 35 *Impacts from Anthropogenic Disturbance Management, Adaptive Management, and* 36 *Mitigation*

37 Limits on anthropogenic disturbance in biologically significant unit (BSU) within PHMAs  
38 and IHMAs where a disturbance threshold objective has been met or exceeded or an  
39 adaptive management trigger has been tripped would decrease the potential for new  
40 ROW/SUAs in those areas. Requiring and ensuring mitigation that provides a net

1 conservation gain could prevent new development where infrastructure could not be co-  
2 located or relocated outside PHMA or IHMA. If infrastructure authorized by land use  
3 authorizations is determined as a causal factor in the decline of GRSG populations in a BSU,  
4 incorporation of adaptive management could result in additional restrictions on ROW/SUA  
5 authorizations in that BSU, including exclusion of future ROWs/SUAs until a positive  
6 GRSG trend is observed over a 3-year period.

#### 7 **4.9 Leasable Minerals (Leased and Unleased), Including Fluid Minerals and Nonenergy** 8 **Solid Leasable Minerals**

##### 9 **4.9.1 Fluid Minerals**

10 This section discusses impacts on fluid minerals from proposed management actions for  
11 other resources and resource uses. Existing conditions concerning fluid minerals are  
12 described in **Section 3.12**.

##### 13 ***Methods and Assumptions***

14 The analysis of impacts on fluid minerals from this LUPA focuses on the impacts of  
15 proposed management actions to protect GRSG. These impacts may be direct or indirect.  
16 For example, a direct impact on oil and gas development would result from closing an area,  
17 particularly an area that has moderate to high potential for the discovery of an oil or gas  
18 resource, to fluid mineral leasing. An indirect impact would result from managing an area as  
19 ROW exclusion, which could prohibit construction of necessary off-lease facilities and  
20 access, thereby changing the economic feasibility of developing the leased resource.  
21 Additional actions or conditions that could cause direct or indirect impacts on oil and gas  
22 leasing and development are described under *Indicators*, below.

##### 23 *Indicators*

24 Indicators of impacts on fluid minerals are as follows:

- 25 • Acres of unleased land with medium oil and gas potential  
26 identified as closed to fluid mineral exploration and  
27 development
- 28 • Acres of unleased land with medium oil and gas potential subject  
29 to no surface occupancy (NSO) stipulations
- 30 • Acres of unleased land with medium oil and gas potential subject  
31 to controlled surface use (CSU) and/or timing limitation (TL)  
32 stipulations
- 33 • Number of leases and acres over which COAs would be applied  
34 to oil and gas development activities on leased parcels for the  
35 protection of GRSG
- 36 • Acres subject to restrictions on geophysical exploration in  
37 GRSG habitat
- 38 • Acres managed as ROW avoidance areas

- Acres managed as ROW exclusion areas

### *Assumptions*

The analysis includes the following assumptions:

- Under all alternatives, reclamation bonds would be required, pursuant to 43 CFR 3104 and 36 CFR 228.109(a), in an amount sufficient to ensure full restoration of lands to the condition in which they were found. In addition, BLM approval of Applications for Permit to Drill would continue to be required prior to commencement of drilling under all alternatives in accordance with 43 CFR 3162.
- The lands in the Curlew Grassland area, as described in the Pocatello RMP, that are administratively unavailable for leasing are included in the total number of acres closed to leasing under Alternative A.
- Management actions proposed in this LUPA would apply to oil and gas activity where the BLM and Forest Service manage the surface over federal fluid mineral estate as well as where federal fluid mineral estate lies beneath private or state surface (split estate).
- For planning purposes, it is assumed that development would occur as described in **Appendix O**, Reasonably Foreseeable Development Scenario, and **Section 3.12**, Mineral Resources. Interest in oil and gas in Idaho is expected to remain sporadic. As the demand for energy increases, so will demand for extracting energy resources in areas with potential.

### *Nature and Type of Effects*

In order to describe the effects of imposing GRSG management actions on oil and gas leasing and development, the above indicators were calculated within GRSG habitat for each alternative. All of these factors are considered to be impediments to oil and gas leasing and development, to varying degrees. In general, an alternative with greater acreages of such restrictions is considered to have a greater impact on oil and gas leasing and development potential than an alternative with fewer acres of such restrictions, especially in areas with medium oil and gas potential.

Closing public lands, especially those with moderate to high oil and gas potential, within GRSG habitat to fluid mineral leasing would directly impact the oil and gas program by removing the opportunity afforded U.S. citizens by the Mineral Leasing Act, to explore and develop mineral resources in those areas. Oil and gas operators would be limited to exploring and developing on non-federal lands, but only if favorable geologic conditions exist. The opportunity for discovery may be lost altogether if such conditions are unique to the federal lands. Closing lands to leasing in areas of moderate to high potential may also result in a loss of royalties to the federal, state, and county governments from oil and gas development.

1 Management actions that prohibit or restrict surface occupancy or disturbance (such as TL  
2 stipulations, NSO stipulations, CSU stipulations, and limitations on the total amount of  
3 surface disturbance in areas) overlying federal oil and gas resources could also directly impact  
4 the development of those resources.

5 In areas where NSO stipulations are applied, federal fluid minerals could be leased, but the  
6 leaseholder/operator's access to the mineral resource is limited to those areas that are not  
7 covered by the NSO stipulation. Proposed drill sites may need to be re-located to an area  
8 with lower potential for discovery of a valuable mineral resource, resulting in development  
9 delays, increased expenses, lower resource recovery and lower royalties collected. While off-  
10 site methods, such as directional drilling, may be employed to access the mineral resource,  
11 the area where directional drilling can be effectively used is limited. Where an NSO  
12 stipulation covers a large area or where no leasing is allowed on surrounding lands, the  
13 mineral resource may be inaccessible. Additionally, because it is not economically practical to  
14 use directional drilling for wildcat wells, an NSO stipulation may preclude drilling of those  
15 wells because the operator does not want to put forth the financial resources to do so.  
16 Applying an NSO stipulation can be nearly as restrictive to oil and gas leasing and  
17 development as closing an area to leasing, however, the operator is aware of the stipulations  
18 when the lease was purchased.

19 Application of CSU stipulations allows some use and occupancy of the surface while limiting  
20 development under certain conditions. While less restrictive than an NSO, a CSU stipulation  
21 allows the BLM to require special operational constraints, to shift the surface-disturbing  
22 activity associated with fluid mineral leasing more than the standard 656 feet (200 meters), or  
23 to require additional protective measures (e.g., restrictions on noise levels) to protect GRSG.  
24 For example, a CSU stipulation might create a buffer around leks within which surface  
25 disturbance is not allowed. While not prohibiting surface-disturbing activities, a CSU  
26 stipulation can influence the location and level of operations within the subject area.

27 TL stipulations may be necessary to protect GRSG from impacts of development during  
28 critical seasons or times of day. These stipulations are necessary if impacts cannot be  
29 mitigated by prohibiting proposed activities for up to 60 days in any lease year, as deemed  
30 reasonable and within lease rights granted (see 43 CFR 3101.1-2). Leases with TL  
31 stipulations would be temporarily off-limits to fluid mineral exploration and development,  
32 surface-disturbing activities, and intensive human activity during identified time frames,  
33 based on seasons or GRSG breeding times. While some routine activities would be allowed  
34 at all times (e.g., vehicle travel and maintenance), construction, well drilling and completions,  
35 and other operations considered to be intensive would not be allowed during the restricted  
36 time frame. Most activities, however, can be initiated and completed outside of the restricted  
37 dates specified in the TL stipulation.

38 Applying appropriate RDFs (see **Appendix B**) and management actions outlined in  
39 **Chapter 2**, to post-lease activities as Conditions of Approval could directly impact oil and  
40 gas operations. These RDFs and management actions include such standards as noise  
41 restrictions, height limitations on structures, design requirements, water development  
42 standards, remote monitoring requirements, and reclamation standards. Additional site-

1 specific planning, such as master development plans and unitization, and reclamation  
2 bonding requirements may also be required. Applying these requirements may impact oil and  
3 gas operations by increasing costs and causing delays to develop the resource.

4 Placing limits on geophysical exploration could reduce the ability to collect geologic data  
5 concerning oil and gas resources on federal mineral estate. TLs on geophysical exploration  
6 could lead to equipment scheduling delays.

7 Management actions creating off-lease ROW exclusion or avoidance areas could indirectly  
8 increase the cost of oil and gas extraction by limiting the available means for transporting oil  
9 and gas from the lease to processing facilities and markets. For example, a new natural gas  
10 pipeline could not be built in a ROW exclusion area. The pipeline may need to take a less  
11 direct route to its destination to avoid the exclusion area, or another mode of conveyance of  
12 the resource may be required. Oil and gas operations may move to nearby private lands  
13 where transport is easier, thereby reducing the number of operations on federal lands.  
14 Impacts would be mitigated where exceptions were allowed for collocating new ROWs  
15 within existing ROWs to recognize valid existing rights.

16 Implementing management for the following resources would have negligible or no impact  
17 on oil and gas; therefore they are not discussed in detail: travel and transportation  
18 management, recreation, range management, solid minerals, fire and fuels management,  
19 habitat restoration and vegetation management, and special designations.

## 20 ***Alternative A***

### 21 *Impacts from Lands and Realty Management*

22 Under Alternative A, 1,028,500 acres (4 percent of BLM-administered and National Forest  
23 System surface in the decision area) would continue to be managed as ROW exclusion areas.  
24 Another 1,956,200 acres (8 percent of BLM-administered and National Forest System  
25 surface in the decision area) would continue to be managed as ROW avoidance areas. This  
26 management would continue to impact the fluid minerals program, as described under  
27 **Nature and Type of Effects.**  
28

### 29 *Impacts from Fluid Minerals Management*

30 Under Alternative A, new leases in most areas within the decision area (6,327,500 acres)  
31 would continue to be open subject to standard terms and conditions. NSO stipulations  
32 would continue to be applied to 931,000 acres of federal oil and gas estate. Approximately  
33 2,714,700 acres of the decision area would remain closed to leasing. These management  
34 actions would continue to have the types of impacts described under **Nature and Type of**  
35 **Effects.**

36 Error! Reference source not found. Error! Reference source not found. **Table 4-72** breaks  
37 down the unleased medium potential acres within the decision area as to whether they would  
38 be open or closed to leasing and what stipulations would be applied.

**Table 4-71**  
**Oil and Gas Leasing Categories in Unleased Medium Potential Areas by Alternative**

Constraint	Alternative A	Alternatives B and F	Alternative C	Alternative D	Alternative E	Proposed Plan
Closed to Leasing	289,500	496,300	601,000	289,500	289,500	257,400
Open Subject to NSO Stipulations	170,400	100,000	51,400	176,900	186,200	348,100
Open Subject to CSU/TL Stipulations	201,100	112,200	65,900	252,800	201,100	121,900
Open Subject to Standard Terms and Conditions <sup>1</sup>	117,000	76,200	66,400	65,600	107,900	57,300

Source: BLM GIS 2015

<sup>1</sup>May have stipulations protecting resources other than GRSG.

1

2 Under Alternative A, 289,500 unleased acres with medium development potential (37  
3 percent of the unleased federal oil and gas estate with medium development potential) would  
4 remain closed to oil and gas leasing. Acres closed in this category would have the greatest  
5 impact on the fluid minerals program by prohibiting oil and gas development on unleased  
6 portions of federal mineral estate with medium potential for such development. Impacts of  
7 closing these areas to leasing are the same type as those described under **Nature and Type**  
8 **of Effects**.

9 Approximately 170,400 unleased acres of federal oil and gas estate with medium  
10 development potential (22 percent of the unleased federal oil and gas estate with medium  
11 development potential) would remain open to leasing subject to NSO stipulations. Acres  
12 subject to NSO stipulations in areas with medium development potential for oil and gas  
13 would have a greater impact on the fluid minerals program, compared to acres subject to  
14 NSO stipulations in areas with low development potential. This is because the likelihood of  
15 developing acres in areas with medium development potential is greater. Impacts of applying  
16 NSO stipulations to these areas are the same type as those described under **Nature and**  
17 **Type of Effects**.

18 Approximately 117,000 unleased acres of federal mineral estate in medium potential areas  
19 would be available for fluid mineral leasing and development with standard lease  
20 stipulations. These lands would not be subject to additional NSO, CSU, or TL stipulations,  
21 thereby providing the most flexibility for oil and gas exploration and development.

22 Geophysical exploration would continue to be allowed in areas open to fluid mineral leasing.  
23 In areas closed to leasing where geophysical exploration would not be allowed, impacts  
24 would continue to be the type described under **Nature and Type of Effects**.

25 Under this alternative, 25 new oil and gas exploratory wells are projected to be developed on  
26 federal mineral estate in the decision area in the next 20 years. This rate of development  
27 would allow oil and gas exploration to continue.

1 Under Alternative A, reclamation bonds would continue to be required, in accordance with  
2 43 CFR 3104. In addition, applications for permits to drill, including drilling plans and  
3 surface use plans of operations, would continue to be required, in accordance with 43 CFR  
4 3162. Unitization would continue to occur on a case-by-case basis at the discretion of  
5 operators.

6 Under Alternative A, restrictive measures to mitigate impacts from oil and gas development  
7 on GRSG would continue to be considered on a case-by-case basis during implementation-  
8 level planning. Wherever these measures are applied to the 63 leases on 69,200 acres within  
9 GRSG habitat in the decision area, they would have impacts similar to those described for  
10 conservation measures under **Nature and Type of Effects**.

### 11 **Alternative B**

#### 12 *Impacts from Lands and Realty Management*

13 Under Alternative B, over 8 million acres (32 percent) of BLM-administered and National  
14 Forest System surface in the decision area (including all PHMA) would be managed as ROW  
15 exclusion areas. However, because all PHMA would be closed to fluid mineral leasing under  
16 Alternative B, managing areas as ROW exclusion in PHMA would have no impact on fluid  
17 minerals.  
18

19 Like Alternative A, over 2.5 million acres (10 percent) of BLM-administered and National  
20 Forest System surface in the decision area (including all GHMA) would be managed as  
21 ROW avoidance under Alternative B. This management would have significant impact on oil  
22 and gas leasing as compared to Alternative A.

#### 23 *Impacts from Fluid Minerals Management*

24 Under Alternative B, 19,632,700 acres, or 70 percent of the decision area, including all  
25 federal oil and gas estate in PHMA, would be closed to oil and gas leasing. These closures  
26 would include 496,300 unleased acres with medium potential (63 percent of the unleased  
27 medium potential acres in the decision area). Closure of these acres would directly impact  
28 the fluid minerals program, as described under **Nature and Type of Effects**. Existing leases  
29 would remain valid through their term but could not be renewed.

30 Under this alternative, 71 percent more unleased acres with medium development potential  
31 would be closed to leasing than under Alternative A (**Table 4-72**). Approximately 10 percent  
32 (76,200 acres) of unleased areas with medium development potential would be open subject  
33 to standard terms and conditions, while another 13 percent (100,000 acres) would be open  
34 subject to NSO stipulations. Closures of unleased areas with medium potential would have  
35 the greatest impacts on oil and gas development in the decision area because these areas  
36 would be the most likely to be developed if no constraints existed. Impacts would be the  
37 same type as those described under **Nature and Type of Effects**.

38 The 18,585,200 acres of federal oil and gas estate within GHMA and outside occupied  
39 habitat (66 percent of the federal oil and gas decision area) would be subject to the same  
40 stipulations and management as under Alternative A.

1 Geophysical exploration would be allowed on the over 8 million acres of federal mineral  
2 estate within PHMA but would be subject to TLs and other restrictions. Most notably,  
3 geophysical exploration would be allowed only for gathering information about fluid mineral  
4 resources outside PHMA. Because of these limitations and the fact that PHMA would be  
5 closed to fluid mineral leasing, geophysical exploration in PHMA would decrease under this  
6 alternative. Decreases in geophysical exploration in PHMA could impact the fluid minerals  
7 program, as described under **Nature and Type of Effects**.

8 Under Alternative B, 15 new oil and gas exploratory wells are projected to be developed on  
9 federal mineral estate in the decision area in the next 20 years. This represents a 40 percent  
10 decrease in projected wells on federal mineral estate, compared to Alternative A.

11 Under Alternative B, conservation measures and RDFs would be applied as COAs to 48  
12 existing leases on 55,000 acres of PHMA overlying federal mineral estate. These RDFs and  
13 conservation measures would include such requirements as surface disturbance limitations,  
14 TLs, noise restrictions, structure height limitations, design requirements, water development  
15 standards, remote monitoring requirements, and reclamation standards. The types of impacts  
16 from these COAs are the same as those described under **Nature and Type of Effects**.

17 In addition to the requirements described above, the COAs would require unitization when  
18 necessary to minimize harm to GRSG and would call for completion of master development  
19 plans for developing fluid mineral resources instead of processing individual applications for  
20 permit to drill. Requiring these plans would result in the impacts described under **Nature  
21 and Type of Effects**.

22 The BLM and Forest Service could not apply COAs that would eliminate reasonable  
23 opportunities to develop the lease. Therefore, although restrictions on development would  
24 increase where COAs were applied, oil and gas development would still be allowed.

### 25 ***Alternative C***

#### 26 *Impacts from Lands and Realty Management*

27 Under Alternative C, over 11 million acres (43 percent) of BLM-administered and National  
28 Forest System surface in the decision area (including all BLM-administered and National  
29 Forest System surface in GRSG habitat) would be managed as ROW exclusion areas.  
30 However, because all GRSG habitat would be closed to fluid mineral leasing under  
31 Alternative C, managing areas as ROW exclusion would have no impact on fluid minerals.  
32

#### 33 *Impacts from Fluid Minerals Management*

34 Under Alternative C, over 22 million acres, or 85 percent of the decision area (including all  
35 federal oil and gas estate in occupied habitat) would be closed to oil and gas leasing (**Table  
36 4-72**). Closure of the area to leasing would directly impact the fluid minerals program, as  
37 described under **Nature and Type of Effects**; however, because nearly two times more  
38 acres in the decision area would be closed under Alternative C than under Alternative A, the  
39 magnitude of those impacts would increase. This alternative would prohibit any new oil and  
40 gas leasing in occupied habitat.

1 Geophysical exploration would be subject to the same restrictions as those under Alternative  
2 B; however, these restrictions would apply to more acres under Alternative C (20,168,900  
3 acres). Therefore, the types of impacts described under **Nature and Type of Effects** would  
4 increase under this alternative.

5 Under this alternative, over two times as many more unleased acres with medium  
6 development potential would be closed to leasing compared with Alternative A (**Table 4-**  
7 **72**). Approximately 8 percent (66,400 acres) of unleased areas with medium development  
8 potential would be open subject to standard terms and conditions, while another nearly 7  
9 percent (51,400 acres) would be open subject to NSO stipulations. Closures of unleased  
10 areas with medium potential would have the greatest impacts on oil and gas development in  
11 the decision area because these areas would be the most likely to be developed if no  
12 constraints existed. Impacts would be the same type as those described under **Nature and**  
13 **Type of Effects**.

14 Under this alternative, 13 new oil and gas exploratory wells are projected to be developed on  
15 federal oil and gas estate in the decision area in the next 20 years. This represents a 48  
16 percent decrease in projected wells on federal oil and gas estate, compared to Alternative A.

17 Management actions applicable to existing leases under Alternative C would be similar to  
18 those under Alternative B, but they would apply to 48 existing leases on 55,000 acres of  
19 federal mineral estate. In addition to applying the restrictive management under Alternative  
20 B to more acres, Alternative C would call for COAs implementing seasonal restrictions on  
21 vehicle traffic and human presence associated with exploratory drilling. This alternative also  
22 would limit new surface disturbance on existing leases to three percent per section, with  
23 some exceptions. Impacts of these operating and siting restrictions are the same type as  
24 those described under **Nature and Type of Effects**.

#### 25 ***Alternative D***

##### 26 *Impacts from Lands and Realty Management*

27 Like Alternative A, under Alternative D, over 1 million acres (4 percent) of BLM-  
28 administered and National Forest System surface in the decision area would be managed as  
29 ROW exclusion areas. Nearly 4 million acres (6 percent), including all IHMA and GHMA,  
30 would be managed as ROW avoidance areas. Where these exclusion or avoidance areas  
31 overlap with areas open to fluid mineral leasing, impacts on the fluid minerals program  
32 would occur, as described under **Nature and Type of Effects**. Because three times more  
33 acres would be managed as ROW avoidance under Alternative D than under Alternative A,  
34 the magnitude of impacts would increase.  
35

##### 36 *Impacts from Fluid Minerals Management*

37 Under Alternative D, fluid mineral allocations in PHMA and IHMA would vary depending  
38 on oil and gas development potential. Federal mineral estate with no or low oil and gas  
39 potential would be closed to leasing, while federal mineral estate with medium oil and gas  
40 development potential would be subject to CSU and TL stipulations, and an NSO  
41 stipulation would apply within 0.6 mile (1 km) of leks. A total of 19,415,000 acres (75

1 percent of the decision area) would be closed under this alternative. Approximately  
2 1,379,700 acres (5 percent) would be subject to NSO stipulations, 1,595,000 acres (6 percent)  
3 would be subject to CSU stipulations, and 2,170,000 acres (8 percent) would be subject to  
4 TL stipulations. Approximately 3,668,800 acres (14 percent of the decision area) would be  
5 open to leasing subject to standard terms and conditions. Impacts of these stipulations  
6 would be the types described in **Nature and Type of Effects**. Closures would cause the  
7 most impacts out of all these management actions due to a 50 percent increase compared  
8 with Alternative A. However, 98 percent of the acres that would be closed under Alternative  
9 D (19,117,900 acres) have low or very low development potential and are less likely to be  
10 developed even without management constraints.

11 New leases in GHMA (regardless of oil and gas potential) would be subject to TLs, and the  
12 0.6-mile NSO buffer would also apply.

13 Under Alternative D, 289,500 unleased acres with medium development potential (37  
14 percent of total unleased acres with medium development potential in the oil and gas  
15 decision area) would be closed to leasing, the same amount as Alternative A (**Table 4-72**).  
16 Approximately 176,900 acres (22 percent) of unleased areas with medium development  
17 potential would be subject to NSO stipulations. This represents a 4 percent increase  
18 compared with Alternative A. Approximately 252,800 acres (32 percent) of unleased federal  
19 oil and gas estate with medium development potential would be subject to CSU and/or TL  
20 stipulations. Because unleased moderate-potential acres subject to CSU and/or TL  
21 stipulations would increase 26 percent compared with Alternative A, the impacts of these  
22 stipulations would increase under Alternative D. Impacts would be the same type as those  
23 described under **Nature and Type of Effects**. Overall, because more acres with medium  
24 development potential would be closed or subject to NSO or CSU/TL stipulations under  
25 Alternative D compared with Alternative A, impacts on unleased oil and gas from fluid  
26 mineral allocations would increase under Alternative D.

27 New leases within PHMA and IHMA would be subject to density limitations and a three  
28 percent disturbance cap for each section. These limitations on surface disturbance would  
29 have the cost impacts described under **Nature and Type of Effects**.

30 Geophysical exploration in GRSG habitat would be subject to TL stipulations. Impacts of  
31 these stipulations are the same types as those described under **Nature and Type of Effects**.  
32 Because these types of stipulations would not be applied under Alternative A, impacts on the  
33 fluid minerals program would increase under Alternative D.

34 Under this alternative, 23 new oil and gas exploratory wells are projected to be developed on  
35 federal mineral estate in the decision area in the next 20 years. This represents an eight  
36 percent decrease in projected wells on federal mineral estate compared with Alternative A.

37 Management of existing fluid mineral leases under Alternative D would be the same as that  
38 under Alternative B, except that all management actions other than RDFs would apply to 63  
39 existing leases on 69,200 acres within GRSG habitat. For this reason, impacts on the fluid

1 minerals program from these actions are more similar to Alternative C. Existing leases in  
2 GHMA could be subject to discretionary mandatory RDFs.

### 3 ***Alternative E***

#### 4 *Impacts from Lands and Realty Management*

5 Like Alternative A, under Alternative E, nearly 1 million acres (4 percent) of BLM-  
6 administered and National Forest System surface in the decision area would be managed as  
7 ROW exclusion areas. Over 7 million acres (28 percent), including all CHZ and IHZ not  
8 already managed as ROW exclusion areas, would be managed as ROW avoidance areas.  
9 Where these exclusion or avoidance areas overlapped with areas open to fluid mineral  
10 leasing, impacts on the fluid minerals program are as described under **Nature and Type of**  
11 **Effects**. Because more acres would be managed as ROW avoidance under Alternative E  
12 than under Alternative A, the magnitude of impacts would increase. Impacts would be  
13 mitigated where exemptions were allowed for ROW development subject to certain  
14 conditions.  
15

#### 16 *Impacts from Fluid Minerals Management*

17 Under Alternative E, fluid mineral management would differ between portions of the  
18 decision area in Idaho and Montana and portions in Utah.

19 Within Idaho and Montana, new leases on federal oil and gas estate within CHZ and IHZ  
20 would be subject to NSO stipulations. Application of NSO stipulations would have the type  
21 of impacts described under Nature and Type of Effects; however, the impacts on fluid  
22 minerals would be mitigated by waivers where certain criteria were met.

23 Within Utah, new leases on federal oil and gas estate within PHMA would be subject to CSU  
24 and TL stipulations. Impacts of these stipulations are the same type as those described under  
25 **Nature and Type of Impacts**.

26 Under Alternative E, 289,500 unleased acres with medium development potential (37  
27 percent of total unleased acres with medium development potential in the oil and gas  
28 decision area) would be closed to leasing, the same amount as Alternative A (**Table 4-72**).  
29 Approximately 186,200 acres (24 percent) of unleased areas with medium development  
30 potential would be subject to NSO stipulations. This represents a 9 percent increase  
31 compared with Alternative A. No CSU stipulations would be applied, the same as under  
32 Alternative A. Impacts would be the same type as those described under **Nature and Type**  
33 **of Effects**. Overall, because more unleased acres with medium development potential would  
34 be closed or subject to NSO stipulations under Alternative E compared with Alternative A,  
35 impacts on unleased oil and gas from fluid mineral allocations would increase under  
36 Alternative E.

37 Within Idaho and southwestern Montana, management of geophysical exploration would be  
38 the same as that under Alternative A, with the same impacts. Within Utah, geophysical  
39 exploration in PHMA would be subject to the same CSU and TL stipulations applied to new  
40 leases in PHMA. Impacts are the same type as those described under **Nature and Type of**

1 **Effects.** Because geophysical exploration in Utah would be restricted under this alternative  
2 and would not be restricted under Alternative A, impacts would increase, compared with  
3 Alternative A.

4 Under this alternative, 13 new oil and gas exploratory wells are projected to be developed on  
5 federal mineral estate in the decision area in the next 20 years. This represents an 18 percent  
6 decrease in projected wells on federal mineral estate, compared to Alternative A.

7 Management of existing leases in the decision area would be similar to that under Alternative  
8 A, except that BMPs would be applied. Because these BMPs would not be mandatory, their  
9 application would not necessarily result in additional impacts on fluid minerals.

## 10 ***Alternative F***

### 11 *Impacts from Lands and Realty Management*

12 Like Alternative C, under Alternative F, over 8.5 million acres (33 percent) of BLM-  
13 administered and National Forest System surface in the decision area (including all BLM-  
14 administered and National Forest System surface within GRSG habitat) would be managed  
15 as ROW exclusion areas. However, because all occupied habitat would be closed to fluid  
16 mineral leasing under Alternative F, managing areas as ROW exclusion in the decision area  
17 would have no impact on fluid minerals.  
18

### 19 *Impacts from Fluid Minerals Management*

20 Unleased fluid minerals management would be the same under Alternative F as that under  
21 Alternative B (**Table 4-72**). All PHMA (70 percent of the decision area) would be closed to  
22 leasing.

23 Under Alternative F, the 52 existing leases in PHMA would be subject to management,  
24 similar to that under Alternative B. However, under Alternative F, TLs would prohibit  
25 human presence and surface-disturbing activities during the nesting and brood-rearing  
26 season. This management would be the most restrictive of all the alternatives.

## 27 ***Proposed Plan***

### 28 *Impacts from Lands and Realty Management*

29 Under the Proposed Plan, 8,365,000 acres (33 percent) of BLM-administered and National  
30 Forest System surface in the decision area (including all PHMA and IHMA) would be  
31 managed as ROW avoidance areas. However, because all acres in PHMA and IHMA would  
32 be either closed to leasing or open subject to NSO stipulations, no oil and gas activities on  
33 future leases within these areas would require new rights-of-way. Therefore, oil and gas  
34 activity in PHMA and IHMA would not be impacted by management of ROW avoidance  
35 areas under the Proposed Plan.

36 All BLM-administered surface in GHMA would be managed as ROW avoidance for high  
37 voltage transmission lines and major pipelines but open to other fluid mineral-related ROW  
38 location under the Proposed Plan. Fluid minerals beneath those acres would be impacted by  
39 the ROW avoidance area, as described under **Nature and Type of Effects**. Overall, more

1 acres in GHMA would be managed as ROW avoidance under the Proposed Plan than under  
2 Alternative A; therefore, impacts on the fluid minerals program from these ROW avoidance  
3 areas would increase under the Proposed Plan.

4 Application of RDFs, BMPs, buffers, and seasonal timing restrictions to ROW construction  
5 in all GRSG habitat would also limit construction of new ROWs for oil and gas  
6 development. If these limitations made it uneconomic to develop a ROW for oil and gas  
7 development, development of federal oil and gas resources in the planning area could  
8 decrease.

9 *Impacts from Fluid Minerals Management*

10 Under the Proposed Plan, approximately 257,400 unleased acres with medium development  
11 potential (33 percent of the federal oil and gas estate with medium development potential)  
12 would remain closed to oil and gas leasing (**Table 4-72**). Closing unleased lands to leasing,  
13 especially those with medium potential would have the greatest impact on the fluid minerals  
14 program by prohibiting oil and gas development. Impacts of closing these areas to leasing  
15 are the same type as those described under **Nature and Type of Effects**.

16 Approximately 348,100 acres, or 44 percent of unleased federal oil and gas estate with  
17 medium development potential (including all areas in PHMA and IHMA not already closed)  
18 would be open to oil and gas leasing subject to NSO stipulations. The Proposed Plan would  
19 apply NSO stipulations to twice as many unleased acres with medium oil and gas  
20 development potential compared with Alternative A. Impacts would be increased because of  
21 the acreage increase and the fact that there would be no waivers or modifications to the  
22 NSO stipulation. Only one exception would exist. A total of 77 percent of unleased federal  
23 oil and gas estate with medium oil and gas potential in the decision area would be  
24 inaccessible, either due to closure or NSO, under the Proposed Plan.

25 Approximately 121,900 unleased acres, or 17 percent of the unleased federal oil and gas  
26 estate with medium oil and gas development potential (including all areas in PGMA not  
27 already closed) would be open to oil and gas leasing, subject to CSU (i.e. lek buffers) and TL  
28 stipulations under the Proposed Plan. These stipulations would restrict the timing and  
29 location of oil and gas exploration and development activities, as described under **Nature**  
30 **and Type of Effects**.

31 Under the Proposed Plan, it is reasonably foreseeable for planning purposes that 15 new oil  
32 and gas exploratory wells would be developed on federal fluid mineral estate in the decision  
33 area in the next 20 years. This represents a 40 percent decrease in projected wells on federal  
34 mineral estate compared to Alternative A.

35 Management of geophysical exploration activities under the Proposed Plan would be the  
36 same as that under Alternative B, with the same impacts.

37 Under the Proposed Plan, the same RDFs would be applied to a larger acreage than under  
38 Alternative B (including GHMA and to existing leases). However, the only management

1 actions related to master development plans and unitization would apply. Impacts of these  
2 restrictions would be the same type as those described under **Nature and Type of Effects**.

3 Application of the three percent disturbance cap in PHMA and IHMA and lek buffers in  
4 GHMA could impact both new and existing fluid mineral activities by preventing or  
5 restricting new surface development. New fluid mineral activities and new surface  
6 development on existing leases could be affected or temporarily delayed if the cap were  
7 exceeded. Applying lek buffer distances when approving actions could also restrict  
8 development of infrastructure related to fluid mineral development.

9 Under the Proposed Plan, the same RDFs described under Alternative B would be applied  
10 as COAs to 41 existing leases on 64,000 acres of occupied habitat overlying federal mineral  
11 estate (2 in Idaho over 4,000 acres; 39 in Montana over 60,000 acres). The types of impacts  
12 from these COAs are the same as those described under **Nature and Type of Effects**. The  
13 BLM and Forest Service could not apply COAs that would eliminate reasonable  
14 opportunities to develop the lease. Therefore, although restrictions on development would  
15 increase where COAs were applied, oil and gas development would still be allowed. There  
16 are no post-lease activities currently pending BLM's approval.

#### 17 4.9.2 Geothermal

##### 18 ***Methods and Assumptions***

19 The analysis of impacts on geothermal resources from this LUPA focuses on the impacts of  
20 conservation measures to protect GRSG. These impacts may be direct or indirect. For  
21 example, a direct impact on geothermal resources would result from closing an area,  
22 particularly a moderate to high geothermal potential area, to fluid mineral leasing. An  
23 indirect impact would result from managing an area as ROW exclusion, which would restrict  
24 off-lease infrastructure such as access roads and transmission lines, and could change the  
25 economic feasibility of developing a site. Additional actions or conditions that might cause  
26 direct or indirect impacts on geothermal leasing, and development are described under  
27 Indicators, below.

##### 28 *Indicators*

29 Indicators of impacts on geothermal leasing and development are as follows:

- 30 • Acres of unleased land with moderate to high geothermal potential identified as  
31 closed to fluid mineral leasing and geophysical exploration
- 32 • Acres of unleased land with no or low geothermal potential identified as closed  
33 to fluid mineral leasing and geophysical exploration
- 34 • Acres of unleased land with moderate to high geothermal potential subject to  
35 NSO stipulation.
- 36 • Acres of unleased land with low geothermal potential subject to NSO  
37 stipulations

- 1 • Acres of unleased land with moderate to high geothermal potential subject to  
2 CSU and/or TLs
- 3 • Acres of unleased land with no or low geothermal potential subject to CSU  
4 and/or TLs
- 5 • Number of leases and acres over which COAs would be applied on geothermal  
6 development activities on leased parcels for the protection of GRSG
- 7 • Acres managed as ROW avoidance areas
- 8 • Acres managed as ROW exclusion areas

9 *Assumptions*

10 The analysis includes the following assumptions:

- 11 • Existing fluid mineral leases would not be affected by the closures proposed  
12 under this LUPA.
- 13 • Fluid mineral operations on existing federal leases, regardless of surface  
14 ownership, would be subject to project-specific COAs by the authorizing officer.  
15 The BLM can deny surface occupancy on portions of leases with COAs to avoid  
16 or minimize resource conflicts if this action does not eliminate reasonable  
17 opportunities to develop the lease or affect lease rights.
- 18 • Existing leases would be managed under the stipulations in effect when the  
19 leases were issued; new stipulations proposed under this LUPA would apply only  
20 on new leases. See the glossary for definitions of stipulations versus COAs.
- 21 • Under all alternatives, reclamation bonds would be required, pursuant to 43 CFR  
22 3261.18 and 43 CFR 3214.10, in an amount sufficient to ensure full restoration  
23 of lands to the condition in which they were found. In addition, BLM approval  
24 of geothermal drilling permits would continue to be required prior to  
25 commencement of drilling under all alternatives in accordance with 43 CFR  
26 3260.
- 27 • The lands in the Curlew Grassland area, as described in the Pocatello RMP, that  
28 are administratively unavailable for leasing will be included in the total number of  
29 acres closed to leasing under Alternative A.
- 30 • As the demand for alternative energy increases, so will the demand for extracting  
31 geothermal resources in areas with potential. Technological advancements could  
32 lead to changes in levels of geothermal development potential throughout the  
33 planning area as developers find ways to produce power from lower temperature  
34 resources and from hot dry rock.
- 35 • As discussed in Section 3.12, Mineral Resources, interest in geothermal leasing in  
36 Idaho is expected to remain sporadic. For planning purposes, it is assumed that  
37 development would occur as described in **Appendix O**, Reasonably Foreseeable  
38 Development Scenario.

1        ***Stipulations would also apply to geothermal leasing on lands overlying federal***  
2        ***mineral estate, which includes federal mineral estate underlying BLM-administered***  
3        ***and National Forest System lands, as well as private lands underlain by federal***  
4        ***mineral estate. Nature and Type of Effects***

5        For geothermal energy, the above criteria were evaluated in addition to areas closed to  
6        leasing, areas with NSO, CSU and TL stipulations, and areas managed as ROW avoidance or  
7        exclusion within GRS habitat. All of these factors are considered to be impediments to  
8        geothermal energy development, to varying degrees. Alternatives with greater acreages of  
9        such restrictions are considered to have a greater impact on geothermal energy development  
10       potential than alternatives with fewer acres of such restrictions, especially in areas with  
11       moderate to high geothermal potential.

12       Geothermal resource leasing and development would be precluded in areas closed to fluid  
13       mineral leasing. Such closures would directly impact the fluid minerals program by removing  
14       the opportunity afforded US citizens by the Mineral Leasing Act and the Geothermal Steam  
15       Act, to explore and develop geothermal resources in those areas, especially if they have  
16       moderate to high geothermal potential. Geothermal developers would be limited in their  
17       choice of project locations and could be forced to develop in areas that are challenging to  
18       access or have fewer economic resources because other, more ideal areas are closed to  
19       leasing. This could raise the cost of geothermal development in the decision area and could  
20       result in operators moving to nearby nonfederal minerals if similar geologic conditions exist,  
21       or the opportunity for discovery may be lost altogether if such conditions are unique to the  
22       federal lands.

23       In areas with NSO stipulations, geothermal resources can only be accessed by directional  
24       drilling from a point on the surface that is not covered by NSO. If much of the lease is  
25       covered by an NSO stipulation, directional drilling may not be feasible. NSO stipulations  
26       can be nearly as restrictive to geothermal energy development as closing an area to leasing.  
27       Any geothermal projects on leases with CSU and/or TL stipulations could have added costs  
28       and scheduling challenges.

29       Applying COAs, which include RDFs (see **Appendix B**) and conservation measures  
30       outlined in **Chapter 2**, to post-lease activities could directly impact fluid mineral operations.  
31       These RDFs and conservation measures include such standards as noise restrictions, height  
32       limitations on structures, design requirements, water development standards, remote  
33       monitoring requirements, and reclamation standards. Additional site-specific planning, such  
34       as master development plans and unitization, and reclamation bonding requirements may  
35       also be included. Applying these requirements through COAs may impact fluid mineral  
36       operations by increasing costs, causing delays, and frustrating attempts to develop the  
37       resource.

38       Placing limits on geophysical exploration could reduce the ability to collect geologic data  
39       concerning geothermal resources on federal mineral estate. TLs on geophysical exploration  
40       could lead to equipment scheduling delays.

1 Lands and realty management actions such as requiring off-lease utilities to be collocated  
 2 within designated corridors could impact geothermal resource development by limiting  
 3 options for ROW and facility design, and increasing development costs. While ROW grants  
 4 are not needed for roads or transmission lines within a leased area, such grants are required  
 5 for roads and transmission lines that are outside the leased areas. The identification of an  
 6 area of land as a ROW exclusion area is likely to hinder any geothermal development in the  
 7 area due to restrictions of access and transmission. ROW avoidance areas can result in  
 8 reroutes and limited options for access and transmission and could either stop a project  
 9 from being developed or increases development costs.

10 ***Impacts Common to All Alternatives***

11 There are no impacts common to all alternatives. **Table 4-73**, Management Actions  
 12 Affecting Geothermal Development, provides an overview of impacts across the alternatives  
 13 on geothermal development potential through showing the various restrictions placed on  
 14 leasing, exploration, and development for both unleased and already leased lands. **Table 4-**  
 15 **74**, Management Actions by Geothermal Potential, provides an overview of impacts across  
 16 the alternatives in areas of high and low geothermal potential.

**Table 4-72**  
**Management Actions Affecting Geothermal Development**

	Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F	Proposed Plan
<b>ROW Exclusion</b>	1,028,500	8,484,100	11,023,100	1,028,500	979,100	8,523,400	1,013,800

1

2 **Alternative A**

3 *Impacts from Fluid Minerals Management*

4 Much of the acreage within the decision area has at least moderate geothermal potential.  
5 Under Alternative A, the federal mineral estate currently open to geothermal leasing would  
6 remain open.

7 There are 18,200 acres of federal geothermal leases within GRSG habitat in the decision  
8 area. Development of these leases would continue to be subject to the existing stipulations  
9 placed upon them. Leases within occupied habitat would continue to be developed in  
10 accordance with their lease terms, which may include lek buffers and TLs in GRSG habitat.  
11 RDFs and BMPs can be applied as COAs to mitigate or prevent impacts to sage grouse on  
12 public lands, so long as they are consistent with existing lease terms and stipulations. Many

1 but not all of BLM and National Forest Service land use plans require mitigation to sage  
2 grouse habitat by applying stipulations such as lek buffers and seasonal timing restrictions  
3 where appropriate, as discussed in Chapter 3. The existing geothermal leases were issued  
4 with stipulations in place, and thus no additional stipulations can be added to those leases.  
5 Geothermal development within the population areas would be subject to COAs placed on  
6 the project at the time of subsequent NEPA analysis. Development would be subject to any  
7 restrictions resulting from ESA Section 7 Consultation with the USFWS regarding any listed  
8 species in the project area. Applying stipulations from existing land use plans in some of the  
9 planning area but not all of it, could degrade important habitat, if post-lease activities are  
10 proposed. Under Alternative A, 756,800 acres of high geothermal potential areas and  
11 2,084,800 acres of low potential areas would be subject to TLs and/or CSUs.

12 Continuing to apply disturbance buffers and seasonal TLs on surface-disturbing and  
13 disruptive activities in portions of GRSG breeding, nesting, and winter habitat would directly  
14 impact development of geothermal resources. It would do this by limiting the siting, design,  
15 and operations of geothermal development projects. This, in turn, could force operators to  
16 use more costly development methods (such as horizontal drilling) than they otherwise  
17 might have used. Equipment shortages could result from applying TLs because a bottleneck  
18 could be created during the period in which activity would be allowed.

19 Alternative A would manage 12,513,900 acres (49 percent of the planning area) as closed to  
20 geothermal leasing. Of this, 2,939,400 acres (33 percent of high potential) would be located  
21 in areas with moderate to high geothermal potential, and 9,574,600 acres (37 percent of low  
22 potential) would be located in areas with low to no geothermal potential. Geophysical  
23 exploration would continue to be allowed in the decision area wherever acres are open to  
24 geothermal leasing. However, geophysical exploration in GRSG habitat would continue to  
25 be subject to any applicable disturbance buffers or TLs required in current LUPs. In areas  
26 closed to leasing where geophysical exploration would not be allowed, impacts would  
27 continue to be the type described under **Nature and Type of Effects**.

28 *Impacts from Lands and Realty Management*

29 Under Alternative A, 1,028,500 acres (4 percent of BLM- and National Forest System-  
30 administered surface in the decision area) would continue to be managed as ROW exclusion  
31 areas. Another 1,956,300 acres (8 percent of BLM-administered and National Forest System  
32 surface in the decision area) would continue to be managed as ROW avoidance areas. This  
33 management would continue to impact the fluid minerals program, as described under  
34 **Nature and Type of Effects**.

35 **Alternative B**

36 *Impacts from Fluid Minerals Management*

37 **Table 4-73**, Management Actions Affecting Geothermal Development, compares the acres  
38 of geothermal potential within the decision area as to whether they would be open or closed  
39 to leasing and what stipulations would be applied.

40 Under Alternative B, all PHMA (8,235,900 acres) would be closed to geothermal leasing, and  
41 would close a total of 19,598,800 acres to geothermal leasing. Of the 19,598,800 acres,

1 5,207,800 are within high geothermal potential areas, and 14,311,000 are within low  
2 geothermal potential areas. Alternative B would manage and additional 7,084,900 acres more  
3 than Alternative A as closed to fluid mineral leasing. As such, Alternative B would be more  
4 restrictive of geothermal exploration and development than Alternative A. An additional  
5 1,940,900 acres would be managed as CSU/TL (496,600 within high potential areas and  
6 1,444,300 within low potential areas), and 1,262,100 acres would be managed as NSO (566,100  
7 in high potential areas and 696,000 in low potential areas)

8 Continuing to apply disturbance buffers and seasonal TLs on surface-disturbing and  
9 disruptive activities in portions of GRSG breeding, nesting, and winter habitat would have  
10 the same impacts as described under Alternative A.

11 Under Alternative B, conservation measures in addition to RDFs would be applied as COAs  
12 to existing leases within PHMA overlying federal mineral estate. These RDFs and  
13 conservation measures would include such requirements as surface-disturbance limitations,  
14 seasonal restrictions on activities in certain areas, noise restrictions, structure height  
15 limitations, design requirements, water development standards, remote monitoring  
16 requirements, and reclamation standards. Application of these requirements through COAs  
17 would impact geothermal operations by increasing costs if they resulted in the application of  
18 additional requirements or use of more expensive technology (such as remote monitoring  
19 systems). To avoid costs, operators could move to nearby nonfederal minerals.

20 Existing geothermal leases were issued with stipulations in place, and no additional  
21 stipulations could be added to these leases. The potential for the development of geothermal  
22 resources within the geothermal reasonable foreseeable development scenario (RFDS) area  
23 under Alternative B is the same as under Alternative A.

24 Geophysical exploration would be allowed on the 8,735,300 acres of federal mineral estate  
25 within PHMA but would be subject to TLs and other restrictions. Most notably, geophysical  
26 exploration would be allowed only for gathering information about fluid mineral resources  
27 outside PHMA. Because of these limitations and the fact that PHMA would be closed to  
28 fluid mineral leasing, geophysical exploration in PHMA would decrease under this  
29 alternative. Decreases in geophysical exploration in PHMA could impact the fluid minerals  
30 program, as described under **Nature and Type of Effects**.

31 *Impacts from Lands and Realty Management*

32 Under Alternative B, 8,484,000 acres (32 percent) of BLM- and National Forest System-  
33 administered surface in the decision area (including all PPMA) would be managed as ROW  
34 exclusion areas. However, because all PPMA would be closed to fluid mineral leasing under  
35 Alternative B, managing areas as ROW exclusion in PPMA would have no additional impact  
36 on fluid minerals.

1 **Alternative C**

2 *Impacts from Fluid Minerals Management*

3 **Table 4-73**, Management Actions Affecting Geothermal Development, compares the acres  
4 of geothermal potential within the decision area as to whether they would be open or closed  
5 to leasing and what stipulations would be applied.

6 Under Alternative C, 21,901,100 acres would be closed to geothermal leasing. Alternative C  
7 would close to leasing an additional 9,387,200 acres over Alternative A. Of the 21,901,100  
8 acres, 6,137,200 are within high potential geothermal areas, and 15,763,900 acres are in low  
9 potential geothermal areas. An additional 1,542,700 acres would be managed as CSU/TL  
10 (382,700 within high potential areas and 1,160,000 within low potential areas), and 959,600  
11 acres would be managed as NSO (454,500 in high potential areas and 505,100 in low potential  
12 areas).

13 Management applicable to existing leases under Alternative C would be similar to those  
14 under Alternative B, but they would apply to 24,400 acres of existing leases on federal  
15 mineral estate within PHMA. In addition to applying the restrictive management under  
16 Alternative B to more acres, Alternative C would also call for COAs implementing seasonal  
17 restrictions on vehicle traffic and human presence associated with exploratory drilling. This  
18 alternative also would limit new surface disturbance on existing leases to three percent per  
19 year across the entire planning area, with some exceptions. Impacts of these operating and  
20 siting restrictions are the same type as those described under Alternative B.

21 Geophysical exploration would be subject to the same restrictions as those under Alternative  
22 B; however, these restrictions would apply to more acres under Alternative C (12,039,500  
23 acres). Therefore, the types of impacts described under **Nature and Type of Effects** would  
24 increase under this alternative.

25 Impacts on the geothermal RFDS area from fluid minerals management are the same as  
26 those described under Alternative B.

27 *Impacts from Lands and Realty Management*

28 Under Alternative C, 11,048,000 acres (43 percent) of BLM-administered and National  
29 Forest System surface in the decision area (including all BLM-administered and National  
30 Forest System surface in GRSG habitat) would be managed as ROW exclusion areas.  
31 However, because all GRSG habitat would be closed to fluid mineral leasing under  
32 Alternative C, managing areas as ROW exclusion would have no additional impact on fluid  
33 minerals.

34 **Alternative D**

35 *Impacts from Fluid Minerals Management*

36 **Table 4-73**, Management Actions Affecting Geothermal Development, compares the acres  
37 of geothermal potential within the decision area by whether they would be open or closed to

38 Under Alternative D, 17,526,500 acres would be closed to geothermal leasing. Alternative D  
39 would close to leasing an additional 5,012,600 acres over Alternative A. Of the 17,526,500

1 acres, 3,215,600 are within high potential geothermal areas, and 14,311,000 acres are in low  
2 potential geothermal areas. An additional 5,545,000 acres would be managed as CSU/TL  
3 (3,027,000 within high potential areas and 2,422,000 within low potential areas), and 1,461,700  
4 acres would be managed as NSO (752,500 in high potential areas and 709,100 in low potential  
5 areas).

6 The CSU stipulations would include noise and tall structure limitations and, at times, a site-  
7 specific plan of development to limit habitat fragmentation. Application of these surface  
8 disturbance restrictions, TLs, and other operating standards would limit the siting, design,  
9 and operations of geothermal development projects in the manner described under  
10 Alternative A. However, these impacts would be mitigated in GHMA, where off-site  
11 mitigation would allow operators to waive the applicable stipulations.

12 For existing leases, the BLM and Forest Service would apply the same RDFs from  
13 Alternative B to all three GRSG management areas. However, exceptions to application of  
14 RDFs could mitigate impacts. Exceptions would occur where a design feature was not  
15 applicable (e.g., a resource is not present on a given site) or where the design feature would  
16 not actually provide additional protection for GRSG or its habitat.

17 Alternative D's RDFs would be the same under Alternative B, except that surface occupancy  
18 buffers and TLs would not apply to surface disturbance; rather, the BLM and Forest Service  
19 would aim to minimize habitat loss, fragmentation, and direct and indirect effects on GRSG  
20 and habitat. The impacts of applying these RDFs and conservation measures are the same  
21 type as those described under Alternative B. On- or off-site mitigation would be used to  
22 minimize impacts on GRSG. Where operators use such mitigation to protect GRSG,  
23 geothermal development costs would increase compared with Alternative A due to the  
24 additional expense of mitigation activities.

25 Geophysical exploration in GRSG habitat would be subject to TL stipulations. Impacts of  
26 these stipulations are the same types as those described under **Nature and Type of Effects**.  
27 Because these types of stipulations would not be applied under Alternative A, impacts on the  
28 fluid minerals program would increase under Alternative D.

29 Impacts on the geothermal RFD area from fluid minerals management are the same as those  
30 described under Alternative A.

#### 31 *Impacts from Lands and Realty Management*

32 Like Alternative A, under Alternative D, 1,028,500 acres (4 percent) of BLM- and National  
33 Forest System-administered surface in the decision area would be managed as ROW  
34 exclusion areas. A total of 10,244,300 acres (40 percent), including all PMMA and PGMA,  
35 would be managed as ROW avoidance areas. Where these exclusion or avoidance areas  
36 overlap with areas open to fluid mineral leasing, impacts on the fluid minerals program  
37 would occur, as described under **Nature and Type of Effects**. Because three times more  
38 acres would be managed as ROW avoidance under Alternative D than under Alternative A,  
39 the magnitude of impacts would increase.

1 **Alternative E**

2 *Impacts from Fluid Minerals Management*

3 **Table 4-73**, Management Actions Affecting Geothermal Development, compares the acres  
4 of geothermal potential within the decision area as to whether they would be open or closed  
5 to leasing and what stipulations would be applied.

6 Under Alternative E, no additional acres of geothermal development would be closed to  
7 geothermal leasing when compared with Alternative A. NSO stipulations would be applied  
8 to 7,441,600 acres including 2,199,400 with high geothermal potential and 4,782,800 with  
9 low geothermal potential. An additional 2,237,000 acres would be managed as CSU/TL  
10 (527,000 within high potential areas and 1,710,000 within low potential areas). Existing leases  
11 would remain valid through their term but could not be renewed.

12 However, under Alternative E, fluid mineral management would differ between portions of  
13 the decision area in Idaho and Montana and portions in Utah. Within Idaho and Montana,  
14 new leases on federal mineral estate within CHZ and IHZ would be subject to NSO  
15 stipulations. Application of NSO stipulations would have the type of impacts described  
16 under Nature and Type of Effects; however, the impacts on fluid minerals would be  
17 mitigated by waivers where certain criteria were met. Within Utah, new leases on federal  
18 mineral estate within PHMA would be subject to CSU and TL stipulations. Impacts of these  
19 stipulations are the same type as those described under **Nature and Type of Impacts**.

20 Overall, because more unleased acres with medium development potential would be closed  
21 or subject to NSO stipulations under Alternative E compared with Alternative A, impacts on  
22 geothermal development from fluid mineral allocations would increase under Alternative E.

23 Within Idaho and southwestern Montana, management of geophysical exploration would be  
24 the same as that under Alternative A, with the same impacts. Within Utah, geophysical  
25 exploration in PHMA would be subject to the same CSU and TL stipulations applied to new  
26 leases in PHMA. Impacts are the same type as those described under **Nature and Type of**  
27 **Effects**. Because geophysical exploration in Utah would be restricted under this alternative  
28 and would not be restricted under Alternative A, impacts would increase, compared with  
29 Alternative A.

30 Management of existing leases in the decision area would be similar to that under Alternative  
31 A, except that BMPs would be applied. Because these BMPs would not be mandatory, their  
32 application would not necessarily result in additional impacts on fluid minerals.

33 *Impacts from Lands and Realty Management*

34 Similar to Alternative A, under Alternative E, 979,100 acres (4 percent) of BLM- and  
35 National Forest System-administered surface in the decision area would be managed as  
36 ROW exclusion areas. However, under Alternative E more acres (7,343,400 or 20 percent)  
37 including all CHZ and IHZ not already managed as ROW exclusion areas, would be  
38 managed as ROW avoidance areas. Where these exclusion or avoidance areas overlapped  
39 with areas open to fluid mineral leasing, impacts on the fluid minerals program are as  
40 described under **Nature and Type of Effects**. Because more acres would be managed as

1 ROW avoidance under Alternative E than under Alternative A, the magnitude of impacts  
2 would increase. Impacts would be mitigated where exemptions were allowed for ROW  
3 development subject to certain conditions.

4 ***Alternative F***

5 *Impacts from Fluid Minerals Management*

6 **Table 4-73**, Management Actions Affecting Geothermal Development, compares the acres  
7 of geothermal potential within the decision area as to whether they would be open or closed  
8 to leasing and what stipulations would be applied.

9 Under Alternative F, 19,598,800 acres would be closed to geothermal leasing. Alternative C  
10 would close to leasing an additional 7,084,900 acres more than Alternative A. Of the  
11 19,598,800 acres, 6,137,200 are within high potential geothermal areas, and 14,311,000 acres  
12 are in low potential geothermal areas. An additional 1,940,900 acres would be managed as  
13 CSU/TL (496,600 within high potential areas and 1,444,300 within low potential areas), and  
14 1,262,100 acres would be managed as NSO (566,100 in high potential areas and 696,000 in low  
15 potential areas).

16 Management applicable to existing leases under Alternative F would be similar to that under  
17 Alternative B, but it would apply to 4,360 acres of existing leases on federal mineral estate  
18 within GHMA. In addition to applying the restrictive management under Alternative B to  
19 more acres, Alternative F would also call for COAs implementing seasonal restrictions on  
20 vehicle traffic and human presence associated with exploratory drilling. This alternative also  
21 would limit new surface disturbance on existing leases to three percent per section, with  
22 some exceptions. Impacts of these operating and siting restrictions are the same type as  
23 those described under Alternative B.

24 Under Alternative F, geophysical exploration would be prohibited on 19,400 acres of federal  
25 mineral estate within PHMA. The closure of this area would reduce the lands available for  
26 geothermal exploration, compared with Alternative A.

27 Impacts on the geothermal RFDS area from fluid minerals management are the same as  
28 those described under Alternative B.

29 *Impacts from Lands and Realty Management*

30 Like Alternative B, under Alternative F, 8,523,400 acres (33 percent) of BLM- and National  
31 Forest System-administered surface in the decision area (including all BLM- administered  
32 and National Forest System surface within GRSG habitat) would be managed as ROW  
33 exclusion areas. However, because all occupied habitat would be closed to fluid mineral  
34 leasing under Alternative F, managing areas as ROW exclusion in the decision area would  
35 have no additional impact on fluid minerals.

36 ***Proposed Plan***

37 ***Impacts from Fluid Minerals Management***

38 Under the Proposed Plan, 11,296,800 acres, or 44 percent of planning areas would remain  
39 closed to geothermal leasing. This includes 2,832,200 acres with moderate to high

1 geothermal potential (32 percent of the moderate to high geothermal potential acres in the  
2 decision area) to geothermal leasing. An additional 8,464,000 acres (34 percent) with no or  
3 low geothermal potential would remain closed to geothermal leasing. The Proposed Plan  
4 would manage the least amount of acres with geothermal potential to geothermal leasing.  
5 Closures in no and low geothermal potential areas would have less of an impact on  
6 geothermal resource development than closures in moderate to high geothermal potential  
7 areas, due to a lower likelihood of discovery of a valuable geothermal resource.

8 In addition to fluid mineral closures, 3,834,400 acres would be subject to TL and CSU  
9 (including 1,278,100 acres in moderate to high geothermal potential areas and 2,556,300  
10 acres in low geothermal potential areas) and 9,630,000 acres would be subject to NSO  
11 stipulations (including 2,906,800 acres in moderate to high geothermal potential areas, and  
12 6,723,200 acres in low geothermal potential areas).

13 Under the proposed plan, RDFs and BMPs would be applied as COAs when a geothermal  
14 drilling permit or other post-lease activity is approved. In addition to affecting new leases,  
15 the COAs would be applied to the 25,571 acres of existing leases within GRSG habitat,  
16 consistent with existing lease terms and special stipulations. These RDFs and proposed  
17 management actions would include such requirements as noise restrictions, structure height  
18 limitations, design requirements, water development standards, remote monitoring  
19 requirements, and reclamation standards as described in **Appendix B**.

20 The BLM and Forest Service could not apply COAs that would eliminate reasonable  
21 opportunities to develop an existing lease. Therefore, although restrictions on development  
22 would increase where COAs were applied, geothermal development would still be allowed.

### 23 ***Impacts from Lands and Realty Management***

24 Under the Proposed Plan, 8,365,000 acres (33 percent) of BLM-administered and National  
25 Forest System surface in the decision area (including all PHMA) would be managed as ROW  
26 avoidance areas where development of new ROWs for land uses could not occur unless the  
27 Anthropogenic Disturbance Development and Exception Criteria (AD-3 and AD-4) were  
28 satisfied (including the requirement that the project would not exceed the 3 percent  
29 disturbance threshold and would be collocated within existing the footprint of existing  
30 infrastructure). These restrictions would only allow new ROWs to be developed pursuant to  
31 a valid existing authorization.

32 Another 1,013,800 acres (4 percent) of BLM-administered and National Forest System  
33 surface in the decision area (including all IHMA) would be managed as ROW exclusion areas  
34 where development of new ROWs for land uses could not occur unless the Anthropogenic  
35 Disturbance Development Criteria (AD-4) were satisfied (including the requirement that the  
36 project would not exceed the 3 percent disturbance threshold). Lessees would be unable to  
37 site off-lease features, such as transmission lines, roads, and pipelines that may be necessary  
38 to transport the product to market, on public lands. These actions could result in the  
39 stranding of a geothermal lease and its resources, if surrounded by federal lands subject to  
40 these constraints.

1 Application of RDFs, BMPs, buffers, and seasonal timing restrictions to ROW construction  
2 in GRSG habitat would also limit the construction of new ROWs for geothermal  
3 development to certain times of the year or in certain locations. If these limitations made it  
4 uneconomic to develop a ROW for geothermal development, development of federal  
5 geothermal resources in the planning area could decrease.

### 6 ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and*** 7 ***Coordination***

8 Under the Proposed Plan, anthropogenic disturbance, including leasable mineral  
9 development, would be limited to 3 percent of nesting and wintering habitat within PHMA  
10 and IHMA within a Conservation Area (i.e., BSUs). In BSUs where the 3 percent cap is  
11 already exceeded, new development of federal leasable mineral resources would be  
12 prohibited until enough habitat was restored to maintain the area under the threshold.  
13 Development of federal leasable mineral resources that would result in exceedance of the 3  
14 percent cap in a BSU would also be prohibited. Impacts would be greatest where these caps  
15 limited development in unleased portions of high geothermal potential because these areas  
16 have the highest potential for leasable mineral development. The uncertainty wrought by  
17 this limitation would decrease the value of the lease, disincentivize renewable energy  
18 development in the western U.S., and could affect valid existing rights on any lease offered  
19 in the future.  
20

## 21 **4.10 Locatable Minerals**

22 This section discusses impacts on locatable minerals from proposed management actions of  
23 other resources and resource uses. Existing conditions concerning locatable minerals are  
24 described in **Section 3.12**.

### 25 **4.10.1 Methods and Assumptions**

26 The analysis of impacts on locatable minerals from this LUPA focuses on the impacts of  
27 proposed management actions to protect GRSG. These impacts may be direct or indirect.  
28 For example, a direct impact on locatable minerals would result from withdrawing an area  
29 from locatable mineral entry. An indirect impact would result by removing a road, which  
30 would change the economic feasibility of developing a site. Additional actions or conditions  
31 that might cause direct or indirect impacts on locatable minerals are described below.

#### 32 ***Indicators***

33 Indicators of impacts on locatable minerals are as follows:

- 34 • Acres withdrawn from locatable mineral entry
- 35 • Acres recommended for withdrawal from locatable mineral  
36 entry
- 37 • Acres over which restrictions, such as RDFs and management  
38 actions, are placed on locatable mineral development activities to

1 prevent unnecessary or undue degradation of GRSG habitat as  
2 the law allows

3 Where information is available, consideration is given to the potential for locatable minerals  
4 on lands recommended for withdrawal from locatable mineral entry. For example, an  
5 indicator of an impact on locatable minerals is if there were substantial withdrawals from  
6 locatable mineral entry recommended in high potential areas.

### 7 ***Assumptions***

8 The analysis includes the following assumptions:

- 9 • Management actions proposed in this LUPA would apply to  
10 locatable mineral activity where the BLM and Forest Service  
11 manage the surface over federal locatable mineral estate as well  
12 as where federal locatable mineral estate lies beneath private or  
13 state surface (split estate).
- 14 • Areas recommended for withdrawal would be withdrawn.  
15 Current mining claims have valid existing rights, provided they  
16 meet the requirements of the General Mining Law of 1872. One  
17 of these requirements is that the claim be supported by the  
18 discovery of a valuable mineral.
- 19 • Locatable mineral development trends described in **Section**  
20 **3.12**, Mineral Resources, are assumed to continue for the life of  
21 the analysis.
- 22 • Because many different and unrelated mineral commodities are  
23 considered locatable, mineral potential was determined by  
24 looking at current mining claim densities in the planning area, as  
25 well as the number of mining plans and notices. Areas with a  
26 high mining claim density and more mining plans and notices  
27 are considered to have higher potential for locatable minerals  
28 than areas with lower claim densities and fewer plans/notices.

#### 29 **4.10.2 Nature and Type of Effects**

30 In order to describe the effects of imposing GRSG management actions on locatable  
31 mineral discovery and development, the above indicators were evaluated for each alternative.  
32 Each of these factors is considered to be an impediment to locatable mineral discovery and  
33 development, to varying degrees. In general, an alternative with greater acreages of such  
34 restrictions is considered to have a greater impact on locatable mineral discovery and  
35 development potential than an alternative with fewer acres of such restrictions, especially in  
36 areas with moderate to high locatable mineral potential.

37 Withdrawing lands from locatable mineral entry reduces the amount of land available to US  
38 citizens by the General Mining Law of 1872, as amended, to access and locate mining claims.  
39 Withdrawing lands removes the potential for future mineral development on public domain  
40 lands. Withdrawal of areas larger than 5,000 acres require Congressional notification.

1 A valid mining claim within areas withdrawn from mineral entry would be considered a valid  
2 existing right. A valid mining claim is one on which there has been a discovery of an  
3 economically valuable mineral deposit on or before the date of withdrawal. A validity exam  
4 could be required to determine claim validity.

5 For each area proposed for withdrawal, a detailed mineral potential analysis must be  
6 prepared by a geologist or mining engineer, that includes an evaluation of the area's present  
7 and potential market demands. Each existing mining claim in an area proposed to be  
8 withdrawn from locatable mineral entry would have to undergo a valid existing rights  
9 determination to determine whether a discovery had been made. Mining claims with a  
10 discovery of a valuable deposit on the date of the withdrawal are valid and would be exempt  
11 from withdrawal for as long as the claimant maintains the claim; all other claims would  
12 become void.

13 The need to perform valid existing rights determinations and mineral potential reports in  
14 areas proposed to be withdrawn from locatable mineral entry would greatly increase the  
15 burden on the BLM and Forest Service.

16 Applying reasonable and appropriate RDFs, BMPs (see **Appendix B**) and management  
17 actions outlined in **Chapter 2**, to plans of operations could directly impact locatable mineral  
18 operations by increasing costs, causing delays, and frustrating attempts to develop the  
19 resource. These RDFs and management actions include such standards as noise restrictions,  
20 height limitations on structures, design requirements, water development standards, remote  
21 monitoring requirements, and reclamation standards. Applying these requirements may  
22 impact locatable mineral operations by increasing costs, causing delays, and frustrating  
23 attempts to develop the resource.

24 Implementing management for the following resources would have negligible or no impact  
25 on locatable minerals; therefore they are not discussed in detail: GRSG, habitat restoration  
26 and vegetation, invasive species, wildland fire, nonenergy solid leasable minerals, salable  
27 minerals, fluid minerals, recreation and visitor services, livestock grazing, and special  
28 designations.

#### 29 **4.10.3 Impacts on Locatable Minerals Common to All Alternatives**

30 The nature and type of impacts described below are common to all alternatives, but the  
31 context and intensity may vary by alternative.

##### 32 ***Impacts from Locatable Minerals Management***

33 Under all alternatives, approximately 5,380,200 acres, 18 percent of the total federal mineral  
34 estate open to mineral entry, would remain withdrawn from the location of mining claims,  
35 precluding new exploration and mining. **Table 4-74**, Quantitative Impacts on Locatable  
36 Minerals, illustrates the change in acres open to locatable mineral entry and to be petitioned  
37 for withdrawal from locatable mineral entry in the decision area across the alternatives.

**Table 4-74**  
**Quantitative Impacts on Locatable Minerals**

Locatable Minerals	Alternatives A, D, and E	Alternatives B and F	Alternative C	Proposed Plan
Total federal mineral estate for locatable minerals	29,754,300	29,754,300	29,754,300	29,754,300
Total acres withdrawn from locatable mineral entry	5,380,200	5,380,200	5,380,200	5,380,200
<i>High likelihood of interest</i>	38,700	38,700	38,700	38,700
<i>Moderate likelihood of interest</i>	100,400	100,400	100,400	100,400
<i>Low likelihood of interest</i>	5,241,200	5,241,200	5,241,200	5,241,200
Total acres recommended for withdrawal from locatable mineral entry	0	7,928,700	11,555,000	2,968,200
<i>High likelihood of interest</i>	0	150,600	415,700	55,900
<i>Moderate likelihood of interest</i>	0	224,700	382,100	42,600
<i>Low likelihood of interest</i>	0	7,553,400	10,757,200	2,869,600
Total acres open to locatable mineral exploration or development	24,374,100	16,373,400	13,904,300	21,405,600
<i>High likelihood of interest</i>	817,500	609,700	428,200	761,500
<i>Moderate likelihood of interest</i>	875,900	651,200	511,100	833,300
<i>Low likelihood of interest</i>	22,680,600	15,112,500	12,965,100	19,810,900

Source: BLM GIS 2015

The management actions being considered in this LUPA could affect both existing and future mining claims. Exploration and development on mining claims would require that a notice be submitted to the BLM with a cumulative surface disturbance of five or fewer acres and a plan of operations for exploration and development greater than five acres, as outlined in 43 CFR Part 3809. On National Forest System lands, a Notice of Intent is required for minor minerals activities on mining claims, or a Plan of Operations if the proposed operations “will likely cause a significant disturbance of surface resources( 36 CFR 228A).

#### 4.10.4 Alternative A

##### *Impacts from Locatable Minerals Management*

Under Alternative A, 5,380,200 acres, 18 percent, of locatable mineral estate in the decision area would remain withdrawn from location under the General Mining Act of 1872. This includes 38,700 acres where there is a high likelihood of future interest in locatable mineral development (5 percent of total acres with a high likelihood of interest in the decision area). Withdrawal of areas with a high likelihood of future interest in locatable mineral development has greater impacts than withdrawal of areas with moderate or low likelihood of interest because high likelihood areas are more likely to be sought after for development. Under current management, exploration and development would continue in PHMA and GHMA for new claims and for prior existing, valid mining claims. Impacts on existing and

1 future mining claims are similar to those described under **Effects Common to All**  
2 **Alternatives.**

3 There are 41 plans of operations and notices in the locatable mineral decision area.  
4 Development of these operations would continue unrestricted under Alternative A.

5 No additional BMPs to protect GRSG are identified under this alternative.

#### 6 **4.10.5 Alternative B**

##### 7 ***Impacts from Locatable Minerals Management***

8 Under Alternative B, 7,928,700 acres of federal locatable mineral estate in PHMA would be  
9 recommended for withdrawal from location under the General Mining Act of 1872.  
10 Combined with the additional 5,380,200 acres previously withdrawn under Alternative A, the  
11 availability of locatable minerals would be limited on over 13 million acres, or 45 percent of  
12 the federal locatable mineral estate (over two times the acreage under Alternative A).  
13 Approximately 189,300 acres with a high likelihood for locatable mineral interest would be  
14 withdrawn or recommended for withdrawal under this alternative (22 percent of total acres  
15 with high likelihood of locatable mineral interest in the decision area). This represents nearly  
16 5 times more high likelihood acres withdrawn under Alternative B compared with  
17 Alternative A. The types of impacts are the same as those described under **Section 4.9.2** and  
18 **Section 4.9.3.** However, because more acres with a high likelihood of locatable mineral  
19 interest would be withdrawn or recommended for withdrawal under Alternative B, the  
20 magnitude of the impacts would increase compared with Alternative A.

21 Of the 41 plans of operations and notices within the locatable mineral decision area, 28 (65  
22 percent) would be in PHMA under this alternative and therefore within the area to be  
23 petitioned for withdrawal. The types of impacts are the same as those described under  
24 **Nature and Type of Effects.**

25 Accessing and extracting locatable minerals of federal mineral estate would not be impacted  
26 by applying the BMPs listed in **Appendix B**; however, mining operations and practices  
27 could be affected if an operator were to agree to apply any of the BMPs on a project-specific  
28 basis.

#### 29 **4.10.6 Alternative C**

##### 30 ***Impacts from Locatable Minerals Management***

31 Impacts under Alternative C are the same as those described under Alternative B, except  
32 that more acres would be recommended for withdrawal (11,555,000 acres of federal  
33 locatable mineral estate in the decision area). Combined with the 5,380,200 acres withdrawn,  
34 a total of over 16 million acres (54 percent) of the locatable mineral decision area would be  
35 impacted. This includes 454,400 acres (53 percent) of federal locatable mineral estate with a  
36 high likelihood of future interest in locatable mineral development. Management under  
37 Alternative B would impact nearly 12 times the acres with a high likelihood of interest  
38 compared with Alternative A. The types of impacts are the same as those described under

1 **Section 4.9.2** and **Section 4.9.3**; however, the magnitude of impacts under this alternative  
2 would increase since more acreage would be affected.

3 Of the 41 plans of operations and notices within the locatable mineral decision area, all  
4 would be in PHMA under this alternative and therefore within the area to be petitioned for  
5 withdrawal. The types of impacts are the same as those described under **Section 4.9.2**.

6 Impacts from applying the BMPs in **Appendix B** are the same as those described under  
7 Alternative B.

#### 8 **4.10.7 Alternative D**

##### 9 ***Impacts from Locatable Minerals Management***

10 Impacts under Alternative D are the same as those described under Alternative A, except  
11 that additional measures to avoid or minimize adverse effects on GRSG and their habitat  
12 would be required for notices and plans of operations in all habitat types. Impacts from  
13 these additional measures would be highly variable, depending on their extent. If these  
14 measures resulted in the potential for these mineral resources not to be accessed or  
15 extracted, an impact on the potential discovery, development, and use of those resources  
16 would occur because the availability of mineral resource would decrease.

17 Impacts from applying the BMPs in **Appendix B** are the same as those described under  
18 Alternative B.

#### 19 **4.10.8 Alternative E**

##### 20 ***Impacts from Locatable Minerals Management***

21 Impacts under Alternative E are the same as those described under Alternative A.

#### 22 **4.10.9 Alternative F**

##### 23 ***Impacts from Locatable Minerals Management***

24 Impacts under Alternative F are the same as those described under Alternative B.

#### 25 **4.10.10 Proposed Plan**

##### 26 ***Impacts from Locatable Minerals Management***

27 Under the Proposed Plan, 2,968,200 acres of federal locatable mineral estate (including all  
28 acres in the SFA) would be recommended for withdrawal from location under the General  
29 Mining Act of 1872. Combined with the additional 5,380,200 acres already withdrawn under  
30 Alternative A, locatable minerals would be unavailable on 8,348,400 acres, or 28 percent of  
31 the federal locatable mineral estate (twice the acreage as under Alternative A). Impacts on  
32 locatable minerals would increase compared with Alternative A in the manner described  
33 under **Nature and Type of Effects**.

34 Of the 231 plans of operations and notices within the locatable mineral decision area, 12 (5  
35 percent) would be within the SFA under this alternative and therefore within the area to be  
36 petitioned for withdrawal. A valid existing rights determination would be required to

1 determine whether a valuable discovery has been made. The types of impacts are the same as  
2 those described under **Nature and Type of Effects**.

### 3 **4.11 Mineral Materials (Salables)**

4 This section discusses impacts on mineral materials from proposed management actions of  
5 other resources and resource uses. Existing conditions concerning mineral materials are  
6 described in **Section 3.12**.

#### 7 **4.11.1 Methods and Assumptions**

8 Analysis of impacts on mineral materials from this LUPA focuses on the impacts of  
9 proposed management actions to protect GRSG. These impacts may be direct or indirect.  
10 For example, a direct impact on mineral materials would result from closing an area to  
11 mineral material disposal. An indirect impact would result from removing a road, which  
12 would change the economic feasibility of developing a site. Additional actions or conditions  
13 that might cause direct or indirect impacts on mineral materials are described under *Indicators*,  
14 below.

#### 15 ***Indicators***

16 Indicators of impacts on mineral materials are as follows:

- 17 • Acres closed to mineral material disposal
- 18 • Acres subject to timing limitations
- 19 • Acres managed as ROW avoidance areas
- 20 • Acres managed as ROW exclusion areas
- 21 • Acres over which RDFs would be applied to mineral material
- 22 disposals.
- 23 • Application of restoration requirements

24 Where information is available, consideration is given to the potential for mineral materials  
25 on lands closed to mineral material disposal. For example, an indicator of an impact on  
26 mineral materials is if there were substantial closures to mineral material disposal in areas  
27 with high occurrence of mineral materials.

#### 28 ***Assumptions***

29 The analysis includes the following assumptions:

- 30 • Management actions proposed in this LUPA would apply to
- 31 mineral material disposal activity where the BLM or Forest
- 32 Service manages the surface over federal mineral material estate
- 33 as well as where federal mineral material estate lies beneath
- 34 private or state surface (split estate).

- Mineral material development trends described in **Section 3.12**, Mineral Resources, are assumed to continue for the life of the analysis.
- Historical patterns of mineral material development in the planning area are used to assess the level of mineral material potential throughout the planning area. Areas with a high level of historical development are considered to have high potential for mineral materials. There is higher demand in more populated areas.

#### 4.11.2 Nature and Type of Effects

In order to describe the effects of imposing GRSG management actions on mineral materials disposal, the above indicators were evaluated for each alternative. Each of these factors is considered to be an impediment to disposal of mineral materials, to varying degrees. In general, an alternative with greater acreages of such restrictions is considered to have a greater impact on disposals of mineral materials than an alternative with fewer acres of such restrictions, especially in populated areas where material sources are scarce. Mineral material disposal by the BLM and Forest Service is discretionary.

Closing areas to mineral material disposal and closing community pits would directly impact the public, including commercial operators, and county highway districts, by removing the mineral material source from availability. This can be a serious problem in some Idaho counties that are covered by vast expanses of volcanic rock with few sand and gravel occurrences. Highway districts may need to seek out sites on private lands, which may not offer materials free-of-charge, as the BLM and Forest Service do. This could result in higher haul costs, higher road maintenance costs, and poorer road conditions. In addition, closing areas could result in an increase in trespass cases.

Applying TLs could delay extraction of mineral material resources. County road districts would be required to schedule their projects around the TL, which could result in the need to stockpile materials off-site and handle materials twice, thereby increasing costs.

Implementing management for the following resources would have negligible or no impact on mineral materials therefore they are not discussed in detail: travel and transportation management, recreation, range management, solid minerals, fire and fuels management, habitat restoration and vegetation management, and special designations.

**Table 4-75**, Mineral Materials by Alternative, shows the number of acres open or closed to mineral materials disposal in the decision area under each alternative.

**Table 4-75  
Mineral Materials by Alternative**

Occurrence	Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F	Proposed Plan
Closed to disposal (acres)	10,707,600	18,589,300	21,174,000	13,211,100	10,707,600	18,589,300	15,529,000
Open to disposal (acres)	17,137,300	9,255,600	6,670,900	14,633,800	17,137,300	9,255,600	12,315,900

Source: BLM GIS 2015

1

2 A discussion of the impacts on mineral materials from management actions applicable to  
3 federal mineral material estate in the decision area under each alternative is below.

4 **4.11.3 Alternative A**

5 ***Impacts from Mineral Materials Management***

6 Approximately 17,137,300 acres (62 percent) of federal mineral material estate within the  
7 decision area would remain open to mineral material disposal under Alternative A.  
8 Approximately 10,707,600 acres (38 percent) of federal mineral material estate within the  
9 decision area would remain closed to mineral material disposal. Impacts of these closures  
10 would be the same type as those described under **Section 4.10.2**.

11 Management under Alternative A would continue to require reclamation of mineral material  
12 pits in accordance with developers' pit development plans.

13 **4.11.4 Alternative B**

14 ***Impacts from Mineral Materials Management***

15 Under Alternative B, approximately 18,589,300 acres (67 percent) of federal mineral material  
16 estate in the decision area (including all PHMA) would be closed to mineral material  
17 disposal. The types of impacts from these closures are the same as those discussed under  
18 **Section 4.10.2**. Because 74 percent more acres of federal mineral material estate would be  
19 closed under Alternative B compared with Alternative A, the magnitude of these impacts  
20 would increase.

21 Management of mineral materials on federal mineral estate outside of PHMA would be the  
22 same as that under Alternative A.

23 **4.11.5 Alternative C**

24 ***Impacts from Mineral Materials Management***

25 Under Alternative C, approximately 21,174,000 acres (76 percent) of federal mineral material  
26 estate in the decision area, including all GRSG habitat, would be closed to mineral material  
27 disposal. The types of impacts from these closures are the same as those discussed under  
28 **Section 4.10.2**. Because twice as many acres of federal mineral material estate with mineral

1 material occurrence would be closed under Alternative C compared with Alternative A, the  
2 magnitude of these impacts would increase.

#### 3 4.11.6 Alternative D

##### 4 ***Impacts from Mineral Materials Management***

5 Under Alternative D, areas within 1.86 miles (3 km) of occupied leks would be closed to  
6 mineral materials disposal. These closures, in addition to existing closures, would result in  
7 approximately 13,211,100 acres (47 percent) of federal mineral material estate in the decision  
8 area, being closed to mineral material disposal. The types of impacts from these closures are  
9 the same as those discussed under **Section 4.10.2**. Because 23 percent more acres of federal  
10 mineral material estate with mineral material occurrence would be closed under Alternative  
11 C than under Alternative A, the magnitude of these impacts would increase.

12 All other federal mineral material estate in GRSG habitat would be subject to TLs, TLs  
13 would also apply to the 144 existing community pits within PHMA and IHMA (70 percent)  
14 of existing community pits in GRSG habitat. All of these TLs would impact mineral  
15 materials as described under **Section 4.10.2**. Because TLs would not be applied under  
16 Alternative A, impacts on mineral materials would increase under Alternative D.

#### 17 4.11.7 Alternative E

##### 18 ***Impacts from Mineral Materials Management***

19 Under Alternative E, mineral materials management would differ between portions of the  
20 decision area in Idaho and Montana and portions in Utah.

21 Management of mineral materials within Idaho and Southwestern Montana would be the  
22 same as that under Alternative A with the same impacts.

23 Within Utah, mineral material operations within PHMA would be subject to TLs and other  
24 restrictions, which would limit mineral material development, as described under **Section**  
25 **4.10.2**.

26 Allocations in the mineral material decision area would be the same as those under  
27 Alternative A. Impacts on mineral materials would increase compared to Alternative A in  
28 Utah due to the restrictions that would be placed on mineral material activities there.

#### 29 4.11.8 Alternative F

##### 30 ***Impacts from Mineral Materials Management***

31 Mineral materials management under Alternative F would be the same as that under  
32 Alternative B with the same impacts.

#### 33 4.11.9 Proposed Plan

##### 34 ***Impacts from Mineral Materials Management***

35 Under the Proposed Plan, 15,529,000 acres (56 percent) of federal mineral material estate in  
36 the decision area (including all PHMA) would be closed to mineral material disposal. The  
37

1 types of impacts from these closures are the same as those discussed under Nature and  
2 Types of Effects, **Section 4.10.2**. Impacts would be mitigated in the Montana portion of the  
3 decision area because new free use permits would still be allowed and existing pits would be  
4 able to expand. Because 45 percent more acres of federal mineral material estate would be  
5 closed under the Proposed Plan compared with Alternative A, the magnitude of these  
6 impacts would increase.

7 Approximately 3,079,100 acres (11 percent) of federal mineral material estate in the decision  
8 area (including all IHMA) would be open to mineral material disposal but only if the  
9 Anthropogenic Disturbance Development and Criteria (AD-4) were satisfied (including the  
10 requirement that the project would not exceed the 3 percent disturbance threshold). Mineral  
11 material activities in IHMA and GHMA would also be subject to RDFs, buffers, and  
12 seasonal timing restrictions. The types of impacts from these limitations are the same as  
13 those discussed under **Section 4.10.2**. Because these types of restrictions would not be  
14 applied under Alternative A, impacts on mineral material development from the restrictions  
15 would increase under the Proposed Plan.

16 Mineral material sales from the 47 existing community pits in GRSG habitat would be  
17 subject to timing restrictions. As described in **Section 4.10.2**, these timing restrictions could  
18 impact some operations and therefore reduce overall sales of federal materials in the  
19 planning area.

#### 20 ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and*** 21 ***Coordination***

22 Under the Proposed Plan, anthropogenic disturbance, including mineral material  
23 development, would be limited to 3 percent of nesting and wintering habitat within PHMA  
24 and IHMA within a Conservation Area (i.e., BSUs). In BSUs where the 3 percent cap is  
25 already exceeded, new development of federal mineral material resources would be  
26 prohibited until enough habitat was restored to maintain the area under the threshold.  
27 Development of federal mineral material resources that would result in exceedance of the 3  
28 percent cap in a BSU would also be prohibited. This cap could potentially impact activities  
29 on 3,079,100 acres of federal mineral material estate in IHMA. The 15,529,000 acres that  
30 would be closed to mineral material disposal under Alternative G would not be impacted by  
31 the disturbance cap because no new mineral material development could occur in the closed  
32 areas.

#### 33 **4.12 Nonenergy Leasable Minerals**

34 This section discusses impacts on nonenergy solid leasable minerals from proposed  
35 management actions for resources and resource uses. Specifically, this section describes  
36 impacts on phosphate, the notable nonenergy leasable mineral within the planning area.  
37 Existing conditions concerning phosphate are described in **Section 3.12**.

##### 38 **4.12.1 Methods and Assumptions**

39 Analysis of impacts on nonenergy solid leasable minerals from this LUPA focuses on the  
40 impacts of proposed management actions to protect GRSG. These impacts may be direct or

1 indirect. For example, a direct impact on nonenergy solid leasable minerals would result  
2 from closing an area to leasing. An indirect impact would result from removing a road,  
3 which would change the economic feasibility of developing a site. Additional actions or  
4 conditions that might cause direct or indirect impacts on nonenergy solid leasable minerals  
5 are described under *Indicators*, below.

### 6 ***Indicators***

7 Indicators of impacts on nonenergy solid leasable minerals are as follows:

- 8 • Acres of unleased KPLAs proposed to be closed to nonenergy  
9 solid mineral leasing
- 10 • Acres over which RDFs would be applied when activities are  
11 proposed on existing unmined phosphate leases

12 Where information is available, consideration is given to the potential for nonenergy solid  
13 leasable minerals on lands closed to leasing. In the planning area, the only nonenergy solid  
14 leasable mineral commodity of any significance is phosphate. The USGS spent many years  
15 sampling and testing the phosphate resource to determine the mineral potential of federal  
16 lands in southeast Idaho. Areas called Known Phosphate Leasing Areas (KPLAs) were  
17 designated in high potential areas, and were offered for lease competitively. Therefore,  
18 unmined phosphate leases have the highest potential for development, while unleased  
19 KPLAs have the next highest potential. Areas of southeast Idaho located outside of KPLAs  
20 have the lowest potential. Unmined phosphate leases have valid existing rights and cannot be  
21 closed to development. An indicator of an impact on nonenergy solid leasable minerals is if  
22 there were substantial closures to nonenergy solid mineral leasing in areas with high potential  
23 for nonenergy solid mineral development, such as unleased KPLAs.

### 24 *Assumptions*

25 The analysis includes the following assumptions:

- 26 • Management actions proposed in this LUPA would apply to  
27 nonenergy leasable mineral activity where the BLM and Forest  
28 Service manage the surface over federal nonenergy leasable  
29 mineral estate as well as where federal nonenergy leasable  
30 mineral estate lies beneath private or state surface (split estate).
- 31 • Unmined phosphate leases have the highest potential for  
32 nonenergy leasable mineral development in the decision area.  
33 Unleased KPLAs have a moderate potential for development,  
34 and lands outside KPLAs have a low potential for development.  
35 Most of the planning area has no potential for development,  
36 because the rock formation that has high amounts of phosphate  
37 resource, designated the Phosphoria Formation, does not exist  
38 in those areas.

- Demand for phosphate resources in the Pocatello FO is expected to remain high, as it has for the past 60 to 100 years. As discussed in **Section 3.12**, Mineral Resources, significant phosphate resources exist in the Pocatello Field Office within the planning area, with 86 active phosphate leases. There are no phosphate leases in PHMA; one phosphate lease (65 acres) in IHMA; and no leases in GHMA. There are 10 leases surrounded by GHMA. No development is planned on these leases for the next 5 to 10 years.

#### 4.12.2 Nature and Type of Effects

Closing an area to nonenergy solid mineral leasing would directly impact the nonenergy solid leasable mineral program by removing the opportunity afforded U.S. citizens by the Mineral Leasing Act, to lease and develop mineral resources in those areas. Mining companies seeking leases may be required to exploit private lands if those lands are available and if similar geologic resources exist, or the opportunity for discovery may be lost altogether if such conditions are unique to the federal lands. Closures would have the greatest impact on unleased areas within KPLAs, as these areas have the greatest potential to be nominated for lease during the life of this LUPA. Closing lands to leasing in KPLAs may also result in a loss of royalties to the federal, state, and county governments from phosphate development. Closures of areas outside KPLAs would likely have less impact, as these areas have lower potential for discovery and development.

Application of RDFs, including such standards as noise restrictions, height limitations on structures, design requirements, water development standards, remote monitoring requirements, and reclamation standards, would place additional requirements on phosphate exploration and initial mine development. These requirements are not practical once mining commences. At that time, compensatory mitigation would be necessary. These restrictions may increase the cost of phosphate mining in the decision area. However, the BLM would not apply restrictions so onerous that they would eliminate reasonable opportunity to develop an existing lease.

Implementing management for the following resources would have negligible or no impact on nonenergy solid leasable minerals; therefore they are not discussed in detail: GRSG, lands and realty, habitat restoration and vegetation, invasive species, wildland fire, locatable minerals, salable minerals, fluid minerals, recreation and visitor services, livestock grazing, and special designations.

**Table 4-77**, Nonenergy Leasable Minerals by Alternative, shows the number of acres open or closed to nonenergy leasable mineral prospecting and leasing as well as restrictions on unmined phosphate leases in the decision area under each alternative.

**Table 4-76  
Nonenergy Leasable Minerals by Alternative**

Management	Alternative						Proposed Plan
	A	B	C	D	E	F	
Open to prospecting and leasing (acres)	15,925,600	8,557,600	6,095,300	8,556,500	15,925,600	8,557,600	11,454,500
<i>Unleased KPLAs open</i>	<i>14,500</i>	<i>14,000</i>	<i>13,500</i>	<i>14,000</i>	<i>14,500</i>	<i>14,000</i>	<i>14,500</i>

Source: BLM GIS 2015

A discussion of the impacts on nonenergy leasable minerals from management actions applicable to federal nonenergy leasable mineral estate in the decision area under each alternative is below.

#### 4.12.3 Alternative A

##### ***Impacts from Nonenergy Solid Leasable Minerals Management***

Under Alternative A, 15,925,600 acres or 57 percent of federal nonenergy solid leasable mineral estate in the nonenergy solid leasable mineral decision area, would remain open to leasing consideration, and 11,799,500 acres or 43 percent, would remain closed to prospecting and leasing. These closures would have the same types of impacts as described under **Section 4.11.2**.

Less than one percent of the acres closed to leasing would be unleased KPLAs (**Table 4-77**, Nonenergy Leasable Minerals by Alternative).

Under Alternative A, 4,870 acres (25 percent) of unleased federal mineral estate within KPLAs in the nonenergy solid leasable mineral decision area would remain closed to nonenergy leasable mineral prospecting and leasing. The impacts of these closures would be the same type as those described under **Section 4.11.2**. The remaining 15,320 acres (80 percent) of federal mineral estate within KPLAs in the nonenergy solid leasable mineral decision area would remain open to nonenergy leasable mineral prospecting and leasing. Impacts of these stipulations would be the same type as those described under **Section 4.11.2**.

Existing federal nonenergy leasable mineral leases in the decision area would continue to be subject to any stipulations or BMPs contained in those leases. Application of BMPs could alter how mineral resources are accessed and extracted and result in the use of different technology than would otherwise have been used.

1                                   **4.12.4 Alternative B**

2                   ***Impacts from Nonenergy Solid Leasable Minerals Management***

3 Under Alternative B, 19,167,400 acres, or 69 percent of the federal nonenergy solid leasable  
4 mineral estate decision area (including all federal nonenergy solid leasable mineral estate in  
5 PHMA), would be closed to prospecting and leasing. Management under this alternative  
6 would close 20 percent more federal nonenergy solid leasable mineral estate to nonenergy  
7 leasable mineral prospecting and leasing than management under Alternative A. New leases  
8 to expand existing mines for phosphate would not be permitted in areas managed as closed.  
9 Closing areas to nonenergy mineral prospecting would result in the same type of impacts as  
10 described under **Section 4.11.2**. Approximately 8,557,600 acres (31 percent) of federal  
11 nonenergy leasable mineral estate in the decision area would remain open subject to standard  
12 terms and conditions.

13 Less than one percent of the acres closed to leasing would be within KPLAs (**Table 4-77**,  
14 Nonenergy Leasable Minerals by Alternative).

15 Under Alternative B, 5,350 acres (28 percent) of unleased federal mineral estate within  
16 KPLAs in the nonenergy solid leasable mineral decision area would be closed to nonenergy  
17 leasable mineral prospecting and leasing —a 10-percent increase compared with Alternative  
18 A. The impacts of these closures would be the same type as those described under **Section**  
19 **4.11.2**. The remaining 14,000 acres (72 percent) of unleased federal mineral estate within  
20 KPLAs in the nonenergy solid leasable mineral decision area would be open to nonenergy  
21 leasable mineral prospecting and leasing. Because the number of unleased acres within  
22 KPLAs that are closed would increase compared with Alternative A, impacts on nonenergy  
23 solid leasable minerals would increase.

24 Under Alternative B, a disturbance cap of 3 percent of PHMA would be applied to all  
25 anthropogenic disturbances, including oil and gas development. In PHMA where the 3  
26 percent cap is already exceeded, no new oil and gas leases would be issued until habitat  
27 within the PHMA was restored to a point that acreage of anthropogenic disturbance was  
28 below the 3 percent cap. However, because all federal mineral estate in PHMA would be  
29 closed to new fluid mineral leasing, new fluid mineral leases would not be impacted by the  
30 disturbance cap. Valid existing lease rights would be honored, but mitigation measures may  
31 be required for development in the areas that exceed the 3 percent disturbance cap.

32 Approximately 1,340 acres of existing unmined federal nonenergy leasable mineral leases in  
33 PHMA would be subject to RDFs. This would limit surface disturbance, vehicle use, siting,  
34 and design of mineral development operations, in addition to imposing reclamation  
35 requirements. Application of RDFs would have the types of impacts described under  
36 **Section 4.11.2**. Because these RDFs would not be applied under Alternative A, impacts  
37 would increase under Alternative B.

1                   **4.12.5 Alternative C**

2                   ***Impacts from Nonenergy Solid Leasable Minerals Management***

3                   Impacts under Alternative C are the same as those described under Alternative B, except  
4                   that more acres would be affected by closures (21,629,700 acres, or 78 percent of the  
5                   nonenergy leasables decision area). As a result, the magnitude of impacts under this  
6                   alternative would increase.

7                   Less than one percent of the acres closed to leasing would be within KPLAs (**Table 4-77**,  
8                   Nonenergy Leasable Minerals by Alternative).

9                   Under Alternative C, 5,870 acres (30 percent) of unleased federal mineral estate within  
10                  KPLAs in the nonenergy solid leasable mineral decision area would be closed to nonenergy  
11                  leasable mineral prospecting and leasing—a 20-percent increase compared with Alternative  
12                  A. The impacts of these closures would be the same type as those described under **Section**  
13                  **4.11.2**. Because the number of unleased acres within KPLAs that are closed would increase  
14                  compared with Alternative A, impacts on nonenergy solid leasable minerals would increase.

15                  Approximately 5,730 acres of existing unmined federal nonenergy leasable mineral leases in  
16                  PHMA and GHMA would be subject to RDFs. This would limit surface disturbance, vehicle  
17                  use, siting, and design of mineral development operations, in addition to imposing  
18                  reclamation requirements. Application of RDFs would have the types of impacts described  
19                  under **Section 4.11.2**. Because these RDFs would not be applied under Alternative A,  
20                  impacts would increase under Alternative C.

21                   **4.12.6 Alternative D**

22                   ***Impacts from Nonenergy Solid Leasable Minerals Management***

23                   Under Alternative D, 11,799,500 acres, or 42 percent of the federal nonenergy leasable  
24                   mineral estate decision area (including all federal nonenergy leasable mineral estate in PHMA  
25                   and IHMA), would be closed to prospecting and leasing—the same amount of acres closed  
26                   as Alternative A. An additional 7,369,000 acres (26 percent) would be closed except fringe  
27                   leases and modifications. Impacts of this limited closure would be similar to those described  
28                   under **Section 4.11.2** except that impacts would increase compared with Alternative A.  
29                   Closing areas to nonenergy mineral prospecting and leasing would result in the same type of  
30                   impacts as described under **Section 4.11.2**; however, because more acres would be closed  
31                   under Alternative D, impacts would increase compared with Alternative A. Impacts would  
32                   be mitigated because fringe acreage leases and lease modifications would be allowed.  
33                   Approximately 8,556,600 acres (31 percent) of federal nonenergy leasable mineral estate in  
34                   the decision area would remain open subject to standard terms and conditions.

35                   Less than one percent of the acres closed to leasing would be within KPLAs (**Table 4-77**,  
36                   Nonenergy Leasable Minerals by Alternative).

37                   Under Alternative D, 4,870 acres (25 percent) of unleased federal mineral estate within  
38                   KPLAs in the nonenergy solid leasable mineral decision area would be closed to nonenergy  
39                   leasable mineral prospecting and leasing under Alternative D. An additional 490 acres (3

1 percent) would be closed except for fringe leases and modifications. The impacts of these  
2 closures would be the same type as those described under **Section 4.11.2**. The remaining  
3 14,000 acres (72 percent) of unleased federal mineral estate within KPLAs in the nonenergy  
4 solid leasable mineral decision area would be open to nonenergy leasable mineral  
5 prospecting and leasing. Because the number of unleased acres within KPLAs that are closed  
6 would slightly increase compared with Alternative A, impacts on nonenergy solid leasable  
7 minerals would increase.

8 Approximately 6,510 acres of existing unmined federal nonenergy leasable mineral leases in  
9 PHMA and GHMA would be subject to RDFs. Applying BMPs as COAs on any new mine  
10 plan and requiring restoration of habitat or off-site mitigation in areas where on-site  
11 restoration is not feasible could alter how mineral resources are accessed and extracted. It  
12 also could result in the use of different technology than would otherwise have been used.  
13 Because these RDFs would not be applied under Alternative A, impacts would increase  
14 under Alternative D.

#### 15 **4.12.7 Alternative E**

##### 16 ***Impacts from Nonenergy Solid Leasable Minerals Management***

17 Impacts from nonenergy solid mineral leasing allocations under Alternative E would be the  
18 same as those impacts described under Alternative A (Error! Reference source not  
19 found. **Table 4-77**). Closing areas to nonenergy mineral prospecting and leasing would result  
20 in the same type of impacts as described under **Section 4.11.2**. Lands open to leasing would  
21 be subject to several stipulations, which include prohibiting permanent structures within  
22 occupied leks, prohibiting tall structures within one mile (1.6 km) of leks, and restrictions on  
23 noise disturbances. Stipulations would restrict the ability of mineral resources to be  
24 developed or extracted and would increase impacts on nonenergy solid leasable minerals  
25 compared with Alternative A.

#### 26 **4.12.8 Alternative F**

##### 27 ***Impacts from Nonenergy Solid Leasable Minerals Management***

28 Management under Alternative F would be similar to that under Alternative B except that  
29 the BLM would close an additional 30,200 acres in PHMAs under Alternative F. However,  
30 because none of these additional acres would be within KPLAs, impacts of closures under  
31 Alternative F would be the same as those described under Alternative B.

32 Like Alternative B, under Alternative F, a disturbance cap of 3 percent of PHMA would be  
33 applied to all anthropogenic disturbances, including oil and gas development. Impacts would  
34 be similar to those under Alternative B except that, because fire would be included in the  
35 disturbance cap, exceedance of the cap (and subsequent restrictions on existing leases) would  
36 be more likely to occur. Therefore, overall impacts on nonenergy solid leasable minerals  
37 would increase under Alternative F.

1           **4.12.9 Proposed Plan**

2  
3           ***Impacts from Nonenergy Solid Leasable Minerals Management***

4           Under the Proposed Plan, 16,270,500 acres, or 59 percent of the federal nonenergy leasable  
5           mineral estate decision area (including all federal nonenergy leasable mineral estate in PHMA  
6           outside KPLAs) would be closed to prospecting and leasing—38 percent more acres closed  
7           compared with Alternative A. Fringe leases and modifications to existing leases would be  
8           allowed in PHMA to satisfy valid existing rights. Impacts of this closure would be similar to  
9           those described under **Section 4.11.2** except that impacts would increase compared with  
10          Alternative A. Approximately 2,899,800 acres, or 10 percent of federal nonenergy solid  
11          leasable mineral estate in the decision area (including all federal nonenergy leasable mineral  
12          estate in IHMA outside KPLAs), would be open to leasing consideration but only if the  
13          Anthropogenic Disturbance Development and Criteria (AD-4) were satisfied (including the  
14          requirement that the project would not exceed the 3 percent disturbance threshold).  
15          Development on these acres would also be subject to RDFs, BMPs, and buffers for  
16          exploration and initial mine development, and compensatory mitigation once mining  
17          commences. Because development of nonenergy leasable minerals in these areas would be  
18          more restricted than under Alternative A, impacts described under **Section 4.11.2** would  
19          increase under the Proposed Plan.

20          Development on 2,729,500 acres of federal nonenergy leasable minerals within GHMA  
21          would also be subject to RDFs, BMPs, and buffers on exploration and initial mine  
22          development. These limitations could increase costs of federal nonenergy leasable mineral  
23          development in the planning area as described under **Section 4.11.2**.

24          Because KPLAs would remain open to nonenergy solid mineral leasing, impacts on federal  
25          nonenergy solid leasable mineral development would be mitigated. The areas considered to  
26          have moderate potential in the decision area would not be constrained.

27          RDFs would be applied to the 1 federal phosphate lease on 70 acres in IHMA with impacts  
28          similar to those described under Alternative D. These restrictions may increase the cost of  
29          phosphate mining in the decision area. However, the BLM would not apply restrictions so  
30          onerous that they would eliminate reasonable opportunity to develop an existing lease.

31          ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and***  
32          ***Coordination***

33          Under the Proposed Plan, anthropogenic disturbance, including nonenergy leasable mineral  
34          development, would be limited to 3 percent of nesting and wintering habitat on new leases  
35          and prospecting permits within IHMA within a Conservation Area (i.e., BSUs). In BSUs  
36          where the 3 percent cap is already exceeded, new parcels would not be offered for lease until  
37          enough habitat was restored to maintain the area under the threshold. New leases of federal  
38          nonenergy leasable mineral resources that would result in exceedance of the 3 percent cap in  
39          a BSU would also be prohibited. Valid existing rights would be honored, but compensatory  
40          mitigation requirements could be applied. This cap could potentially impact activities on  
41          2,900,100 acres of unleased federal nonenergy leasable mineral estate in IHMA, including  
42          400 unleased acres within KPLAs. Impacts would be greatest where these caps limited

1 development in unleased portions of KPLAs because these areas have the highest potential  
2 for nonenergy leasable mineral development. The 16,270,500 acres that would be closed to  
3 nonenergy solid mineral leasing under the Proposed Plan would not be impacted by the  
4 disturbance cap because no new nonenergy leasable mineral development could occur in the  
5 closed areas.

## 6 **4.13 Special Designations**

### 7 **4.13.1 ACECs and ZAs**

8 This section discusses impacts on ACECs and ZAs from proposed management actions of  
9 other resources and resource uses. Existing conditions concerning ACECs are described in  
10 **Section 3.13**, Special Designations. See **Appendix S**, BLM Areas of Critical Environmental  
11 Concern Evaluation and Forest Service Zoological Areas, for the evaluation of relevant and  
12 important values for proposed ACECs. There are no existing Forest Service ZAs in the sub-  
13 region. As stated previously, it is anticipated that GRSG management would have beneficial  
14 or negligible effects on other special designations areas (e.g., National Historic Trails, Wild  
15 and Scenic Rivers, Wilderness Areas, Wilderness Study Areas, National Monuments, and  
16 National Conservation Areas). The BLM manual for each NLCS unit type will be adhered to  
17 during any site-specific analysis, and the BLM would manage them to safeguard the reasons  
18 for which they were designated. Due to this, the analysis of impacts on special designations  
19 will focus on ACECs and ZAs.

### 20 **4.13.2 Methods and Assumptions**

21 Direct impacts on ACECs are considered to be those that either impair or enhance the  
22 relevant and important values for which the ACEC was proposed for designation. As such,  
23 this analysis focuses on relevance and importance criteria for each potential ACEC. There  
24 are no relevance and importance criteria for Forest Service ZAs. It also focuses on impacts  
25 on these values from either the special management derived from ACEC or ZA designation  
26 or, under alternatives where an ACEC or ZA is not proposed for designation, the  
27 management actions for other resources. All impacts discussed are direct, though some may  
28 not occur immediately after implementation of management actions.

#### 29 *Indicators*

30 Impacts on ACECs would occur from management actions that protect or impair relevant  
31 and important ACEC values, including “important historic, cultural, or scenic values, fish  
32 and wildlife resources or other natural systems or processes” (BLM Manual 1613 – Areas of  
33 Critical Environmental Concern). As such, indicators of impacts are allocations for surface-  
34 disturbing activities within existing or potential ACECs that could affect the relevant and  
35 important values for which the ACEC was designated.

#### 36 *Assumptions*

37 The analysis includes the following assumptions:

- 38 • Management of existing ACECs was determined in the  
39 applicable LUPs to be adequate to support the relevant and

1 important values at the time of their designation. Impacts on  
2 these ACECs are not further discussed because the BLM would  
3 continue to manage these ACECs to protect their relevant and  
4 important values. Management to protect GRSG under the  
5 various alternatives could provide additional protections for  
6 existing ACECs and, at a minimum, would provide  
7 complementary management.

- 8 • Although management actions for most resources and resource  
9 uses have application throughout the decision area, ACEC and  
10 ZA management prescriptions apply only to those lands within  
11 each specific ACEC or ZA.
- 12 • Permitted activities would not be allowed to impair the relevant  
13 and important values for which the ACECs are designated. The  
14 exception is locatable minerals; until withdrawn from mineral  
15 entry, a mining claim can be filed, and subsequent mining  
16 activities could have an impact. However, measures would have  
17 to be identified in a mine plan to mitigate unnecessary and  
18 undue degradation.
- 19 • ACEC designation provides protection and focused  
20 management of relevant values beyond that provided through  
21 general management of the relevant and important values  
22 elsewhere in the decision area.
- 23 • Any designated ACEC that falls within a WSA would be  
24 managed according to BLM Manual 6330, Management of  
25 Wilderness Study Areas, unless the ACEC management is more  
26 restrictive. Because activities within WSAs must meet the  
27 nonimpairment criterion, which generally restricts new surface  
28 disturbance, a WSA would generally protect relevant and  
29 important values. Also, it would have a beneficial effect on  
30 overlapping designated and undesignated ACECs. If Congress  
31 were to release a WSA from further consideration, the special  
32 management in designated ACECs would be designed to protect  
33 and enhance the relevant and important values.

#### 34 **4.13.3 Nature and Type of Effects**

35 In general, management actions that protect resources—such as surface-disturbance  
36 restrictions, management for desired habitats, travel restrictions and closures, and recreation  
37 restrictions—would help maintain and improve the important and relevant values within  
38 ACECs. Management actions that create the potential for resource degradation—such as  
39 mineral development, livestock grazing, and infrastructure development—could impact the  
40 relevant and important values for which an ACEC is designated. Recreation and travel  
41 within ACECs could also impact their values. Limiting motorized travel to existing routes

1 and trails would reduce surface disturbance and potentially reduce disturbance to the values  
2 for which the ACECs were designated.

3 Implementing management for the following resources would have negligible or no impact  
4 on GRSG and are therefore not discussed in detail: mineral split-estate.

5 ***Wildland Fire***

6 Depending on their extent, location, and severity, wildfires could cause short- and long-term  
7 damage to ACEC values. Emergency stabilization and restoration would be applied to  
8 minimize impacts where special values are at risk. If these techniques are successful, wildfires  
9 could also cause long-term improvement in ACEC values by maintaining natural vegetation  
10 ecosystem cycles.

11 ***Lands and Realty***

12 Managing ACECs as ROW exclusion or avoidance areas would protect relevant and  
13 important values by reducing (for avoidance areas) or eliminating (for exclusion areas)  
14 impacts from development. These impacts would require a ROW permit, including utilities,  
15 access roads, and renewable energy projects. Impacts from ROW development on ACECs  
16 include compaction and erosion.

17 ***Mineral Resources***

18 Energy and mineral development could impact ACEC values by increasing soil erosion  
19 potential and removing or disrupting unique vegetation. Where GRSG habitat exists, energy  
20 and mineral development could degrade and fragment habitat. Construction, operation, and  
21 maintenance could disturb GRSG populations. Closing ACECs to fluid minerals leasing  
22 would help protect relevant and important values by eliminating the surface disturbance  
23 associated with such development.

24 ***Livestock Grazing***

25 Livestock grazing could impact ACEC values by increasing soil erosion potential and  
26 reducing understory plant species, such as forbs and grasses. Closing ACECs to livestock  
27 grazing would help protect relevant and important values by eliminating soil and vegetation  
28 disturbance associated with grazing, but it could also increase the risk of fire due to increased  
29 fuel loads.

30 ***Special Designations***

31 Special status species management would prevent degradation of, and could improve,  
32 relevant and important values where an ACEC is designated to protect such values. New  
33 ACECs designated under Alternatives C and F would protect GRSG. Refer to **Section 4.2**,  
34 Special Status Species – Greater Sage-Grouse, for a discussion of impacts from these  
35 ACECs on GRSG habitat. None of the existing ACECs in the planning area are designated  
36 to protect GRSG but would experience indirect protections from management actions in  
37 other resource programs aimed at GRSG conservation.  
38

**Impacts Common to All Alternatives**

Impacts on the relevant and important values of ACECs would mainly be from surface-disturbing activities that cause direct damage to the values, introduce modifications to the landscape that affect the area’s scenic quality or historical or cultural context, or that result in erosion, sedimentation, or increased runoff. All of the action alternatives would generally result in greater restrictions, compared to the continuation of existing management under Alternative A. Adopting more restrictive management of surface-disturbing activities under the action alternatives would be complementary to the protection of the relevant and important values of the existing ACECs. Therefore, in general, the action alternatives would enhance the relevant and important values of the existing ACECs to a greater extent than Alternative A.

**Table 4-77**, Comparison of ACEC-Affecting Management Actions by Alternative provides a quantitative overview of how the ACEC-affecting management actions under an applicable resource program would vary across alternatives.

**Table 4-78**, Acres of Proposed ACECs within the Planning Area by Habitat Type and Alternative displays the acres of the proposed ACECs within each habitat type under the different alternatives. Different management would apply to the different areas, as described in **Chapter 2**, impacts of which are discussed in **Section 4.2**, Special Status Species – Greater Sage-Grouse, and **Section 4.3**, Vegetation (Including Noxious Weeds; Riparian and Wetlands).

**Table 4-77**

**Table 4-78**  
**Acres of Proposed ACECs within the Planning Area by Habitat Type and Alternative**

Habitat	Alternative C	Alternative F1	Alternative F2
PHMA (acres)	2,655,000	6,929,600	1,379,100
GHMA (acres) <sup>1</sup>	N/A	0	0
RHMA (acres) <sup>1</sup>	N/A	0	0

Source: BLM GIS 2015

<sup>1</sup>There is no GHMA or RHMA that would be designated under Alternative C.

2

3 **4.13.4 Alternative A**

4 Under Alternative A, the BLM would continue managing the 59 existing Idaho and Montana  
5 ACECs containing 469,200 acres of occupied GRSG habitat to protect the identified  
6 relevant and important values. Current management would continue protecting those values.  
7 Sagebrush habitat is not identified as a relevant and important value in any of the existing  
8 ACECs.

9 **4.13.5 Alternative B**

10 No new ACECs would be designated. However, management protecting the 469,200 acres  
11 of occupied GRSG habitat within existing ACECs may provide indirect protection to the  
12 relevant and important values for which these ACECs were designated. Management actions  
13 that could impact ACECs include the management of areas as ROW avoidance and ROW

1 exclusion, fire management, mineral development, travel management, and the management  
2 of areas as open or closed to livestock grazing. The ways in which these management actions  
3 could impact ACECs is described in **Nature and Types of Effects**.

#### 4 **4.13.6 Alternative C**

5 Under Alternative C, 39 new BLM ACECs encompassing approximately 2.7 million acres of  
6 occupied GRSG habitat would be designated as sagebrush reserves for the relevant and  
7 important value of GRSG. Refer to **Section 4.2, Special Status Species – Greater Sage-**  
8 **Grouse**, for a discussion of impacts on GRSG habitat.

#### 9 **4.13.7 Alternative D**

10 No new ACECs would be designated. Impacts are the same as those described under  
11 Alternative B.

#### 12 **4.13.8 Alternative E**

13 No new ACECs would be designated. Impacts are the same as those described under  
14 Alternative B.

#### 15 **4.13.9 Alternative F**

16 Under Alternative F, 17 or 18 new BLM ACECs and 12 new Forest Service GRSG ZAs  
17 encompassing up to 6.9 million acres of occupied GRSG habitat would be designated as  
18 sagebrush reserves for the relevant and important value of GRSG. Refer to **Section 4.2,**  
19 **Special Status Species – Greater Sage-Grouse**, for a discussion of impacts on GRSG habitat.

#### 20 **4.13.10 Proposed Plan**

21 Impacts on the relevant and important values of ACECs would mainly be from surface-  
22 disturbing activities that cause direct damage to the values, introduce modifications to the  
23 landscape that affect the area's scenic quality or historical or cultural context, or that result in  
24 erosion, sedimentation, or increased runoff. The Proposed Plan would generally result in  
25 greater restrictions compared to the continuation of existing management under Alternative  
26 A. Adopting more restrictive management of surface-disturbing activities under the  
27 Proposed Plan would be complementary to the protection of the relevant and important  
28 values of the existing ACECs. Therefore, in general, the Proposed Plan would enhance the  
29 relevant and important values of the existing ACECs to a greater extent than would  
30 Alternative A.

#### 31 ***Impacts from Lands and Realty Management***

32 Under the Proposed Plan, management actions that could impact ACECs include  
33 management of areas as ROW avoidance and ROW exclusion. As discussed in **Nature and**  
34 **Types of Effects**, managing areas as ROW avoidance and ROW exclusion would provide  
35 complementary management to adjacent and near-by ACECs. **Table 4-78, Comparison of**  
36 **ACEC-Affecting Management Actions by Alternative**, displays the difference in the amount  
37 of acres managed as ROW avoidance and exclusion by alternative. Under the Proposed Plan,  
38 10,200 more acres are managed as ROW exclusion and 73,900 more acres are managed as

1 ROW avoidance than under Alternative A. A greater number of acres managed as ROW  
2 avoidance and exclusion would likely result in a greater amount of incidental protection to  
3 ACECs.

#### 4 ***Impacts from Habitat Restoration and Vegetation Management***

5 Vegetation management to protect, enhance, and restore GRSG habitat would be prioritized  
6 under the Proposed Plan, and ACECs encompassing or adjacent to GRSG habitat could  
7 receive additional protection through this management. Vegetation management could  
8 create temporary disturbance to ACECs through surface-disturbing activities, but the BLM  
9 would manage all ACECs and special designations to safeguard the reasons for which they  
10 were designated. Therefore, vegetation management and habitat restoration could result in  
11 temporary disturbance to special designations but would not cause long-term damage.

12 Refer to **Section 4.2**, Special Status Species- Greater Sage-Grouse, for a discussion of  
13 impacts from special designation management on GRSG habitat.

#### 14 ***Impacts from Wildland Fire Management***

15 Wildland fire management could result in impacts to ACECs as described in **Nature and**  
16 **Types of Effects**. ACECs that encompass GRSG habitat could experience additional  
17 protections under the Proposed Plan through fuels management and fire suppression  
18 management actions that prioritize the protection of GRSG and GRSG habitat.

#### 19 ***Impacts from Leasable Fluid Minerals Management***

20 More restrictions would be placed on mineral development under the Proposed Plan than  
21 would be under Alternative A. **Table 4-78**, Comparison of ACEC-Affecting Management  
22 Actions by Alternative, displays the differences in the amount of acres and types of  
23 restrictions on mineral development that would occur by alternative. Under the Proposed  
24 Plan, NSOs and CSUs are applied to more acres (174,400 and 26,600, respectively) than  
25 under Alternative A. Additionally, 3,500 more acres are closed to oil and gas leasing than  
26 under Alternative A. Under the Proposed Plan TLs are not applied to any acres, unlike under  
27 Alternative A where TLs are applied to 52,600 acres. The greater the number of acres  
28 experiencing restrictions on mineral development would likely result in a greater amount of  
29 incidental protection to ACECs.

#### 30 ***Impacts from Travel and Transportation Management***

31 Under the Proposed Plan motorized travel would be limited to existing roads, primitive  
32 roads, and trails. Additionally, areas adversely affected by OHVs would be closed to use until  
33 adverse effects are eliminated. These actions could result in indirect protections to ACECs  
34 that would not be present under Alternative A. Restrictions on travel would result in impacts  
35 described in **Nature and Types of Effects** and could result in additional protect to ACECs,  
36 particularly to ACECs that encompass or are adjacent to GRSG habitat.

#### 37 ***Impacts from Livestock Grazing Management***

38 More restrictions would be placed on livestock grazing under the Proposed Plan than would  
39 be under Alternative A. **Table 4-78**, Comparison of ACEC-Affecting Management Actions  
40 by Alternative, displays the number of acres that would be open and closed to livestock

1 grazing by alternative. Under the Proposed Plan, 400 fewer acres would be closed to  
2 livestock grazing than would be under Alternative A. Closing acres of land to livestock  
3 grazing could result in the types of impacts described in **Nature and Type of Effects**. The  
4 Proposed Plan is likely to result in more indirect protections to ACECs than Alternative A  
5 even though the Proposed Plan would have the same amount of active AUMs as Alternative  
6 A because under the Proposed Plan additional provisions would be made to ensure livestock  
7 grazing is compatible with GRSG. Some of these provisions could result in additional  
8 protections to ACECs where ACECs overlap with or are adjacent to GRSG habitat.

9 ***Impacts from Special Designations Management***

10 There are no decisions regarding special designations under the Proposed Plan. Current  
11 management of special designations under Alternative A would continue to protect the  
12 values for which existing ACECs were designated. Under the Proposed Plan, ACECs could  
13 receive additional protection through restrictions on resource uses, activities, and surface-  
14 disturbance put in place to protect GRSG and GRSG habitat. The ways in which these  
15 management actions could provide incidental protection to ACECs is described in **Nature  
16 and Types of Effects**.

17 ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and  
18 Coordination***

19 Under the Proposed Plan, adaptive management would use hard and soft population and  
20 habitat triggers to determine when to apply additional restrictions to various habitat areas. In  
21 the event a trigger is reached in a habitat area that is either in or adjacent to an ACEC, the  
22 ACEC could receive additional indirect protections from the increased restrictions on uses  
23 in the GRSG habitat.

24 Similarly, anthropogenic disturbance management would involve a strict increase in  
25 restrictions in the event the three percent anthropogenic disturbance cap is reached within  
26 PHMA or IHMA. In the event a disturbance cap is reached for a habitat area in or adjacent  
27 to an ACEC, the ACEC could experience indirect protections from the restrictions on uses  
28 and surface-disturbing activities enacted by the anthropogenic disturbance management.

29 **4.14 Lands with Wilderness Characteristics and Roadless Areas**

30 This section discusses impacts on lands with wilderness characteristics from proposed  
31 management actions of other resources and resource uses. Existing conditions are described  
32 in **Section 3.20, Lands with Wilderness Characteristics**. Wilderness characteristics  
33 considered in this analysis are roadless areas of sufficient size, naturalness, and outstanding  
34 opportunities for solitude or a primitive and unconfined type of recreation and supplemental  
35 values. In the planning area, 390,800 acres on BLM-administered lands have been found to  
36 have wilderness characteristics. None of the 390,800 acres with wilderness characteristics  
37 specifically managed to protect those characteristics; however, management addressing other  
38 programs such as visual and cultural resources or recreation management may limit impacts  
39 on those characteristics. There are approximately 1,152,400 acres of Roadless Areas on  
40 National Forest System lands. All Roadless Areas experience some level of protection.  
41 Restrictions on activities such as road construction, tree cutting, and mineral development

1 are applied to Roadless Areas in various degrees based on the management classification of  
2 the Roadless Area (36 CFR 294).

#### 3 4.14.1 Methods and Assumptions

##### 4 *Indicators*

5 Indicators of impacts on lands with wilderness characteristics are the management actions  
6 and allowable uses that would either protect or degrade the inventoried characteristics to a  
7 level at which the value of one or more wilderness characteristic would no longer be present  
8 within the specific area. The inventoried wilderness characteristics are roadless areas of  
9 sufficient size, naturalness, outstanding opportunities for solitude or a primitive and  
10 unconfined type of recreation, and supplemental values, as described in **Section 3.20,**  
11 **Wilderness Characteristics.** Roadless Areas already experience some protections from Forest  
12 Service management, however, management actions that restrict uses in order to protect the  
13 GRSG would provide additional protections to Roadless Areas.

##### 14 *Assumptions*

15 The analysis includes the following assumption:

- 16 • Some inventoried lands with wilderness characteristics have not  
17 yet been assessed in a LUP revision; therefore, no decisions have  
18 been made about whether to protect their wilderness  
19 characteristics. In this analysis, these lands with wilderness  
20 characteristics are treated like their wilderness characteristics are  
21 not protected to the same degree that congressionally designated  
22 wilderness areas would be protected and are discussed in this  
23 analysis. Lands with wilderness characteristics that are not  
24 managed only to exclusively protect those characteristics will  
25 simply be referred to as lands with wilderness characteristics  
26 throughout the remainder of the analysis in this section.

#### 27 4.14.2 Nature and Type of Effects

28 Wilderness characteristics are primarily influenced by actions that impact the undeveloped  
29 nature of the area or activities that increase the sights and sounds of other visitors.  
30 Generally, actions that create surface disturbance degrade the natural characteristics of lands  
31 with wilderness characteristics, as well as the setting for experiences of solitude and primitive  
32 recreation. In addition, restrictions on dispersed recreation (e.g., prohibited campfires and  
33 camping permitted only in designated sites) diminish the opportunities for unconfined  
34 recreation.

35 Management actions that could impact an area's natural appearance are the presence or  
36 absence of roads and trails, use of motorized vehicles along those roads and trails, fences  
37 and other improvements, nature and extent of landscape modifications, or other actions that  
38 result in or preclude surface-disturbing activities. All of these activities affect the presence or  
39 absence of human activity and, therefore, could affect an area's natural appearance.

1 Prohibiting surface-disturbing activities and new developments within lands with wilderness  
2 characteristics would protect naturalness.

3 There could be indirect impacts from management of other resources that would enhance  
4 wilderness characteristics. Stipulations associated with special status species could indirectly  
5 improve the naturalness of lands with wilderness characteristics and help protect those  
6 characteristics. Management actions that protect resources would impact lands with  
7 wilderness characteristics by preserving or enhancing naturalness, as well as opportunities for  
8 solitude and primitive recreation. Roadless Areas would also be impacted by surface-  
9 disturbing activities and allowable uses that decrease wilderness attributes on Roadless Areas.  
10 The nature and types of impacts on Roadless Areas would be similar to those on lands with  
11 wilderness characteristics; however Roadless Areas would be less susceptible to such impacts  
12 due to the protections placed on Roadless Areas based on their management classification.  
13 In particular, Roadless Areas would be less prone to impacts from road construction and  
14 reconstruction, timber removal, and mineral development, as Roadless Areas are protected  
15 specifically from these activities (36 CFR 294).

16 Implementing management for the following resource would have negligible or no impact  
17 on wilderness characteristics and Roadless Areas; therefore it is not discussed in detail:  
18 mineral split-estate.

#### 19 ***Vegetation Management and Habitat Protection***

20 While vegetation treatments are implemented, both naturalness and solitude experienced by  
21 recreationists could be reduced in the short term. After the treatment is over, solitude would  
22 be restored. Over the long term, naturalness would likely be enhanced by restoring natural  
23 vegetation structures and patterns.

#### 24 ***Wildland Fire***

25 Managing for wildfire could impact lands with wilderness characteristics. In areas where  
26 suppression is a priority, there is the potential for vegetation modification to prevent the  
27 spread of fires, potentially reducing the naturalness of appearance. Fire suppression,  
28 prescribed burns, and firebreaks could all have short-term impacts on wilderness  
29 characteristics by disturbing naturalness.

#### 30 ***Lands and Realty***

31 Permitted activities, such as construction of utility ROWs, involve the presence of  
32 equipment and personnel that could impact wilderness characteristics. Construction would  
33 reduce opportunities for solitude in the short term and could result in long-term impacts as  
34 well. ROW exclusions would prohibit all development of ROWs which would likely protect  
35 wilderness characteristics.  
36

#### 37 ***Mineral Resources***

38 Allowing any type of energy or mineral development, such as that for fluid, coal, nonenergy  
39 solid, locatable, and salable minerals, as well as renewable energy, would result in surface  
40 disturbance that would diminish the area's natural characteristic. Any new roads authorized  
41 for access to the development area could eliminate wilderness characteristics of the entire

1 unit if the road were to bisect the unit so that it would no longer be considered a roadless  
2 area of adequate size. In addition, regular access to the lease area or mine site by developers  
3 would reduce the opportunities for solitude.

#### 4 ***Recreation***

5 Two other wilderness characteristics—outstanding opportunities for solitude and primitive  
6 unconfined types of recreation—are related to the human experience in an area. Visitors can  
7 have outstanding opportunities for solitude or for primitive unconfined recreation when the  
8 sights, sounds, and evidence of other people are rare or infrequent; where visitors can be  
9 isolated, alone, or secluded from others; where the area is accessed by nonmotorized  
10 nonmechanized means; and where there are no or only minimally developed recreation  
11 facilities. High concentrations of recreation users (large group sizes or frequent group  
12 encounters) would decrease outstanding opportunities for solitude. Limiting visitor use only  
13 as necessary to prevent substantial degradation to wilderness characteristics (i.e., naturalness  
14 and opportunities for solitude) would protect opportunities for unconfined recreation.

#### 15 ***Travel and Transportation***

16 A significant increase in motorized and mechanized travel on designated routes would  
17 impact wilderness characteristics. By increasing sights and sounds of other people,  
18 opportunities for solitude would be reduced. Motorized and mechanized access would also  
19 reduce opportunities for primitive recreation. The existence of motorized and mechanized  
20 trails could reduce the natural appearance in the vicinity of the trails. Effects would be  
21 localized and might not be experienced in the unit as a whole.

22 Prohibiting motorized and mechanized use on lands with wilderness characteristics would  
23 protect wilderness characteristics by restricting activities that could impact natural  
24 appearance and opportunities for solitude and primitive and unconfined recreation.  
25 Exceptions to exclusions on motorized and mechanized vehicles could result in a short-term  
26 detraction from the natural character of the areas. These impacts would be uncommon and  
27 of short duration if they were to occur. On a more regular basis, motorized and mechanized  
28 use by established livestock grazing permittees would impact opportunities for solitude and  
29 naturalness of appearance.

#### 30 ***Livestock Grazing***

31 Impacts on lands with wilderness characteristics are possible from livestock grazing,  
32 particularly from new developments in these areas (e.g., water developments and fences),  
33 which could lessen the naturalness of appearance or limit unconfined recreation. Existing  
34 range improvements used for grazing, such as fences, stock trails, springs, and stock ponds,  
35 would continue to be maintained. Structures could diminish the naturalness characteristic of  
36 lands with wilderness characteristics. Maintenance of range improvements could result in  
37 short-term impacts on solitude and naturalness.

#### 38 ***Special Designations***

39 Where lands with wilderness characteristics overlap or are next to eligible or suitable Wild  
40 and Scenic River segments or ACECs, management of these other areas could also indirectly  
41 protect wilderness characteristics due to the measures proposed for the other areas. These

1 protective measures would include complementary management objectives and could offer  
2 some indirect protection of wilderness characteristics for units managed primarily for other  
3 resource considerations.

4 **4.14.3 Impacts on lands with Wilderness Characteristics Common to All**  
5 **Alternatives**

6 The nature and type of impacts described below are common to all alternatives, but the  
7 context and intensity may vary by alternative.

8 ***Impacts from Travel and Transportation Management***

9 Under all alternatives, approximately 4,310 acres of lands with wilderness characteristics  
10 would be closed to motorized travel (**Table 4-80, Acres of Allocations Potentially Affecting**  
11 **Lands with Wilderness Characteristics and Roadless Areas**). Under all alternatives other than  
12 Alternative A and Alternative D, which both would close 4,460 acres to motorized travel, no  
13 acres of Roadless Areas would be closed to motorized travel. Because the difference  
14 between these numbers are small, differences in impacts would likely be negligible. Where  
15 motorized travel is closed or limited to existing roads, there would be indirect protection of  
16 wilderness characteristics. Restricting motorized travel would reduce the noise of human  
17 visitors and the disturbance caused by motorized vehicles, which would enhance experiences  
18 of solitude and naturalness. Impacts from closing areas on motorized travel are the same  
19 under all alternatives.

Table 4-79

1

2

#### 4.14.4 Alternative A

3

Management actions to protect other resources and special designation areas offer some protection of wilderness characteristics and Roadless Areas. Alternative A includes the fewest GRSG protections and is least restrictive of surface-disturbing activities that could alter the natural setting, as well as reduce opportunities for solitude or primitive recreation, of lands with wilderness characteristics. Therefore, wilderness characteristics are likely to be degraded under this alternative. Roadless Areas are also least likely to experience additional protections under this alternative.

4

5

#### **Impacts from Lands and Realty Management**

6

Under Alternative A, 12,100 acres of lands with wilderness characteristics are managed as ROW exclusion (Table 4-80) and 178,600 acres of Roadless Areas are managed as ROW exclusion. This provides indirect protection to wilderness characteristics (preserving naturalness and opportunities for solitude and primitive recreation) and Roadless Areas by prohibiting disturbance from transmission lines, roads, and other utility developments. Additionally, 35,700 acres of lands with wilderness characteristics and 514,300 acres of Roadless Areas are managed as ROW avoidance areas, which would have similar effects on lands with wilderness characteristics and Roadless Areas as ROW exclusion.

7

8

9

10

11

12

13

14

15

16

17

18

1       ***Impacts from Leased Fluid Minerals Management***

2       Under Alternative A, 8,130 acres of lands with wilderness characteristics and 1,129,200 acres  
3       of Roadless Areas are closed to oil and gas leasing. Closing acres to fluid minerals leasing  
4       could protect wilderness characteristics by prohibiting development and infrastructure  
5       related to those actions, subject to valid existing rights. However, interest in oil and gas  
6       leasing in Idaho is sporadic. There is some interest in leasing oil and gas resources within  
7       occupied habitat in the Bear Lake area, but no drilling permits have been applied for or  
8       issued in Idaho, and this trend is expected to continue. As such, impacts from oil and gas  
9       leasing are likely to be minimal under all alternatives due to the anticipated lack of  
10       development.

11       ***Impacts from Recreation and Visitor Services Management***

12       Under Alternative A, 670 acres of recreation sites overlap with lands with wilderness  
13       characteristics. These would continue to be managed under current guidance, which would  
14       result in no additional protections or degradation of wilderness characteristics.

15       ***Impacts from Livestock Grazing Management***

16       Under Alternative A, 560 acres of lands with wilderness characteristics and 69,000 acres of  
17       Roadless Areas are closed to livestock grazing. Livestock grazing can impact opportunities  
18       for solitude and naturalness of appearance. New developments, such as fences, related to  
19       livestock grazing could also lessen naturalness of appearance or limit unconfined recreation,  
20       although additional development would be limited. Those areas with wilderness  
21       characteristics that are not closed to grazing would continue to be affected in a limited way  
22       by grazing activities and grazing-related development.

23       ***Impacts from Special Designations Management***

24       Under Alternative A, the existing 59 ACECs in the planning area would to be maintained.  
25       The 19,400 acres of ACECs that overlap lands with wilderness characteristics would  
26       continue to provide indirect protections to those characteristics. Under this alternative, no  
27       additional ACECs would be designated, so no additional protection to wilderness  
28       characteristics would result. Additionally, no ZAs would overlap with Roadless Areas and,  
29       therefore, Roadless Areas would not receive additional protection from Zoological Areas  
30       under this alternative.

31       **4.14.5 Alternative B**

32       ***Impacts from Lands and Realty Management***

33       Under Alternative B, 326,100 acres of lands with wilderness characteristics (314,000 more  
34       acres than under Alternative A) and 575,600 acres of Roadless Areas (397,000 more acres  
35       than under Alternative A) would be managed as ROW exclusion areas. Additionally, 53,100  
36       acres of lands with wilderness characteristics and 474,700 acres of Roadless Areas would be  
37       managed as ROW avoidance areas. Types of impacts are described under Alternative A.

38       ***Impacts from Leased Fluid Minerals Management***

39       Under Alternative B, 325,200 acres of lands with wilderness characteristics would be closed  
40       to oil and gas leasing, 317,070 more acres than under Alternative A, thereby potentially  
41       offering more protection of lands with wilderness characteristics. Under this alternative

1 1,027,400 acres of Roadless Areas would be closed to oil and gas leasing, which is a 101,800  
2 fewer acres than under Alternative A. This could result in fewer additional protections to  
3 Roadless Areas as compared with Alternative A. However, as discussed under Alternative A,  
4 oil and gas development interests in Idaho are minimal so impacts on wilderness  
5 characteristics from oil and gas development are likely to be minimal across all alternatives.

6 ***Impacts from Recreation and Visitor Services Management***

7 Under Alternative B, 670 acres of recreation sites would overlap lands with wilderness  
8 characteristics. In PHMA, the only recreation allowed would be neutral or beneficial to  
9 GRSG. Some types of restrictions, such as those that would limit visitor use and surface  
10 disturbance, would likely enhance experiences of solitude and provide protections to  
11 wilderness characteristics. However, other types of restrictions, such as limits on dispersed  
12 recreation, could degrade wilderness characteristics by limiting opportunities for primitive  
13 and unconfined recreation.

14 ***Impacts from Livestock Grazing Management***

15 Impacts would be approximately the same as those described under Alternative A, as only  
16 7,500 more acres with wilderness characteristics on BLM-administered and National Forest  
17 System land would be closed under Alternative B as under Alternative A.

18 ***Impacts from Special Designations Management***

19 Under Alternative B, 19,100 acres of lands with wilderness characteristics would overlap  
20 with ACECs and would experience indirect protections. Impacts on Roadless Areas would  
21 be the same as those described under Alternative A.

22 **4.14.6 Alternative C**

23 ***Impacts from Lands and Realty Management***

24 Under Alternative C, 379,300 acres of lands with wilderness characteristics (367,200 more  
25 acres than under Alternative A) and 1,050,200 acres of Roadless Areas (871,600 more acres  
26 than under Alternative A) would be managed as ROW exclusion areas. No lands with  
27 wilderness characteristics or Roadless Areas would be designated as ROW avoidance areas  
28 under Alternative C.. Alternative C would offer more indirect protections to lands with  
29 wilderness characteristics and Roadless Areas through ROW exclusion and avoidance than  
30 would Alternative A.

31 ***Impacts from Leased Fluid Minerals Management***

32 Under Alternative C, 385,200 acres of lands with wilderness characteristics and 1,045,300  
33 acres of Roadless Areas would be closed to oil and gas leasing. Impacts would be similar to  
34 those described under Alternative A.

35 ***Impacts from Recreation and Visitor Services Management***

36 Impacts are the same as those described under Alternative B.

1 ***Impacts from Livestock Grazing Management***

2 Under Alternative C, 385,600 acres of lands with wilderness characteristics would be closed  
3 to livestock grazing, 385,040 more acres than under Alternative A. Consequently, Alternative  
4 C would provide more protection of wilderness characteristics than Alternative A

5 ***Impacts from Special Designations Management***

6 Under Alternative C, 39 new ACECs would be designated, which would indirectly protect  
7 260,000 acres of land with wilderness characteristics and 32,767 acres of Roadless Areas that  
8 overlap the new ACECs.

9 **4.14.7 Alternative D**

10 ***Impacts from Lands and Realty Management***

11 Under Alternative D, impacts from ROW exclusion areas on lands with wilderness  
12 characteristics would be the same as those under Alternative A. Additional protection would  
13 result from the 369,500 acres of lands with wilderness characteristics which would be  
14 managed as ROW avoidance areas, and 973,800 acres which would be managed as ROW  
15 avoidance with limited exclusion. Managing lands with wilderness characteristics as ROW  
16 avoidance areas would result in more protection under this alternative than under Alternative  
17 A. More acres of Roadless Areas would be managed as ROW exclusion (178,600 acres) and  
18 ROW avoidance (973,800) under this alternative than under any of the other alternatives.  
19 Roadless Areas would experience more additional protection from restrictions on ROWs  
20 under this alternative than under any of the other alternatives.

21 ***Impacts from Leased Fluid Minerals Management***

22 Under Alternative D, 310,200 acres of lands with wilderness characteristics would be closed  
23 to oil and gas leasing (302,070 more acres than under Alternative A) and 1,129,100 acres of  
24 Roadless Areas would be closed to oil and gas leasing (100 acres less than under Alternative  
25 A). Impacts would be similar to those under Alternative A.

26 ***Impacts from Recreation and Visitor Services Management***

27 Impacts are similar to those described under Alternative B, except that Alternative D would  
28 also try to minimize adverse recreation effects on GRSG.

29 ***Impacts from Livestock Grazing Management***

30 Impacts are the same as those described under Alternative A.

31 ***Impacts from Special Designations Management***

32 Impacts on lands with wilderness characteristics are the same as those described under  
33 Alternative A.

34 **4.14.8 Alternative E**

35 ***Impacts from Lands and Realty Management***

36 Under Alternative E, 12,100 acres of lands with wilderness and 140,800 acres of Roadless  
37 Areas would be managed as ROW exclusion. This is the smallest number of acres out of all  
38 the alternatives and would result in fewer acres of Roadless Areas and lands with wilderness

1 characteristics receiving protections from ROW exclusions. Additionally, 274,000 acres of  
2 lands with wilderness characteristics would be managed as ROW avoidance areas. As such,  
3 this alternative would offer more protection to lands with wilderness characteristics than  
4 under Alternative A. Roadless Areas would also experience more protection under  
5 Alternative E than under Alternative A, with 715,400 acres managed as ROW avoidance.

6 ***Impacts from Leased Fluid Minerals Management***

7 Under this alternative, 8,140 acres of lands with wilderness characteristics would be closed to  
8 oil and gas leasing, offering negligibly more protection than Alternative A. Additionally  
9 1,033,400 acres of Roadless Areas would be closed to oil and gas leasing, which would result  
10 in less additional protection to Roadless Areas than would occur under Alternative A.  
11 Impacts would be similar to those under Alternative A due to minimal oil and gas  
12 development interest.

13 ***Impacts from Recreation and Visitor Services Management***

14 Impacts would be similar to those described under Alternative B, except that Alternative E  
15 would also apply seasonal, timing, and travel restrictions in order to reduce impacts on  
16 GRSG.

17 ***Impacts from Livestock Grazing Management***

18 Impacts are the same as those described under Alternative B.

19 ***Impacts from Special Designations Management***

20 Impacts on lands with wilderness characteristics are the same as those described under  
21 Alternative B.

22 **4.14.9 Alternative F**

23 ***Impacts from Lands and Realty Management***

24 Impacts of ROW exclusion areas under Alternative F are the same as under Alternative B.  
25 Under Alternative F, 53,300 acres of lands with wilderness characteristics and 474,700 acres  
26 of Roadless Areas would be managed as ROW avoidance areas. Types of impacts are would  
27 be similar to those described under Alternative B.

28 ***Impacts from Leased Fluid Minerals Management***

29 Impacts are the same as those described under Alternative B.

30 ***Impacts from Recreation and Visitor Services Management***

31 Impacts are the same as those described under Alternative B.

32 ***Impacts from Livestock Grazing Management***

33 Impacts are the same as those described under Alternative A.

34 ***Impacts from Special Designations Management***

35 Under Alternative F, 17 or 18 new BLM ACECs would be designated, which would  
36 indirectly protect either 334,100 acres or 120,500 acres of land with wilderness characteristics  
37 and either 496,100 acres or 76,900 acres of Roadless Areas that overlap the new ACECs.

1           **4.14.10 Proposed Plan**

2           ***Impacts from Lands and Realty Management***

3           Managing areas as ROW avoidance and ROW exclusion could impact lands with wilderness  
4           characteristics and Roadless Areas. Under the Proposed Plan, 34,400 fewer acres would be  
5           managed as ROW exclusion than would be under Alternative A. Additionally, under the  
6           Proposed Plan 500,700 more acres would be managed as ROW avoidance than under  
7           Alternative A, and this would likely result in indirect protections to lands with wilderness  
8           characteristics (preserving naturalness and opportunities for solitude and primitive  
9           recreation) and Roadless Areas by prohibiting disturbance from transmission lines, roads,  
10          and other utility developments, as discussed in **Nature and Types of Effects**.

11          **Table 4-80**, Acres of Allocations Potentially Affecting BLM Lands with Wilderness  
12          Characteristics and Forest Service Roadless Areas, displays the difference in the amount of  
13          acres managed as ROW avoidance and exclusion between Alternative A and the Proposed  
14          Plan. A greater number of acres managed as ROW avoidance and exclusion would likely  
15          result in a greater amount of incidental protection to lands with wilderness characteristics  
16          and Roadless Areas.

17          ***Impacts from Habitat Restoration and Vegetation Management***

18          Vegetation management to protect, enhance, and restore GRSG habitat would be prioritized  
19          under the Proposed Plan, and lands with wilderness characteristics encompassing or adjacent  
20          to GRSG habitat could be impacted by this management. Vegetation management and  
21          habitat restoration could result in temporary disturbance to lands with wilderness  
22          characteristics, as discussed in **Nature and Types of Effects**, but would not likely result in  
23          any long-term damage.

24          ***Impacts from Wildland Fire Management***

25          Wildland fire management could result in impacts to lands with wilderness characteristics  
26          and Roadless Areas as described in **Nature and Types of Effects**. Lands with wilderness  
27          characteristics and Roadless Areas that encompass or are adjacent to GRSG habitat are most  
28          likely to experience these impacts from the prioritizing of fire suppression under the  
29          Proposed Plan.

30          ***Impacts from Leased Fluid Minerals Management***

31          Closing acres to fluid minerals leasing, as well as placing restrictions such as timing  
32          limitations (TL), no-surface occupancy (NSO), and CSU (controlled surface use), on fluid  
33          mineral leasing would protect wilderness characteristics by prohibiting or restricting  
34          development and infrastructure related to those actions, subject to valid existing rights.  
35          Under Alternative A 759,000 more acres are closed to oil and gas leasing than under the  
36          Proposed Plan. More acres closed to oil and gas leasing on BLM-administered lands could  
37          result in more protection to lands with wilderness characteristics. However, the Proposed  
38          Plan would apply NSO stipulations to 816,500 acres, which is more acres than would be  
39          applied under any of the other alternatives. This would effectively make up in protection the  
40          difference in acres closed to fluid mineral leasing.

1 Under the Proposed Plan 760,200 more acres would be managed as NSO than under  
2 Alternative A, 71,800 more acres would be managed as CSU under the Proposed Plan than  
3 under Alternative A, and 38,600 fewer acres would be managed as TL under the Proposed  
4 Plan than under Alternative A.

5 Oil and gas development interest in IHMA, PHMA, and GHMA in Idaho is sporadic and  
6 minimal. There is some interest in leasing oil and gas resources within occupied habitat in  
7 the Bear Lake area, but no drilling permits have been applied for or issued in Idaho, and this  
8 trend is expected to continue. As such, impacts from oil and gas leasing are likely to be  
9 minimal due to anticipated lack of development.

10 **Table 4-70**, Acres of Allocations Potentially Affecting BLM Lands with Wilderness  
11 Characteristics and Forest Service Roadless Areas, displays the differences in restrictions on  
12 mineral development between alternatives. In general a greater number of acres experiencing  
13 restrictions in mineral development would result in more indirect protections to lands with  
14 wilderness characteristics and Roadless Areas.

15 ***Impacts from Recreation and Visitor Services Management***

16 Restrictions on recreation could impact lands with wilderness characteristics and Roadless  
17 Areas as discussed under **Nature and Types of Effects**. Under the Proposed Plan, new  
18 recreation facilities would not be constructed within PHMA and IHMA unless the  
19 development would have a net conservation gain to GRSG habitat. Some types of  
20 restrictions, such as those that would limit visitor use and surface disturbance, would likely  
21 enhance experiences of solitude and provide protections to wilderness characteristics that  
22 overlap or are adjacent PHMA, IHMA, and GHMA. However, other types of restrictions,  
23 such as limits on dispersed recreation, could degrade wilderness characteristics by limiting  
24 opportunities for primitive and unconfined recreation.

25 **Table 4-80**, Acres of Allocations Potentially Affecting BLM Lands with Wilderness  
26 Characteristics and Forest Service Roadless Areas, shows the acres of recreation sites in  
27 Lands with Wilderness Characteristics and Roadless Areas by alternative.

28 ***Impacts from Travel and Transportation Management***

29 Under the Proposed Plan motorized travel would be limited to existing roads, primitive  
30 roads, and trails. Additionally, areas adversely affected by OHVs would be closed to use until  
31 adverse effects are eliminated. These actions could result in indirect protections to lands with  
32 wilderness characteristics and Roadless Areas. Restrictions on travel would result in impacts  
33 as described in **Nature and Types of Effects** and could especially result in protections to  
34 lands with wilderness characteristics and Roadless Areas that encompass or are adjacent to  
35 GRSG habitat.

36 Under the Proposed Plan, fewer acres would be closed to motorized travel than under  
37 Alternative A, as shown in **Table 4-80**, Acres of Allocations Potentially Affecting BLM  
38 Lands with Wilderness Characteristics and Forest Service Roadless Areas. Closing fewer  
39 acres to motorized travel could result in lands with wilderness characteristics and Roadless

1 Areas experiencing fewer indirect protections under the Proposed Plan than under  
2 Alternative A.

### 3 ***Impacts from Livestock Grazing Management***

4 More restrictions would be placed on livestock grazing under Alternative A than would be  
5 under the Proposed Plan. **Table 4-80**, Acres of Allocations Potentially Affecting BLM  
6 Lands with Wilderness Characteristics and Forest Service Roadless Areas, displays the  
7 number of acres that would be closed to livestock grazing by alternative. Closing acres of  
8 land to livestock grazing could result in the types of impacts described in **Nature and Type**  
9 **of Effects**. The Proposed Plan could result in less indirect protection to ACECs than  
10 Alternative A because 21,200 fewer acres would be closed to livestock grazing under the  
11 Proposed Plan than under Alternative A. However, the Proposed Plan would have the same  
12 amount of active AUMs as Alternative A, and under the Proposed Plan additional provisions  
13 would be made to ensure livestock grazing is compatible with GRSG. Some of these  
14 provisions could result in additional protections to lands with wilderness characteristics and  
15 Roadless areas where these areas overlap with or are adjacent to GRSG habitat.

### 16 ***Impacts from Special Designations Management***

17 No decisions regarding special designations or lands with wilderness characteristics or  
18 Roadless Areas were made under the Proposed Plan. Due to this, the amount of lands with  
19 wilderness characteristics and Roadless Areas that overlap with ACECs and other special  
20 designations vary slightly due to differences in habitat delineations, but impacts would be the  
21 same under Alternatives A and the Proposed Plan.

### 22 ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and*** 23 ***Coordination***

24 Under the Proposed Plan, adaptive management would use hard and soft population and  
25 habitat triggers to determine when to apply additional restrictions to various habitat areas. In  
26 the event a trigger is reached in a habitat area that is either in or adjacent to lands with  
27 wilderness characteristics or Roadless Areas, the lands with wilderness characteristics or  
28 Roadless Areas could receive additional indirect protections from the increased restrictions  
29 on uses in the GRSG habitat.

30 Similarly, anthropogenic disturbance management would involve a strict increase in  
31 restrictions in the event the three percent anthropogenic disturbance cap is reached within  
32 PHMA or IHMA. In the event a disturbance cap is reached for a habitat area in or adjacent  
33 to lands with wilderness characteristics or Roadless Areas, the lands with wilderness  
34 characteristics or Roadless Areas could experience indirect protections from the restrictions  
35 on uses and surface-disturbing activities enacted by the anthropogenic disturbance  
36 management.

## 37 **4.15 Social and Economic Conditions (Including Environmental Justice)**

38 This section discusses social and economic impacts from proposed GRSG management  
39 actions related to other resources and resource uses. Existing social and economic conditions  
40 are described in **Section 3.22**, Social and Economic Conditions (Including Environmental

1 Justice). This section also addresses environmental justice impacts and the differences among  
2 alternatives for the social and economic impacts identified.

3 This section is organized slightly differently than the sections for other resource areas.  
4 Rather than grouping the analysis of impacts by alternative, the analysis of economic impacts  
5 is grouped by affected resource followed by an overall discussion of social impacts. This  
6 grouping assists with the reader's understanding of the analytical approach and assumptions  
7 used to analyze economic and social impacts associated with each resource use and facilitates  
8 interpretation of results. Impacts are grouped by alternative in **Table 4-82** and **Table 4-83**  
9 of the **Summary of Social and Economic Impacts** and in **Table 4-84, Environmental**  
10 **Justice Impacts**.

#### 11 **4.15.1 Methods and Assumptions**

##### 12 ***Indicators***

13 Conservation measures related to GRSG habitat could have impacts on resource uses on  
14 BLM and Forest Service administered lands; impacts on social and economic conditions  
15 could result from these changes in resource uses. Many of the indicators used to characterize  
16 social and economic conditions are quantitative, including population, demographics (e.g.,  
17 age and gender breakouts), local industry (e.g., recreation and mineral development),  
18 employment, personal income, and presence of minority and low-income populations. Other  
19 indicators, especially for social conditions, are qualitative.

20 For the analysis of economic impacts, quantitative estimates are provided where sufficient  
21 data or estimates are available on the potential changes in authorized uses of federal lands  
22 under each alternative. When quantitative estimates of economic impacts were not possible,  
23 a qualitative discussion of the potential economic impacts of management actions associated  
24 with specific authorized uses is presented. Therefore, the overall economic impacts are a  
25 combination of quantitative estimates and qualitative discussion.

26 When sufficient information was available to quantify the potential economic impact of  
27 alternatives, the IMPLAN model, which captures the indirect and induced economic effects  
28 of management alternatives in the Socioeconomic Study Area, was used to estimate impacts  
29 on outcomes, employment, and earnings in the study area. This was the case of the analysis  
30 of impacts through livestock grazing. The analysis using IMPLAN includes those impacts  
31 derived from the multiplier effect, which captures the impact of several rounds of  
32 expenditures that follow an initial direct expenditure in the Socioeconomic Study Area.  
33 These additional expenditures are due to income received by suppliers and employees  
34 directly benefiting from the initial expenditure, and who go on to spend a share of their  
35 income locally. This allows for a more complete picture of the economic impacts of the  
36 management alternatives in the planning area. However, the IMPLAN model is a static  
37 model, and it does not capture changes in the industrial composition of a region over time,  
38 nor does it capture dynamic effects that may be associated with processes of growth or  
39 decline, such as changes in technology or labor productivity or the feasibility of economic

1 operations that require scale. There is, therefore, a degree of uncertainty in the estimates of  
2 impacts obtained through the IMPLAN model.

### 3 ***Assumptions***

- 4 • The analysis of economic impacts of management alternatives on grazing used  
5 billed AUMs as a baseline, estimated as a multi-year average share of active  
6 AUMs. Active AUMs measure the amount of forage from land available for  
7 grazing. Forest Service terms this measure “permitted” AUMs. Billed AUMs  
8 measure the amount of forage for which BLM and Forest Service bill annually.  
9 Forest Service uses the term “authorized” AUMs for the same concept.
- 10 • Implementing management for the resources not analyzed in detail in this section  
11 were considered to have negligible or no impact on socioeconomic and  
12 environmental justice indicators across alternatives. For recreation, BLM and  
13 Forest Service recreational specialists determined that the overall number of  
14 visits to BLM lands and National Forests would be unchanged because  
15 potentially affected recreational activities are unlikely to occur during the times  
16 that overlap with GRSG using leks, and any displaced recreational activity would  
17 be likely to move to another nearby location. To the extent that there are  
18 circumstances in which individual permits for special activities or events are  
19 affected in terms of timing and/or location for GRSG protection, the overall  
20 socioeconomic impacts associated with these effects are expected to be  
21 negligible.
- 22 • Implementation of conservation measures in all resource or program areas will  
23 contribute to conservation of GRSG habitat and GRSG benefits, as qualitatively  
24 discussed in this section, and detailed in other sections of Chapter 4.

#### 25 26 **4.15.2 Nature and Types of Effects**

27 The main economic impacts derived from changes in resource management are reflected in  
28 changes in local employment and earnings, costs incurred by the private sector, fiscal  
29 revenues and regional growth prospects.

30 For the analysis of social impacts, two types of impacts capture the main social impacts that  
31 can be expected from changes in resource management. The first is that which is derived  
32 from migration induced by management actions. These impacts are induced by economic  
33 opportunities that drive population into or out of specific areas and affect population growth  
34 as well as the demand for housing and public services. The second is that associated with  
35 specific interest groups, community livelihoods, or minority and low income populations  
36 (i.e., effects described in the section on Environmental Justice).

37 To the extent that there is a degree of uncertainty regarding the changes in authorized uses  
38 of federal lands under each management alternative, this uncertainty is carried forward to the  
39 socioeconomic impacts of management alternatives.

1 The Proposed Plan includes a 3 percent disturbance cap on PHMA, independent of surface  
2 ownership and an adaptive management plan. If the disturbance cap is reached, economic  
3 activity on BLM and Forest Service lands could be curtailed further than what is described in  
4 this section. This disturbance cap would be the same as under Alternative B, more restrictive  
5 than the disturbance cap in Alternatives D and E, but less so than the disturbance cap in  
6 Alternatives C and F. Under the adaptive management plan, additional measures could be  
7 taken to protect GRSG habitat based on triggers linked to indicators monitored by BLM and  
8 the Forest Service. If triggered, these additional measures could also impose additional  
9 restrictions on economic activity. However, because the 3 percent disturbance cap and  
10 adaptive management soft and hard triggers only apply to PHMA, they would only generate  
11 additional socioeconomic impacts through economic activities that are not already restricted  
12 in PHMA.

13 The Proposed Plan designates sagebrush focal areas (SFAs), representing recognized  
14 “strongholds” for GRSG that have the strongest levels of protection. These SFAs are mostly  
15 within PHMA, but include some non-habitat areas, thereby increasing the potential for  
16 restrictions to economic activity with impacts in some areas under the Proposed Plan.

17 As a landscape level planning effort, none of the alternatives prescribe project-level or site-  
18 specific activities on BLM or Forest Service managed lands. Furthermore, the agencies’  
19 selection of an alternative does not authorize funding to any specific project or activity nor  
20 does it directly tie into the agencies’ budgets as appropriated annually through the Federal  
21 budget process. As a consequence, agencies’ costs and differences in program costs across  
22 alternatives have not been quantified. Information has been presented in several resource  
23 impact sections on the types of costs that might be associated with various sage-grouse  
24 conservation measures.

### 25 **4.15.3 Economic Impacts**

#### 26 ***Impacts from Management Actions Affecting Grazing Allotments***

27 Economic impacts for grazing are quantified for Alternatives C and F where grazing would  
28 not be allowed in all or portions of GRSG habitat. Impacts for all alternatives are  
29 qualitatively discussed for other types of restrictions or design feature requirements that are  
30 contingent upon proximity to lek areas and/or, meeting desired range conditions,  
31 disturbance caps, or other protocol for specifying when and where conservation measures  
32 are adopted.

#### 33 ***Overall Employment, Earnings, and Output per Job Impacted by Management Alternatives***

34 The potential impacts of management alternatives affecting grazing on output and  
35 employment were estimated quantitatively using the IMPLAN economic model. Detailed  
36 assumptions for the quantitative analysis are described in **Appendix AA**, Economic Impact  
37 Analysis Methodology. Alternatives A, B, D, E, and the Proposed Plan are estimated to have  
38 similar economic effects because no unconditional grazing closures or losses of AUMs occur  
39 under those alternatives, although Alternatives B, D, E, and the Proposed Plan (along with  
40 Alternatives C and F) could carry increased restrictions on lessees’ ability to construct or

1 maintain range improvements and Alternatives B, D, and the Proposed Plan could restrict  
2 the lessees' ability to conduct treatments (e.g., vegetation treatments). These restrictions, as  
3 well as compliance with adaptive management, habitat objectives, and disturbance caps, may  
4 have implications for operator costs as discussed below.

5 Although grazing on federal lands not containing GRSG habitat would not be directly  
6 affected by the choice of alternatives, it could be affected indirectly, to the extent that loss of  
7 access to federal lands for grazing affects the feasibility of the grazing operations.

8 The IMPLAN model used 2011 and 2013 data for active AUMs. The model used an average  
9 of 2000 to 2011 data for billed AUMs on lands permitted by BLM, because billed AUMs  
10 fluctuate from year to year (BLM 2012d, BLM 2013b, BLM 2013c). On Forest Service lands,  
11 the analysis assumed a billed to active ratio of 100 percent.

12 For the analysis, the BLM and Forest Service calculated economic impacts for each  
13 alternative based on an estimated reduction in the number of billed AUMs. By multiplying  
14 the number of AUMs lost under each alternative relative to Alternative A by the estimated  
15 output, employment, and earnings per AUM (shown in Table R-4 and Table R-5 of  
16 **Appendix AA**, Economic Impact Analysis Methodology), changes in output, employment,  
17 and earnings lost by alternative, relative to Alternative A, are estimated. **Table 4-81**, Annual  
18 Impact of Management Actions Affecting Livestock AUMs on Output, Employment, and  
19 Earnings Compared to Alternative A, shows the resulting estimates. As explained in  
20 **Appendix AA**, the low impact scenario reflects the loss of all billed AUMs in GRSG habitat  
21 under Alternative C and the loss of 25 percent of billed AUMs in GRSG habitat under  
22 Alternative F. Actual economic impacts could be less than these estimates. For example,  
23 where the number of billed AUMs is less than the number of active AUMs, ranchers could  
24 shift grazing from lands closed to grazing to lands that remain open for grazing. In other  
25 words, ranchers could use non-billed active AUMs as a buffer to absorb reductions in AUMs  
26 imposed by management alternatives, resulting in reduced economic impact. The high  
27 impact scenario represents the case where the loss of AUMs on public lands leads to the loss  
28 of additional AUMs due to seasonal limitations of grazing areas. This would be the case if  
29 livestock operations have no reasonable alternative to seasonal grazing, implying broader  
30 impacts to livestock grazing. BLM estimated the additional loss of AUMs due to seasonal  
31 limitations on livestock grazing based on Torell et al. (2014). Further details are provided in  
32 **Appendix AA**, Economic Impact Analysis Methodology. Note that the employment  
33 estimates include the labor of proprietors and employees, but not unpaid or paid-in-kind  
34 family labor, which is typically not accounted for in labor force statistics. If family labor were  
35 included, then labor use differences among alternatives would be larger.

**Table 4-80**  
**Annual Impact of Management Actions Affecting Livestock AUMs on Output, Employment, and Earnings Compared to Alternative A**

	Alternatives B, D, E, and Proposed Plan <sup>1</sup>	Alternative C		Alternative F	
		Low Impact Scenario	High Impact Scenario	Low Impact Scenario	High Impact Scenario
<b>Primary Study Area</b>					
Output (\$ millions)	See notes	-\$100.6	-\$190.1	-\$26.1	-\$36.9
Employment	See notes	-997	-1,842	-259	-361

Employment	See notes	-997	-1,842	-259	-361
Earnings (\$ millions)	See notes	-\$34.6	-\$65.8	-\$9.0	-\$12.7

Source: Calculated using the IMPLAN model, applied to active and billed AUMs for each alternative (BLM 2012d, 2013b, 2013c; and Forest Service 2013c), as explained in the text and in **Appendix AA**, Economic Impact Analysis Methodology.

Note: Output and earnings are in millions of 2010 dollars.

<sup>1</sup> Based on available AUMs, there would be no change in economic activity from grazing in Alternatives B, D, E or the Proposed Plan. However, as described in the text, management actions in Alternatives B, D, E, and the Proposed Plan would result in restrictions to range improvements, which may increase ranch operators' costs or lead to other adverse economic impacts.

1

2

3

4

Beyond economic impacts linked to closing federal lands to livestock grazing under Alternatives C and F, management alternatives could impose other costs on livestock operators as follows:

5

6

7

8

- Under Alternatives C and F, closure of federal lands to grazing could mean additional costs to livestock operators with respect to construction of new infrastructure on private lands, such as water developments, if previously used infrastructure is no longer accessible.

9

10

11

- Under Alternatives B, C, D, F, and the Proposed Plan, restrictions to motorized travel could affect access of livestock operators to allotments with associated time and financial costs.

12

13

14

- Under Alternatives B, D, F, and the Proposed Plan, post-fire management actions to restore habitat could impose limitations on grazing during the restoration period.

- 1 • Under Alternatives B, D, F, and the Proposed Plan, vegetation treatments  
2 prioritizing GRSG habitat could require changes in livestock management with  
3 potentially associated costs.
- 4 • Disturbance caps under Alternatives B, C, D, F , and the Proposed Plan could  
5 reduce the capacity of livestock operators to build improvements or could limit  
6 infrastructure (e.g., roads) with potential increased costs to operators.
- 7 • For Alternatives B, D, E, and the Proposed Plan, in habitat and/or active lek  
8 areas (e.g., nesting or breeding seasons where desired conditions for GRSG are  
9 not being met) seasonal modifications to grazing management strategies may be  
10 needed such as changes in pasture rotation or fencing. These modifications have  
11 the potential for increased costs and/or limitations to grazing duration, intensity  
12 or location for some allotments. Habitat conditions for GRSG are less explicit  
13 under Alternative E which may afford greater flexibility for modifying  
14 management strategies. Potential for impacts related to seasonal management  
15 modifications is therefore relatively greater for Alternatives B, D, and the  
16 Proposed Plan, and relatively lower for Alternative E. Additional Forest Service  
17 guidelines for habitat (e.g., 7 inch stubble height for nesting habitat) may  
18 increase potential for impacts for some permittees, depending on specific  
19 conditions on allotments.
- 20 • For Alternatives B, D, E, F, and the Proposed Plan, design features (e.g., fence  
21 tags) or best management practices may be required to protect active lek areas,  
22 implying potential for increased costs for livestock operators; potential is  
23 relatively greater for Alternatives B, D, F, and the Proposed Plan compared to  
24 Alternative E. Additional guidelines under the proposed plan (e.g., trailing,  
25 fencing, range improvements) may affect some allotments.

26 Alternative A—Under Alternative A, grazing on federal lands would not be affected. The  
27 alternative would not change the amount of land open for grazing (BLM 2013b; Forest  
28 Service 2013c). Thus, there would be no change in annual output, annual jobs, or annual  
29 earnings relative to current trends. Based on the location of current federal grazing lands, the  
30 economic contribution of grazing would be similar to the pattern under current  
31 management, with particular concentrations in Cassia, Gooding, Jerome, Lincoln, and  
32 Owyhee Counties, Idaho. These are the counties in which 20 percent or more of earnings  
33 are attributable to livestock, according to **Section 3.22**, Social and Economic Conditions,  
34 Including Environmental Justice.

35 Alternative B—Under Alternative B, economic activity attributable to AUMs on federal  
36 lands with GRSG habitat is likely to be similar to that under Alternative A because there  
37 would be no changes in the amount of GRSG habitat unconditionally open for grazing. In  
38 the long term, livestock grazing in priority habitat may be reduced in this alternative  
39 compared to in Alternative A to conform to GRSG habitat objectives, although impacts  
40 would be site-specific and likely occur gradually over time. Some decisions on range

1 improvements and vegetation treatments would be subject to the conservation,  
2 enhancement, or restoration of GRSG habitat, potentially reducing forage available because  
3 permittees would be required to move livestock off-range if necessary to protect habitat.  
4 Seasonal restrictions could also be imposed, requiring that permittees move their livestock  
5 elsewhere, adding costs to their operations. The extent to which these additional constraints  
6 would reduce grazing on federal lands is not clear, but Alternative B would likely result in  
7 some additional operating costs and reductions in economic activity compared to Alternative  
8 A.

9 Alternative C—Under Alternative C, economic activity attributable to grazing on federal  
10 lands would be reduced. Livestock grazing on federal lands would be restricted to those with  
11 no GRSG habitat (BLM 2013b; Forest Service 2013c). Adverse impacts on output,  
12 employment, and earnings would be greater in Alternative C than any other alternative, with  
13 an estimated reduction in employment between 997 and 1,842 annual jobs relative to  
14 Alternative A. The economic impact of Alternative C may also be greater if the change in  
15 management actions, such as the removal of GRSG habitat from livestock grazing, impairs  
16 the economic viability of some grazing operations—especially if the private ranch land is  
17 then left unused. Management actions that prevent the viability of grazing operations could  
18 reduce the value of private land as a function of livestock productivity (land values as a  
19 function of other uses may increase or decrease).

20 Alternative D—Economic activity associated with AUMs on federal lands with GRSG  
21 habitat would likely be similar to Alternatives A and B because there would be no changes in  
22 the amount of GRSG habitat unconditionally open for grazing (BLM 2013b; Forest Service  
23 2013c). Some restrictions on range improvements or seasonal restrictions that require  
24 permittees to move livestock off-range could affect the availability of forage. In addition,  
25 measures to limit impacts on leks by trailing livestock and structural range improvements  
26 could result in additional costs. The extent to which these additional constraints would affect  
27 economic activity from grazing on federal lands is not clear. However, Alternative D would  
28 likely result in some reductions in economic activity compared to Alternative A, but less so  
29 than alternatives B or E.

30 Alternative E—Economic activity associated with AUMs on federal lands with GRSG  
31 habitat is likely to be similar to Alternatives A, B, and D because there would be no change  
32 in the amount of GRSG habitat unconditionally open for grazing (BLM 2013b; Forest  
33 Service 2013c). Some limitations would apply to structural range improvements, which could  
34 increase costs for construction and maintenance of improvements or impact the ability to  
35 distribute livestock. Similar to Alternative B, Alternative E could also impose seasonal  
36 restrictions that may increase costs for operators. These restrictions would more likely be  
37 imposed on lands designated as core or priority GRSG habitat, rather than general GRSG  
38 habitat (BLM 2013b). The extent to which these additional constraints would affect  
39 economic activity from grazing is not clear. However, Alternative E may result in some  
40 reductions in economic activity compared to Alternative A. Changes in grazing management  
41 would be tailored to address site-specific habitat needs.

1 Alternative F—Under Alternative F, economic activity due to grazing on federal lands would  
2 be reduced because of closure of some GRSG habitat to livestock grazing as well as actions  
3 to prohibit grazing after fire and prohibit new range improvements, which would result in  
4 increased costs for ranchers. Under Alternative F there would be an estimated reduction in  
5 employment between 259 and 361 annual jobs relative to Alternative A. The impact of  
6 Alternative F may be greater than shown if the reduction in federal AUMs impairs the  
7 economic viability of some grazing operations. The impact would also be greater if the  
8 private ranch land is then left unused. Management actions that prevent the viability of  
9 grazing operations could reduce the value of private land as a function of livestock  
10 productivity. Economic impacts under Alternative F would be less than under Alternative C  
11 but still substantially more than under Alternatives A, B, D, E, and the Proposed Plan.

12 Proposed Plan – Under the Proposed Plan, there would be no change in the amount of  
13 GRSG habitat unconditionally open for livestock grazing, relative to Alternative A. The  
14 BLM would use the assessment and monitoring data related to the objectives to evaluate  
15 whether rangeland health standards are being met, starting with allotments in SFA. The  
16 Forest Service would use Seasonal Habitat Desired Conditions for GRSG and Grazing  
17 Guidelines for GRSG Seasonal Habitat. If rangeland health standards are not being met,  
18 adjustments to livestock grazing would be implemented at the allotment level, and may  
19 include a variety of management approaches, such as changing rotation systems, season or  
20 timing or use, distribution of livestock use, intensity of use, type of livestock, class of  
21 livestock (e.g., yearlings vs. cow-calf pairs), duration of grazing use, and rest period or  
22 stocking rates. It is unknown to what extent permittees may need to change livestock  
23 management and what economic costs those changes might entail. In general, there may be  
24 some increased costs to implement management when it is identified that livestock  
25 management is conflicting with meeting GRSG habitat objectives. Because BLM takes a  
26 collaborative, site-specific approach to modifying livestock grazing, permittees are afforded  
27 the opportunity to work with BLM to develop management approaches that minimize  
28 impacts on their operations, while addressing identified habitat issues. Some permittees may  
29 prefer to reduce grazing overall, while others may prefer to increase management inputs  
30 (e.g., herding or maintaining let-down fences) to prevent a reduction in their authorized use,  
31 when provided with more than one viable alternative towards meeting rangeland health  
32 standards and GRSG habitat objectives. The Proposed Plan allows for design and  
33 implementation of allotment-specific management that will meet GRSG habitat objectives  
34 appropriate for each area, while providing the flexibility to minimize economic impacts to  
35 operators, rather than implementing a blanket reduction in grazing, which may provide  
36 benefits in some areas, while unnecessarily inflicting economic impacts in areas where  
37 ongoing management is resulting in satisfactory on-the-ground habitat conditions for  
38 GRSG.

39 In summary, economic impacts from closures in GRSG habitat to livestock grazing and  
40 potential increases in costs to operators are greatest under Alternative C, followed by  
41 Alternative F. Although no unconditional closures of grazing occur under Alternatives B, D,  
42 E, and the Proposed Plan, restrictions on motorized travel, vegetation treatments, and  
43 structural improvements could have increased costs to operators. Potential reductions in  
44 AUMs and operating costs under alternatives B, D, E, and the Proposed Plan are conditional

1 on meeting habitat objectives, satisfying disturbance caps, and operator discretion about how  
2 to modify grazing strategies and management to meet objectives and design feature  
3 requirements. The likelihood of AUM reductions or increases in costs under Alternatives B,  
4 D, E, and the Proposed Plan are therefore substantially lower than Alternatives C and F.  
5 Potential for costs under the Proposed Plan may be somewhat greater than Alternative D,  
6 and lowest for E. However, estimating the potential cost impacts to livestock grazing  
7 operators associated with management alternatives is not possible due to the landscape level  
8 of this planning effort and uncertainty about how individual operators could be affected and  
9 how they may operationally respond.

10 As previously noted, **Table 3-67** shows that, although livestock grazing has some  
11 importance to all counties in the study area it constitutes a larger share of earnings in Cassia,  
12 Gooding, Jerome, Lincoln, and Owyhee Counties. **Figures 2-1 through 2-12** show that  
13 GRSG habitat intersects with all these counties, particularly Gooding, Lincoln, and Owyhee.  
14 This suggests economic impacts of management alternatives on livestock grazing may be of  
15 particular importance to these three counties. Within these counties, communities may be  
16 impacted differently, contingent on each communities' dependency on livestock grazing  
17 where it overlaps with GRSG habitat.

18 Output, employment, and earnings losses reported above, although stemming from direct  
19 impacts to livestock grazing, would not all occur in the livestock ranching industry, but also  
20 in industries that provide inputs and services to these activities and in industries where labor  
21 earnings from livestock ranching are spent. Additional discussion of the potential impacts on  
22 communities is included in **Section 4.15.4, Social Impacts**.

#### 23 *Other Values Associated with Livestock Grazing*

24 As described in **Chapter 3**, BLM-administered and National Forest System land managed  
25 for livestock grazing provides both market values and non-market values; the latter include  
26 open space and western ranch scenery, which provide value to some residents and outside  
27 visitors. Ranches may also provide some value to the non-using public (e.g., the cultural icon  
28 of the American cowboy). Some residents and visitors also perceive non-market opportunity  
29 costs associated with livestock grazing; in addition, some of the lifestyle value of ranching is  
30 likely to be captured in markets (e.g., property values of ranches adjacent to BLM-  
31 administered and National Forest System lands). In contrast, other residents or visitors may  
32 perceive non-market opportunity costs (i.e., damages) associated with livestock grazing and  
33 therefore prefer alternative land uses.

34 The "Other Values" discussion in **Section 3.22, Socioeconomics and Environmental Justice**,  
35 and **Appendix BB, Non-Market Valuation Methods**, provide additional discussion of these  
36 values. Overall, the process for incorporating potential non-market values associated with  
37 the management of BLM-administered and National Forest System land for livestock  
38 grazing into analyses of net public benefits remains difficult as it implies the need to consider  
39 non-market values and uses associated with landscape characteristics and opportunities that  
40 would exist in absence of grazing and ranch activity. Since the scientific and economic  
41 literature on the topic does not provide adequate data or a consensus theoretical framework

1 from which to analyze these values further, this analysis does not attempt to quantify these  
2 values for the present study.

3 To the degree that there are net benefits associated with non-market values attached to  
4 livestock grazing and ranching, these would be greatest in Alternatives A, B, D, and E, as  
5 these alternatives are likely to result in similar levels of livestock grazing operations in the  
6 study area (albeit with some restrictions for Alternatives B, D, and E). If the net non-market  
7 value associated with livestock grazing and ranching is positive, then the likelihood of  
8 preserving the value would be greatest under Alternative A, slightly lower under Alternatives  
9 B, D, and E, lower still under Alternative F, and lowest of all under Alternative C, in line  
10 with the expected impacts on market values discussed above. Non-market benefits linked to  
11 alternative landscapes and land uses may help offset potential losses in non-market benefits  
12 associated with grazing and ranches.

### 13 ***Impacts from Management of Oil and Gas Leases***

14 The potential economic impacts of management alternatives affecting oil and gas drilling,  
15 completion, and production were not analyzed using IMPLAN, given the relatively small  
16 number of wells that would be affected and that no oil has been commercially produced in  
17 the study area to date. Based on the restrictions identified for the management alternatives,  
18 BLM oil and gas specialists projected that the number of wells and production capacity  
19 would be the same for Alternatives A and D. In Alternatives B, C, F, and the Proposed Plan,  
20 management actions would restrict exploration and development activity and result in  
21 approximately half of the production capacity (BLM 2015). The reduction in production  
22 capacity relative to Alternative A would not be expected to be as pronounced under  
23 Alternative E.

24 Alternative A—Alternative A would continue current trends in economic activity associated  
25 with oil and gas leases. The BLM predicts that, under Alternative A up to 37 wells would be  
26 drilled, including 25 wildcat wells and 12 step-out wells, over a 20 year period (BLM 2015).  
27 Of the 37 wells, 16 are predicted to be drilled in GRSG habitat (those in the Four Rivers  
28 Field Office, Caribou National Forest, and half of the wells in the Dillon Field Office are not  
29 in GRSG habitat). For analysis purposes, the BLM predicts that 16 wells would be  
30 productive (8 of those in GRSG habitat), with 28 billion cubic feet of production capacity.  
31 There would be no change in trends in annual output, annual jobs, or annual earnings  
32 compared to current management. Based on cost and direct employment estimates recently  
33 developed for neighboring Utah (BLM 2013g), 16 wells at a drilling and completion cost of  
34 \$3.25 million each, could generate an average of 11 annual direct jobs during the period and  
35 approximately \$700 thousand in direct annual earnings, if approximately 75 percent of  
36 expenditures were done locally. Additional jobs and earnings could be generated indirectly.  
37 Production of 28 billion cubic feet over a 20 year period could add an additional 2 annual  
38 direct jobs and \$200 thousand in direct annual earnings, with additional jobs and earnings  
39 being generated indirectly.

40 Alternative B—Alternative B would close PHMA to fluid mineral leasing but would have the  
41 same restrictions as Alternative A in GHMA. Drilling and production would drop, compared  
42 to Alternative A, with approximately 19 wells drilled, including 13 wildcat wells and 6 step-

1 out wells; 8 wells would be productive, all of which would be outside GRSG habitat (BLM  
2 2015). These wells would have 20.5 billion cubic feet of production capacity. On existing  
3 leases, RDFs would be imposed as appropriate to the proposed activity. Alternative B would  
4 also impose costs related to required full site-specific reclamation bonds to cover costs to  
5 restore the lands to pre-disturbance condition. As a result of implementing Alternative B,  
6 economic activity and associated output, employment, and earnings related to oil and gas  
7 production would decrease by approximately 30 to 50 percent compared to Alternative A, to  
8 something between 6 and 9 annual direct jobs, \$450 thousand to \$630 thousand in annual  
9 earnings, and additional indirect jobs and earnings. Impacts of reduced oil and gas  
10 development would likely be mostly felt in Bear Lake County (ID), Beaverhead County  
11 (MT), and surrounding areas.  
12

13 Alternative C—Economic impacts under Alternative C would be similar to those under  
14 Alternative B. Alternative C would cause a further reduction in economic activity by closing  
15 80 percent of the planning area to oil and gas leasing. As in the case of Alternative B,  
16 nineteen wells are predicted under Alternative C, including 13 wildcat wells and 6 step-out  
17 wells. Eight wells would be productive (none in GRSG habitat), with 20.5 billion cubic feet  
18 of production (BLM 2015).  
19

20 Alternative D— Implementation of Alternative D is predicted to result in drilling of 35  
21 wells, including 23 wildcat wells and 12 step-out wells; 16 wells are assumed to be  
22 productive. The reduction in 2 wells with respect to Alternative A would be expected for the  
23 Rogerson/Jarbridge area (Twin Falls County). Production capacity is predicted to be the same  
24 as Alternative A. The 16 productive wells would be expected to have the same economic  
25 impact as those under Alternative A (BLM 2015).

26 Alternative E—Under Alternative E, CHZ and IHZ in Idaho would be open to oil and gas  
27 leasing, subject to an NSO stipulation. Implementation of Alternative E would have  
28 economic impacts most similar to Alternative B in Idaho, although with some increased off-  
29 limits acreage in IHZ. Implementation of Alternative E would have economic impacts  
30 similar to Alternative A in Montana. Under Alternative E, wells could be drilled in the Dillon  
31 Field Office, consistent with the Dillon RMP. Under Alternative E, it is predicted that 19  
32 wildcat wells and 10 step-out wells would be drilled for a total of 29 wells (BLM 2015). The  
33 overall economic impact would be slightly less than under Alternative B, with an expected 11  
34 wells producing (six in the Dillon Field Office area, MT, three of those in GRSG habitat,  
35 and 5 in Idaho, none in GRSG habitat). As a result of implementing Alternative E,  
36 economic activity and associated output, employment, and earnings related to oil and gas  
37 production would be estimated to be slightly more than under Alternatives B and C. Impacts  
38 of reduced oil and gas development would likely be mostly felt in Bear Lakes County (ID)  
39 and surrounding areas. Alternative E involves some restrictions to surface development to  
40 minimize impacts on GRSG habitat on existing leases, which would have minor economic  
41 impacts.  
42

43 Alternative F—Economic impacts under Alternative F would be similar to the impacts  
44 under Alternatives B and C.

1 Proposed Plan—Under the proposed plan, as under Alternative E, PHMA and IHMA would  
2 be open to oil and gas leasing, subject to a No Surface Occupancy stipulation.  
3 Implementation of the proposed plan would have economic impacts most similar to  
4 Alternative E in Idaho, but impacts would be greater than Alternative E in Montana, due to  
5 the NSO stipulation under the proposed plan. Under the proposed plan, it is predicted that  
6 15 wildcat and 6 step-out wells would be drilled for a total of 21 wells (BLM 2015). The  
7 overall economic impact would be similar to Alternatives B and C, with 8 wells producing.  
8 As a result of implementing the Proposed Plan, estimates of economic activity and  
9 associated output, employment, and earnings related to oil and gas production would be  
10 similar to Alternative B and C with between 6 and 9 annual direct jobs, \$450 thousand to  
11 \$630 thousand in annual earnings, and additional indirect jobs and earnings. Impacts of  
12 reduced oil and gas development would likely be felt more in Bear Lakes County (ID),  
13 Beaverhead County (MT), and surrounding areas.  
14

### 15 ***Impacts from Management of Phosphate and Locatable and Salable Minerals***

16 As described in **Chapter 3**, the study area produces phosphate and several salable and  
17 locatable minerals, including Oakley stone, silver, sand, gravel, and some industrial minerals  
18 (e.g., molybdenum). Areas with phosphate and Oakley stone production potential overlap  
19 with GRSG habitat, which could have implications for mining activity in the long-term.

20 As discussed in **Chapter 3**, the three active phosphate operations in Idaho, with at least a  
21 portion of the phosphate being mined from leases of Federal minerals, are not located  
22 within GRSG habitat. As shown in Figure 3-13, Unleased Known Phosphate Leasing Areas,  
23 most of the about 48,500 unleased KPLA acres are located in Caribou and Bear Lake  
24 Counties. Only three of these acres intersect with general habitat.

25 The Paris-Bloomington KPLA area, consisting of approximately 1,640 acres and located  
26 within Bear Lake County, is situated entirely in IHMA and PHMA. Of these 1,640 acres,  
27 Federal minerals underlay 460 acres. Of the 460 acres of Federal minerals, 65 acres are leased  
28 (the only phosphate lease in GRSG habitat out of 86 Federal phosphate leases in Idaho), 240  
29 acres are under a prospecting lease, and the BLM has received indications that a phosphate  
30 lease application for 35 acres will be submitted in the near future. All of this activity is  
31 associated with potential Paris Hills Phosphate project (BLM 2013h; BLM 2014).

32 An estimated 40,000 tons of Oakley stone are mined annually from unpatented mining  
33 claims in southern Idaho and northern Utah, providing full-time employment for  
34 approximately 60 people and seasonal employment for an additional 100 to 200 laborers  
35 (BLM 2013h).

36 Many community pits of sand and gravel also fall within GRSG habitat. Economic activity  
37 associated with stone quarries and mineral materials disposal and sales could decrease under  
38 several of the GRSG habitat management alternatives (BLM 2013h).

39 Potential impacts from management actions in each alternative are detailed below.

1 Under Alternatives A and E, KPLAs would be open to phosphate mining. No additional  
2 lands would be withdrawn from locatable mineral entry (see **Section 4.10**, Locatable  
3 Minerals). No additional lands would be closed to mineral material disposal.

4 Alternatives B, C, and F would close priority habitat to phosphate mining. Of the KPLAs,  
5 the only one affected would be in the Paris-Bloomington area. In December 2012, Stonegate  
6 Agricom announced positive results of its Feasibility Study for the development of an  
7 underground phosphate mine (known as the Paris Hills Phosphate project). The project has  
8 been estimated to have a mine life of 19 years producing a total of 16.7 million tonnes of  
9 phosphate rock ore (Agapito Associates, Inc. 2013). The proportion of these production  
10 projections that could be attributable to Federal minerals is not known. However, to the  
11 extent that Federal minerals account of a portion of estimated reserves, the closing of  
12 PHMA to leasing could remove up to 395 acres of federal mineral estate from being  
13 accessed (BLM 2015). Valid existing rights associated with the current lease of 65 acres  
14 would prevent this area from closure, but any development would be subject to RDFs  
15 which, as discussed in **Section 4.12** Nonenergy Leasable Minerals, would limit surface  
16 disturbance, vehicle use, siting, and design of mineral development operations, in addition to  
17 imposing reclamation requirements. If implementing RDFs is not feasible once mining  
18 operations commence on this existing lease, off-site mitigation may be required. Together  
19 these management actions could result in a reduction of phosphate recovered and increased  
20 costs of the project<sup>1</sup>. Impacts under Alternative D may be relatively less because, while  
21 Alternative D closes PHMA and IHMA to future leasing and prospecting of phosphate, it  
22 allows for exceptions for lease modifications and fringe leases where valid existing rights  
23 may be affected.

24 With the exception of the Paris-Bloomington KPLA discussed above, no economic impacts  
25 on future phosphate development in other KPLA areas are expected due to the minimal  
26 GRSG habitat in these areas.

27 The potential for phosphate production from federal lands outside of KPLAs is generally  
28 low. However, if this were to occur, prospecting or mining would be affected in areas  
29 outside of KPLAs that overlap with PHMA under Alternatives B, C, D, and F, since PHMA  
30 would be closed to phosphate development. Furthermore, under Alternative D, management  
31 actions in GHMA would restrict exploration and development of nonenergy leasable  
32 minerals including timing restrictions, specific stipulations, and possible off-site mitigation.  
33 These management actions could affect the cost of exploration and development of  
34 phosphate in general habitat. However, overall, potential economic impacts associated with  
35 phosphate-related activities under Alternatives B, C, D and F outside of KPLAs are  
36 anticipated to be minimal given the limited amount of priority habitat in areas of southeast  
37 Idaho where phosphate occurs.

---

<sup>1</sup> As of January 26, 2015, Stonegate Agricom has temporarily suspended permitting activities on this project due to financial constraints (Stonegate Agricom 2015).

1 Under the Proposed Plan, KPLAs would remain open to phosphate mining, as under  
2 Alternatives A and E. PHMA outside of KPLAs would be closed to leasing, subject to valid  
3 existing rights. As explained above, these actions would have minor economic impacts  
4 outside of KPLAs that overlap PHMA. RDFs would apply to existing leases during  
5 exploration and mine development and could have costs to operators to the extent that they  
6 differ from current practices.

7 Alternatives A, D, and E would not recommend any new withdrawals from locatable mineral  
8 development. Alternatives B, C, and F would recommend withdrawing PHMA from  
9 locatable mineral development. These would be the most under Alternative C. The Proposed  
10 Plan would recommend withdrawal of SFAs from locatable mineral development, resulting  
11 in more withdrawals or recommended withdrawals than alternatives A and D, but less than  
12 B, C, and F. Under Alternatives B, C, F, and the Proposed Plan, withdrawals could have  
13 adverse economic impacts on specific communities to the extent that they reduce mineral  
14 development in the future. The extent of these economic impacts is not possible to estimate  
15 with the information available. Withdrawal recommendations for areas over 5,000 acres are  
16 subject to Congressional control and a number of statutory requirements would need to be  
17 satisfied.

18 Alternatives A and E would keep GRSG habitat open to mineral materials disposal. Under  
19 Alternatives B, C, and F mineral material disposal would be closed in PHMA and restoration  
20 of salable mineral pits no longer in use would be required to meet GRSG conservation  
21 objectives (see **Section 4.11**, Mineral Materials). Alternative D closes fewer acres to mineral  
22 material disposal, but does include restrictions across all GRSG habitat. Specifically, no new  
23 mineral material pits would be authorized within 3 km of an occupied lek and mineral  
24 disposal in GRSG habitat would be subject to timing restrictions. Alternative D would also  
25 require restoration of salable mineral pits no longer in use and would require reclamation  
26 bonds for new (commercial or non-profit) authorizations in PHMA. The Proposed Plan  
27 would close all PHMA to salable minerals and its economic impacts would be most similar  
28 to Alternative B. Restrictions in accessing mineral materials increase their cost to local users,  
29 particularly local governments, because they would need to obtain mineral materials at  
30 greater distances. Transportation costs are a major component of the total price of mineral  
31 materials.

32 Economic activity associated with management of phosphate, locatable minerals, and salable  
33 mineral materials would be the same for Alternatives A and E, slightly lower (due to reduced  
34 exploration activity) under Alternative D, lower still under Alternatives B and F, and lowest  
35 under Alternative C. The Proposed Plan would have similar impacts to Alternatives A and E  
36 for phosphate development; Alternatives B and F for locatable mineral development; and  
37 Alternative B for salable mineral development. Any adverse impacts on mining under  
38 Alternatives B, C, F, and the Proposed Plan would mostly likely be felt in counties such as  
39 Caribou, where the mining industry is an important economic contributor for some  
40 communities, and Cassia, where mineral activity may overlaps with GRSG habitat.

1       ***Impacts from Management Actions Affecting Geothermal Exploration and***  
2       ***Development***

3       Economic impacts from geothermal exploration and development are a function of  
4       construction and operation expenditures for geothermal electricity development, including  
5       drilling wells, constructing power plants, and operating facilities. As of 2013, there were 25  
6       federal geothermal leases covering approximately 60,000 acres in Idaho, primarily near Raft  
7       River, Crane Creek, and Parma; 17 were located in GRSG habitat (BLM 2013i).

8       Over the next 20 years, BLM expects geothermal exploration to occur in six different parts  
9       of the planning area. Two power plants would be possible, in the Raft River and Crane  
10      Creek areas.

11      Alternative A—Under Alternative A, the BLM predicts geothermal exploration and  
12      development activity would include 21 new exploratory (temperature gradient) wells with 18  
13      production wells and 12 injection wells. The Burley Field Office has received applications to  
14      drill up to 18 wells on federal leases in the Raft River area. Of these, it is assumed that 10  
15      wells would be production wells, while 8 wells would be used for injection. It is assumed that  
16      12 wells would be drilled at Crane Creek, in Washington County (7 production and 5  
17      injection wells); however, no activity has occurred on those leases since around 2010. Both  
18      these areas are within GHMA and have stipulations to protect GRSG habitat. No other  
19      areas are forecasted for geothermal development. Mitigation on existing leases can include  
20      the RDFs identified under Alternative D without affecting valid existing rights. Alternative A  
21      would not impact economic activity associated with geothermal leases, relative current  
22      management trends.

23      Alternative B—Under Alternative B, lands in PHMA would be closed to geothermal leasing,  
24      exploration and development. Existing leases at Raft River and Crane Creek lie within  
25      PHMA. The lands north and west of the Raft River leases and the federal lands surrounding  
26      the Crane Creek leases would be closed to future leasing outside the existing leases. For  
27      Alternative B, the RFDS forecasts that 18 temperature gradient wells would be drilled and  
28      fewer seismic operations would be allowed than under Alternative A. Implementation of  
29      Alternative B is predicted to result in the same number of production and injection wells as  
30      Alternative A, since there are valid existing rights on the existing leases. The economic  
31      impact would be slightly reduced relative to Alternative A due to the reduced local  
32      expenditures associated with drilling of exploratory wells.

33      Alternative C—Under Alternative C, lands in all GRSG habitat would be closed to leasing,  
34      and existing leases would be relinquished if doing so would mitigate the impact of a  
35      proposed development, or if relinquishment would mitigate the unanticipated impacts of an  
36      approved development (see MLS-9). Terminating leases would directly impact valid existing  
37      rights. No wells would be drilled at Raft River or Crane Creek. The reduced drilling and  
38      production would have an adverse economic impact in the form of reduce local employment  
39      and earnings in the counties of Cassia and Washington and surrounding areas. The federal  
40      government would not realize any production royalties.

1 Alternative D—Under Alternative D, the number of wells would be the same as under  
2 Alternative A, because no lands with moderate to high geothermal potential would be closed  
3 and no leases would be terminated. Applying RDFs imposed under Alternative D to post-  
4 lease actions would not result in additional economic impacts compared to Alternative A.

5 Alternative E and Proposed Plan—Under Alternative E and the Proposed Plan,  
6 CHZ/PHMA and IHZ/IHMA would be open to geothermal leasing, subject to an NSO  
7 stipulation. Existing leases at Raft River and Crane Creek lie within GHZ/GHMA under  
8 these alternatives and, therefore, would not be affected. There is some IHZ/IHMA  
9 immediately north of leases at Raft River and there would be increased off-limits acreage in  
10 IHZ/IHMA at Crane Creek. Implementation of Alternative E and the Proposed Plan would  
11 have economic impacts slightly greater than those of Alternative B due to a slightly greater  
12 reduction in expected exploratory wells. Alternative E and the Proposed Plan also have  
13 some restrictions to surface development to minimize impacts on GRSG habitat on existing  
14 leases, which would have minor potential costs to operators. However, BLM can impose  
15 these same RDFs to proposed actions on existing leases under Alternative A.

16 Alternative F—Economic impacts under Alternative F would be similar to the impacts  
17 under Alternative B.

18 The greatest impact on economic activity associated with geothermal development would be  
19 expected under Alternative C, where drilling and production in GRSG habitat would be  
20 substantially reduced, impacting local employment and earnings in the counties of Cassia and  
21 Washington and surrounding areas. Under Alternatives A and D current trends in  
22 geothermal development would be maintained. There would be a slight reduction in  
23 economic activity associated with geothermal exploratory drilling under Alternatives B and F  
24 relative to Alternative A, and slightly greater reductions under Alternative E and the  
25 Proposed Plan. However, existing leases would not be affected.

### 26 ***Impacts from Management Actions Affecting Wind Energy Development***

27 The amount of future wind development in the study area is uncertain. One application for  
28 wind energy development in the study area was recently removed (China Mountain, in Twin  
29 Falls, Idaho). Current wind energy development in the study area includes one project, Bell  
30 Rapids, near Hagerman, Idaho, with a proposed capacity of 40 MW. Using estimates of the  
31 economic impact of the China Mountain project as a reference (BLM 2011b), scaled  
32 proportionally to the size of the project that would be built on BLM-administered lands (i.e.,  
33 about one-tenth the size of the figures reported in the China Mountain Wind Project Draft  
34 EIS), then the Bell Rapids project would be estimated to generate about 75 jobs for a 2-year  
35 construction duration and about 5 long-term annual full-time jobs during operations. These  
36 estimates include direct, indirect and induced positions. The jobs in the Bell Rapids project  
37 would most likely be in Elmore and Gooding Counties, based on the location of that  
38 project.

39 Based on the RFDS for wind energy, under Alternatives A and F, this level of development  
40 would be maintained. BLM anticipates that Alternatives B through D and the Proposed Plan  
41 may prevent wind energy development entirely. In this case, the planning area would see a

1 loss of jobs equal to what is described above. Alternative E could limit future wind energy  
2 development, with some development possible, depending on fulfillment of criteria  
3 established by the alternative. Thus, Alternatives B through D and the Proposed Plan would  
4 result in lower annual output, employment, and earnings related to wind energy development  
5 compared to Alternatives A and F. This may also be the case of Alternative E.

6 ***Impacts from Management Actions Affecting Land and Realty and Travel***  
7 ***Management***

8 Management actions that affect development of infrastructure could have important  
9 hindering effects on employment and earnings in the area. Limitations on new ROWs for  
10 power lines, pipelines, and access routes or restrictions to route construction and to travel on  
11 existing roads could increase the cost of new economic investments or make them no longer  
12 economically viable. Additional information about changes in cost effectiveness and  
13 efficiency associated with restrictions on ROW, corridors, and treatments are discussed in  
14 **Section 4.7**, Lands and Realty, and **Section 4.3**, Vegetation. A qualitative discussion of the  
15 potential for economic impacts from restrictions to land use and transportation is provided  
16 below for each alternative.

17 Alternative A—Alternative A would place the fewest restrictions on ROW development and  
18 route construction and maintain the largest area open to travel, among the alternatives.  
19 According to RFDS developed by BLM specialists, of the proposed 516 miles of new 500-  
20 kV transmission lines approximately 100 miles of new transmission lines could reasonably be  
21 expected to be built under Alternative A.

22 Alternative B—Alternative B could result in adverse impacts to economic activity related to  
23 lands and realty and travel management by closing areas to ROW authorizations, limiting  
24 motorized travel on existing roads, and limiting new road construction in areas with primary  
25 GRSG habitat. In addition to restricted economic activity associated with road use and  
26 development restrictions, economic impacts would include increased costs associated with  
27 mandatory mitigation for surface disturbance that exceeds three percent for the area. Based  
28 on the RFDS, the BLM projects no new transmission lines under Alternative B. Alternative  
29 B would impose greater limitations and added costs to future economic investments in the  
30 study area compared with Alternative A.

31 Alternative C—Under Alternative C, economic impacts on lands and realty and travel  
32 management are expected to be the same as under Alternative B, although a larger area  
33 would be excluded for development.

34 Alternative D—Alternative D would result in economic impacts slightly less than those  
35 under Alternatives B and C. Alternative D would apply similar restrictions on motorized  
36 travel, except the restrictions would apply to general habitat as well as priority habitat.  
37 However, unlike Alternatives B and C, Alternative D would not impose costs related to  
38 mandatory mitigation for surface disturbance. Costs resulting from restriction to  
39 infrastructure development under Alternative D would be greater than under Alternative A  
40 but less than under Alternatives B or C.

1 Alternative E—Management under Alternative E would have similar impacts as under  
2 Alternative A and fewer impacts than under Alternatives B, C, and D. However, Alternative  
3 E considerably increases the land area subject to avoidance when compared to Alternative A.  
4 The BLM estimates that Alternative E could result in some new transmission lines,  
5 depending on whether the proposed projects meet established criteria. New linear  
6 developments could, however, face increased costs due to the avoidance stipulations that  
7 may impose alternative alignments or mitigation measures.

8 Alternative F—Economic impacts from Alternative F would be similar to those under  
9 Alternatives B and C, except that Alternative F would limit motorized travel in restoration  
10 areas, as well as primary habitat, and would prohibit new road construction within a four-  
11 mile buffer from leks. However, the BLM does expect that development of transmission  
12 lines would be similar to that under Alternative A, with 100 miles of new transmission lines  
13 in the foreseeable future.

14 Proposed Plan— Under the Proposed Plan, development of major ROWs in PHMA would  
15 be avoided, rather than excluded as they would be under Alternative D. This could result in  
16 fewer adverse impacts to ROWs, as more acres would be available for major ROW  
17 development under the proposed plan versus Alternative D. The Proposed Plan would have  
18 impacts similar to Alternatives E and fewer impacts than under Alternatives B, C, D, and F.  
19 As under Alternative E, the BLM estimates that some new transmission lines could be built,  
20 depending on whether the proposed projects meet established criteria. However, new  
21 developments could face increased costs due to the avoidance stipulations that may impose  
22 alternative alignments or mitigation measures.

23 Under Alternative B, C, E, F, and the Proposed Plan, agencies would aim to remove, bury or  
24 modify existing power lines in PHMAs. Under Alternative D, new power and  
25 communication lines (50 kV or less), outside of existing ROWs, would be buried, where  
26 physically feasible. During the reauthorization of existing distribution lines, the physical  
27 feasibility of burying lines would also be considered. These Alternative D management  
28 actions would apply to PHMA, PMMA, and PGMA. All the action alternatives include  
29 restrictions in habitat that might require all new ROW or SUA routes to be modified or to  
30 implement mitigation. Some public comments on the Draft LUPA/EIS expressed concern  
31 with the costs of these measures and potential impacts on rate payers. Unit cost information  
32 for constructing transmission lines provides context for potential impacts of relocating or  
33 rerouting a transmission line. A 2012 WECC study provides information on transmission  
34 line costs per mile, ranging from \$927 thousand to \$2,967 thousand depending on voltage  
35 and whether lines are single or double circuit lines. The same study provides cost multipliers  
36 for difficult terrains, reaching up to 2.25 in the case of forested lands (WECC 2012). New  
37 construction of underground transmission lines can be between 4 and 14 times higher (PSC  
38 2011), depending on terrain, although burial of existing lines would be a fraction of the cost  
39 of new lines. Burial of distribution lines would be considerably less, averaging under \$500  
40 per mile in rural areas (EIA 2012). According to the Energy Information Administration, on  
41 average in the U.S., transmission costs account for approximately 11 percent of the cost of  
42 energy bills, and distribution costs account for 31 percent, with the remaining being power  
43 generation costs (EIA 2013). Because utility providers allocate costs on to their rate base,

1 per-customer rate impacts would be greater where the rate payer base is smaller, all else equal  
2 (i.e., given an identical fixed cost associated with burial of transmission lines). Areas with  
3 smaller/local utility providers with fewer rate payers would be required to absorb a greater  
4 proportion of the costs of relocation or rerouting compared to areas serviced by larger,  
5 multi-state providers.

6 In summary, the most restrictions on economic activity relative to Alternative A, associated  
7 with land and realty development and travel management, would be expected to occur under  
8 Alternatives B, C, and F, with slightly less restrictions under Alternative D, and less still  
9 under Alternative E and the Proposed Plan.

### 10 ***Impacts from Management Actions Affecting Special Status Species***

#### 11 *Other Values Associated with Populations of GRSG*

12 As described in **Chapter 3**, economists and policy makers have long recognized that rare,  
13 threatened, and endangered species have economic values beyond those associated with  
14 active “use” through viewing or hunting. **Chapter 3** and **Appendix BB**, Non-Market  
15 Valuation Methods, document current methods to estimate these “non-use” values,  
16 including a description of the literature review that the BLM and Forest Service conducted  
17 to determine if there were existing non-use value studies for GRSG. Although there are no  
18 existing studies on valuation specific to the GRSG, several studies published in peer-  
19 reviewed scientific journals for bird species with similar characteristics find average stated  
20 willingness-to-pay between \$15 and \$58 per household per year in order to restore a self-  
21 sustaining population or prevent regional extinction (see **Appendix BB**, Non-Market  
22 Valuation Methods, for details). These values represent a mix of use and non-use values, but  
23 the non-use components of value are likely to be the majority share since the studies  
24 primarily address species that are not hunted.

25 Because GRSG protection is a public good available to all households throughout the  
26 intermountain west, if similar per-household values apply and if even a small portion of the  
27 per-household value represents a non-use value, then the aggregate regional non-use value  
28 could be substantial. However, the BLM and Forest Service did not quantify the aggregate  
29 value because of several factors, including uncertainty associated with the comparability of  
30 the existing studies to the GRSG context and the documented difference between stated and  
31 actual willingness-to-pay.

32 From a qualitative perspective, however, the non-use values associated with populations of  
33 GRSG would be expected to correspond to the degree of habitat protection associated with  
34 each alternative. Current management, Alternative A, provides the least amount of  
35 protection for GRSG in the planning area and consequently could result in the most adverse  
36 impacts on GRSG. As a result, to the degree that there are non-use values associated with  
37 populations of GRSG, management under Alternative A would have the greatest adverse  
38 impacts on those values.

39 As discussed in **Section 4.2**, Sage-Grouse and Sage-Grouse Habitat, most of the  
40 management actions under the alternatives would be beneficial for GRSG. It is therefore  
41 estimated that in comparison to Alternative A, each alternative would have a positive impact

1 on non-use values associated with populations of GRSG. However, because so many factors  
2 (e.g., vegetation and soils management, livestock grazing management, fire and fuels  
3 management, recreation management, renewable energy development) impact the  
4 protectiveness of each alternative, it is difficult to anticipate the comparative protection, and  
5 therefore non-use values, provided by Alternatives B through F.

#### 6 ***Impacts on Tax Revenues and Payments to States and Counties***

7 Reductions in economic activity have the potential to result in reduced tax revenues for local  
8 and state governments, as well as the federal government. At the state level, tax revenue  
9 reductions could take the form of reductions in mineral severance taxes, mining taxes, sales  
10 and use taxes, or personal and corporate income taxes. At the local level, revenues could be  
11 reduced if property or sales taxes decrease.

12 As described in **Section 3.22**, Social and Economic Conditions (Including Environmental  
13 Justice), most Idaho state revenues come from sales and use taxes, income taxes, and  
14 property taxes. Most of Montana's state revenues come from individual income taxes and  
15 severance taxes, including oil and gas production taxes, although most of the mineral  
16 production in Montana is outside the planning area. Idaho's overall economic output, which  
17 provides a measure of its sales tax base, was almost \$53 billion in 2010 (2010 dollars).  
18 Montana had a 2010 gross state product of almost \$35 billion in year 2010 dollars (BEA  
19 2013). Based on the information available, it is not possible to quantify potential impacts of  
20 management alternatives on tax revenues as a share of State overall tax bases or tax  
21 collections. However, local government tax revenues could be affected in areas that would  
22 experience considerable changes in economic activity. As described in **Section 3.22**, Social  
23 and Economic Conditions (Including Environmental Justice), Idaho counties receive most  
24 of their revenue from property taxes, charges for local services, and redistribution of state  
25 and federal resources. In Montana, local government tax collections come almost entirely  
26 from property taxes. In both Idaho and Montana, counties receive a portion of federal  
27 mineral royalties from mining activities on federal land, as well as fees for grazing, recreation,  
28 and rents of ROW and oil and gas tax. Although specific impacts on local government tax  
29 revenues could not be quantified, the anticipated changes (both positive and negative) in  
30 economic activity as a result of the various alternatives suggest that local tax revenues could  
31 be affected more in certain counties than in others, particularly Cassia, Gooding, Jerome,  
32 Lincoln and Owyhee Counties, in Idaho, because of impacts on grazing.

#### 33 **4.15.4 Social Impacts**

##### 34 ***Impacts from Management Actions Affecting Migration***

###### 35 *Population*

36 The decrease in employment opportunities in the study area that would occur under  
37 Alternative C from the adverse impacts on farming, corresponds to less than 0.45 percent of  
38 the current employment in the study area (**Table 4-82**). The BLM and Forest Service do not  
39 expect this change in employment to be sufficiently large to induce perceptible changes in  
40 population in any particular county, or to impact the capacity of counties in the study area to  
41 attract and retain its labor force, with implications for population growth. It is possible that,  
42 within counties, specific communities highly dependent on livestock operations could lose

1 sufficient employment opportunities under Alternative C to affect their capacity to attract  
2 and retain labor, affecting in turn their population growth trends.

3 *Housing and Public Services*

4 Housing demand would not be affected in a substantial way by any of the alternatives. No  
5 alternative would sufficiently increase employment opportunities to generate an inflow of  
6 new population to any specific county affecting housing demand in the communities  
7 capacity to provide the demand housing or the associated public services.

8 However, the abilities of counties to supply public services could be reduced, particularly in  
9 Alternative C, in accordance with potential reductions in local tax revenues. State tax  
10 revenues would not be affected substantially, as documented in the section on fiscal  
11 conditions.

12 ***Impacts from Management Actions Affecting Specific Groups and Communities***

13 *Consistency with County Land Use Plans*

14 The decision under consideration may result in amended BLM and Forest Service LUPs  
15 throughout the study area. BLM GRSG habitat mapping does not necessarily coincide with  
16 mapping made by counties (e.g., Custer County) due to differences in methodology. Also,  
17 the Custer County GRSG plan does not recognize livestock grazing as a threat to GRSG  
18 habitat. Under FLPMA, the BLM and Forest Service management plans and LUPs must be  
19 consistent with state and local LUPs to the extent possible within the context of other  
20 mandates of the BLM and Forest Service, and any amendments to be made would aim to  
21 maintain consistency to the degree possible. This would be the case under all alternatives.

22 *Interest Groups and Communities of Place*

23 As described in **Chapter 3**, there is a range of groups in the study area with overlapping and  
24 divergent interests. Groups centered on recreation, livestock grazing, mining, land  
25 development, infrastructure development, business development, and conservation of  
26 natural resources would be impacted differently by the management alternatives. Within  
27 these interest groups, some could be particularly affected. Among the interest groups most  
28 likely to be affected by the choice of alternative are those associated with livestock grazing  
29 and wildlife conservation.

30 Specific communities will be impacted in different ways by the management alternatives.  
31 Communities with more diversified economies, and particularly those less dependent on  
32 livestock grazing, would likely be less impacted.

33 The BLM and Forest Service reviewed the scoping report and the notes from the regional  
34 economic strategies workshop to identify any comments related to specific communities that  
35 may be particularly affected by various management alternatives. Multiple commenters  
36 discussed concerns specific to the Magic Valley in Idaho and Twin Falls County, in  
37 particular. The commenters identified the importance of grazing for the local economy  
38 (BLM and Forest Service 2012). With respect to grazing management actions in other  
39 communities, comments included requesting that BLM consider maintaining livestock

1 operations in the Jarbidge Planning Area and that BLM preserve customary agricultural use  
2 in Custer County (BLM and Forest Service 2012).

3 A few comments expressed concern with potential impacts of management alternatives on  
4 recreation, including concern with recreation in Owyhee County and Blaine County. As  
5 previously discussed, the BLM and Forest Service do not expect overall levels of visitation to  
6 recreation areas on BLM and Forest Service managed lands to differ among management  
7 alternatives. One scoping comment identified Clark County, Idaho, as a vulnerable area,  
8 explaining that 75 percent of the County is publicly owned. The commenter expressed  
9 concern that restrictions on use of BLM-administered and National Forest System lands  
10 could have negative consequences for Clark County residents (BLM and Forest Service  
11 2012).

12 The BLM and Forest Service also reviewed public comments made on the Draft LUPA/EIS  
13 for specific concerns with impacts to individual counties and towns or specific interest  
14 groups. Several commenters expressed concern with impacts of management alternatives on  
15 livestock operations and mining activities and their effects on local communities. For  
16 example, Custer County was highlighted as having an economy based on mining and  
17 agriculture/ranching with any GRSG management plans on grazing having potentially  
18 serious impacts on the viability of individual farms or the history and culture of the  
19 community. Several comments focused on the importance of phosphate to southeastern  
20 Idaho. Others expressed in general terms that the analysis of impacts should be done at a  
21 level of specific counties or communities. Additional analysis will be done during  
22 implementation of resource management plans and land use plans to properly assess the  
23 geographically localized impacts of management actions that many of the public comments  
24 to the draft LUPA/EIS expressed concern with.

25 Alternatives C and F would have the most adverse impacts on livestock grazing operators  
26 throughout the study area. Although economic impacts would be most felt in those counties  
27 where livestock operations are a greater share of employment and earnings, individuals and  
28 interest groups associated with livestock grazing could be affected in all counties where  
29 GRSG habitat intersects with areas commonly used for grazing. In some communities (e.g.,  
30 Caribou and Custer Counties, Idaho), Alternatives C and F could have adverse impacts  
31 through their effects on mining activities. Conservation interests could benefit under these  
32 management alternatives. Communities would likely be impacted differently by each  
33 alternative, depending on the balance of economic activities and social values in each  
34 community.

### 35 ***Summary of Social and Economic Impacts***

36 Alternative actions evaluated in this EIS consist of different packages of conservation  
37 measures that include land use restrictions, management practices or design features, habitat  
38 priorities or desired conditions, and monitoring protocols. These conservation measures, in  
39 aggregate, are intended to address threats to, and provide protection for GRSG (see  
40 **Chapter 2** of this EIS). This section has evaluated the social and economic impacts resulting  
41 from conservation measures that address threats associated with specific land and resource  
42 uses (e.g., grazing, minerals) which are linked to social and economic conditions (e.g.,

employment). There are other conservation measures included in the alternatives (to varying degrees) that address other threats such as fire, invasive plants, and vegetation (e.g., pinyon-juniper) encroachment on GRSG habitat that would have direct impacts on local economies of communities as well as effects on broader GRSG conservation benefits. However, the extent of these impacts is not known at this planning stage and due to uncertainty (e.g., occurrence of fire). Therefore, while the regional economic impacts of these conservation measures were not evaluated in this section, they would not only play a critical and complementary role in helping meet the goal of effectively protecting GRSG from a full spectrum of threats, but also support local economic activity.

The discussion and tables below summarize the range of potential social and economic impacts that may occur as a result of the subset of conservation measures that affect land or resource uses linked to readily identifiable social or economic conditions.

**Table 4-82**, Economic Impacts Relative to Alternative A, provides a summary of potential economic effects of management alternatives in the study area. Alternative A represents impacts associated with current management.

**Table 4-81**  
**Economic Impacts Relative to Alternative A**

	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F	Proposed Plan
GRAZING	Potential operational costs and/or reduced efficiencies	-1,420 jobs (0.54% of 2010 baseline) and -\$50.1 million in earnings (0.29% of 2010 baseline)	Potential operational costs and/or reduced efficiencies	Potential operational costs and/or reduced efficiencies	-310 jobs (0.12% of 2010 baseline) and -\$10.8 million in earnings (0.06% of 2010 baseline)	Potential operational costs and/or reduced efficiencies
Oil and Gas	50% reduction in employment and earnings from production of federal minerals in GRSG habitat	50% reduction in employment and earnings from production of federal minerals in GRSG habitat	No reduction in employment and earnings relative to Alternative A	Reduction in employment and earnings relative to Alternative A less than under Alternatives B, C, F or Proposed Plan	50% reduction in employment and earnings from production of federal minerals in GRSG habitat	50% reduction in employment and earnings from production of federal minerals in GRSG habitat
Phosphate	Reduced employment and earnings from phosphate mining in the Paris Hills KPLA	Reduced employment and earnings from phosphate mining in the Paris Hills KPLA	No impact on KPLAs	No impact on KPLAs	Reduced employment and earnings from phosphate mining in the Paris Hills KPLA	No impact on KPLAs

**Table 4-81  
Economic Impacts Relative to Alternative A**

	<b>Alternative B</b>	<b>Alternative C</b>	<b>Alternative D</b>	<b>Alternative E</b>	<b>Alternative F</b>	<b>Proposed Plan</b>
Locatable Minerals	Withdrawal recommendation in PHMA could limit future potential employment and earnings	Withdrawal recommendation in PHMA would have the greatest potential impact on employment and earnings	No impact relative to Alternative A	No impact relative to Alternative A	Same as Alternative B	Withdrawal recommendation in SFA would have less potential impacts than Alternatives B, C and F, more than A, D and E
Geothermal	Reduction employment and earnings from geothermal development in GRSG habitat on BLM and FS managed lands	Most reduction in employment and earnings from geothermal development in GRSG habitat on BLM and FS managed lands	No reduction	Less reduction in employment and earnings from geothermal development when compared to Alternatives B and F	Reduction in employment and earnings from geothermal development in GRSG habitat on BLM and FS managed lands	Less reduction in employment and earnings from geothermal development when compared to Alternatives B and F
Wind	May prevent employment and earnings from wind energy development in GRSG habitat on BLM and FS managed lands	May prevent employment and earnings from wind energy development in GRSG habitat on BLM and FS managed lands	May prevent employment and earnings from wind energy development in GRSG habitat on BLM and FS managed lands	Potential reduction in employment and earnings from wind energy development relative to Alternative A	No impact relative to Alternative A	May prevent employment and earnings from wind energy development in GRSG habitat on BLM and FS managed lands
Lands and Realty and Travel Management	Most potential for reduced employment and earnings from ROW investments and increased costs from travel management restrictions on GRSG habitat on BLM and Forest Service managed lands	Most potential for reduced employment and earnings from ROW investments and increased costs from travel management restrictions on GRSG habitat on BLM and Forest Service managed lands	Less potential for reduced employment and earnings from ROW investments and increased costs from travel management restrictions on GRSG habitat on BLM and Forest Service managed lands	Least potential for reduced employment and earnings from ROW investments and increased costs from travel management restrictions on GRSG habitat on BLM and Forest Service managed lands	Most potential for reduced employment and earnings from ROW investments and increased costs from travel management restrictions on GRSG habitat on BLM and Forest Service managed lands	Least potential for reduced employment and earnings from ROW investments and increased costs from travel management restrictions on GRSG habitat on BLM and Forest Service managed lands

Source: Impacts for grazing calculated using the IMPLAN model, as explained in the text and in **Appendix AA**, Economic Impact Analysis Methodology. Grazing values are the mid-point between the low and high impact scenarios. Percent of 2010 baseline is calculated from value of impacts and baseline information provided in **Section 3.22**, Social and Economic Conditions (Including Environmental Justice). Earnings values are in millions of year 2010 dollars.

Impacts associated with grazing would occur throughout the study area, with concentrations in Cassia, Gooding, Jerome, Lincoln, and Owyhee Counties in Idaho. Impacts associated with reduced oil and gas development would likely be mostly felt in Bear Lake County (ID), Beaverhead County (MT), and surrounding areas. Impacts associated with phosphate would be felt mostly in Bear Lake County. Impacts associated with geothermal development would most likely be felt in the counties of Cassia and Washington and surrounding areas. Employment associated with the Bell Rapids wind project would most likely be in Elmore and Gooding Counties, based on the location of that project. Impacts associated with lands and realty and travel management would like be dispersed throughout the study area.

Other impacts not discussed in **Table 4-82** include potential impacts on salable minerals (dispersed throughout the study area), locatable minerals (potentially around counties such as Caribou and Cassia), and state and local tax revenues (largely tied to economic output and earnings, affected as described above).

The BLM and Forest Service do not expect changes in employment in the study area under any of the alternatives to be sufficiently large to induce perceptible changes in population in any particular county. Similarly, no increased demand for housing or public services would be expected that could not be accommodated by current trends.

Communities with strong interest groups revolving around conservation and primitive recreational activities could experience benefits from Alternatives B, C, D, E, F, and the Proposed Plan. Communities with strong interest groups focused on livestock grazing would likely experience the most adverse impacts from Alternatives C and F.

**Table 4-83**, Social Impacts Relative to Alternative A, summarizes the social impacts of the management alternatives.

**Table 4-82**

Non-market benefits from the management alternatives would be derived from the ability of the full spectrum of conservation measures to conserve, enhance, and/or restore GRSG habitat by reducing, eliminating, or minimizing threats to GRSG habitat. Furthermore, as discussed, alternatives also specify different types and levels of mechanisms, such as disturbance caps, adaptive management protocols, and desired conditions or objectives, to guide when and where conservation measures, design features, and treatments are implemented and that will have an important influence on the overall effectiveness and efficiency of the alternatives. The magnitude of benefits associated with stabilizing or improving GRSG populations or habitat has not been monetized or quantified due to the absence of specific data on the values of non-market benefits of GRSG and uncertainty about quantifying projected responses of GRSG habitat and populations to conservation measures.

A qualitative evaluation of the benefits from potential changes in GRSG populations and habitat resulting from the subset of conservation measures addressing land and resource uses and extraction, as evaluated in this section, indicates alternatives have the following capability to protect or improve benefits from GRSG:

- Alternative A has the lowest capability.
- Alternative B has greater capability than A, but lower capability than Alternative F.
- Alternative C has the greatest capability.
- Alternative D has greater capability than Alternatives A, B or E but less Alternatives C or F.
- Alternative E has the second lowest capability after Alternative A.
- Alternative F has second greatest capability after Alternative C.
- The Proposed Plan has greater capability than Alternatives A, B, D and E but less than Alternatives F and C.

1  
2 In addition to the conservation measures directly associated with social or economic impacts  
3 considered in this section, there are other conservation measures that address other threats  
4 (e.g., fire, non-native plants, encroachment) that also contribute to GRSG and GRSG habitat  
5 protection and corresponding benefits that are not addressed here. As a consequence, for a  
6 complete description of potential improvements in GRSG habitat protection resulting from  
7 the full spectrum of conservation measures under each alternative, the reader is referred to  
8 the effects summary tables provided in Chapter 2. Social and economic impacts cannot be  
9 considered in isolation or exclusive of other impact indicators discussed in this EIS.

#### 10 **4.15.5 Environmental Justice Impacts**

11 The BLM and Forest Service considered information on the presence of minority and low-  
12 income populations (from **Chapter 3**) along with additional information, described in this  
13 section, to assess the potential for the alternatives to result in disproportionately high and  
14 adverse impacts on minority or low-income populations. Although conservation measures  
15 would be implemented consistently across all identified habitat, with no discrimination over  
16 particular populations, environmental justice guidance requires agencies to consider also  
17 whether their actions could unintentionally result in disproportionately high and adverse  
18 effects.

19 To help guide the analysis of potential environmental justice impacts, the BLM and Forest  
20 Service considered the information gathered in the Economic Strategies Workshop that was  
21 conducted in June 2012. That workshop was convened to identify public concerns related to  
22 potential social, economic, and environmental justice impacts that could result from the  
23 management alternatives. The BLM and Forest Service also reviewed the scoping report for  
24 the present EIS to identify any comments related to environmental justice issues. None of  
25 the public comments received during that workshop or presented in the scoping report  
26 called out a specific concern related to minority populations (BLM and Forest Service 2012;  
27 BLM 2013d).

##### 28 ***Potential Impacts on Minority Populations***

29 As discussed in **Chapter 3**, CEQ guidance identifies a community or a specific population  
30 group as a minority population when either: (1) minorities in the affected area exceed 50  
31 percent of the total population; or (2) the percentage of minorities in the affected area is  
32 meaningfully greater than the percentage in the general population or appropriate unit of  
33 geographical analysis. Based on the description of minority presence in the study area in  
34 **Chapter 3**, several counties have minority presence considerably above that of the state as a  
35 whole, including Clark County, Idaho, whose minority population is 42.9 percent of its total  
36 population; Minidoka County, Idaho (34.6 percent); and Power County, Idaho (34 percent).  
37 In total, 14 counties of the study area in Idaho (and neither of the counties in Montana) have  
38 a higher percentage of minority presence than the state as a whole. For the purposes of this  
39 LUPA/EIS, all 14 counties were considered minority populations. These counties are:  
40 Bingham, Blaine, Cassia, Clark, Elmore, Gooding, Jerome, Lincoln, Minidoka, Owyhee,  
41 Payette, Power, Twin Falls, and Washington Counties.

1 The extent to which existing minority populations are disproportionately impacted by high  
2 and adverse human health or environmental effects depends on the existence of high and  
3 adverse human health or environmental effects from management alternatives on any of the  
4 resources analyzed, and whether minority populations are particularly vulnerable to these  
5 impacts or more likely to be exposed to such impacts. Adverse impacts of alternatives were  
6 identified under the various resources analyzed and are described in their respective sections  
7 of **Chapter 4**. None of the alternatives could be considered to have a high and adverse  
8 impact on the study area as a whole.

9 The BLM and Forest Service considered the possibility that adverse impacts could be  
10 concentrated in few counties in the study area and could then constitute a high and adverse  
11 impact in those counties. As previously noted, losses of employment and earnings related to  
12 grazing would be particularly important for Cassia, Gooding, Jerome, Lincoln, and Owyhee  
13 Counties, where over 20 percent of earnings are attributable to livestock farming. For the  
14 purposes of this LUPA/EIS, each of these counties is considered a minority population. If  
15 grazing impacts, particularly under Alternative C, were high and adverse in these counties,  
16 Alternative C would disproportionately impact minority populations. Employment impacted  
17 through grazing under Alternative C was estimated in 1,420 jobs. This represents about 3.6  
18 percent of the total employment in these five counties. However, based on the intersection  
19 of GRSG habitat and the study area, grazing impacts would not likely be concentrated in  
20 these five counties alone and no disproportionately high and adverse impacts on these  
21 minority populations would occur.

22 One issue of potential concern relates to interests of Native American tribes. The planning  
23 area is within the traditional and/or historical use area of several tribes, see **Section 3.18**,  
24 Tribal Interests. Members of these tribes hunt on federal lands outside of the boundaries of  
25 their reservations. Although hunting would be impacted in certain areas under some  
26 management alternatives, the proposed management actions would not affect the overall  
27 tribes' ability to hunt in the study area and no disproportionately high and adverse impact  
28 would be expected.

29 Based on available information about the nature and geographic incidence of impacts,  
30 neither specific minority populations nor tribal populations would be expected to be  
31 exposed to disproportionately high and adverse impacts under any of the management  
32 alternatives considered.

### 33 ***Potential Impacts on Low-Income Populations***

34 About half (15 of 29) of the counties in the study area have a concentration of low-income  
35 populations that exceeds the state average, as discussed in **Chapter 3**. These are: Bear Lake,  
36 Bingham, Butte, Camas, Cassia, Custer, Gem, Gooding, Jerome, Lemhi, Lincoln, Madison,  
37 Owyhee and Payette counties in Idaho, and Beaverhead in Montana. For the purpose of this  
38 LUPA/EIS, all these counties were considered low-income populations. It is also possible  
39 that there are smaller communities in the remaining counties that constitute low-income  
40 populations, given the large geographic spread of each county.

1 The extent to which low-income populations are disproportionately impacted by high and  
2 adverse human health or environmental effects depends on the existence of high and  
3 adverse human health or environmental effects from management alternatives on any of the  
4 resources analyzed, and whether low-income populations are specifically vulnerable to these  
5 impacts or more likely to be exposed to such impacts.

6 Similar to the analysis for minority populations, the BLM and Forest Service reviewed the  
7 impacts of alternatives described in the respective sections of **Chapter 4**. None of the  
8 alternatives could be considered to have a high and adverse impact on the study area as a  
9 whole. The BLM and Forest Service also considered the possibility that adverse impacts  
10 could be concentrated in few counties in the study area and could then constitute a high and  
11 adverse impact in those counties. As previously explained, the BLM and Forest Service  
12 found no evidence that impacts would be sufficiently concentrated in a few counties to  
13 constitute high and adverse impacts. Based on available evidence, there would be no  
14 disproportionately high and adverse impacts on low income populations in the study area.

15 **Table 4-84** provides a summary of the findings of this analysis with respect to  
16 disproportionately high and adverse effects of the alternatives.

**Table 4-84**

Disproportionately high and adverse impacts on low-income populations	No Impact	No Impact	No Impact	No Impact	No Impact	No Impact

17  
18 **4.16 The Relationship Between Short-Term Uses of the Human Environment and**  
19 **Maintenance and Enhancement of Long-Term Productivity**

20 This section compares the potential temporary effects of the alternatives analyzed in this  
21 LUPA/EIS on the environment with the potential effects on its long-term productivity. The  
22 BLM and Forest Service must consider the degree to which the action alternatives would  
23 sacrifice a resource value that might benefit the environment in the long term for some  
24 temporary value to the proponent or the public.

25 Implementation of the action alternatives would restrict the use of the environment for  
26 mineral extraction, energy projects, livestock grazing, recreation, and lands and realty  
27 authorizations. These restrictions would protect soils, vegetation, water quality and supplies,  
28 air quality, and visual resources. These measures would also maintain the storage of any such

1 mineral or energy resources for potential future use beyond the timeframe of the restrictions  
2 outlined in the action alternatives.

3 For as long as the LUPA is valid, regional economies could experience decreased economic  
4 activity from these restrictions. This is because there would be decreases in income-  
5 generating livestock grazing and fewer employment opportunities related to construction  
6 and energy extraction. However, such economic activity could be restored to these lands  
7 through future changes in their management, with a subsequent NEPA analysis.

8 Implementation of the Alternative A would require fewer resource protections and would  
9 allow for greater productivity of the lands.

#### 10 **4.17 Irreversible and Irrecoverable Commitment of Resources**

11 NEPA Section 102(2)(C) and Section 1502.16 of the CEQ NEPA implementing regulations  
12 require that the discussion of environmental consequences include a description of "...any  
13 irreversible or irretrievable commitment of resources which would be involved in the  
14 proposal should it be implemented."

15 An irreversible commitment of a resource is one that cannot be reversed or cannot be  
16 renewed within a reasonable timeframe. Extinction of a species or disturbance to cultural  
17 resources would constitute irreversible impacts, as would extraction of sand, gravel, or oil or  
18 gas because these minerals cannot be renewed in the ground within a reasonable timeframe.

19 An irretrievable commitment of a resource occurs when the resource or its use is lost for a  
20 period. For example, a decision not to treat juniper encroachment into adjacent sagebrush  
21 habitat results in the irretrievable loss of forage production from the grassland community.  
22 This action is not irreversible because a treatment applied to the encroaching juniper could  
23 restore the forage production of the sagebrush habitat.

24 The decision to select one of the seven alternatives described in this Proposed LUPA/FEIS  
25 does not constitute an irreversible or irretrievable commitment of resources because the  
26 decision does not authorize implementation-level activities. Instead, decisions made under  
27 the selected alternative serve to guide future actions and subsequent site-specific decisions.  
28 Following the signing of the ROD for the LUPA, the BLM and Forest Service will develop  
29 and implement implementation plans (activity- or project-specific). Implementation  
30 decisions require appropriate project-specific planning and NEPA analysis and constitute  
31 BLM and Forest Service final approval authorizing on-the-ground activities to proceed.  
32 Overall, the action alternatives analyzed in this EIS are protective of resources over existing  
33 conditions and would not subject any of them to irreversible or irretrievable commitments.

#### 34 **4.18 Unavoidable Adverse Impacts**

35 NEPA Section 102(C) also mandates disclosure of "any adverse environmental effects which  
36 cannot be avoided should the proposal be implemented." These are impacts for which there  
37 are no mitigation measures or impacts that remain even after the implementation of  
38 mitigation measures.

1 Implementation of the LUPA along the theme of the action alternatives would not result in  
2 unavoidable adverse impacts on any resources. Conversely, proposed restrictions on some  
3 activities, such as OHV use, energy development, and livestock grazing intended to protect  
4 sensitive resources and resource values, would result in unavoidable adverse impacts on  
5 some users, operators, and permittees by limiting their ability to use BLM-administered and  
6 National Forest System lands and potentially increasing their operating costs.

7

Administrative Draft  
Cooperating Agency Review

This Page Intentionally Blank

Administrative Draft  
Cooperating Agency Review

**Issue: High-voltage Transmission and Major Pipeline ROWs and Corridors****Direction:**

1) Apply the recommended NPT allocation guidance for PHMA and GHMA of avoidance.

2) For sub-regions that have planned priority transmission lines that traverse their planning area (Gateway West, Boardman to Hemingway, and TransWest Express, including those portions of Gateway South that are co-located), apply the following language as a management action in their ADPP:

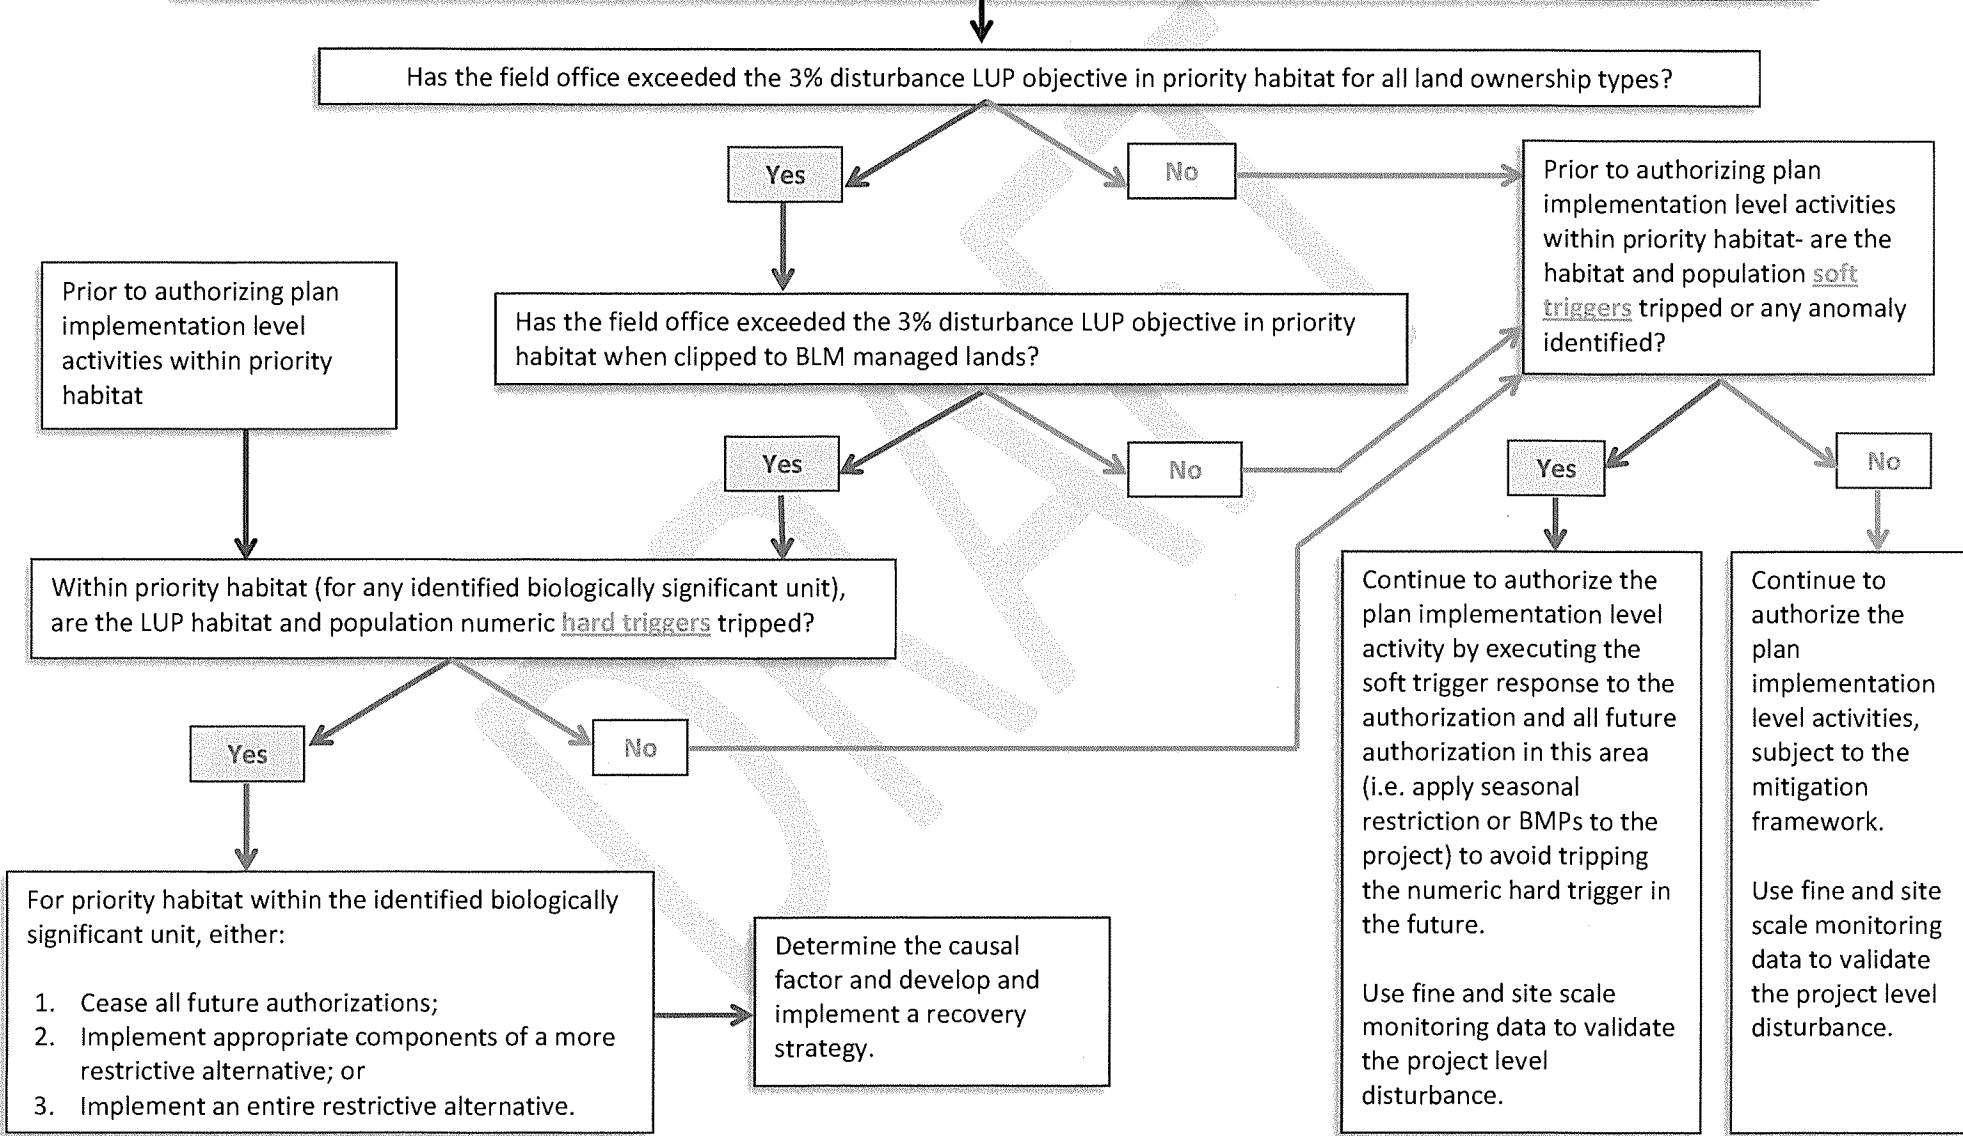

*“Priority Habitat Management Areas (PHMAs) and General Habitat Management Areas (GHMAs) are designated as avoidance areas for high voltage transmission line ROWs, except for the transmission projects specifically identified below. All authorizations in these areas, other than the excepted projects, must comply with the conservation measures outlined in this proposed plan, including the RDFs and avoidance criteria presented in [insert citation here] of this document. The BLM is currently processing an application for [Insert name of transmission project] and the NEPA review for this project is well underway. The BLM is analyzing GRSG mitigation measures through the project’s NEPA review process.”*

**Drop In Language for Direct/Indirect Impact Analysis**

The BLM is currently processing an application for [insert name of transmission project], a high-voltage transmission line, which includes alternatives through GRSG habitat. Conservation measures for GRSG are being addressed in the planning process for [insert name of transmission project] and therefore, the [insert name of transmission project] is excepted from the conservation measures identified in this plan. Because the certainty of [insert name of transmission project] is unknown, please see the cumulative effects analysis for a detailed discussion of potential impacts from [insert name of transmission project].

### Approach to Disturbance Threshold Objectives & the Relationship with Adaptive Management Triggers

Annually Report: 1. Disturbance in the PACs for each population (all lands); 2. Disturbance in the PACs for each population (clipped to BLM/FS lands); and 3. Disturbance in the PACs for each population (within the Field Office boundaries, clipped to BLM/FS lands)

**Subject:** Sage Grouse FEIS - Updated Impact Analysis Section for Lands and Realty  
**Attachments:** IDMT\_SG-FEIS\_CH4\_lands and realty\_20140929.docx

Hi Natalie,

I hope all is well with you!

As we inch closer to having a Final EIS for Sage Grouse, I am attaching for your review an updated impacts analysis section for lands and realty (Alternative G only). This revised section incorporates the input from the lands and realty ID team members, including the Forest Service as well as minor changes based on the updated proposed plan.

Please feel free to contact me anytime if you have questions or would like to discuss.

Thanks!

Peter

**4. ENVIRONMENTAL CONSEQUENCES**

**DO NOT DELETE THIS PAGE** from the MS Word file

THROW THIS PAGE AWAY & DELETE FROM PDF

# CHAPTER 4

## ENVIRONMENTAL CONSEQUENCES

---

### 4.1 LANDS AND REALTY

#### 4.1.1 Methods and Assumptions

##### *Indicators*

Indicators of impacts on lands and realty are as follows:

- Acres of BLM-administered and National Forest System surface ownership, which include federal surface with private minerals, in the planning area.
- Acres of BLM-administered and National Forest System surface ownership affected by ROW and Special Use Authorization (SUA) allocations (i.e., exclusion, avoidance, open).
- Acres of BLM-administered and National Forest System surface ownership affected by ROW and SUA restrictions (e.g., BMPs, RDFs, seasonal restrictions, buffers).
- Acres/miles of designated ROW corridors open to ROW and SUA development in the planning area.
- Number, acres, type, and density of surface-disturbing ROWs, SUAs, and leases in the planning area.
- Acres of land tenure adjustments (i.e., lands identified as suitable for disposal, acquisition, or exchange) in the planning area.

##### *Assumptions*

The analysis includes the following assumptions:

- Authorized ROWs, SUAs, permits and leases would continue to be managed subject to valid existing rights.
- Mitigation by burying power lines, collocation, or including design features (e.g., perch deterrents) reduces impacts on GRSG.

- The demand for both energy- and non-energy ROWs/SUAs is anticipated to remain steady or gradually increase over time.
- No utility-scale (20 MW) solar energy ROWs/SUAs are anticipated due to low solar energy potential.
- Activities proposed or approved for mineral exploration or development have potential implications for lands and realty decisions for associated ROWs/SUAs.
- Collocation does not eliminate the potential for new temporary or permanent surface disturbance.
- The BLM and Forest Service would continue to manage all previously withdrawn lands as withdrawn from entry, appropriation, or disposal under the public land laws. Withdrawals would be reviewed as needed and recommended for extensions, modifications, revocations, or terminations. All existing withdrawals initiated by other agencies would be continued unless the initiating agency, BLM, or the Forest Service requests that the withdrawal be extended, modified, revoked, or terminated.
- Any lands that become unencumbered by withdrawals or classifications will be managed according to the decisions made in this LUPA. If the LUPA has not identified management prescriptions for these lands, they will be managed the same as adjacent or comparable public lands within the decision area.
- Designated utility corridors have a higher probability for development because of their designation in existing land use plans.
- Upgrades to existing power lines will occur within existing designated corridors, unless an alternate route benefits GRSG.

#### 4.1.2 Nature and Type of Effects

BLM and Forest Service management of resources and uses affects the lands and realty program by increasing or decreasing the BLM and Forest Service lands and realty programs' ability to carry out land use authorization or land tenure/land ownership adjustment actions. Effects on the lands and realty program are typically the result of management that excludes or avoids ROWs or SUA in certain areas, requires stipulations on land use activities, or applies criteria for land tenure actions.

Forest Service land use plan prescriptions are similar to BLM exclusion and avoidance areas. Prescriptions can restrict or prohibit certain uses in a planning area. The Forest Service grants SUAs (granting ROWs, permits, easements, and leases), while the BLM grants ROWs on their respective agency lands. The Forest Service completes landownership adjustments (purchase, exchange, donation, and ROW acquisition), while the BLM conducts land tenure adjustments (withdrawals, disposals, and acquisitions)

Within a ROW exclusion area, the authorization of new ROWs is not allowed under any conditions. The Forest Service screening process for SUAs would reject applications in exclusion areas. A ROW avoidance area may be available for ROW location but requires special stipulations such as resource surveys and reports, construction and reclamation engineering, long-term monitoring, special design features, special siting requirements, timing limitations, regional mitigation, and rerouting. Such stipulations could restrict project location or delay the availability of an energy supply by delaying or restricting construction of pipelines, transmission lines, or renewable energy projects. Additionally, such stipulations could limit future access, delay or increase the cost of energy supplies, or delay or restrict communications service availability. As a result of such stipulations, alternative routes may need to be identified and selected to protect GRS habitat and there may be increased processing time and costs due to the potential need to relocate facilities or due to greater design, mitigation, and siting requirements.

Management that restricts ROW development in a certain area will eventually increase the concentration of ROW development in adjacent areas where restrictions are not present. Increased ROW density can limit new siting options in non-restricted areas, decrease service reliability to rural areas, increase conflict among facilities, and intensify impacts on other resources and uses.

Collocating infrastructure in existing ROWs, corridors, or existing disturbed areas reduces land-use conflicts and limits disturbance to the smallest footprint, and limits impacts to greater sage-grouse or their habitats. Collocation policies also clarify the preferred locations for utilities, simplifying processing on BLM-administered and National Forest System lands, and minimize the need for system-wide redundancy, particularly for electrical transmission line networks. However, collocating can limit options for infrastructure development and could reduce network redundancy and potentially affect service reliability in some areas.

Land tenure and landownership adjustments are intended, among other things, to maintain or improve the landownership pattern for the protection and management of resources, including management of GRS habitat. Land disposal, exchange, purchase, or sale can result in a more contiguous decision area, thus increasing the efficiency of BLM and Forest Service management.

Implementing management for the following resources would have negligible or no impact on lands and realty management and are not discussed in detail: travel and transportation management, recreation, range management, locatable minerals, non-energy leaseables, mineral split estate, fire and fuels management, habitat restoration and vegetation management, and ACECs.

#### **4.1.3 Alternative G**

There are no impacts common to all alternatives.

### **Impacts from Lands and Realty Management**

#### *Land Use Authorizations*

Unless a new ROW/SUA is proposed within an existing designated corridor (see figure xx), the BLM and Forest Service would avoid new ROW/SUA development on 4,618,800 acres in CMZs (89 percent of CMZs) and 2,977,400 acres (95 percent) in important habitat areas. Within CMZs and important habitat areas, there are a total of 54,900 acres of designated corridors. Any new development proposed outside corridors would be subject to RDFs and avoidance criteria (e.g. buffers, disturbance mitigation, and seasonal timing restrictions). The avoidance criteria and RDFs have the potential to increase project costs and could result in a greater proportion of new development occurring outside CMZs and important habitat areas. Concentrating new development in a smaller portion of the planning area could lead to higher density of ROW/SUA development in general and non-habitat areas with impacts consistent with those described in the Nature and Types of Effects.

Although existing designated corridors would be considered first for new ROW development in GRSG habitat areas, because corridors are typically located adjacent to existing infrastructure, power companies are reluctant to locate new infrastructure in those areas given redundancy concerns. New ROW development would be likely in corridors where those corridors provide a cost effective, direct route to demand centers that also avoid conflicts with populated areas. If an area outside GRSG core and important habitat areas provides this option, then a developer would likely pursue that route instead of placing within a corridor within core and important GRSG habitat.

In general habitat areas, 1,676,500 acres would be open for proposals for new ROW/SUA development, while 687,300 acres would be managed as avoidance areas. RDFs for new ROW/SUAs in general habitat could further deter development in those areas resulting in a greater likelihood for development in non-habitat areas. The decline in new ROW and SUA development applications in general habitat would be less than in CMZs and important habitat areas.

The overall proposed increase in ROW restrictions under Alternative G would affect the BLM and Forest Service's ability to accommodate the demand for new linear energy-related ROW development. Compared to Alternative A, energy suppliers Alternative G would have limited options to place new transmission lines without costly route adjustments or design modifications. These requirements may reduce region-wide per capita power availability and energy costs.

#### *Wind and Solar*

BLM and Forest Service management of CMZs as ROW/SUA exclusion areas for wind and solar would prevent the development of new utility-scale wind and solar energy generation facilities on 5,197,500 acres of GRSG habitat. Due to low solar energy potential in the planning area, there would be negligible to no

impacts on solar energy development. Because wind resources in the planning area are sufficient to support utility-scale wind energy development, excluding wind energy ROW/SUAs would prevent the BLM and Forest Service from accommodating future demand. Projects currently proposed would not be authorized. Excluding wind energy development in core and important habitat would distribute new development to general and non-habitat areas. Demand for new transmission lines, access roads, and related ancillary features to serve new wind generation projects on non-habitat or private lands could result in new ROW/SUA applications in core and important habitat. Where transmission lines, access roads, and related ancillary features would cross core and important habitat, management of those areas as ROW/SUA avoidance areas could deter or prevent wind energy development on non-habitat or private lands.

Management of CMZs as exclusion areas for hydropower development would result in localized impacts where development potential exists.

Excluding nuclear energy development in CMZs would prevent any future nuclear energy development in those areas (5,197,500 acres). However, because the demand for nuclear energy in Idaho is historically very low or non-existent in most areas, there would be no impacts from excluding such development in core and important habitat areas.

Although general habitat areas would be open for proposals for new wind, nuclear, or hydropower development, RDFs and avoidance criteria (e.g. buffers, disturbance mitigation, and seasonal timing restrictions) could affect wind development by limiting the number of turbines per project and the ability to access generation sites. Where wind development on private land or non-habitat requires new access roads, RDFs for roadways, including requirements to use existing roads, could limit access and subsequent energy development opportunities on private land or non-habitat areas.

#### *Other Land Use Authorizations*

Excluding landfills and commercial service airports in CMZs would shift any new development and associated disturbance to important, general, or non-habitat areas. However, because there is little to no demand for these uses within CMZs managing CMZs as exclusion for these uses is not anticipated to affect the BLM lands and realty program or hinder future refuse disposal or air services opportunities in the planning area. Landfill areas, even if transferred to non-federal ownership, would be considered a disturbance.

In all GRSG habitat areas, restrictions on temporary (less than 3 years) authorizations (e.g., apiaries and filming) would be subject to seasonal or timing restrictions and mitigation requirements regarding habitat loss. Seasonal or timing restrictions on temporary uses could prevent those uses during certain times of year (e.g., lekking season) and could prevent the BLM and the Forest Service from accommodating demand for those uses.

Impacts from management of water development ROW/SUAs would be minimal. Seasonal timing restrictions may temporarily limit the use of some water developments.

#### *Land Tenure*

Land tenure actions in CMZs and important habitat areas that create a more contiguous decision area would also increase land management efficiency, as described in the **Nature and Types of Effects**. Land exchanges or disposal to remove low-quality habitat from BLM-administered land and National Forest System land would also increase efficiency where those lands are isolated and difficult to manage.

#### ***Impacts from Salable Minerals Management***

Closing CMZs to new salable mineral authorizations would decrease the need for new ROWs/SUAs to serve those uses. It also would require source material for maintenance of existing gravel road ROWS to be obtained from existing sites in core, important, or existing or expanded sites in general habitat or non-habitat. If the amount of source material is insufficient to properly maintain the road, access via those roadways to valid existing ROW/SUAs (e.g., transmission lines) and leases (e.g., communication sites) could be impacted. Requiring existing sites to be subject to RDFs and avoidance criteria (e.g. buffers, disturbance mitigation, and seasonal timing restrictions) could impact the ability of the sites to remain open and the availability of source material.

#### ***Impacts from Leased Fluid Minerals Management***

Restrictions on surface occupancy for new fluid mineral development in CMZs and important habitat areas could decrease the potential for new fluid mineral development in those areas and subsequently the demand for associated ROWs/SUAs to serve those uses. Surface-disturbing activities could be shifted, additional protective measures could be required, and extraction delays could occur.

#### ***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and Mitigation***

Limits on anthropogenic disturbance in biologically significant unit (BSU) within CMZs and important habitat areas where a disturbance threshold objective has been exceeded or an adaptive management trigger has been tripped would decrease the potential for new ROW/SUAs in those areas. The requirement to provide compensatory mitigation projects to offset the residual impacts of infrastructure development in BSUs within core and important habitat could prevent new development where infrastructure could not be co-located or relocated outside core or important areas. If infrastructure authorized by land use authorizations is determined as a causal factor in the decline of GRSG populations in a BSU, incorporation of adaptive management could result in additional restrictions on ROW/SUA authorizations in that BSU, including

exclusion of future ROWs/SUAs until a positive GRSG trend is observed over a 3-year period.

**Acronyms**

BSU – biologically significant unit

RDF – required design feature

ROW – right-of-way

SUA – special use authorization

**Attachments:** IDMT\_SG-FEIS\_CH4\_CTTM\_20140929.docx

Hi Robin,

Based on the travel management ID team's work over the summer and more recent updates to the proposed plan, I am attaching for your review an updated impacts analysis section for travel management (Alternative G only). This revised section incorporates the input provided by the travel management ID team members during our webinars and subsequent team review/comment period. The GIS calculations are also up-to-date.

If you have questions or would like to discuss, please feel free to contact me.

Thanks!

Peter

# CHAPTER 4

## ENVIRONMENTAL CONSEQUENCES

---

### 4.1 COMPREHENSIVE TRAVEL AND TRANSPORTATION MANAGEMENT

#### 4.1.1 Methods and Assumptions

##### Indicators

Indicators of impacts on Greater Sage-Grouse are as follows:

- The acreages designated as open, limited, or closed to motorized travel
- The types and timing of transportation activities occurring on routes that could impact GRSG or its habitat

##### Assumptions

The analysis includes the following assumptions:

- The BLM recognizes roads, primitive roads, and trails as the three types of linear features that comprise the existing transportation system. These features are formally recognized based on an inventory of the planning area. Some routes may be designated for specific uses in a travel management plan. Other linear features used for transportation but not formally recognized are considered linear disturbances. These features are not part of the BLM transportation system (BLM 2006).
- Because roads accommodate year round passenger vehicles and volume of traffic is highest, roads by comparison translate into the greatest potential for impacts on GRSG and its habitat. Primitive roads are seasonally passable in many areas and compared to roads have a lower traffic volume, lower travel speeds, and fewer impacts on GRSG. Because trails are seasonally passible, have the lowest traffic volume and are typically only used by foot travelers, mountain cyclists, equestrians, and OHVs, impacts on GRSG are the fewest of the three feature types.

Commented [PG1]: Ensure these terms are defined in the glossary:

**Road:** A linear route declared a road by the owner, managed for use by low-clearance vehicles having four or more wheels, and maintained for regular and continuous use.

**Primitive Road:** A linear route managed for use by four-wheel drive or high clearance vehicles. Primitive roads do not normally meet any BLM road design standards.

**Trail:** A linear route managed for human-powered, stock, or off-highway vehicle forms of transportation or for historical or heritage values. Trails are not generally managed for use by four-wheel drive or high-clearance vehicles.

Commented [PG2]: IDT suggested moving this to the GRSG section

- Some primitive roads and trails in the northern portion of the planning area and higher elevations may not be used during GRSG lekking and wintering seasons because they are not passable, while those in the southern part of planning area and in lower elevation areas may receive higher use.
- The demand for general access to travel routes on BLM-administered and Forest Service-administered lands would remain steady or increase over the life of the LUPs.
- The BLM and Forest Service acknowledge that snow machines and mechanized access in the snow is expanding, but generally occurs in higher elevations areas where there is consistent snow pack and less GRSG habitat.
- Administration of updated agency travel management policy, rules, and planning and design guidelines is improving public land travel systems, making them more sustainable while decreasing potential impacts on resources.
- OHV use will continue to increase and with this increase the potential for resource and user conflict may increase.
- The designation of individual routes is an implementation level process and is not part of this planning process.
- Travel systems are dynamic and will be changed through subsequent implementation-level planning.
- Implementation of a travel management plan would include increased public education, signing, enforcement, and resource monitoring in regard to travel management.

**4.1.2 Nature and Type of Effects**

Impacts on travel and transportation management are those that restrict or enhance travel, such as managing areas as closed or limited to off highway motorized travel or restrict where new routes can be created and existing ones expanded.

Table 4-Table 4-xx, OHV Area Designations by Alternative, summarizes motorized travel designation by alternative.

Formatted: Font: Bold

**Table 4-xx  
OHV Area Designations by Alternative**

		Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F	Alternative G
BLM	Open	2,873,600	670,600	0	0	2,882,800	249,700	3,400
	Limited to existing routes	5,558,100	7,719,000	8,389,600	8,389,600	5,542,200	8,627,200	8,550,200
	Closed	885,100	879,900	879,900	905,700	881,700	892,800	893,000
Forest Service	Limited to designated routes	2,040,700	1,861,700	1,861,700	2,039,400	1,867,000	1,861,800	1,576,900

Source: **BLM 2013a; Forest Service 2013a**

Management actions that prohibit cross-country motorized travel would minimize the creation of new transportation linear disturbances, enabling BLM and Forest Service travel management actions to manage and improve access on linear features in the transportation system.

Restrictions on new route construction or expansion of existing routes would direct users elsewhere in the transportation network, potentially impacting those areas from the added activity. Additionally, management actions that restrict future route construction, including adaptive management strategies that prohibit future disturbance upon reaching a disturbance cap, would limit the ability of the transportation system to accommodate increased travel demands over time. Conflicts among route users could increase if the existing network becomes congested.

Implementing management for all other resources and uses would have negligible or no impact on comprehensive travel and transportation management; therefore they are not discussed in detail.

#### 4.1.3 Proposed Plan

Under all alternatives the BLM would defer travel management planning (i.e. route designations) to a separate process following the current LUPA process. As such, for each alternative, the BLM would maintain current management of areas closed to cross-country motorized travel and would manage varying acreages as limited to existing routes. The Forest Service has already undertaken a route designation process. As a result, motorized travel is limited to designated routes on National Forest System lands under all alternatives. ~~Table 4-Table 4-xx~~, OHV Area Designations by Alternative, summarizes the total areas open, limited, and closed to cross-country motorized travel by alternative.

Formatted: Font: Bold

#### **Impacts from Travel and Transportation Management**

Impacts from limiting motorized travel to existing routes on 99 percent (10,127,100 acres) of the planning area would be consistent with those described in the **Nature and Types of Effects**.

During subsequent travel management planning, the designation of individual routes would allow BLM to manage the types of travel on individual routes to avoid impacts on GRSG and its habitat. Restricting motorized travel on roads and primitive roads in lower elevations of the planning area would result in greater effects on travel opportunities because these routes are passable year-round and have higher traffic volumes.

Seasonal restrictions to minimize impacts on GRSG and its habitat would prevent road maintenance and could make certain roads impassable until the required maintenance could be performed.

***Impacts from Anthropogenic Disturbance Management, Adaptive Management, and Coordination***

If there is a future decline in GRSG or its habitat and the decline is attributable to travel management, the BLM would evaluate management alternatives that could result in more restrictions on travel and decrease travel opportunities.

Where re-routing new roads is required to avoid GRSG impacts (habitat and/or disturbance), those actions could result in longer roads with overall greater surface disturbance.

If the 3% disturbance cap within a BSU is hit, new surface disturbance within the BSU would be prohibited, thus preventing new road development. In these areas, the BLM and Forest Service would be unable to accommodate additional travel demand until the disturbance falls below the disturbance cap.

**Attachments:** brtegrazingdont.pdf

Drew, as before, I have concerns about continually mentioning the targeted grazing in fuels and fire management, we should leave it as a possible "biological treatment", in the suite of treatment types. I realize the political side, but, the attached research should be headed and included in the appendix, as I am sure it will be brought to light in the future. Other than that the only comment is to change ER&R to ES&R. Thanks, Glen

Hi Everyone,

I've attached the revised Chapter 4 Wildland Fire Management impacts section for your review. During our initial review period in early August, the only requested change was to make sure the reader could find a description of FRCC; I've added a note in the first Indicator referencing Section 3.7 where FRCC is discussed in detail. I have also made a few changes in light of revisions to the Proposed RMP. Thank you,

Drew

# Conditions favouring *Bromus tectorum* dominance of endangered sagebrush steppe ecosystems

Michael D. Reisner<sup>1\*†</sup>, James B. Grace<sup>2</sup>, David A. Pyke<sup>3</sup> and Paul S. Doescher<sup>4</sup>

<sup>1</sup>Department of Environmental Studies, Augustana College, Rock Island, IL 61201, USA; <sup>2</sup>US Geological Survey, National Wetlands Research Center, 700 Cajundome Blvd., Lafayette, LA 70506, USA; <sup>3</sup>US Geological Survey, Forest and Rangeland Ecosystem Science Center, 3200 SW Jefferson Way, Corvallis, OR 97331, USA; and <sup>4</sup>Department of Forest Ecosystems and Society, Oregon State University, Corvallis, OR 97331, USA

## Summary

1. Ecosystem invasibility is determined by combinations of environmental variables, invader attributes, disturbance regimes, competitive abilities of resident species and evolutionary history between residents and disturbance regimes. Understanding the relative importance of each factor is critical to limiting future invasions and restoring ecosystems.

2. We investigated factors potentially controlling *Bromus tectorum* invasions into *Artemisia tridentata* ssp. *wyomingensis* communities across 75 sites in the Great Basin. We measured soil texture, cattle grazing intensity, gaps among perennial plants and plant cover including *B. tectorum*, biological soil crusts (BSCs) and bare soil. Using *a priori* knowledge, we developed a multivariate hypothesis of the susceptibility of *Artemisia* ecosystems to *B. tectorum* invasion and used the model to assess the relative importance of the factors driving the magnitude of such invasions.

3. Model results imply that bunchgrass community structure, abundance and composition, along with BSC cover, play important roles in controlling *B. tectorum* dominance. Evidence suggests abundant bunchgrasses limit invasions by limiting the size and connectivity of gaps between vegetation, and BSCs appear to limit invasions within gaps. Results also suggest that cattle grazing reduces invasion resistance by decreasing bunchgrass abundance, shifting bunchgrass composition, and thereby increasing connectivity of gaps between perennial plants while trampling further reduces resistance by reducing BSC.

4. *Synthesis and applications.* Grazing exacerbates *Bromus tectorum* dominance in one of North America's most endangered ecosystems by adversely impacting key mechanisms mediating resistance to invasion. If the goal is to conserve and restore resistance of these systems, managers should consider maintaining or restoring: (i) high bunchgrass cover and structure characterized by spatially dispersed bunchgrasses and small gaps between them; (ii) a diverse assemblage of bunchgrass species to maximize competitive interactions with *B. tectorum* in time and space; and (iii) biological soil crusts to limit *B. tectorum* establishment. Passive restoration by reducing cumulative cattle grazing may be one of the most effective means of achieving these three goals.

**Key-words:** bare ground, biological soil crusts, cattle grazing, disturbance, diversity, invasion, plant gaps

## Introduction

Ecosystem invasibility is governed by a complex collection of biotic and abiotic factors including environmental conditions, disturbance regimes and responses of native

species to those regimes, as well as the biotic resistance provided by the resident community (Lonsdale 1999; Richardson & Pysek 2006). Biotic resistance is especially important in limiting the magnitude of invasive species after they have established (Levine, Adler & Yelenik 2004). Changes that increase resource availability are likely to increase susceptibility to invasion (Davis, Grime & Thompson 2000). Further, the introduction of an exotic herbivore with which resident species have no

†Present address: Environmental Studies Department, Augustana College, Rock Island, IL 61201, USA.

\*Correspondence author. E-mail: michaelreisner@augustana.edu

evolutionary history may exacerbate the magnitude of non-native plant invasions if it reduces the competitive abilities of native plants and increases resource availability (Parker, Burkepile & Hay 2006). Developing a predictive understanding of invasibility requires that we develop an understanding of how the various factors work together to limit invasion (Agrawal *et al.* 2007).

*Artemisia tridentata* big sagebrush ecosystems of the Intermountain West, USA, evolved with little herbivore pressure until the introduction of livestock (Mack & Thompson 1982). Within these ecosystems, lower elevation, more arid, *A. tridentata* ssp. *wyomingensis* (henceforth *Artemisia*) communities are the most common, but least resistant to invasion by exotic annual plants and least resilient to disturbance (Miller *et al.* 2011). Even in the absence of fire, these communities are especially vulnerable to invasions by *Bromus tectorum* L., and under some circumstances, *B. tectorum* can dominate the herbaceous understorey community (Miller *et al.* 2011). Previous studies have demonstrated the importance of several factors in the invasion process (soil texture, landscape orientation, competition-driven biotic resistance from native bunchgrasses and biological soil crust (BSC) communities (Table 1). Livestock grazing has been implicated in the spread and dominance of *B. tectorum* via several mechanisms (Mack & Thompson 1982; Table 1). Nonetheless, we have a poor understanding of how these factors work together and their relative importance in determining the magnitude of *B. tectorum* invasions (Miller *et al.* 2011).

Once *B. tectorum* sufficiently dominates the understorey and fills interspaces among plants, it creates a continuous, highly flammable fuel that significantly increases the risk of fire (Pyke 2011). Once a fire occurs, *B. tectorum* increases the frequency of fires. This change in fire regime

may lead to a 'catastrophic regime shifts' (Scheffer *et al.* 2009), whereby native shrub-steppe communities are transformed into annual grasslands dominated by *B. tectorum* and other invasives (Miller *et al.* 2011). For practical purposes, these shifts are irreversible because of the significant investments necessary to restore these systems (Pyke 2011).

Preventing such regime shifts will require a better understanding of the simultaneous interacting factors that determine the magnitude of *B. tectorum* invasion once it has established in pre-fire *Artemisia* communities (Miller *et al.* 2011). Managers would benefit from understanding the causal network of mechanisms by which these factors interact with each other and how they collectively influence *B. tectorum* dominance. They would also benefit from an early warning indicator that the cumulative resistance of the resident community has been compromised to the point that *B. tectorum* likely dominates the understorey and thereby potentially setting the stage for a regime shift with the next fire.

Using *a priori* knowledge, we developed a multivariate hypothesis of the invasibility of *Artemisia* ecosystems to *B. tectorum* invasion in the absence of fire based upon the findings of previous studies in this system. The model included abiotic (soil physical properties, landscape orientation), cattle grazing disturbance and biotic factors (resident community abundance, composition and structure), predicted to be important determinants of *B. tectorum* dominance (Fig. 1, Table 1). Our analyses addressed the following questions: (i) What combination of abiotic and biotic conditions limit the magnitude of *B. tectorum* dominance? (ii) Can shifts in community structure, measured by the size and connectivity of gaps between native plants, serve as an indicator of susceptibility to *B. tectorum*

**Table 1.** Components of hypothesis represented by initial metamodel (Fig. 1)

Path	Hypothesized mechanism
1	(–) Cattle herbivory decreases <i>Bromus tectorum</i> abundance (Hempy-Mayer & Pyke 2009). (+) Cattle increase abundance by dispersing seeds and increasing propagule pressure (Schiffman 1997)
2	Cattle trampling decreases biological soil crusts cover and increases safe sites for <i>B. tectorum</i> establishment (Ponzetti, McCune & Pyke 2007)
3	Cattle herbivory decreases bunchgrass abundance (Briske & Richards 1995)
4	Cattle herbivory alters bunchgrass community composition by favouring more grazing-resistant species (Briske & Richards 1995)
5	Higher heat loads and spring insolation increase <i>B. tectorum</i> abundance (Stewart & Hull 1949; Chambers <i>et al.</i> 2007)
6	Lower heat loads increase bunchgrass productivity (Davies, Bates & Miller 2007)
7	Deeper, coarser-textured soils increase <i>B. tectorum</i> abundance (Stewart & Hull 1949)
8	Changes in bunchgrass composition influence community structure because species have different life forms (Grime 1977; James <i>et al.</i> 2008)
9	Changes in bunchgrass composition influence invasibility because species have different competitive abilities (Goldberg & Barton 1992) and patterns of resource use (James <i>et al.</i> 2008)
10	Bunchgrass abundance is inversely related to the size of and connectivity between gaps in perennial vegetation (Herrick <i>et al.</i> 2005)
11	Native bunchgrass abundance decreases <i>B. tectorum</i> abundance by reducing resource availability (Chambers <i>et al.</i> 2007)
12	Safe sites increase <i>B. tectorum</i> establishment rates (Fowler 1988).
13	Sagebrush abundance may increase <i>B. tectorum</i> abundance via facilitation (Griffith 2010) or decrease abundance via competition (Reichenberger & Pyke 1990).
14	Increases in the size of and connectivity between gaps in perennial vegetation increase <i>B. tectorum</i> abundance by increasing general resource availability (James <i>et al.</i> 2008; Okin <i>et al.</i> 2009)

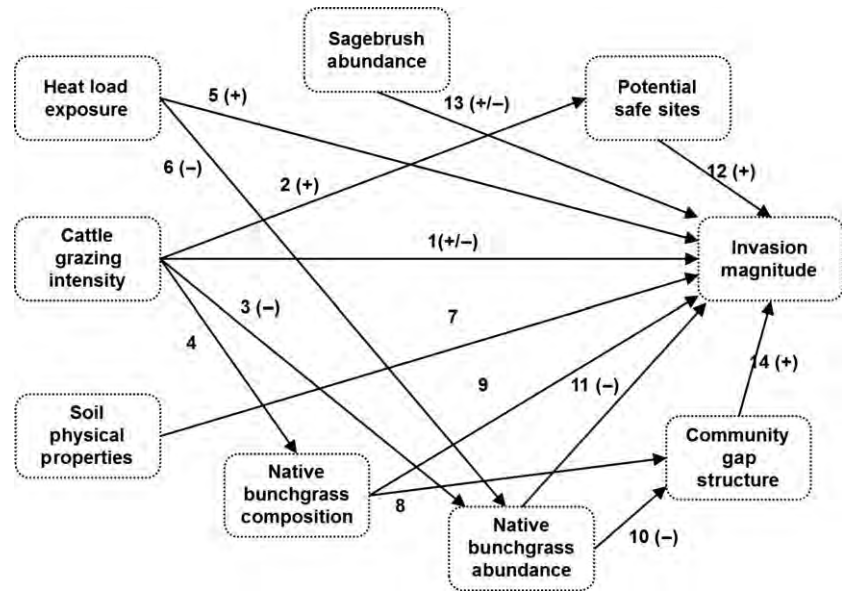

Fig. 1. Conceptual *a priori* multivariate model of *Artemisia* ecosystem susceptibility to *Bromus tectorum* dominance in the absence of fire. Dotted-line boxes represent conceptual variables hypothesized to influence invasibility. Components of the overall hypothesis are described in Table 1.

dominance and thereby vulnerability to a regime shift with the next fire?

We used structural equation modelling (SEM) to evaluate a multivariate hypothesis across 75 sites already invaded by *B. tectorum*. SEM provides a means of representing complex hypotheses about causal networks and testing for model data consistency (Grace 2006). It represents an advance over classical regression approaches (e.g. multiple regression) when used with observational data (Grace, Youngblood & Scheiner 2009). The advance provided by SEM comes partially from incorporating the associations among predictors into the overall hypothesis rather than to simply ignore or control for them. This is accomplished by extending the univariate model ( $y = a + \beta x + \epsilon$ ) to allow  $y$ s to depend on other  $y$ s and thereby represent networks of relationships in SEMs ( $y = a + \beta x + \gamma y + \epsilon$ ).

Because of this capability, SEM models can be used to specify hypotheses about mediating pathways and address questions, such as Can an association between *A* and *C* be explained by the factor *B*? This is achieved by evaluating a model such as  $A \rightarrow B \rightarrow C$  and determining whether or not  $r_{AC} = r_{AB}r_{BC}$ . By assuming (and justifying based on prior information) that if *A* were manipulated, *B* could show a response, and similarly, if *B* were manipulated, *C* could show a response, then a test of the conditional independence of *A* and *C* in our example ( $A \perp C | B$ ) could permit a result leading us to reject that possibility (*A* not independent of *C* when conditioned on *B*). SEMs thus build on causal assumptions to yield testable implications that can be evaluated with data. Estimated parameters obtained for a selected model then represent a set of predictions for further testing. The ultimate test of an SEM model is its ability to correctly predict future samples. For individual applications, the plausibility of causal assumptions (e.g. previous demonstrations that varying *A* can lead to response in *B* or known mechanisms whereby *A* can influence *B*) is often sufficient for reasonable inferences to be made.

Our results suggest that bunchgrass community structure, abundance and composition, and BSCs all play critical roles in limiting the magnitude of *B. tectorum* dominance. Cattle grazing may exacerbate the magnitude of invasion by reducing biotic resistance. Model evaluations imply that cattle grazing can reduce bunchgrass cover and shift bunchgrass community composition towards grazing-tolerant species and thereby increase the size and connectivity of gaps among perennial vegetation exacerbating invasion. Cattle trampling may also exacerbate invasion by reducing BSC cover. Ultimately, increases in the size and connectivity of gaps among native perennial vegetation may provide managers with an early warning indicator of increased susceptibility to *B. tectorum* dominance of *Artemisia* communities and thereby increased vulnerability to regime shifts in one of North America's most widespread but endangered ecosystems.

## Materials and methods

### STUDY AREA AND SAMPLING DESIGN

The study examined 75 *Artemisia* sites scattered across 4700 km<sup>2</sup> (roughly the size of state of Rhode Island) with elevations between 1265 and 1580 m across five *Artemisia*-dominated plant associations of the northern Great Basin floristic province of Oregon, USA. Natural Resource Conservation Service (NRCS) Ecological Site Descriptions and digital soil maps (<http://websoil-survey.nrcs.usda.gov>) were used to ensure coverage of spatial variation in water stress driven by soil texture. Plant communities varied in dominant perennial tussock grasses and included the following ecological sites (ES): (i) loamy 254–308 mm precipitation zone (PZ) with *Pseudoroegneria spicata* and *Achnatherum thurberianum*; (ii) sandy loam 203–254 mm PZ with *Hesperostipa comata* and *P. spicata*; (iii) clayey 254–308 mm PZ with *A. thurberianum* and *Poa secunda*; and (iv and v) north slopes and south slopes 152–254 mm PZ with *P. spicata* and *A. thurberianum* co-dominating north and south slopes, respectively.

Each ES was delineated into three landscape substrata using 10-m resolution US Geological Survey Digital Elevation Models (DEM) to ensure variation in heat loads and water stress associated with changes in landscape orientation: (i) northerly aspects (0–90°, 270–360°), (ii) southerly aspects (90–270°) or (iii) flat. Study plots were located at different distances from the nearest livestock watering locations to capture variation in cattle grazing intensity. Random points were selected and field verified to ensure that plots were located: (i) every 200–400 m, starting at 100 m and extending to >3200 m from the nearest water; (ii) in as many soil–landscape strata combinations as possible; and (iii) >200 m from the nearest road to minimize related effects. To reduce potential confounding effects of time since fire, all sites burned since 1930 were excluded using a fire perimeter data base (<http://sagemap.wr.usgs.gov> accessed 17/3/2008).

### SAMPLING

Thirty of the 0.39-ha study plots were sampled in 2008 and another 45 in 2009. Six 25-m transects were established in each plot using a spoke design, and herbaceous, shrub and BSC cover measured using line–point intercept (Herrick *et al.* 2005). All sampling occurred between 10 May and 15 July in both years to capture peak herbaceous biomass. Aspect and slope of each plot were calculated from DEM using Arc-GIS 13.0 and, with latitude, used to calculate potential heat loads for each plot (McCune 2007).

Potential variation in water stress was inferred by the following measurements: (i) soil texture at 0–15 cm soil depth; (ii) potential effective rooting depth, which was measured by digging a soil pit until bedrock, a restrictive layer (clay accumulation layer) or 2 m depth was reached; and (iii) amount and timing of precipitation for each study site derived from PRISM at 2-km<sup>2</sup> cell resolution (Daly *et al.* 2008). Sampling-year precipitation for all study plots was estimated for three seasons: 1 August to 31 October (fall), 1 November to 31 March (winter) and 1 April to 31 July (spring–summer).

Cattle grazing intensity was quantified by four measurements: field-verified distance from the nearest water; dung frequency and dung density from 12, 1 × 25 m belt transects; and bunchgrass (tussock) basal area. Basal circumference (*C*) of 30 randomly selected bunchgrasses was measured in each plot and used to calculate bunchgrass basal area (cm<sup>2</sup>) using the following formula: Area =  $\pi (C/2\pi)^2$ .

Bare soil cover was calculated using line–point intercept data to represent exposed soil surface not covered by vegetation, visible BSC, dead vegetation, litter or rocks (Herrick *et al.* 2005). Soil surface aggregate stability was assessed in interspace microsites at 18 random sampling points along transects using soil from the upper 0–4 mm (Herrick *et al.* 2005). Two indicators of soil erosion resistance were calculated: mean soil stability and proportion of samples rated as extremely stable (Beever, Huso & Pyke 2006).

We assessed the structure of the native perennial community by quantifying the size of and connectivity of gaps between such vegetation using the basal gap intercept method (Herrick *et al.* 2005). We calculated mean gap length and the proportion of transects covered by large gaps (>200 cm in length).

### MULTIVARIATE ANALYSIS

Species cover, distance from nearest water, dung density, bunchgrass basal area, heat loads, soil depth, precipitation, gap size

and herbaceous biomass data were log-transformed to improve distributional properties, correlations with ordination axes and variation explained by ordinations (McCune & Grace 2002). Other variables were not transformed.

Non-metric multidimensional scaling (NMS) ordination was used to relate patterns in community composition to environmental gradients (PC-Ord™; McCune & Grace 2002). Joint plots and Pierson's correlations were used to describe relationships between environmental gradients and the strongest patterns of community composition.

We used nonparametric multiplicative regression (NPMR) in HyperNiche™ to quantify the relationship between species' cover and environmental gradients (McCune 2009). Predictors were scores of the three ordination axes. These scores represented an integrated measure of complex environmental gradients associated with dominant patterns of herbaceous community composition. Response variables were the cover of each species using a local mean estimator and Gaussian kernel function. To control for potential interactions between axes, response curves were generated using partial models and focal variables (McCune 2009). A final NPMR model was run using the three axes' scores as predictors. Final model fit was assessed with a cross-validated *R*<sup>2</sup> (McCune 2009).

Hierarchical agglomerative cluster analysis was used to identify groups of sites differing in community composition (McCune & Grace 2002). Multivariate differences in community composition between identified groups were tested using multiresponse permutation procedures (MRPP) ( $\alpha = 0.05$ ). Identified groups were overlaid onto ordinations to accentuate relationships between groups and environmental gradients. Multivariate differences in relativized environmental variables between groups were tested with MRPP. Differences in individual environmental variables between groups were assessed with ANOVA ( $\alpha = 0.10$ ), and Bonferroni-adjusted 90% confidence intervals were used to quantify differences between groups.

### STRUCTURAL EQUATION MODELLING

In our study, an initial conceptual model was used as a SEM meta-model, representing a family of possible models (Fig. 1, Table 1). Our modelling process considered the available observed variables to identify 'indicator variables' (the observed variables that will serve as proxies for conceptual variables in the meta-SEM) using procedures described in Grace *et al.* (2012). Except for 'Potential Safe Sites', all model constructs were represented using single indicator variables. *Bromus tectorum* cover was selected as the indicator to measure 'Invasion Magnitude'. Bunchgrass and sagebrush cover were selected to measure their abundances. The three NMS ordination axes of bunchgrass species' cover data were used to develop an indicator of 'Bunchgrass Community Composition'. Distance from nearest water was selected as the indicator to measure cumulative 'Cattle Grazing Intensity'. Heat load was selected to measure 'Heat load Exposure', and percent sand content at 0–15 soil depth was selected to measure 'Soil Physical Properties'. The proportion of transects covered by large gaps (>200 cm in length) was selected as the measure of 'Community Gap Structure'. Two indicators were selected to represent 'Potential Safe Sites' – BSC and cover of bare soil.

All SEM analyses were conducted using AMOS 18.0 software (SPSS 2010). Maximum likelihood procedures were used for model evaluation and parameter estimation. Model fit was

evaluated by sequentially evaluating likelihood ratios by using the single-degree-of-freedom chi-squared goodness-of-fit statistic. Modification indices were used to evaluate the need to include links or error correlations not in the original model. This process produced a final inferential model. The stability of the final model was evaluated by introducing other available indicators to determine whether they represented additional contributing information. For example, our initial indicator for cattle grazing intensity was 'distance from nearest water'. The three alternative potential indicators (cow pie frequency, cow pie density and bunchgrass basal area) for this construct did not improve model fit or amount of variation in cheatgrass dominance explained and were no longer included.

## Results

### PATTERNS OF INVASIBILITY – CONVENTIONAL MULTIVARIATE RESULTS

Nearly 92% of variation in community composition was explained by the final ordination (Fig. 2). Axis 1 was the dominant axis explaining 60.9% of variation in composition data. Axis 1 was a strong gradient of decreasing cattle grazing disturbance and heat stress (Fig. 2): dung density ( $r = -0.35$ ); dung frequency ( $r = -0.36$ ); distance from water ( $r = 0.41$ ); deep-rooted bunchgrass basal area ( $r = 0.71$ ); and heat loads ( $r = -0.44$ ). In addition, BSC cover, soil aggregate stability and proportion of soil aggregate stability values rated as highly stable increased along Axis 1 (Fig. 2). The size of and connectivity between gaps and amount of bare soil decreased strongly

**Fig. 2.** Ordination of plots in community composition space. Non-metric multidimensional scaling ordination with final stress of 9.92; final instability of <0.01; Monte Carlo test  $P$ -value < 0.05. Vectors show the strength and direction of correlations between environmental variables and axes. Only variables with significant  $R^2$  (>0.20) are shown. Different plot symbols show groups derived from cluster analysis that differ in composition and environmental factors. State 1A and 1B communities have understoreys dominated by native bunchgrasses; phase-at-risk communities are co-dominated by bunchgrasses and non-natives, and State 2 and State 3 communities are dominated by non-native species.

along Axes 1 and 2 (Fig. 2) (see Table S1, Supporting Information).

Axes 2 and 3 represented weaker relationships explaining 19.3% and 11.6% of the variation, respectively. Axis 2 showed a strong gradient of decreasing sand, increasing clay and increasing fall and winter precipitation (Fig. 2). Axis 3 demonstrated a weaker gradient of decreasing cattle grazing associated with decreasing dung density and frequency and increasing deep-rooted bunchgrass basal area (see Table S1, Supporting Information).

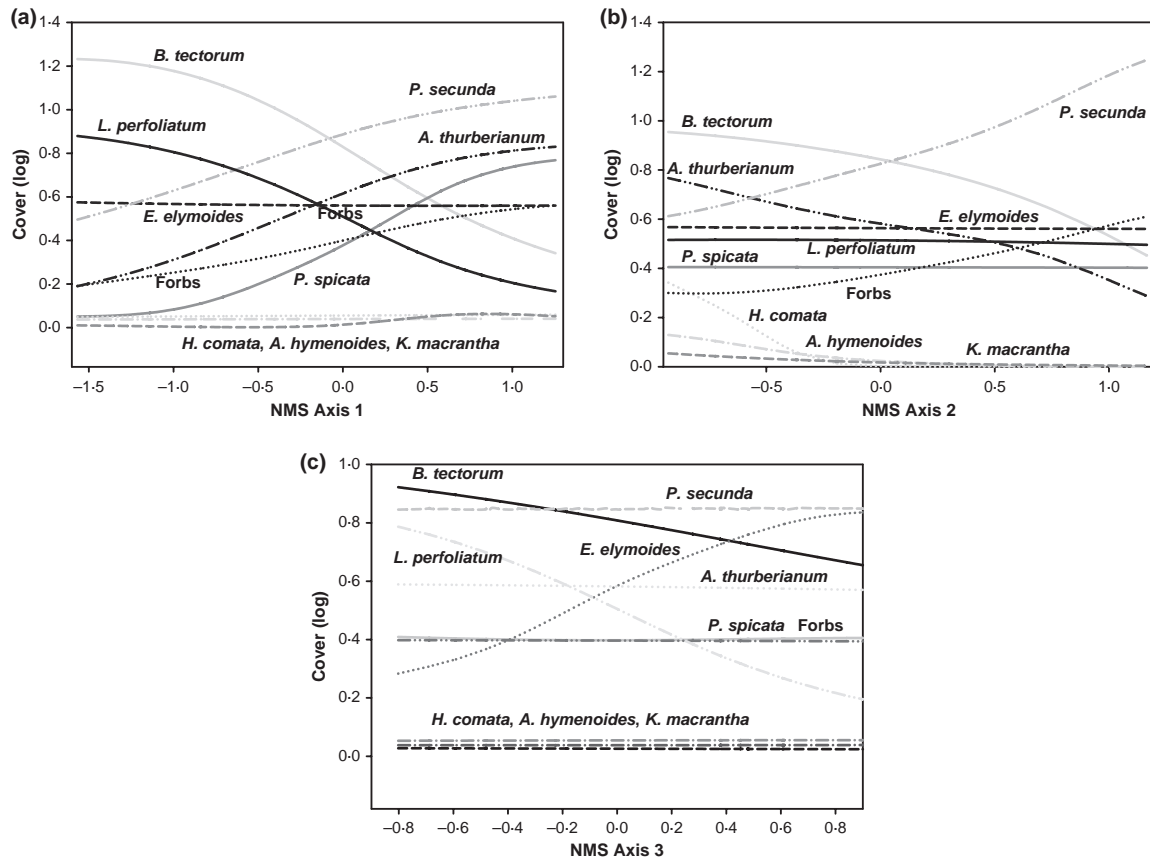

Nonparametric multiplicative regression model sensitivities indicate that Axis 1 was the best predictor of non-native species. The strength of the relationship between cover of native species and these three axes varied considerably (Fig. 3; see Table S2, Supporting Information). *P. spicata*, *A. thurberianum*, *P. secunda* and forbs had strong positive relationships with Axis 1, *P. secunda* and forbs had strong positive relationships with Axis 2, and *Elymus elymoides* had a strong positive relationship with Axis 3 (Fig. 3).

Cluster analysis identified five distinct groups of communities with 0% of the information remaining (MRPP using species data:  $A = 0.33$ ,  $P < 0.01$ ; Fig. 4; See Tables S3 and S4, Supporting Information). Several species were uniquely associated with one or more groups (Fig. 4; See Table S3, Supporting Information). Combined heat loads, soil physical properties, BSC cover, bare soil cover, soil stability, community gap structure and cattle grazing intensity differed significantly among groups (MRPP using environmental data:  $A = 0.59$ ,  $P < 0.0001$ ; Fig. 5; See Table S4, Supporting Information).

State 1 consisted of two groups (1A and 1B) of communities with an intact herbaceous understorey dominated by native bunchgrasses and forbs (Fig. 4). Thirty-one percentage of study plots were in one of these groups. State 1 also contained phase-at-risk communities (communities at risk of crossing a biological threshold to being dominated by *B. tectorum*; 25% of study plots) with an understorey co-dominated by native species and *B. tectorum*. States 2 (23% of study plots) and 3 (21% of study plots) consisted of communities that have crossed a biological threshold and had understoreys dominated by *B. tectorum* and the non-native annual forb, *Lepidium perfoliatum*.

Communities in Groups 1A and 1B had the lowest levels of cattle grazing combined with the smallest and least connected gaps between perennial vegetation (Fig. 5). Group 1B communities had higher heat loads and finer-textured soils compared to those of Group 1A. Communities comprising phase-at-risk communities were characterized by intermediate levels of cattle grazing, heat loads, water stress and size of and connectivity between gaps (Fig. 5).

State 2 communities were characterized by intermediate to high levels of cattle grazing and intermediate levels of heat loads and water stress. State 3 communities had the highest levels of cattle grazing and bare soil cover, largest and most connected gaps and lowest soil aggregate stability (Fig. 5).

**Fig. 3.** Nonparametric multiplicative regression response curves showing relationship between species cover and gradients represented by non-metric multidimensional scaling ordination axes. Axis 1 is a gradient of decreasing cattle grazing intensity and heat load exposure (a), Axis 2 is a gradient of decreasing water stress (b), and Axis 3 is a gradient of decreasing cattle intensity (c).

#### STRUCTURAL EQUATION MODELLING RESULTS

The final SEM model ( $\chi^2 = 18.88$ ;  $P = 0.54$ ; 20 d.f.) showed very close fit between model and data. A number of the initially hypothesized relationships (Table 1) were not supported by data. Sagebrush abundance did not help explain invasion magnitude, either directly or indirectly. As a result, that variable was removed from the final model. Heat load exposure, cattle grazing intensity and native bunchgrass cover were indirect predictors of invasion magnitude in the final model (Fig. 6). Unanticipated in the initial model was dependence of safe sites on heat loads and sand, and dependence of bunchgrass composition on sand content. The final model explained 72% of the variation in the magnitude of invasions among sites.

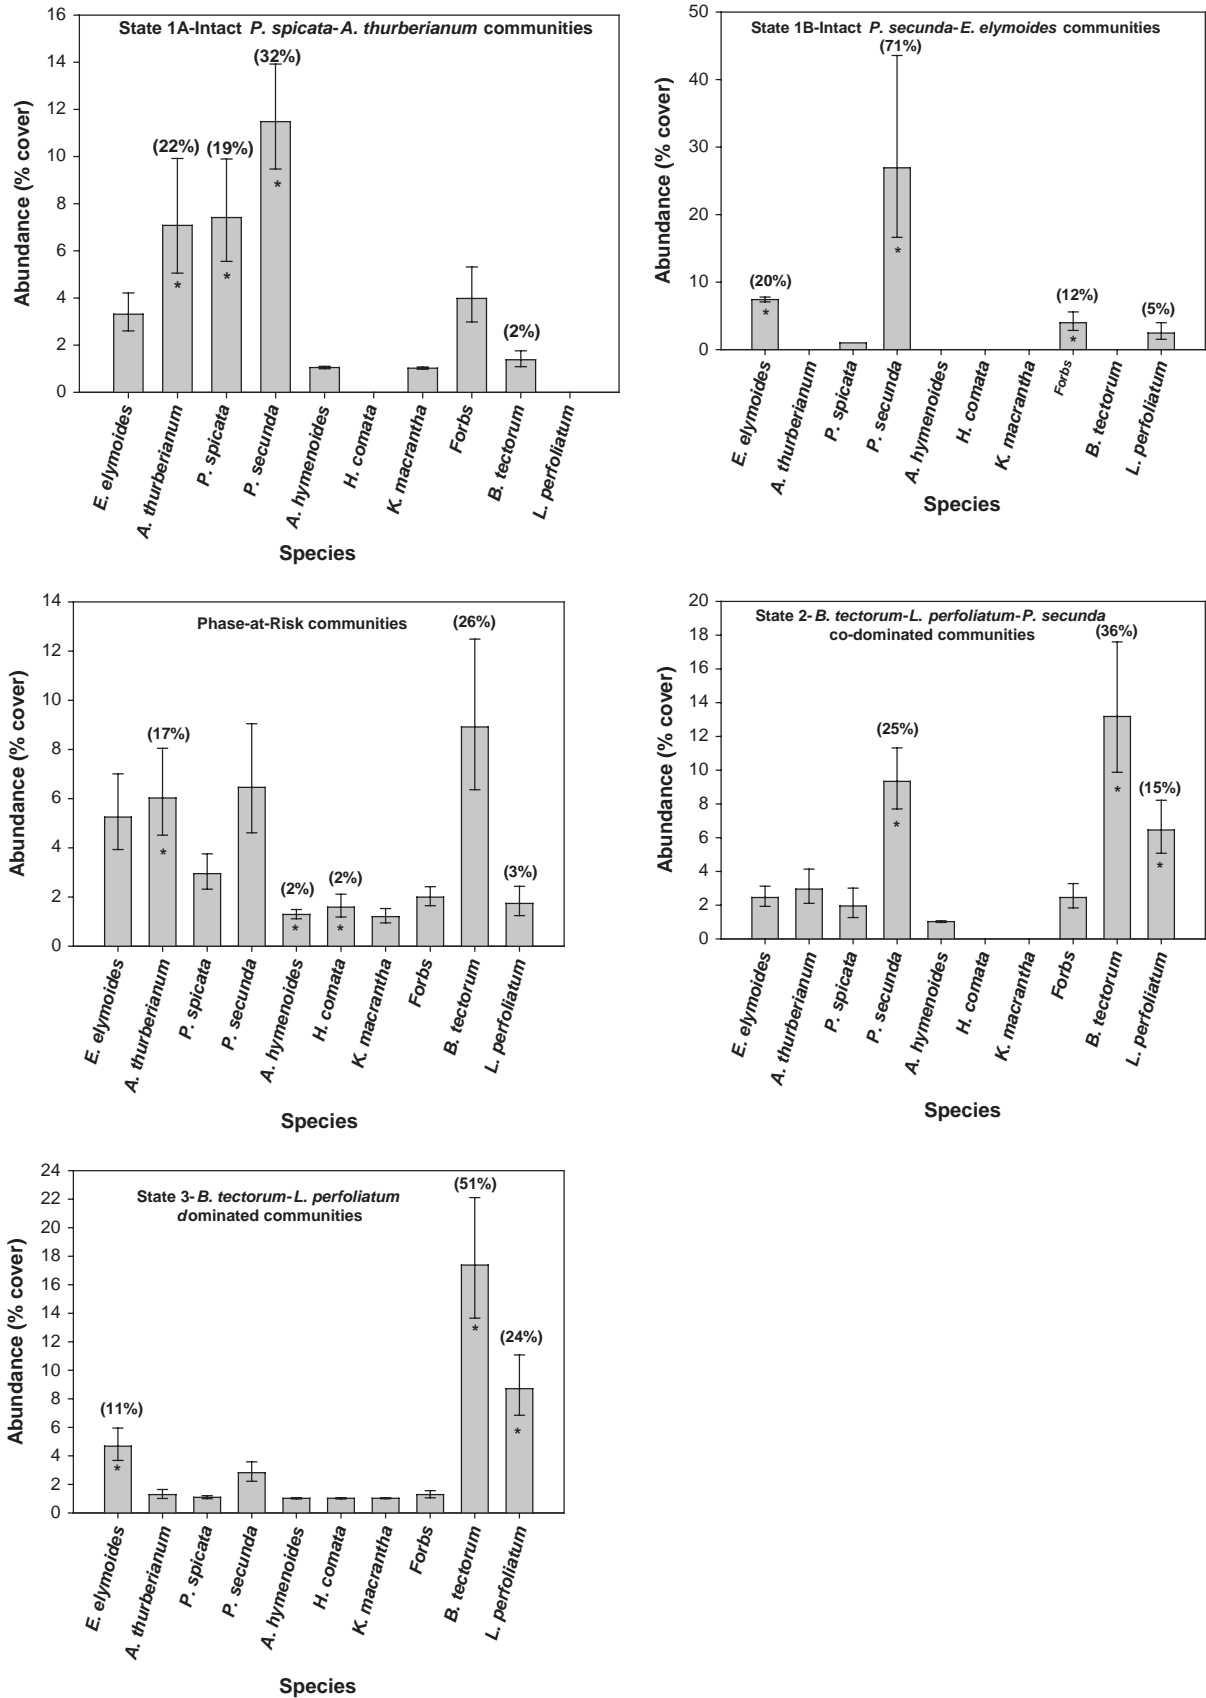

Concerning strengths of linkages in the final model, changes in community gap structure, that is, increases in the size of and connectivity between gaps among native plants, were predictive of higher levels of *B. tectorum* cover ( $r = 0.83$ ). Native bunchgrass cover and composition were not direct predictors of *B. tectorum* cover, rather they were indirect predictors through their relationship to gaps. Gaps characterized by bare soil had a strong positive association with *B. tectorum* cover ( $r = 0.38$ ), whereas gaps characterized by BSC cover had

a strong negative association with *B. tectorum* cover ( $r = -0.26$ ).

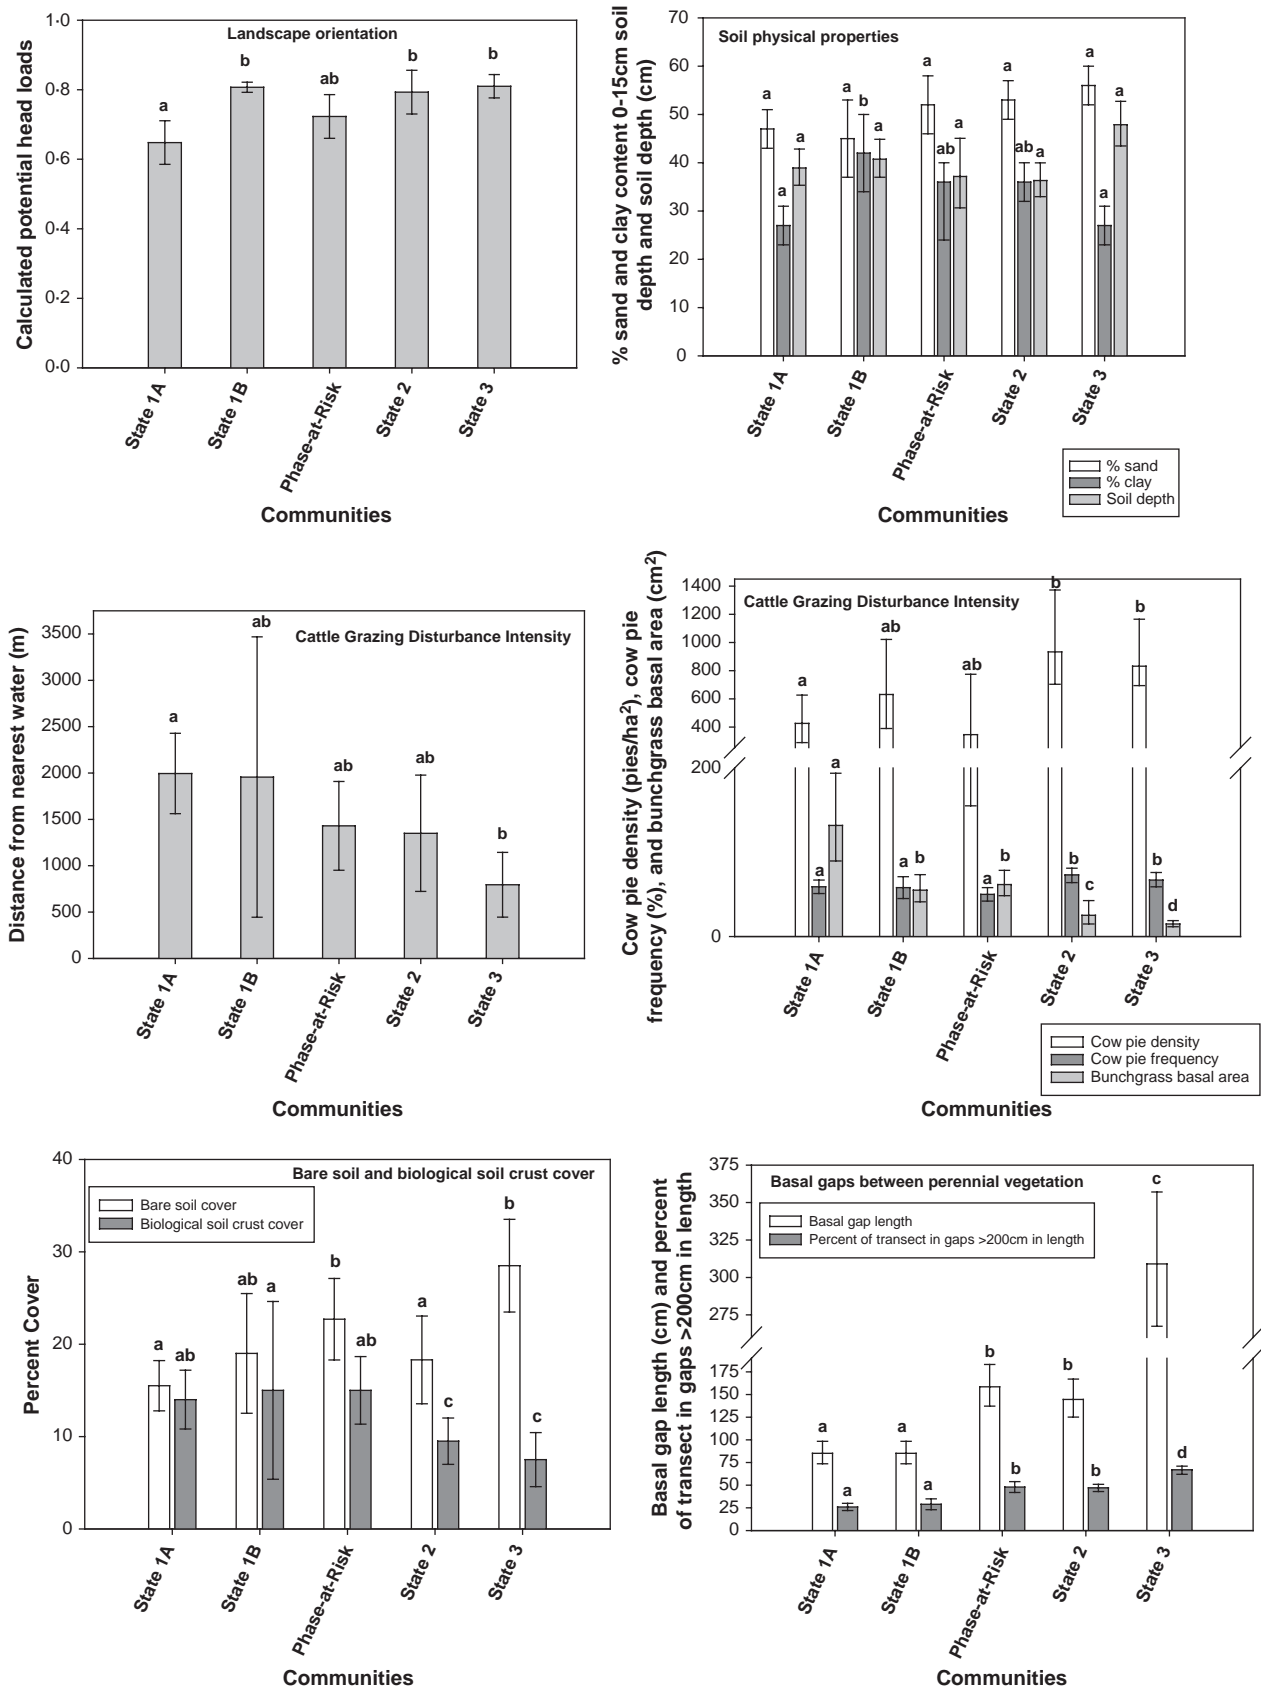

Cattle grazing intensity was positively associated with *B. tectorum* cover through three independent pathways. Because distance from water is inversely related to cattle grazing levels, positive path coefficients indicate a negative relationship between cattle grazing and the response variable in the model (Fig. 6). Thus, model results imply that pathways from cattle grazing to *B. tectorum* cover propagate through (i) negative influences on bunchgrass abundance (0.34), (ii) negative influences on BSC abundance (0.29) and (iii) impacts on bunchgrass community composition (Axis 2) (0.22). There was no evidence that cattle grazing directly decreased or increased *B. tectorum* cover independent of these stated routes.

High levels of heat load exposure were associated with lower levels of bunchgrass ( $-0.46$ ) and BSC ( $-0.36$ ) abundance. Coarser-textured soils were more likely to have higher levels of *B. tectorum*, regardless of the other factors (i.e. a direct linkage of 0.48). Coarser-textured soils also had an indirect path through effects on bare soil cover and bunchgrass community composition (Axis 3) that increased *B. tectorum* cover.

By adding up the path strengths, it is possible to compute what is referred to as 'total effects' of predictors on

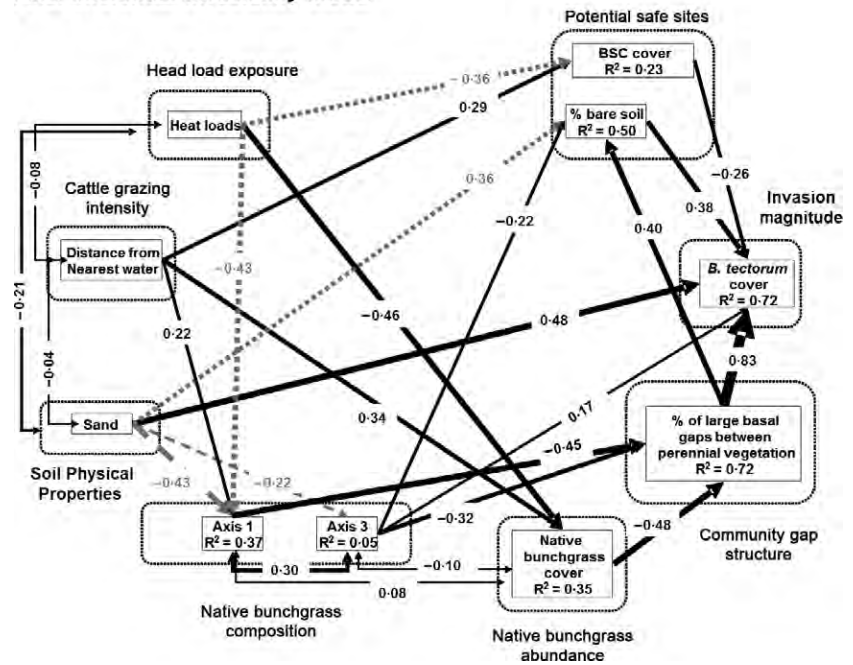

**Fig. 4.** Community composition of five groups derived from cluster analysis. \*Denotes species with highest three indicator values for the group from indicator species analysis. Reported values are back-transformed means, and error bars are 90% Bonferroni-adjusted confidence intervals. (%) is the relative abundance of the species calculated as the proportion of total cover of the group.

**Fig. 5.** Differences in heat loads, soil physical properties, biological soil crusts, bare soil cover, soil stability, community gap structure and cattle grazing intensity of five groups identified by cluster analysis. Error bars represent Bonferroni-adjusted 90% confidence intervals. Different lower-case letters above bars indicate significant differences between groups ( $\alpha = 0.10$ ).

Final Inferential Invasibility Model

**Fig. 6.** Final inferential model of *Artemisia* ecosystem invasibility. Single-headed arrows represent significant linkages ( $\alpha = 0.05$ ). Double-headed arrows indicate significant correlations between variables and their residuals. The magnitudes of standardized path coefficients are represented by line thicknesses. Dotted grey lines are unanticipated significant paths. Because distance from water is inversely related to cattle grazing intensity (i.e. grazing intensity increases with decreasing distance), positive path coefficients and correlations between grazing intensity and variables indicate an inverse relationship (i.e. increasing cattle grazing intensity decreases bunchgrass abundance).  $R^2$  values depict the proportion of variation of endogenous variables explained by the model. The dotted boxes depict conceptual variables of the meta-structural equation modelling (Fig. 1).

downstream responses. Computed total effects of predictor variables on *B. tectorum* in order of importance were as follows: (i) community gap structure (0.68), (ii) soil physical properties (0.42), (iii) safe sites (bare soil cover, 0.38), (iv) heat load exposure (0.37), bunchgrass community composition (NMS#1, -0.31), (v) safe sites (BSC cover, -0.26), (vi) cattle grazing disturbance (-0.26), (vii) bunchgrass abundance (-0.24) and (viii) bunchgrass community composition (NMS#3, 0.04).

**Discussion**

By combining SEM with an observational approach, we were able to gain important new insight into the relative importance of the numerous factors determining the magnitude of *B. tectorum* invasions of *Artemisia* ecosystems and gain valuable insight into potential underlying mechanisms. Our results provide strong support for some *a priori* hypothesized mechanisms (i.e. cattle trampling reduces bunchgrass and BSC abundance) and no support for others (i.e. cattle reduce invasions by grazing *B. tectorum*). Our SEM findings should help prioritize future experiments to test our inferences regarding underlying mechanisms and more landscape-scale observational studies to further evaluate and refine the model and construct predictive models (Grace 2006).

In this study, model results support the idea that a complex causal network of simultaneously operating factors and mechanisms are driving invasion of *B. tectorum* in *Artemisia* ecosystems. Based upon the SEM results, shifts in community structure, as measured by the size of and connectivity of gaps between native plants, exert a strong positive effect on the magnitude of *B. tectorum* invasion. This finding is consistent with growing evidence

in semi-arid and arid ecosystems showing that increases in gap connectivity (Busso & Bonvissuto 2009; Okin *et al.* 2009) and changes in how species abundance is distributed in a community (James *et al.* 2008) are associated with a loss of ecosystem resistance to invasion (Scheffer *et al.* 2009). We define resistance as the collective ability of the resident sagebrush community to limit *B. tectorum* dominance in the face of invasion (Chambers *et al.* 2007). Increases in the connectivity of these gaps were associated with a dramatic increase in the magnitude of such invasions (Okin *et al.* 2009). This loss of resistance to invasion probably increases the magnitude of *B. tectorum* dominance after subsequent disturbances and may set the stage for a regime shift to *B. tectorum*-dominated grasslands with the next fire (Scheffer *et al.* 2009).

Our research suggests that two environmental factors influence the inherent resistance of *Artemisia* ecosystems to *B. tectorum* invasion. Communities located on coarser-textured soils or characterized by higher potential heat loads (Stewart & Hull 1949) were inherently least resistant to *B. tectorum* invasion. These communities are characterized by higher levels of water stress and lower productivity. The inherent structure of these communities that consists of larger and more connected gaps among perennial vegetation and higher amounts of bare soil may make them vulnerable to other disturbances that increase the size of gaps.

Consistent with other studies, biotic resistance from resident bunchgrass and BSC communities played pivotal roles and appears to limit the magnitude of *B. tectorum* invasion (Richardson & Pysek 2006). Water availability is the primary controlling factor of seedling establishment in these ecosystems (Schupp 1995). Several studies have found a strong negative association between BSC community integrity and *B. tectorum* abundance (Ponzetti, McCune & Pyke

2007; Ponzetti & McCune 2008) and showed that BSCs reduce *B. tectorum* germination and establishment rates by impeding root penetration and growth (Serpe *et al.* 2008). Our findings suggest that BSC communities are especially important in limiting the magnitude of *B. tectorum* invasions in gaps between perennial vegetation by minimizing potential safe sites for establishment.

Consistent with other studies, we found that bunchgrasses reduced the magnitude of *B. tectorum* invasions most likely by reducing water and nutrient availability (Chambers *et al.* 2007; Prev y *et al.* 2010). Our findings provide important insight into this mechanism. Nearly all the biotic resistance effect was indirect through a strong direct effect of bunchgrass abundance and composition on community structure. By limiting the size and connectivity of gaps, bunchgrasses likely minimize resources available to *B. tectorum* spatially. Further, three species, *P. spicata*, *A. thurberianum* and *P. secunda*, appear to be especially important determinants of such resistance. *P. spicata* and *A. thurberianum* are dominant deep-rooted bunchgrasses with most active growth in later spring, whereas *P. secunda* is a shallow-rooted bunchgrass that is active in late winter and early spring. This combination of differing structure and phenology reflects their differing abilities to acquire resources at different soil depths (James *et al.* 2008) and seasons and thereby provide continuous interaction with *B. tectorum* and collectively limit available resources temporally and at different soil depths.

By controlling for several potentially confounding factors (Knick *et al.* 2011), we gained important insights into the role of cattle grazing as a determinant of ecosystem resistance to *B. tectorum* invasion. We found no evidence that cattle grazing, even at the high intensities 100 m from the nearest water development, reduced *B. tectorum* cover. To the contrary, we found strong evidence that increasing cattle grazing intensity indirectly promotes an increase in the magnitude of *B. tectorum* dominance. Cattle herbivory was found to be associated with reduced native bunchgrass abundance, shifts in bunchgrass composition to only the most grazing-tolerant species and aggregated bunchgrasses beneath protective sagebrush canopies (Reisner 2010). These collective cattle-induced changes thus appear to ripple through the community by increasing the size and connectivity of gaps between perennial vegetation. As gaps get bigger and more connected, both live and dead (litter) herbaceous soil cover decreases and the amount of bare soil increases. Cattle trampling reduced resistance within these larger gaps by reducing BSC cover.

Changes in community structure and how species' abundance is distributed in the community may increase general resource availability (James *et al.* 2008). As cattle grazing increased, *P. spicata*, *A. thurberianum* and *P. secunda* cover decreased, *E. elymoides* cover did not change, and *B. tectorum* cover increased. These shifts parallel the relative differences in grazing avoidance and tolerance mechanisms among these species. Cattle grazing introduced a novel disturbance regime into this system

where most bunchgrasses are highly sensitive to herbivory (Mack & Thompson 1982). To the contrary, *B. tectorum* exhibits a collection of grazing avoidance and tolerance attributes that makes it extremely tolerant of even highly intensive grazing (Vallentine & Stevens 1994; Hempy-Mayer & Pyke 2009). Because of its attributes (Chambers *et al.* 2007), *B. tectorum* is well positioned to take maximum advantage of this window of invasion opportunity by exploiting larger and more connected gaps.

If the goal is to conserve and restore resistance of these systems to invasion, managers should consider focusing their efforts on maximizing the pre-emption of resources provided by BSC and bunchgrasses. We suggest three priorities: first, maintain and/or restore high overall bunchgrass cover and community structure characterized by spatially dispersed bunchgrasses in interspaces and small gaps between such individuals to maximize the capture of resources; second, maintain and/or restore a diverse assemblage of bunchgrass species with different spatial and temporal patterns of resource use to maximize capture of resources at different soil depths and times; third, maintain and/or restore a BSC community to limit safe sites for *B. tectorum* establishment within gaps.

Our findings suggest that multiple factors (bunchgrass cover, BSC cover, cattle grazing, etc.) may influence the susceptibility of these ecosystems to *B. tectorum* invasion. Importantly, many of these influences are mediated by the size and connectivity of gaps, as well as the conditions of gaps. Thus, gaps in perennial vegetation may serve as an important early warning indicator of when cattle grazing or other stressors are compromising resistance of these systems to *B. tectorum* invasion. Our findings raise serious concerns regarding proposals to use cattle grazing to control *B. tectorum* in these systems where remnant bunchgrass communities persist (Vallentine & Stevens 1994). In contrast, our findings support recent guidance for passively restoring resistance of these systems by reducing grazing levels (Pyke 2011). Future research should focus on gathering information concerning the size of and connectivity of such gaps across a range of ES consistent with maintaining resistance. These data could be used to develop indicators for adaptive management frameworks to conserve and restore these endangered systems.

**Subject:** IDMT Sage-grouse Minerals Revised Proposed Plan Analysis  
**Attachments:** IDMT\_SG-FEIS\_CH4\_minerals\_20141010.docx

Hi all,

Attached is a revised version of the minerals proposed plan analysis based on the updated proposed plan and Karen's comments on the previous version from July 31<sup>st</sup>. Outstanding questions and gaps are highlighted. Due to the pending additional GIS request for the total acreages of various types of mineral estate, percentages of the decision areas have not been filled in. I have also included some responses to comments in comment bubbles explaining why certain changes have not been made. I would be happy to discuss any of this further at your convenience.

Take care,

**Katie Patterson, JD**

# CHAPTER 4

## ENVIRONMENTAL CONSEQUENCES

---

### 4.1 FLUID LEASABLE MINERALS (OIL AND GAS AND GEOTHERMAL)

#### 4.1.1 Oil and Gas

##### *Methods and Assumptions*

The analysis of impacts on fluid minerals from this LUPA focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on oil and gas development would result from closing an area with oil and gas development potential to fluid mineral leasing. An indirect impact would result from managing an area as ROW exclusion, which would restrict access and change the economic feasibility of developing a site. Additional actions or conditions that might cause direct or indirect impacts on oil and gas leasing and development are described under *Indicators*, below.

##### *Indicators*

Indicators of impacts on oil and gas leasing and development are as follows:

- Acres of unleased land with moderate oil and gas potential identified as closed to fluid mineral exploration and development
- Acres of unleased land with low or no oil and gas potential identified as closed to fluid mineral exploration and development
- Acres of unleased land with moderate oil and gas potential subject to no surface occupancy (NSO) stipulations
- Acres of unleased land with low or no oil and gas potential subject to NSO stipulations
- Acres of unleased land with moderate oil and gas potential subject to controlled surface use (CSU)/timing limitation (TL) stipulations

- ~~Acres of unleased land with low or no oil and gas potential subject to CSU/TL stipulations. [Note to BLM: GIS data received still has CSU and TL stipulations separated. Please advise on whether these are to be combined. If so, please provide updated calculations with the acreages combined.]~~

Formatted: Highlight

- ~~Acres of unleased land with moderate oil and gas potential subject to TLs~~

Formatted: Indent: Left: -0.25"

- ~~Acres of unleased land with low or no oil and gas potential subject to TLs [Note to BLM: Waiting for final decision on whether CSUs and TLs should be combined or kept separate based on what the GIS shows as far as whether they are applied more together or separately. Current GIS calculations show acres with both CSUs and TLs as only CSUs since these are considered to be more restrictive.]~~
- Acres subject to restrictions on geophysical exploration in GRSG habitat
- Acres managed as ROW avoidance areas
- Acres managed as ROW exclusion areas

~~Where information is available, consideration is given to oil and gas development potential on lands closed to leasing. For example, an indicator of an impact on oil and gas is if there were substantial reductions in federal leasing and development of oil and gas resources in high potential areas.~~

#### Assumptions

The analysis includes the following assumptions:

- Under all alternatives, reclamation bonds would be required, pursuant to 43 CFR 3104 and 36 CFR 228.109(a), in an amount sufficient to ensure full restoration of lands to the condition in which they were found. In addition, BLM approval of Applications for Permit to Drill would continue to be required prior to commencement of drilling under all alternatives in accordance with 43 CFR 3162.
- The lands in the Curlew Grassland area, as described in the Pocatello RMP, that are administratively unavailable for leasing are included in the total number of acres closed to leasing under Alternative A.
- Management actions proposed in this LUPA would apply to oil and gas activity where the BLM and Forest Service manage the surface over federal fluid mineral estate as well as where federal fluid mineral estate lies beneath private or state surface (split estate).
- Information on existing fluid mineral allocations is not available for 38,600 acres of federal fluid mineral estate in the Butte Field Office in Montana (less than one percent of the federal fluid mineral decision

area). These acres are assumed to be open to oil and gas leasing under Alternative A.

- ~~If an area is leased, it could be developed. For planning purposes, it is assumed that development is expected would occur~~ as described in **Appendix XX**, Reasonably Foreseeable Development Scenario, and **Section 3.12**, Mineral Resources, ~~are assumed to continue for the life of the analysis~~. Interest in oil and gas in Idaho is expected to remain sporadic. As the demand for energy increases, so will demand for extracting energy resources in areas with potential. ~~Technological advancements, such as directional drilling, could lead to changes in levels of fluid mineral development potential throughout the planning area as additional resources become more easily accessible.~~ **[Note to BLM: According to the notes from the general indicators/assumptions call, the last two sentences of this bullet may need to be deleted from here and incorporated into the RFD instead. Please provide final direction.]**

#### **Nature and Type of Effects**

The following analysis describes the nature and type of impacts that could affect oil and gas in the Idaho and southwestern Montana planning area. Details on how the occurrence of each impact would vary by alternative are described under the various subheadings.

Closing areas within GRSG habitat to fluid mineral leasing would directly impact the oil and gas program by removing the potential for mineral resources in that area to be accessed and extracted. Oil and gas operations may move to nearby private lands if similar geologic conditions exist, thereby reducing the number of operations on federal mineral estate. Closing lands to leasing would also result in a loss of royalties to the federal, state, and county governments from oil and gas development.

Management actions that prohibit or restrict surface occupancy or disturbance (such as TLs, NSO stipulations, CSU stipulations, and limitations on the total amount of surface disturbance in areas) overlying federal oil and gas resources ~~would could~~ also directly impact the development of those resources. They would do this by restricting the ability of ~~lessees to explore for and develop~~ mineral resources ~~to be developed or extracted~~. Surface-disturbing activities could be ~~shifted/relocated~~, additional protective measures could be required, and extraction delays could occur.

In areas where NSO stipulations are applied, federal fluid minerals could be leased, but the leaseholder/operator would have to use off-site methods, such as directional drilling, to access the mineral resource. The area where directional drilling can be effectively used is limited, meaning some minerals may be inaccessible in areas where an NSO stipulation covers a large area or where no leasing is allowed on surrounding lands. Additionally, because it is not

economically practical to use directional drilling for wildcat wells, an NSO stipulation ~~would may~~ preclude drilling of those wells.

Application of CSU stipulations allows some use and occupancy of the surface. While less restrictive than an NSO, a CSU stipulation allows the BLM to require special operational constraints, to shift the surface-disturbing activity associated with fluid mineral leasing more than the standard 656 feet (200 meters), or to require additional protective measures (e.g., restrictions on noise levels) to protect GRSG. For example, a CSU stipulation might create a buffer around leks within which surface disturbance is not allowed. While not prohibiting surface-disturbing activities, a CSU stipulation can influence the location and level of operations within the subject area.

TL stipulations may be necessary to protect GRSG from impacts of development during critical seasons or times of day. These stipulations are necessary if impacts cannot be mitigated within the standard 60-day suspension of operation period afforded by regulation. Areas where TL stipulations are applied would be temporarily closed to fluid mineral exploration and development, surface-disturbing activities, and intensive human activity during identified time frames, based on seasons or GRSG breeding times. While some operations would be allowed at all times (e.g., vehicle travel and maintenance), construction, drilling, completions, and other operations considered to be intensive would not be allowed during the restricted time frame. Most activities, however, can be initiated and completed outside of the restricted dates specified in the TL stipulation.

Applying appropriate required design features (RDFs) (see **Appendix C**) and conservation measures outlined in **Chapter 2 (Table 2-20)**, to ~~leases-post-lease activities as conditions of approval c~~would directly impact oil and gas operations. These RDFs and conservation measures include such standards as noise restrictions, height limitations on structures, design requirements, water development standards, remote monitoring requirements, and reclamation standards. Additional site-specific planning, such as master development plans and unitization, and reclamation bonding requirements may also be ~~included~~required. Applying ~~all of~~ these requirements ~~would may~~ impact oil and gas operations by restricting the extraction of oil and gas resources. Such restrictions may result in higher costs of development or development delays resulting from additional pre-construction planning requirements.~~To avoid these restrictions, operators may move to nearby state or private minerals, thereby decreasing the number of oil and gas operations on federal mineral estate.~~

Placing limits on geophysical exploration could ~~reduce hinder~~ the collection of geologic data concerning availability of data on oil and gas resources on federal mineral estate. TLs on geophysical exploration could lead to ~~extraction equipment scheduling~~ delays.

Management actions creating off-lease ROW exclusion or avoidance areas could indirectly increase the cost of oil and gas extraction by limiting the available means for transporting oil and gas from the lease to processing facilities and markets. For example, a new natural gas pipeline could not be built in a ROW exclusion area. The pipeline may need to take a less direct route to its destination to avoid the exclusion area, or another mode of conveyance of the resource may be required. Oil and gas operations may move to nearby private lands where transport is easier, thereby delaying development on federal mineral estate or reducing the number of operations on federal mineral estate. Impacts would be mitigated where exceptions were allowed for collocating new ROWs within existing ROWs to satisfy valid existing rights.

Commented [KP1 ]: Did not delete this sentence because operators may choose to reprioritize their development plans based on any number of factors. This would not necessarily mean that the restrictions had removed all reasonable opportunity to develop the lease.

Implementing management for the following resources would have negligible or no impact on oil and gas; therefore they are not discussed in detail: travel and transportation management, recreation, range management, solid minerals, fire and fuels management, habitat restoration and vegetation management, and special designations.

#### **Alternative G**

##### *Impacts from Lands and Realty Management*

Under Alternative G, ~~XX~~ 8,283,500 acres (~~XX~~ percent) of BLM- and Forest Service-administered surface in the decision area (including all ~~CMZs-PHMA~~s and ~~IMZs-IHMA~~s) would be managed as ROW avoidance areas. However, because all acres in ~~CMZs and IMZs-PHMA~~s and ~~IHMA~~s would be ~~either closed to leasing or open~~ subject to NSO stipulations on oil and gas leases, no oil and gas activities on future leases within these areas would require new ~~rights-of-way~~ ROWs. Therefore, oil and gas activity in ~~PHMA~~s and ~~IHMA~~s ~~CMZs and IMZs~~ would not be impacted by lands and realty management under Alternative G.

Application of RDFs, BMPs, buffers, and seasonal timing restrictions to ROW development would also limit construction of new ROWs for oil and gas development in all GRSG habitat. If these limitations made it comparably uneconomic to develop a ROW for oil and gas development, development of federal oil and gas resources in the planning area could decrease.

##### *Impacts from Fluid Minerals Management*

Under Alternative G, ~~XX~~ 676,100 acres, or ~~XX~~ percent of the federal oil and gas estate decision area, ~~including all areas with no or low potential in CMZs,~~ would be closed to oil and gas leasing. These closures would include 61,600 acres with moderate potential (XX percent of the moderate potential acres in the decision area). ~~Acres with moderate potential closed under this alternative would be the same as those under Alternative A.~~

Formatted: Highlight

Another ~~XX~~ 9,670,400 acres, or ~~XX~~ percent of the federal oil and gas estate decision area, including all areas in ~~PHMA~~s and ~~IHMA~~s ~~IMZs~~ and ~~all areas with moderate potential in CMZs~~, would be open to oil and gas leasing subject to NSO stipulations. These stipulations would apply to ~~XX~~ 325,900 acres with

moderate potential (XX percent of the moderate potential acres in the decision area).

**Table 4-XX**  
**Oil and Gas Leasing Categories in the Decision Area, Alternatives A and G**

Oil and Gas Potential	Closed to Leasing (acres)	Open Subject to NSO Stipulations (acres)	Open Subject to CSU/TL Stipulations (acres)	Open Subject to Standard Terms and Conditions (acres)
<b>Alternative A</b>				
Moderate	XX133,900	XX143,900	XX	XX60,900
Leased	XX	XX	XX	XX
Unleased	XX	XX	XX	XX
Low	XX3,095,900	XX899,100	XX	XX7,211,400
Leased	XX	XX	XX	XX
Unleased	XX	XX	XX	XX
<b>Total</b>	<b>XX3,229,800</b>	<b>XX1,043,000</b>	<b>XX</b>	<b>XX7,272,300</b>
Leased	XX	XX	XX	XX
Unleased	XX	XX	XX	XX
<b>Alternative G</b>				
Moderate	61,600	325,900	XX	30
Low	614,500	9,344,500	XX	27,700
<b>Total</b>	<b>676,100</b>	<b>9,670,400</b>	<b>XX</b>	<b>27,730</b>

Source: BLM 2014x

[Note to BLM: Please instruct, based on how the GIS data look, whether we should remove the "Leased" fields from these tables since there are no longer any existing oil and gas leases in GRSG habitat. Are there still leases in the decision area?]

Alternative G would close 54 percent fewer acres with moderate oil and gas potential compared with Alternative A. However, management under Alternative G, would apply NSO stipulations to twice as many acres with moderate oil and gas potential as management under Alternative A. Because more total federal oil and gas estate with moderate development potential would be closed or subject to NSO stipulations under Alternative G, impacts would increase compared with Alternative A as described under **Nature and Type of Effects**.

A similar pattern exists for acres with low oil and gas potential. Management under Alternative G would close 80 percent fewer acres with low oil and gas potential compared with Alternative A but would apply NSO stipulations to ten times as many acres as Alternative A. Because more total federal oil and gas estate with low development potential would be closed or subject to NSO stipulations under Alternative G, impacts would increase compared with Alternative A. However, as described under **Nature and Type of Effects**,

~~closing areas with low oil and gas potential would not have as much of an impact as closing areas with moderate oil and gas potential.~~

Formatted: Not Highlight

~~[Note to BLM: A comparison of unleased moderate potential acres subject to NSO stipulations compared with Alternative A will be added when GIS data are received. Similar analysis will be added for unleased low potential acres, noting the lower impact on these acres because they are less likely to be developed anyway.][Note to BLM: Discussion with BLM on July 25, 2014 concluded that there are no longer any existing leases in GRSG habitat because the two leases on the Bear Lake Plateau had been canceled and closed, respectively. However, comments from Karen Porter on August 4, 2014 indicate that there are still two existing leases within GRSG habitat. Please clarify which is accurate.]~~

~~XX acres of federal oil and gas estate with moderate potential within General Management Zones/GMHAs would be subject to CSU and/or TL stipulations. These stipulations would restrict oil and gas development and could reduce overall development of federal oil and gas resources as described under Nature and Type of Effects.~~

Under Alternative G, it is reasonably foreseeable for planning purposes that XX new oil and gas exploratory wells would be developed on federal fluid mineral estate in the decision area in the next 20 years. This represents a XX percent decrease in projected wells on federal mineral estate compared to Alternative A. ~~[Note to BLM: Waiting for projected number of wells from Karen]~~

~~[Note to BLM: The section on impacts from anthropogenic disturbance has been removed since the AD 3 and AD 4 criteria are applied only to waive the NSO stipulation rather than used to limit development independent of fluid mineral management. The anthropogenic disturbance criteria are no longer referenced anywhere in the fluid mineral management actions under Alternative G. Because PHMAs and IHMAs are NSO, it does not seem like the anthropogenic disturbance criteria would ever need to apply to fluid mineral development. Please confirm that the anthropogenic disturbance criteria do not need to be discussed here.]~~

**4.1.2 Geothermal**

[To be completed by another EMPSi specialist]

**4.2 LOCATABLE MINERALS**

**4.2.1 Methods and Assumptions**

The analysis of impacts on locatable minerals from this LUPA focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on locatable minerals would result from withdrawing an area from locatable mineral entry. An indirect impact would result by removing a road, which would change the economic feasibility of developing a site. Additional actions or conditions that might cause direct or indirect impacts on locatable minerals are described below.

**Indicators**

Indicators of impacts on locatable minerals are as follows:

- Acres withdrawn from locatable mineral entry
- Acres recommended for withdrawal from locatable mineral entry
- Acres over which restrictions, such as RDFs and conservation measures, are placed on locatable mineral development activities to prevent unnecessary or undue degradation of GRS habitat as the law allows

Where information is available, consideration is given to the potential for locatable minerals on lands withdrawn from locatable mineral entry. For example, an indicator of an impact on locatable minerals is if there were substantial withdrawals from locatable mineral entry in high potential areas.

**Assumptions**

The analysis includes the following assumptions:

- Management actions proposed in this LUPA would apply to locatable mineral activity where the BLM and Forest Service manage the surface over federal locatable mineral estate as well as where federal locatable mineral estate lies beneath private or state surface (split estate).
- Information on existing locatable mineral withdrawals is not available for 33,000 acres of federal locatable mineral estate in the Butte Field Office in Montana (less than one percent of the federal locatable mineral decision area). These acres are assumed to be open to locatable mineral entry under Alternative A.
- Areas recommended for withdrawal would be withdrawn.
- Locatable mineral development trends described in **Section 3.12**, Mineral Resources, are assumed to continue for the life of the analysis.
- Historical patterns of locatable mineral development in the planning area are used to assess the level of locatable mineral potential throughout the planning area. Areas with a high level of historical development are considered to have high potential for locatable minerals.

**4.2.2 Nature and Type of Effects**

Withdrawal of federal locatable mineral estate from locatable mineral entry removes the potential for future mineral development.

~~Existing~~ Each existing mining claims in an areas withdrawn from locatable mineral entry would have to undergo a validity exam to determine whether a

Commented [KP2]: Did not add "proposed to be withdrawn" because validity exams are only required in areas that are actually withdrawn or segregated.

~~discovery had been made. Existing mining claim notices or plans of operations, filed in accordance with 43 CFR Subpart 3809, would also have to undergo a validity exam before review (for notice) or approval (for plan of operations) of any material change to the operation. to be reviewed for notices or approved for plans of operations. Mining claims with an economic discovery of a valuable deposit on the date of the withdrawal are valid and would be exempt from the withdrawal for as long as the claimant maintains the claim; all others other claims become void. Withdrawal of areas larger than 5,000 acres would require Congressional approval. The need to perform validity exams in areas withdrawn from locatable mineral entry would also greatly increase the burden on the BLM and Forest Service associated with processing mining claims, notices, and plans of operations.~~

~~Existing notices or plans of operations would also have to undergo a validity exam before review (for notice) or approval (for plan of operations) of any material change to the operation. The need to perform validity exams in areas withdrawn from locatable mineral entry would also greatly increase the burden on the BLM and Forest Service associated with processing mining claims, notices, and plans of operations.~~

~~Management actions creating ROW exclusion or avoidance areas could indirectly increase the cost of or delay locatable mineral extraction by limiting the available means for transporting minerals from the mining operation to processing facilities and markets. For example, a new road could not be built in a ROW exclusion area. The road may need to take a less direct route to its destination to avoid the exclusion area, or another mode of conveyance of the resource may be required. Impacts would be mitigated where exceptions were allowed for collocating new ROWs within existing ROWs to satisfy valid existing rights.~~

Implementing management for the following resources would have negligible or no impact on locatable minerals; therefore they are not discussed in detail: GRSG, ~~lands and realty~~, habitat restoration and vegetation, invasive species, wildland fire, nonenergy solid leasable minerals, salable minerals, fluid minerals, recreation and visitor services, livestock grazing, and special designations.

#### 4.2.3 Alternative G

##### **Impacts from Lands and Realty Management**

~~Under Alternative G, 8,283,500 acres (XX percent) of BLM- and Forest Service-administered surface in the decision area (including all PHMAs and IHMAs) would be managed as ROW avoidance areas. Management of these areas as ROW avoidance could impact locatable mineral development as described in **Section 4.2.2, Nature and Type of Effects.**~~

~~Application of RDFs, BMPs, buffers, and seasonal timing restrictions to ROW/development would also limit construction of new ROWs for locatable mineral development in all GRSG habitat. If these limitations made it comparably~~

Commented [KP3]: Did not add discussion of impacts from RDFs and conservation measures because these are not proposed for application to locatable minerals under Alternative G. Only "reasonable and appropriate conditions of approval" are proposed, and no specific measures are described. Any impact analysis related to these conditions of approval would be speculative.

Formatted: Not Highlight

Commented [KP4]: Will need to add impacts from lands and realty management to locatables analysis for all other alternatives at some point.

Formatted: Highlight

Formatted: Font: Bold, Highlight

Formatted: Level 4

uneconomic to develop a locatable mineral claim, development of federal locatable minerals in the planning area could decrease.

#### **Impacts from Locatable Minerals Management**

Impacts under Alternative G are similar to those described under Alternative D except that measures to prevent unnecessary or undue degradation of GRSG habitat would only be applied to plans of operations in the decision area and not notices, thereby reducing impacts under Alternative G. Impacts on locatable minerals would still increase compared with Alternative A in the manner described under **Nature and Type of Effects**.

### **4.3 MINERAL MATERIALS (SALABLES)**

#### **4.3.1 Methods and Assumptions**

Analysis of impacts on mineral materials disposals from this LUPA focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on mineral materials would result from closing an area to mineral material disposal. An indirect impact would result from removing a road, which would change the economic feasibility of developing a site. Additional actions or conditions that might cause direct or indirect impacts on mineral materials are described under *Indicators*, below.

#### **Indicators**

Indicators of impacts on mineral materials are as follows:

- Acres closed to mineral material disposal
- Acres subject to timing limitations
- Acres managed as ROW avoidance areas
- Acres managed as ROW exclusion areas
- Acres over which RDFs would be applied to mineral material disposals.
- Application of restoration requirements

Where information is available, consideration is given to the potential for mineral materials on lands closed to mineral material disposal. For example, an indicator of an impact on mineral materials is if there were substantial closures to mineral material disposal in areas with high occurrence of mineral materials.

#### **Assumptions**

The analysis includes the following assumptions:

- Management actions proposed in this LUPA would apply to mineral material disposal activity where the BLM ~~and/or~~ Forest Service manages the surface over federal mineral material estate as well as where federal

Commented [KP5]: Did not add proposed to be closed because the analysis assumes that under each alternatives the management actions would be implemented as soon as the ROD is signed. The only exception is locatable minerals since the BLM itself does not have the authority to withdraw areas.

mineral material estate lies beneath private or state surface (split estate).

- Information on existing mineral material allocations is not available for 1,444,100 acres of federal mineral material estate in the Butte and Dillon Field Offices in Montana (five percent of the federal mineral material decision area). These acres are assumed to be open to mineral material disposal under Alternative A.
- Mineral material development trends described in **Section 3.12**, Mineral Resources, are assumed to continue for the life of the analysis.
- Historical patterns of mineral material development in the planning area are used to assess the level of mineral material potential throughout the planning area. Areas with a high level of historical development are considered to have high potential for mineral materials. There is higher demand in more populated areas.

#### 4.3.2 Nature and Type of Effects

The predominant mining methods for mineral materials are small-scale surface mining and hand collection of building stone; therefore, any restrictions on surface-disturbing activities effectively close the subject areas to mineral material mining.

Closing areas to mineral material disposal and closing community pits would directly impact mineral materials by removing the potential for mineral resources in that area to be accessed and extracted. In addition, ~~closed mineral material pits could be trespassed~~ing areas could result in trespass cases.

Closing ~~acres~~ areas to commercial mineral material development would prevent large-scale commercial operations, while allowing county and community operations, which are generally smaller scale.

Applying TLs could delay extraction of mineral material resources. However, small-scale mineral material operations would likely be better suited to work around TLs than larger-scale commercial mineral material operations. Most mineral material operations in the decision area are small-scale, so impacts of TLs are expected to be limited.

~~Applying RDFs (see Appendix C), to mineral material development would directly impact mineral material activity. These RDFs include such standards as road design and siting standards and reclamation standards. Applying these requirements would impact mineral material activities by restricting the extraction of mineral materials. To avoid these restrictions, developers may move to nearby state or private minerals, thereby decreasing the number of mineral material pits on federal mineral estate.~~

Managing areas as ROW avoidance or exclusion could decrease new construction, such as roads, thereby decreasing demand for mineral materials in those areas. This, in turn, could decrease the number of mineral material pits on federal mineral estate.

Implementing management for the following resources would have negligible or no impact on mineral materials; therefore they are not discussed in detail: travel and transportation management, recreation, range management, solid minerals, fire and fuels management, habitat restoration and vegetation management, and special designations.

**Table 4-63**, Mineral Materials by Alternative, shows the number of acres open or closed to mineral materials disposal in the decision area under each alternative Alternatives A and G.

**Table 4-63  
Mineral Materials by Alternative**

Management	Alternative	
	A	G
Closed to disposal (acres)	1,442,300	2,258,600
Open to disposal (acres)	30,144,000	10,658,300

Source: BLM 2013a; BLM 2014x

Formatted Table

Formatted: Not Highlight

Formatted: Not Highlight

A discussion of the impacts on mineral materials from management actions applicable to federal mineral material estate in the decision area under each alternative is below.

**4.3.3 Alternative G**

**Impacts from Lands and Realty**

Under Alternative G, ~~4,618,800~~ acres (~~XX~~ percent) of BLM- and Forest Service-administered surface in the decision area (including all ~~Core Management Zones~~ PMHAs) would be managed as ROW avoidance areas where development of new ROWs for land uses could not occur unless the Anthropogenic Disturbance Development and Exception Criteria (AD-3 and AD-4) were satisfied (including the requirement that the project would not exceed the 3 percent disturbance threshold and would be collocated within existing the footprint of existing infrastructure). However, because all ~~Core Management Zones~~ PMHAs would be closed to mineral material disposal under Alternative G, managing these areas as ROW avoidance would not impact demand for mineral materials.

Another ~~2,977,400~~ acres (~~XX~~ percent) of BLM- and Forest Service-administered surface in the decision area (including all ~~Important Management Zones~~ HMAs) would be managed as ROW avoidance areas where

development of new ROWs for land uses could not occur unless the Anthropogenic Disturbance Development Criteria (AD-4) were satisfied (including the requirement that the project would not exceed the 3 percent disturbance threshold). However, because mineral material activities in ~~IMZs~~ ~~IHMAs~~ would be subject to the same Anthropogenic Disturbance Development Criteria, ROW management is unlikely to impact mineral material development in ~~IMZs~~ ~~IHMAs~~. In any areas within ~~IMZs~~ ~~IHMAs~~ where ROW development could not meet the Development Criteria, mineral materials development would probably also not meet the criteria; therefore neither would be allowed. Because mineral material development would not be allowed in these areas, the inability to develop ROWs is not expected to reduce mineral material activity through reduced demand.

Application of RDFs, BMPs, buffers, and seasonal timing restrictions would also limit construction of new ROWs in all GRSG habitat. If these limitations made it uneconomic to develop a ROW, demand for federal mineral material resources in GRSG habitat could decrease.

#### **Impacts from Mineral Materials Management**

Under Alternative G, ~~XX~~ ~~6,735,200~~ acres (~~XX~~ percent) of BLM- and Forest Service-administered surface in the decision area (including all ~~CMZs~~ ~~PHMAs~~) would be closed to mineral material disposal. The types of impacts from these closures are the same as those discussed under **Section 4.10.2**. Because ~~XX~~ ~~three~~ times more acres of federal mineral material estate would be closed under Alternative G compared with Alternative A, the magnitude of these impacts would increase.

Approximately ~~XX~~ ~~3,071,500~~ acres (~~XX~~ percent) of BLM- and Forest Service-administered surface in the decision area (including all ~~IMZs~~ ~~IHMAs~~) would be open to mineral material disposal but only if the Anthropogenic Disturbance Development and Criteria (AD-4) were satisfied (including the requirement that the project would not exceed the 3 percent disturbance threshold). Mineral material activities in ~~Important and General Management Zones~~ ~~IHMAs~~ and ~~GHMAs~~ would also be subject to RDFs, buffers, and seasonal timing restrictions. The types of impacts from these limitations are the same as those discussed under **Section 4.10.2**. Because these types of restrictions would not be applied under Alternative A, impacts on mineral material development from the restrictions would increase under Alternative G.

Mineral material sales from the ~~120~~ existing pits in GRSG habitat would be subject to timing restrictions. As described in **Section 4.10.2**, these timing restrictions could impact large commercial operations and therefore reduce overall sales of federal materials in the planning area.

### **Impacts from Anthropogenic Disturbance Management, Adaptive Management, and Coordination**

Under Alternative G, anthropogenic disturbance, including mineral material development, would be limited to 3 percent of nesting and wintering habitat within ~~Core and Important Management Zones, PHMAs and IHMAs~~ within a Conservation Area (i.e., BSUs). In BSUs where the 3 percent cap is already exceeded, new development of federal mineral material resources would be prohibited until enough habitat was restored to maintain the area under the threshold. Development of federal mineral material resources that would result in exceedance of the 3 percent cap in a BSU would also be prohibited. This cap could potentially impact activities on XX acres of federal mineral material estate. The XX acres that would be closed to mineral material disposal under Alternative G would not be impacted by the disturbance cap because no new mineral material development could occur in the closed areas. *[Note to BLM and Forest Service: Do we have any existing information on where BSUs stand in relation to the disturbance caps at this time?]*

## **4.4 NONENERGY LEASABLE MINERALS**

### **4.4.1 Methods and Assumptions**

Analysis of impacts on nonenergy solid leasable minerals from this LUPA focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on nonenergy solid leasable minerals would result from closing an area to leasing. An indirect impact would result from removing a road, which would change the economic feasibility of developing a site. Additional actions or conditions that might cause direct or indirect impacts on nonenergy solid leasable minerals are described under *Indicators*, below.

#### **Indicators**

Indicators of impacts on nonenergy solid leasable minerals are as follows:

- Acres of unleased KPLAs ~~closed to nonenergy solid mineral leasing~~
- Acres over which RDFs would be applied when activities are proposed on existing unmined phosphate leases

Where information is available, consideration is given to the potential for nonenergy solid leasable minerals on lands closed to leasing. For example, an indicator of an impact on nonenergy solid leasable minerals is if there were substantial closures to nonenergy solid mineral leasing in areas with high potential for nonenergy solid mineral development, ~~such as unleased KPLAs~~.

#### **Assumptions**

The analysis includes the following assumptions:

- Management actions proposed in this LUPA would apply to nonenergy leasable mineral activity where the BLM and Forest Service manage the

Commented [KP6]: Did not add proposed to be closed, because the analysis assumes that under each alternative the management actions would be implemented as soon as the ROD is signed. The only exception is locatable minerals since the BLM itself does not have the authority to withdraw areas.

Commented [KP7]: Did not add existing unmined leases because these could not be closed to leasing.

surface over federal nonenergy leasable mineral estate as well as where federal nonenergy leasable mineral estate lies beneath private or state surface (split estate).

- Information on existing nonenergy solid leasable mineral allocations is not available for 1,444,100 acres of federal nonenergy solid leasable mineral estate in the Butte and Dillon Field Offices in Montana (five percent of the federal nonenergy solid leasable mineral decision area). These acres are assumed to be open to nonenergy leasable mineral prospecting and leasing under Alternative A.
- Unmined phosphate leases have the highest potential for nonenergy leasable mineral development in the decision area. Unleased KPLAs have a moderate potential for development, and lands outside KPLAs have a low potential for development.
- Demand for phosphate resources in the Pocatello FO is expected to remain high, as it has for the past 60 years. As discussed in **Section 3.12, Mineral Resources**, significant phosphate resources exist in the Pocatello Field Office within the planning area, with 86 active phosphate leases. While there are no phosphate leases in PPMAs/CMZs or IMZs; there are ten active phosphate leases within PGMA/GMZs. No development is planned on these leases for the next 5 to 10 years.

#### 4.4.2 Nature and Type of Effects

Closing an area to nonenergy solid mineral leasing would directly impact ~~the~~ nonenergy solid leasable ~~minerals-mineral program~~ by removing the potential for minerals resources in that area to be accessed and extracted. Mining operations may ~~abandon their leases and/or~~ move to nearby private lands if similar ~~geologic~~ resources exist, thereby reducing the number of operations on federal mineral estate. Closures would have the greatest impact on unleased areas within KPLAs, as these areas are seen as having ~~a moderate~~ ~~the greatest~~ potential to be ~~developed-nominated for lease~~ during the life of this LUPA. Closures of areas outside KPLAs would have less impact as these areas have ~~low~~ potential for ~~discovery and~~ development.

~~Seasonal and daily TLs could be applied as post-lease conditions of approval to proposals for exploration and initial mine development activities such as timber removal, shrub clearing, etc.; however once mining begins, such restrictions are no longer applicable. Applying TLs to initial mine development cApplication of seasonal and daily TLs would restrict the timing of phosphate development. [Note to BLM: Karen checking on whether TLs can be applied to existing phosphate leases] Application of RDFs, including such standards as noise restrictions, height limitations on structures, road siting and design requirements, water development standards, remote monitoring requirements, and reclamation standards, would place additional requirements on phosphate development up until commencement of mining. At that time, compensatory mitigation would be~~

Commented [KP8]: Did not add discussion on royalties because this would be covered in the socioeconomic section.

necessary. If these TLs and RDFs made phosphate development costly enough that developers-lessees chose not to develop unmined phosphate leases, overall development of federal phosphate resources in the decision area could decrease.

Implementing management for the following resources would have negligible or no impact on nonenergy solid leasable minerals; therefore they are not discussed in detail: GRSG, lands and realty, habitat restoration and vegetation, invasive species, wildland fire, locatable minerals, salable minerals, fluid minerals, recreation and visitor services, livestock grazing, and special designations.

**Table 4-XX**, Nonenergy Leasable Minerals by Alternative, shows the number of acres open or closed to nonenergy leasable mineral prospecting and leasing as well as restrictions on unmined phosphate leases in the decision area under each alternative Alternatives A and G.

**Table 4-XX**  
**Nonenergy Leasable Minerals by Alternative**

Management	Alternative	
	A	G
Open to prospecting and leasing (acres)	<del>10,089,200</del>	<del>5,535,300</del>
Unleased KPLAs open	<del>1,550</del>	<del>400</del>
Closed to prospecting and leasing (acres)	<del>2,831,900</del>	<del>6,990,200</del>
Unleased KPLAs closed	<del>70</del>	<del>0</del>
Unmined leases not subject to RDFs/TLs (acres)	<del>0</del>	<del>0</del>
Unmined leases subject to RDFs/TLs (acres)	<del>29,700</del>	<del>65</del>

Source: BLM 2013a; BLM 2014x

*[Note to BLM: The numbers above do not appear to make sense. There appear to be far more unleased KPLAs and unmined leases under Alternative A than under Alternative G. Please double check GIS data.]*

A discussion of the impacts on nonenergy leasable minerals from management actions applicable to federal nonenergy leasable mineral estate in the decision area under each alternative is below.

**4.4.3 Alternative G**

**Impacts from Nonenergy Solid Leasable Minerals Management**

Under Alternative G, ~~6,990,200~~ acres, or ~~XX~~ percent of the federal nonenergy leasable mineral estate decision area (including all federal nonenergy leasable mineral estate in ~~CMZs-PHMAs~~ outside KPLAs) would be closed to prospecting and leasing—~~XX~~ *timestwice* as many acres closed compared with Alternative A. Fringe leases and modifications to existing leases would be allowed to satisfy valid existing rights. Impacts of this closure would be similar to those described under **Section 4.11.2** except that impacts would increase compared with Alternative A. Approximately ~~2,891,100~~ acres, or ~~XX~~

Commented [KP9]: Did not change to "valid existing rights could be harmed" because lessees may just choose to prioritize other areas as they might due to changing economic conditions or other factors. Does not automatically represent harm to a valid existing right.

percent of federal nonenergy solid leasable mineral estate in the decision area (including all federal nonenergy leasable mineral estate in ~~IMZs-IHMAs~~ outside KPLAs), would be open to leasing consideration but only if the Anthropogenic Disturbance Development and Criteria (AD-4) were satisfied (including the requirement that the project would not exceed the 3 percent disturbance threshold). Development on these acres would also be subject to RDFs, ~~BMPs~~, buffers, and seasonal ~~and daily~~ timing restrictions. Because development of nonenergy leasable minerals in these areas would be more restricted than under Alternative A, impacts described under **Section 4.11.2** would increase under Alternative G.

Commented [KP1 0]: Did not change this sentence to limit to exploration and initial mine development since these restrictions would be applied to new leases and therefore could apply to all activities on the lease.

Development on ~~XX-2,643,800~~ acres of federal nonenergy leasable minerals within ~~GMZs-GHMAs~~ would also be subject to RDFs, BMPs, buffers, and seasonal timing restrictions. These limitations could reduce federal nonenergy leasable mineral development in the planning area due to increased costs as described under **Section 4.11.2**.

Commented [KP1 1]: Did not change this sentence to limit to exploration and initial mine development since these restrictions would be applied to new leases and therefore could apply to all activities on the lease.

Because KPLAs would remain open to nonenergy solid mineral leasing ~~and prospecting~~, impacts on federal nonenergy solid leasable mineral development would be mitigated. The areas ~~considered to have moderate potential most likely to be developed~~ in the decision area would not be constrained.

Seasonal and daily TLs as well as RDFs would be applied to exploration activities or initial mine development on the ~~10~~ one undeveloped federal phosphate leases covering ~~XX-65~~ acres within GRS habitat ~~IHMAs~~ with impacts similar to those described under Alternative D. *[Note to BLM: Please confirm that there is now only one undeveloped federal phosphate lease in GRS habitat. Based on emails between Karen Porter and Josh Sidon, it appears that habitat boundaries have been redrawn for all alternatives to exclude the other 10 leases that were previously within GRS habitat.] [Note to BLM: Karen to check on whether BLM can apply seasonal TLs to existing phosphate leases as COAs]* If these restrictions made development of the unmined phosphate leases so costly that the developers chose not to develop the leases, development of federal phosphate resources could be reduced as described under **Section 4.11.2**.
